Modalities, Cohesion, and Information Flow

G. A. KAVVOS, Wesleyan University, United States of America

It is informally understood that the purpose of modal type constructors in programming calculi is to control the flow of information between types. In order to lend rigorous support to this idea, we study the category of classified sets, a variant of a denotational semantics for information flow proposed by Abadi et al. We use classified sets to prove multiple noninterference theorems for modalities of a monadic and comonadic flavour. The common machinery behind our theorems stems from the the fact that classified sets are a (weak) model of Lawvere's theory of axiomatic cohesion. In the process, we show how cohesion can be used for reasoning about multi-modal settings. This leads to the conclusion that cohesion is a particularly useful setting for the study of both information flow, but also modalities in type theory and programming languages at large.

1 INTRODUCTION

Taming the flow of information within a computer system has been a problem of significant interest since the early days of Computer Science; see, for example, the models of Bell and LaPadula [LaPadula and Bell 1996; Rushby 1986], and the influential work of Denning [1976], which was the first to introduce the use of lattices for modelling secure information flow. The objective of these models is usually to express the property that data cannot flow in or out of certain regions of a computer system, thus achieving a certain form of confidentiality or integrity.

A modern way of achieving the above objective is to make it language-based. That is: to enrich a programming language with features that specify or control the flow of data, so that the programs we write are correct—or rather, secure—by design. One way of doing so is through the use of type systems which annotate variables or program expressions with security levels. It then suffices to prove that the type system ensures some form of noninterference property, which invariably states that, in a well-typed program, data cannot flow contrary to our wishes, e.g. from a type labelled as being of high security to one of low security. Several type systems of this form have been proposed, but all seem to be in some sense ‘equivalent;’ see e.g. the recent work of Rajani and Garg [2018].

Many of these type systems feature some form of modality, which is broadly construed as a unary type constructor of some sort: see e.g. [Abadi et al. 1999; Miyamoto and Igarashi 2004; Shikuma and Igarashi 2008]. The rules that govern the behaviour of a modality almost always silently endow it with certain information flow properties. This is intuitively well-known both by modal type theorists, as well as practitioners who use modal type systems in programming calculi.

Nevertheless, the implicit properties of these systems have not been subjected to a detailed treatment. Given the recent resurgence of interest in modal type theory—as exemplified by cohesive homotopy type theory [Shulman 2018], and guarded type theory [Clouston et al. 2016] on the theoretical side, but also calculi for functional reactive programming [Krishnaswami 2013], effects [Curien et al. 2016] or coeffects [Petricek et al. 2014] on the more application-driven end—we believe that there is a need for a more universal approach to modal type theory. There have been major recent advances on the syntactical side, particularly through the fibrational framework of Licata et al. [2017]. However, we are still lacking a ‘Swiss-army-knife model’ that can help us understand and prove properties about the information flow of these modalities. This is the subject of the present paper.

Author’s address: G. A. Kavvos, Department of Mathematics and Computer Science, Wesleyan University, 265 Church Street, Middletown, Connecticut, 06459, United States of America, gkavvos@wesleyan.edu.
For this purpose, we introduce a refinement of the dependency category of Abadi et al. [1999], which we call the category of classified sets. These are sets equipped with indexed logical relations that encode indistinguishability, and thus a form of data hiding. Abadi et al. [1999] used a variant of this model to prove noninterference theorems for various information flow calculi that they translated to their dependency core calculus.

We will present a different, significantly more ‘high tech’ approach. First, we notice that the relations of indistinguishability that classified sets carry must be respected: that is, if $x R y$ then $f(x) R f(y)$ for any morphism $f : X \to Y$ of our model. Thus, if $x R y$, the ‘points’ $x$ and $y$ of $X$ can be considered to be ‘arbitrarily close’ to each other in a ‘space.’ So close, in fact, as to not be distinguishable. This analogy is rife with topological intuition. In fact, we will see these relations describe a sort of cohesion between points. It so happens that an axiomatic approach to this idea has been developed by Lawvere [2007], and that classified sets form a weak model of this theory.

Once this fact is established, we can show that many of the information flow properties that we wish to establish follow directly from this abstract framework of cohesion. From that point, we want to (a) identify appropriate structure in the category of classified sets for modelling a host of modal type theories that are used in information flow control, and (b) use this structure to prove noninterference theorems for these type theories.

This paper proceeds as follows. In §2 we introduce the category of classified sets, and show that it is a finitely complete and cocomplete, bicartesian closed category, and hence a model of the simply typed $\lambda$-calculus. Then, in §3 we will present the rudiments of axiomatic cohesion, and show that classified sets are pre-cohesive relative to ordinary sets. This will introduce some modal operations, and lead us to prove some basic noninterference theorems in §4.

Then, in §5, we present a levelled view of cohesion. Classified sets are defined parametrically in a set of security levels $L$. If we add a new set $\pi$ of security levels, then the new category of sets—which is classified over $L \cup \pi$—is pre-cohesive over the category of sets classified over $L$. This generates some more modal operators, which are now ‘level-sensitive.’ These are used in §6 to prove another set of noninterference theorems. We make some concluding remarks in §7.

Category theory is used extensively throughout the paper. The main tool is that of adjunctions, and their close relationship to (co)monads, both of which are beautifully covered in [Awodey 2010, §9-10]. We only use one advanced concept, namely that of (co)reflective subcategories, which correspond to idempotent monads and comonads; this covered in [Mac Lane 1978, §IV.3], [Borceux 1994, Vol. II, §4.2.4], or the nLab wiki.¹

## 2 CLASSIFIED SETS

Reynolds integrated these two strands of thought and formulated a general principle of relational parametricity that is applicable to a wide range of contexts for capturing the notion of “information hiding” or “abstraction.” Unfortunately, we believe that the magnitude of this achievement has not been sufficiently recognized

Let $L$ be a set of labels, which we call security levels. We assume precisely nothing about $L$, so our theory is curiously independent of its structure (finite, infinite, partial order, lattice, etc.).

**Definition 1.** A classified set $S$ over $L$ (or: a set $S$ classified over $L$) consists of

1. an ordinary carrier set $|S|$, and
2. a family of relations $(R_\ell)_{\ell \in L}$ on $|S|$, one for each level $\ell \in L$.

¹[https://ncatlab.org/nlab/show/reflective+subcategory](https://ncatlab.org/nlab/show/reflective+subcategory)
such that each $R_\ell$ is reflexive.

We will—more often than not—write $x \in S$ to mean $x \in |S|$. The underlying intuition pertaining to a classified set is that each level $\ell \in \mathcal{L}$ is to be understood as a security clearance, and the relation $R_\ell$ models indistinguishability for users at that clearance. That is: if $x R_\ell y$, then a user with clearance $\ell$ must not be able to distinguish between $x$ and $y$. Reflexivity models the simple fact that $x$ should be indistinguishable to itself. In logical relations, reflexivity is a theorem; but since not everything is defined inductively here, it must become an explicit requirement.\(^2\)

The kind of functions admissible in our mathematical universe shall be precisely those that map indistinguishable inputs to indistinguishable outputs.

**Definition 2.** Let $S$ and $S'$ be sets classified over $\mathcal{L}$. A morphism of classified sets $f : S \to S'$ is a function $f : |S| \to |S'|$ such that $x R_\ell y$ implies $f(x) R_\ell f(y)$ for all $\ell \in \mathcal{L}$.

Classified sets over $\mathcal{L}$ and their morphisms constitute a category, which we denote as $\textsc{CSet}_\mathcal{L}$.

## 2.1 Limits and Colimits

We move on to the examination of what kind of limits and colimits exist in classified sets, which tells us which kinds of data type we are able to construct.

We let $1$ be the classified set with a singleton carrier set $\{\ast\}$, and $\ast R_\ell \ast$ for all $\ell \in \mathcal{L}$.

**Proposition 1.** $1$ is a terminal object in $\textsc{CSet}_\mathcal{L}$.

That is: there is a unique function from a classified set $X$ to $1$; it maps everything to $\ast$, hence collapsing all related pairs to one element, which cannot be distinguished from itself.

Similarly, we let the classified set $0$ be the set whose carrier is the empty set, and all of whose relations are empty. Since there are no relations to preserve, it is evident that the unique empty function from $0$ to any $|A|$ is a morphism, so

**Proposition 2.** $0$ is an initial object in $\textsc{CSet}_\mathcal{L}$.

For classified sets $A$ and $B$, we let $|A \times B| \overset{\text{def}}{=} |A| \times |B|$. Given any $\ell \in \mathcal{L}$, we define

$$ (a_1, b_1) R_\ell (a_2, b_2) \iff a_1 R_\ell a_2 \land b_1 R_\ell b_2 $$

Hence, two pairs are indistinguishable exactly when they are so componentwise. If, for example, the second components are distinguishable, then so are the pairs; but this does not entail that we can distinguish the first components! In this way, we can ‘classify’ pairs without resorting to more complicated sets of labels, e.g. $\mathcal{L} \times \mathcal{L}$.

The standard set-theoretic projections preserve $R_\ell$, as does the standard set-theoretic product morphism $(f, g) : |C| \to |A| \times |B|$ for any $f : C \to A$ and $g : C \to B$. Hence,

**Proposition 3.** The classified set $A \times B$ is the categorical product of $A$ and $B$ in $\textsc{CSet}_\mathcal{L}$.

A similar story applies to coproducts: given $A$ and $B$, we define

$$ |A + B| \overset{\text{def}}{=} |A| + |B| = \{ (0, a) \mid a \in |A| \} \cup \{ (1, b) \mid b \in |B| \} $$

and, naturally, we define $R_\ell$ to be

$$(0, a) R_\ell (0, a') \iff a R_\ell a', \quad (1, b) R_\ell (1, b') \iff b R_\ell b'$$

and $\neg((i, x) R_\ell (j, y))$ for $i \neq j$. The injections $|A| \to |A| + |B|$ and $|B| \to |A| + |B|$ clearly preserve $R_\ell$, as does the set-theoretic coproduct morphism, so

\(^2\)[Abadi et al. 1999] did not require their relations to be reflexive, which is a key property in showing pre-cohesion in §3.
**Proposition 4.** The classified set $A + B$ is the categorical coproduct of $A$ and $B$ in $\text{CSet}_\mathcal{L}$.

In a similar fashion, if we are given two parallel arrows $A \xrightarrow{f/g} B$, we can see that the set $E \overset{\text{def}}{=} \{ a \in A \mid f(a) = g(a) \}$ equipped with $R_\ell \mid E$, the relations $R_\ell$ restricted to $E$, is a classified set, that the inclusion $E \hookrightarrow A$ is trivially a morphism, and that

**Proposition 5.** $E$ is the equalizer of $f : A \to B$ and $g : A \to B$.

Constructing coequalizers is slightly more complicated. Recall that given two ordinary functions $A \xrightarrow{f/g} B$, their coequaliser is the set $B$ quotiented by the equivalence relation $\sim_{f,g}$, which is the least equivalence relation such that $(f(a), g(a)) \in \sim_{f,g}$. The elements of $B/\sim_{f,g}$ are then equivalence classes $[b]$ of elements we wish to ‘lump together’. Suppose now that $A$ and $B$ are classified; how can we classify $B/\sim_{f,g}$? We may consider two of its equivalence classes indistinguishable whenever it happens that two elements, one from each equivalence class, are ‘lumped together’ by $R_\ell$. So we define

$$[b] R_\ell [b'] \iff \exists x \in [b]. \exists y \in [b']. x R_\ell y$$

and thus turn $B/\sim_{f,g}$ into a classified set. The quotient map $B \to B/\sim_{f,g}$ is then automatically a morphism of classified sets. It is not then hard to show that

**Proposition 6.** $B/\sim_{f,g}$ is the coequaliser of $A \xrightarrow{f/g} B$ in $\text{CSet}_\mathcal{L}$.

In short, we have the following theorem:

**Theorem 1.** $\text{CSet}_\mathcal{L}$ is finitely complete and finitely cocomplete.

### 2.2 Exponentials

In a manner identical to that of logical relations, we are able endow the set of morphisms from a classified set to another with an indistinguishability relation. The idea is that two morphisms are indistinguishable if they map indistinguishable inputs to indistinguishable outputs. Note that this furnishes our theory with an extensional view of functions, where they are understood to be indistinguishable precisely when their input-output behaviour is.

Given classified sets $A$ and $B$ over $\mathcal{L}$, we define the classified set $B^A$ by

$$|B^A| \overset{\text{def}}{=} \text{Hom}_{\text{CSet}_\mathcal{L}}(A, B)$$

$$f R_\ell g \iff \forall a R_\ell a'. f(a) R_\ell g(a')$$

This is the usual definition of logical relations at function types. We can then define a function $\text{ev} : B^A \times A \to B$ by $(f, a) \mapsto f(a)$, and the definition of $B^A$ makes it a morphism. From that point, it is trivial to show that

**Proposition 7.** $B^A$ is the exponential of $A$ and $B$.

Hence,

**Theorem 2.** $\text{CSet}_\mathcal{L}$ is a bicartesian closed category.

Thus the category $\text{CSet}_\mathcal{L}$ is rich enough to model the simply typed $\lambda$-calculus with coproducts. In the following sections we will also show that there is enough structure to model a multitude of modal operators on types.
3 \ COHESION

The modal structure on classified sets is closely related to—or, more precisely, induced by—Lawvere’s theory of axiomatic cohesion. But what is axiomatic cohesion? It is a theory developed by [Lawvere 2007] as an attempt to capture the very broad idea of mathematical spaces that are endowed with some kind of cohesion, i.e. the idea that some points are ‘very close to each other’ or ‘stuck together.’ The prototypical example of this is the topological space, which is a set of points equipped with a topology, a set of subsets of those points—the open sets—the choice of which bestows cohesion, continuity, connectedness, convergence etc. on the underlying set.

If we write $\textbf{Top}$ for the category of topological spaces, there is an obvious forgetful functor $U : \textbf{Top} \rightarrow \textbf{Set}$ which ‘forgets’ the cohesive structure of a topological space, and gives the underlying set of points. Conversely, given a set, there are two canonical ways to construct a topological space. The first is to specify that no points are stuck together. This is achieved by the discrete topology, where every subset is an open set. It forms a functor,

$$\Delta : \textbf{Set} \rightarrow \textbf{Top}$$

that is the identity on functions: every function on sets is trivially a continuous function between the same sets seen as discrete spaces, so $\Delta$ is full and faithful.

The other way is to specify that all points are stuck together, and is achieved by endowing the set with the codiscrete topology, where the only open sets are the empty set and the entire space. It forms another functor,

$$\nabla : \textbf{Set} \rightarrow \textbf{Top}$$

that is the identity on functions: every function on sets is trivially a continuous function between the same sets seen as codiscrete spaces.

The relationship between these functors is simple: they form a string of adjoints:

$$\Delta \dashv U \dashv \nabla$$

This categorifies the following two simple observations: every function $X \rightarrow \nabla Y$ from a topological space into a codiscrete space is continuous (as everything is collapsed into a single block of points); and every function $\Delta X \rightarrow Y$ from a discrete space into a topological space $Y$ is continuous (as there is no cohesion to preserve in a discrete space).

But this is not the whole story. Consider a continuous function $X \rightarrow \Delta Y$ into the discrete space with points $Y$. Since it is continuous, it must preserve cohesion. Namely, it must map points of $X$ that are ‘stuck together’ to points that are ‘stuck together’ in $\Delta Y$. But points are only ‘stuck’ to themselves in the discrete space $\Delta Y$, so in fact a continuous function must map all points ‘stuck’ to each other in $X$ to a single point of $Y$. Thus, if we could somehow reduce $X$ down to a set $C(X)$ where points ‘stuck’ together are collapsed to a single point, the continuous function $X \rightarrow \Delta Y$ would define an ordinary function $C(X) \rightarrow Y$. Such a functor $C$ does exist, and maps the topological space $X$ to its set $C(X)$ of connected components. It is evidently left adjoint to $\Delta$.

We are very close to showing that topological spaces are cohesive relative to sets. We will, however, not use this full notion in this paper, as the weaker notion of pre-cohesion, due to [Lawvere and Menni 2015], is more than sufficient for our purposes:

**Definition 3.** In a situation of the form

$$\begin{array}{c}
\mathcal{E} \\
\downarrow C \\
\downarrow \Delta \\
\downarrow U \\
\downarrow \nabla \\
\mathcal{S}
\end{array}$$

where $\mathcal{E}$ and $\mathcal{S}$ are extensive categories, we call $\mathcal{E}$ pre-cohesive relative to $\mathcal{S}$ if
The second requirement essentially expresses that a connected component of the product of two spaces is exactly a connected component in each of the two spaces. The third requirement, the nullstellensatz, has many equivalent forms, and essentially requires that the ‘quotient’ map that maps a point to its connected component is a kind of surjection (i.e. all connected components are nonempty).

The reason that a setting of pre-cohesion is of direct interest to modal type theory is that it automatically induces three modalities on the pre-cohesive category \( \mathcal{E} \) by composing each pair of adjoint functors. The first one,

\[
\boxdef \equiv \Delta U : \mathcal{E} \to \mathcal{E}
\]

is a comonad. Intuitively, \( \boxdef \) takes a cohesive space, strips its points of their cohesive structure, and gives them the discrete structure: it ‘unsticks’ all points. The second one,

\[
\Diamonddef \equiv \nabla U : \mathcal{E} \to \mathcal{E}
\]

is a monad. It does the opposite: it ‘sticks’ all the points of a cohesive space together. Finally,

\[
\intdef \equiv \Delta C : \mathcal{E} \to \mathcal{E}
\]

is a monad. Intuitively, \( \int \) collapses each connected component into a single point, and then presents that set of connected components as a discrete space.

Summarising, the above setting endows these functors with the following properties:

**Corollary 1 (Fundamental Corollary of Pre-Cohesion).**

1. \( U : \mathcal{E} \to S \) preserves limits and colimits.
2. \( \Delta : S \to \mathcal{E} \) preserves limits and colimits.
3. \( \nabla : S \to \mathcal{E} \) preserves limits.
4. \( C : \mathcal{E} \to S \) preserves products and colimits.
5. \( U\Delta \equiv \Id_S : S \to S \)
6. \( U\nabla \equiv \Id_S : S \to S \)
7. \( \boxdef \equiv \Delta U : \mathcal{E} \to \mathcal{E} \) is an idempotent comonad. It is exact, i.e. preserves finite limits and colimits.
8. \( \Diamonddef \equiv \nabla U : \mathcal{E} \to \mathcal{E} \) is an idempotent monad. It is left exact, i.e. preserves finite limits.
9. \( \intdef \equiv \Delta C : \mathcal{E} \to \mathcal{E} \) is an idempotent monad. It preserves products and colimits.
10. \( \int \dashv \boxdef \dashv \Diamonddef \)

**Proof.** (1)-(4) follow by the fact each of these functors is a left or right adjoint, or by some assumption. (5) and (6) follow by the Yoneda lemma and the fact \( \Delta/\nabla \) are faithful; e.g. for any \( D \in S \)

\[
\Hom_S(D, U\Delta A) \equiv \Hom_E(\Delta D, \Delta A) \equiv \Hom_S(D, A)
\]

(7)-(9) follow from (1)-(4) and the fact \( \Delta/\nabla \) are full and faithful and thus generate idempotent (co)monads (see e.g. [Borceux 1994, §4.3.2]). (10) follows from \( C \dashv \Delta \dashv U \dashv \nabla \). \( \square \)

The rest of the section is devoted to showing that

**Theorem 3.** \( \mathbb{CSet}_L \) is pre-cohesive relative to \( \mathbb{Set} \).
A variant of this fact (namely that reversible reflexive graphs are cohesive relative to sets) is already present in [Lawvere 2007]. There is an evident forgetful functor from classified sets to sets:

$$U : \text{CSet}_L \to \text{Set}$$

$$X \mapsto |X|$$

which forget all the relations \(R_\ell\). We can then return to classified sets using the functor

$$\Delta : \text{Set} \to \text{CSet}_L$$

which adds to the set \(X\) the diagonal relation \(x R_\ell x\) at each level \(\ell \in L\). This is the finest equality that can be supported by this framework, in that each element is only indistinguishable to itself. In that sense, \(\Delta X\) is a classified set with carrier \(X\) that is completely transparent, in a manner reminiscent of the discrete topology on a set. Any function \(f : X \to Y\) is trivially a function \(f : \Delta X \to \Delta Y\), as the diagonal relation is trivially preserved. Thus \(\Delta\) is indeed a functor. Moreover, it is easy to see that it is full and faithful, and that

**Proposition 8.** \(\Delta : \text{Set} \to \text{CSet}_L\) is left adjoint to the forgetful functor.

**Proof.** Any morphism \(f : \Delta X \to Y\) is a function \(f : X \to |Y| = UY\). Conversely, any function \(f : X \to UY\) can be seen as a morphism \(f : \Delta X \to Y\) of classified sets, as it trivially preserves the diagonal relation. Naturality is trivial. \(\square\)

We then define

$$\nabla : \text{Set} \to \text{CSet}_L$$

to map a set \(X\) to itself, but equipped with the complete relation \(R_\ell \overset{\text{def}}{=} |X| \times |X|\) at each \(\ell \in L\). That is: no element of \(\nabla X\) is distinguishable from any other. Thus \(\nabla X\) is the classified set with carrier \(X\) that is maximally opaque. This reminds us of the codiscrete topology on \(X\). Again, rather trivially, any function \(f : X \to Y\) can be seen as a morphism \(f : \nabla X \to \nabla Y\), as it evidently preserves the complete relation on \(X\). It is not hard to see that \(\nabla\) is a full and faithful functor, and that

**Proposition 9.** \(\nabla : \text{Set} \to \text{CSet}_L\) is right adjoint to the forgetful functor.

**Proof.** Any function \(f : |X| \to Y\) can be seen as a morphism \(f : X \to \nabla Y\): it trivially preserves all the related pairs in \(X\)—no matter what they are—for \(\nabla Y\) relates all elements of \(Y\). Conversely, any morphism \(f : X \to \nabla Y\) can be seen as a function \(f : |X| \to Y\), as this is what it is. Naturality is again trivial. \(\square\)

We now move on to connected components. Suppose we have a morphism \(f : X \to \Delta Y\). Then, as each \(R_\ell\) in \(\Delta Y\) is simply reflexivity, we have that, for any \(\ell \in L\),

$$x R_\ell x' \text{ (in } X) \implies f(x) R_\ell f(x') \text{ (in } \Delta Y) \implies f(x) = f(x')$$

That is: \(f\) collapses related elements of \(X\) that are related at some—any!—level to a single element in \(Y\). We cannot phrase this in terms of quotients yet, for \(R_\ell\) need not be an equivalence relation. So, let us define the relation \(R^* \subseteq |X| \times |X|\) to be the reflexive, symmetric, transitive closure of \(\bigcup_{\ell \in L} R_\ell\), i.e. the least equivalence relation containing all the \(R_\ell\)’s. We can now define \(|X|/R^*\). This extends to a functor,

$$C : \text{CSet}_L \to \text{Set}$$

by letting \(C(X) \overset{\text{def}}{=} |X|/R^*\), and defining \(Cf : |X|/R^* \to |Y|/R^*\), where

$$f^*([x]) \overset{\text{def}}{=} [f(x)]$$
$f^*$ is well-defined: if $x R^* x'$, then there is a (possibly empty) sequence $x_0, \ldots, x_n$ of elements of $X$ and of sequence of levels $\ell_0, \ldots, \ell_{n+1}$ such that

$$x R\ell_0 x_0 R\ell_1^{-1} x_1 \cdots R\ell_n^{-1} x_n R\ell_{n+1} x'$$

But $f$ preserves all of these, mapping inverses to inverses, so

$$f(x) R\ell_0 f(x_0) R\ell_1^{-1} f(x_1) \cdots R\ell_n^{-1} f(x_n) R\ell_{n+1} f(x')$$

and hence $[f(x)] = [f(x')]$, so the choice of equivalence class representative is immaterial. We hence obtain a functor that gives us for each classified set $X$ its set of connected components, i.e. the set of equivalence classes $|X|/R^*$. Any two elements in the same equivalence class are indistinguishable at some level $\ell \in \mathcal{L}$.

Let us return to the function $f : X \to \Delta Y$. Define the relation

$$x \sim_f x' \overset{\text{def}}{=} f(x) = f(x')$$

This is clearly an equivalence relation, and we know that $\bigcup_{\ell \in \mathcal{L}} R\ell \subseteq \sim_f$. But $R^*$ is the least equivalence relation such that the above is true, so $R^* \subseteq \sim_f$. Hence, $Uf : |X| \to Y$, which respects $\bigcup_{\ell \in \mathcal{L}} R\ell$, can be uniquely factored as

$$|X| \xrightarrow{\eta_X} |X|/R^* \xrightarrow{\hat{f}} Y$$

where $\eta_X$ is the quotient map, and $\hat{f}([x]) \overset{\text{def}}{=} f(x)$. So we can uniquely take $f : X \to \Delta Y$ to $\hat{f} : CX \to Y$, and

**Proposition 10.** $C : \mathbf{CSet}_\mathcal{L} \to \mathbf{Set}$ is left adjoint to $\Delta : \mathbf{Set} \to \mathbf{CSet}_\mathcal{L}$.

It is easy to see that the canonical map $C(X \times Y) \to CX \times CY$ is $[(x, y)] \mapsto ([x], [y])$, and that, due to the behaviour of the relations on the product, it has an inverse. Moreover, in the case of classified sets, the nullstellensatz is trivial: applying the hom-set isomorphism of $\Delta \dashv U$ to the identity $id_{UX} : UX \to UX$, which is really the identity function $id_{|X|} : |X| \to |X|$, yields the unit $\eta_X : \Delta UX \to X$, which is again the identity function on $\Delta UX = \Delta |X|$, which is injective and hence monic.

Thus, Theorem 3 holds.

## 4 NONINTERFERENCE I: MONADS AND COMONADS

The cohesive structure of classified sets that we have developed so far is enough to show some basic information flow properties for monadic and comonadic calculi. In this section, we will state and prove noninterference properties for (a) Moggi’s monadic metalanguage, and (b) the Davies-Pfenning calculus. Both of these proofs follow from an axiom of cohesion, which we call codiscrete contractibility, and which we discuss first.

Central to our noninterference proofs will be two canonically constructed objects. Both will be classified sets over the carrier

$$\mathbb{B} \overset{\text{def}}{=} \{ \texttt{t, f} \}$$

of booleans. The first one is the ‘discrete’ booleans $\Delta \mathbb{B}$, in which if $b R\ell b'$ it follows that $b = b'$. Thus these are the booleans that are visible to everyone. The second one will be the ‘codiscrete’

---

3These are referred to as the ‘low security booleans’ by [Abadi et al. 1999], and denoted $\text{bool}_L$. 

, Vol. 1, No. 1, Article . Publication date: September 2018.
booleans $\nabla B$, in which $b \trianglerighteq b'$ for all pairs of booleans $(b, b')$, which are invisible at all levels. Note that

\[
\begin{align*}
B & \equiv 1 + 1 \\
\Delta B & \equiv \Delta 1 + \Delta 1 \equiv 1 + 1 \\
\nabla B & \equiv \nabla U \Delta B \equiv \spadesuit(1 + 1)
\end{align*}
\]

These all follow from the fundamental corollary (Corollary 1). The first isomorphism is by definition. The second holds because $\Delta$ preserves isomorphisms, colimits (+) and limits (1). The final one is obtained by using $U \Delta \equiv \mathbf{Id}$, then the second one, and finally the definition $\spadesuit \overset{\text{def}}{=} \nabla U$.

### 4.1 Contractible codiscreteness and information flow

We have carefully described the string of adjoints $C \dashv \Delta \dashv U \dashv \nabla$ that expresses the idea of (pre-)cohesion. In particular, for each $X$, $\nabla X$ is intuitively understood as the object with points $X$ and maximal cohesion, i.e. 'everything stuck together.' A property that is intuitively clear from this intuition is that, if one looks at the the connected components of $\nabla X$, one will find but one. Unfortunately, this is not something that readily follows from pre-cohesion, but we can ask for it.

**Definition 4.** If $E$ is pre-cohesive relative to $S$ with $C \dashv \Delta \dashv U \dashv \nabla$, then this pre-cohesion satisfies contractible codiscreteness if codiscrete objects have a single connected component. That is, for any $X \in S$,

$$C(\nabla X) \equiv 1$$

In [Lawvere and Menni 2015] a very similar concept is called connected codiscreteness. The more general formulation, as well as the name contractible codiscreteness are due to [Shulman 2018].

It is easy to see that

**Proposition 11.** The pre-cohesion of $\mathbf{CSet}_L$ relative to $\mathbf{Set}$ satisfies contractible codiscreteness.

This is a fancy way of stating the following obvious fact: if we start with a set $X$, and equip it with the complete relation at each level $\ell \in L$, and we then take the connected components of that, there will be but one. However, this abstract way of stating this property will be very useful presently, as the following proposition will be the core of our noninterference proofs:

**Proposition 12.** Let $C \dashv \Delta \dashv U \dashv \nabla$ exhibit $E$ to be pre-cohesive over $S$, in a way that satisfies contractible codiscreteness. Then

1. Morphisms $\spadesuit A \rightarrow \Delta B$ for $A \in E$ and $B \in S$ naturally correspond to points $1 \rightarrow B$.
2. Morphisms $\nabla A \rightarrow \Box B$ for $A \in S$ and $B \in E$ naturally correspond to points $1 \rightarrow UB$.

**Proof.**

1. The following isomorphisms hold naturally:

   $E(\spadesuit A, \Delta B) \equiv E(\nabla U A, \Delta B) \quad \text{by definition of } \spadesuit$

   $\equiv S(C \nabla U A, B) \quad \text{as } C \dashv \Delta$

   $\equiv S(1, B) \quad \text{by contractible codiscreteness}$

2. The following isomorphisms hold naturally:

   $E(\nabla A, \Box B) \equiv E(\nabla A, \Delta U B) \quad \text{by definition of } \Box$

   $\equiv S(C \nabla A, UB) \quad \text{as } C \dashv \Delta$

   $\equiv S(1, UB) \quad \text{by contractible codiscreteness}$

\[\Box\]
In the concrete case of $\text{CSet}_L$, the above lemma says that morphisms of type $\Delta A \rightarrow \Delta B$ or $\Delta A \rightarrow \Delta B$ are constant functions. Indeed, the first isomorphism in either proof is an identity, and the second one collapses all elements of $\Delta UA$ or $\Delta A$ to a single element.

A special case of (1), ‘manually’ proven for the particular case of $\text{CSet}_L$ and $B = \mathbb{B}$, forms the central reasoning involved in the noninterference proofs of [Abadi et al. 1999]. Our result generalises this to any setting of pre-cohesion, and also yields the heretofore unnoticed dual (2).

We will now apply (1) and (2) to construct two noninterference proofs.

### 4.2 Moggi’s monadic metalanguage

Moggi [1991] introduced the monadic metalanguage, a typed $\lambda$-calculus which, for each type $A$ features a type of computations $TA$. The ‘result’ of a computation $M : TA$ is a ‘value’ of type $A$. Indeed, each ‘value’ is a trivial computation, as can be witnessed by the introduction rule:

$$
\Gamma \vdash M : A \\
\Gamma \vdash [M] : TA
$$

The idea is that types of the form $TA$ encapsulate various ‘notions of computations,’ nowadays referred to as effects (recursion, nondeterminism, operations on the store, etc.). Very little is assumed of the type constructor. To quote Moggi,

“Rather than focusing on a specific $T$, we want to find the general properties common to all notions of computation.”

Moggi then showed in [Moggi 1991, §3] that there is a categorical semantics of this language, where $T$ is interpreted by a strong monad on a category $C$. The category $C$ is then the category of values, whereas the Kleisli category $C_T$ of the monad $T : C \rightarrow C$ is the category of programs.

The key information flow property enjoyed by monads is that, once something is ‘inserted’ into the monad, then it cannot flow out. The monad identifies a region of the language which is impure, in that evaluating terms within the region causes effects. If the results of those effects were to flow ‘outside’ the monad, the outcome would be the loss of referential transparency. This information flow property is evident if one looks at the elimination rule for $T$:

$$
\Gamma \vdash M : TA \\
\Gamma, x : A \vdash N : TB \\
\Gamma \vdash \text{let } x = M \text{ in } N : TB
$$

If we have a computation $M : TA$ that yields a result of type $A$, the let construct allows us to substitute it for a variable of type $A$, but only as long as this to be used within another computation $N : TB$. Thus values of type $TA$ cannot ‘escape’ the scope of $T$.

It is not hard to show that $\text{CSet}_L$ is a model of Moggi’s monadic metalanguage (with booleans), with $T$ being interpreted by $\emptyset$, and $\text{Bool}$ by $\Delta B$: the only thing that remains to show is that $\emptyset$ is a strong monad, which is true by a more general result (Proposition 16). If we follow the usual conventions of categorical semantics, a term $x : TA \vdash M : \text{Bool}$ is interpreted as a morphism $\emptyset \llbracket A \rrbracket \rightarrow \Delta \mathbb{B}$; hence, by Prop. 12 we know it is interpreted by a constant function in the model.

Nevertheless, this is not a noninterference result yet, for it tells us something about a particular model, namely $\text{CSet}_L$, but nothing about the equational theory of Moggi’s calculus. To infer something about it from one of its models, some completeness property of that model must be established. We will use the simplest one of all, which is known as adequacy. It is the most basic form of completeness, and is commonly used in the study of calculi with recursion, e.g. PCF [Plotkin 1977; Streicher 2006]. A model of a calculus is adequate exactly when it is complete at ground types, which—for the purpose of this paper—we define as types definable by a collection of constants, along with an elimination and computation rule. For example, $\text{Bool}$ is such a ground type: it may...
be presented with introduction rules

\[ \Gamma \vdash t : \quad \Gamma \vdash \mathbf{f} : \text{Bool} \]

and the elimination rule

\[
\Gamma \vdash M : \text{Bool} \quad \Gamma \vdash E_0 : C \quad \Gamma \vdash E_1 : C \\
\overline{\Gamma \vdash \text{if } M \text{ then } E_1 \text{ else } E_0 : C}
\]

with the two computation rules:

\[
\begin{align*}
\text{if } t t \text{ then } E_1 \text{ else } E_0 &= E_1 \\
\text{if } \mathbf{f} \mathbf{f} \text{ then } E_1 \text{ else } E_0 &= E_0
\end{align*}
\]

Suppose that a (non-dependent, possibly modal) type theory satisfies canonicity at ground types, i.e. for every ground type \(G\) and every term \(\vdash M : G\) there is a unique constant \(c : G\) such that \(\vdash M = c : G\). Suppose now that we interpret the type theory in a category in the standard way—e.g. as shown in [Abramsky and Tzevelekos 2011; Crole 1993; Kavvos 2017a; Moggi 1991]—so that (a) closed terms \(\vdash M : G\) are interpreted as points \(1 \rightarrow \lbrack G\rbrack\), (b) the interpretation is sound, in the sense that \(\vdash M = N : A\) implies \(\lbrack M \rbrack = \lbrack N \rbrack : 1 \rightarrow \lbrack G\rbrack\), and that (c) the interpretation of the constants of each ground type \(G\) is injective, in the sense that distinct constants have distinct interpretations. Then, the interpretation is automatically adequate:

**Lemma 1 (Adequacy).** Suppose that a type theory satisfies canonicity at ground types, and has a sound categorical interpretation which is injective at every ground type \(G\), in the sense that

\[
\lbrack \vdash c_i : G \rbrack = \lbrack \vdash c_j : G \rbrack : 1 \rightarrow \lbrack G \rbrack \quad \implies \quad c_i \equiv c_j
\]

Then this interpretation is adequate for \(G\), in the sense that

\[
\lbrack \vdash M : G \rbrack = \lbrack \vdash c_i : G \rbrack \quad \implies \quad \vdash M = c_i : G
\]

**Proof.** By canonicity, for any \(\vdash M : G\) we have \(\vdash M = c_j : G\) for some constant \(c_j\) of \(G\). But then \(\lbrack c_i \rbrack = \lbrack M \rbrack = \lbrack c_j \rbrack\) by soundness, so \(c_i \equiv c_j\), and hence \(\vdash M = c_i : G\). \(\Box\)

This lemma applies to Moggi’s monadic metalanguage (with booleans): define a sound interpretation as in [Moggi 1991, §3], and interpret booleans by \(\Delta \mathbb{B}\) in the standard way. Re-establishing soundness after the addition of booleans is straightforward, and it follows that

**Theorem 4 (Noninterference for Moggi).** Let \(x : TA \vdash M : \text{Bool}\). Then, for any \(\vdash E, E' : TA\), we have

\(\vdash M[E/x] = M[E'/x] : \text{Bool}\)

**Proof.** \(\text{Bool}\) satisfies the assumptions of Lemma 1. Hence, the interpretation of the calculus is adequate for it. We have that

\[
\lbrack \vdash M[F/x] : \text{Bool} \rbrack = \lbrack x : TA \vdash M : \text{Bool} \rbrack \circ \lbrack \vdash F : TA \rbrack : 1 \rightarrow \Delta \mathbb{B}
\]

for any \(\vdash F : TA\). But, by Proposition 12(1), \(\lbrack x : TA \vdash M : \text{Bool} \rbrack : \top \lbrack A \rbrack \rightarrow \Delta \mathbb{B}\) is a constant function, so

\[
\lbrack M[E/x] \rbrack = \lbrack x : TA \vdash M : \text{Bool} \rbrack \circ \lbrack E \rbrack = \lbrack x : TA \vdash M : \text{Bool} \rbrack \circ \lbrack E' \rbrack = \lbrack M[E'/x] \rbrack
\]

for any \(\vdash E, E' : TA\). By adequacy, it follows that \(\vdash M[E/x] = M[E'/x] : \text{Bool}\). \(\Box\)
4.3 The Davies-Pfenning calculus

Davies and Pfenning introduced a comonadic modal type theory as a type system for binding-time analysis in [Davies and Pfenning 1996, 2001]. The idea was that data could not arbitrarily flow from type $A$ to type $\Box A$. This is clearly reflected in the structure of the type system. Each typing judgment comes with two contexts, and has the shape

$$\Delta \mid \Gamma \vdash M : A$$

where $\Delta$ are the ‘modal’ variables, and $\Gamma$ are normal variables. A ‘modal’ variable can be used as a normal variable, as witnessed by the variable rule $\Delta, u : A \mid \Gamma \vdash u : A$. However, when introducing terms of type $\Box A$, we can only use ‘modal’ variables from $\Delta$:

$$\Delta \mid \cdot \vdash M : A$$

It is not hard to define a non-trivial morphism $\text{Bool} \to \text{Bool}$:

$$b : \text{Bool} \vdash \text{if } b \text{ then } tt \text{ else } ff : \Box \text{Bool}$$

However, it is impossible to pass from $A \to B$ to $\Box(A \to B)$ in general. This property was used by Davies and Pfenning to separate things that were available statically, by isolating them under the box, from things that are available dynamically (and thus cannot always be used for metaprogramming). For example, one can always use a boolean constant for metaprogramming, as shown above, but one cannot use ‘live’ piece of code, a function $A \to B$. However, if one has prudently arranged to have a copy of the source code of a function $A \to B$ available, that would be of type $\Box(A \to B)$, and one can then use it for metaprogramming.

Terms of type $\Box A$ are used by substituting for a variable in the ‘modal’ context. This yields the following elimination rule:

$$\Delta \mid \Gamma \vdash M : \Box A \quad \Delta, u : A \mid \Gamma \vdash N : B$$

along with the reduction $\text{let } u = M \text{ in } N : B$.

Even though the information flow properties of the Davies-Pfenning calculus are intuitive, it is not at all evident how to express them as a noninterference theorem. Whilst, in Moggi’s calculus, the monad $T$ blocked all information flow out of it, the Davies-Pfenning calculus allows some flow into the modal types, as witnessed by the non-trivial morphism $\text{Bool} \to \Box \text{Bool}$ constructed above.

The way out is to consider the dual of the statement used to prove noninterference for the meta-language, namely Proposition 12(2). In the place of booleans, we will use the codiscrete booleans $\text{Bool}_c$. These are introduced explicitly by

$$\Delta \mid \Gamma \vdash tt : \text{Bool}_c \quad \Delta \mid \Gamma \vdash ff : \text{Bool}_c$$

and the elimination rule

$$\Gamma \vdash M : \text{Bool}_c \quad \Gamma \vdash E_0 : C \quad \Gamma \vdash E_1 : C \quad C \text{ is codiscrete}$$

$$\Gamma \vdash \text{if } M \text{ then } E_1 \text{ else } E_0 : C$$

with the same computation rules as before. The side condition that $C$ is codiscrete is defined by (I) unit (if we have it) and $\text{Bool}_c$ are codiscrete; (II) if $A$ and $B$ are codiscrete, then so is $A \times B$; (III) if $B$ is codiscrete, then so is $A \to B$. We will discover the roots of this definition in §5.2.1. For now, let us say that the intended meaning is that, when interpreted in $\text{CSet}_L$, $\llbracket C \rrbracket$ will be a codiscrete object, i.e. isomorphic to $\Diamond \llbracket C \rrbracket$. 
Now, let us note that the Davies-Pfenning calculus (with booleans) satisfies canonicity, and has a standard interpretation in any cartesian closed category with a product-preserving comonad on it, as shown e.g. by [Hofmann 1999; Kavvos 2017a]. In this setting, we may again show adequacy:

**Lemma 2 (Davies-Pfenning Adequacy).** Suppose we have a sound categorical semantics for the Davies-Pfenning calculus, as well as a ground type $G$ with an injective interpretation, so that
\[ \vdash c : G \Rightarrow \vdash c : G : 1 \to [G] \]  
Then this interpretation is adequate for $\Box G$, in the sense that
\[ \vdash M : \Box G \Rightarrow \vdash \text{box } c : \Box G \]  

**Proof.** Note that the canonical forms of type $\Box G$ are precisely those of the form $\text{box } c_i$. We therefore have that $\vdash M = \text{box } c_i : \Box G$ for some $c_i$. But then, if $\llbracket M \rrbracket = \llbracket \text{box } c_j \rrbracket$ we have—writing $(-)^*$ for the co-Kleisli extension and using soundness—that
\[ \llbracket c_j \rrbracket^* = \llbracket \text{box } c_j \rrbracket = \llbracket M \rrbracket = \llbracket \text{box } c_i \rrbracket = \llbracket c_i \rrbracket^* \]  
Post-composing with the counit (see [Kavvos 2017b, Prop. 4, §7.3.2]) we obtain $\llbracket c_j \rrbracket = \llbracket c_i \rrbracket$, and hence $c_i \equiv c_j$. \hfill $\Box$

By Corollary 1, we know that $\Box : \text{CSet}_L \longrightarrow \text{CSet}_L$ is a product-preserving comonad, and thus a model of the Davies-Pfenning calculus. Moreover, we can interpret $\text{Bool}_G$ by $\forall \Box$. By Proposition 12(2), any term $\cdot \mid x : \text{Bool}_G \vdash M : \Box A$ is interpreted by a constant function in the category $\text{CSet}_L$. This interpretation is seen to be sound by standard methods, and hence we obtain

**Theorem 5 (Noninterference for Davies-Pfenning).** Let $\cdot \mid x : \text{Bool}_G \vdash M : \Box G$ for any ground type $G$. Then, for any $\vdash E, E' : \text{Bool}_G$, we have
\[ \vdash M[E/x] = M[E'/x] : \Box G \]  

**Proof.** We have that
\[ \llbracket M[E/x] \rrbracket = \llbracket \cdot \mid x : \text{Bool}_G \vdash M : \Box G \circ [F] \]  
for any $\vdash F : \text{Bool}_G$. But $\llbracket \cdot \mid x : \text{Bool}_G \vdash M : \Box G \llbracket$ is a constant function, so $\llbracket M[E/x] \rrbracket = \llbracket M[E'/x] \rrbracket$ for any $\vdash E, E' : \text{Bool}_G$. By adequacy, it follows that $\vdash M[E/x] = M[E'/x] : \Box G$. \hfill $\Box$

## 5 Levelled Cohesion

Whilst useful for discussing the properties of monadic and comonadic modalities, the results presented above are not particularly interesting in terms of information flow. For each classified set $X$, the set $\Box X$ is a version of it where everything is visible, whereas $\Diamond X$ is a version of it where nothing is. Might we be able to use the same ideas about pre-cohesion to make something similar, yet far more expressive? The key lies in relating pre-cohesion to the set of labels $L$, of which we have not yet made any use.

Given a subset $\pi \subseteq L$ of labels, there is a 'partially forgetful' functor,
\[ U_\pi : \text{CSet}_L \longrightarrow \text{CSet}_{L-\pi} \]
which maps classified sets over $L$ to classified sets over $L - \pi$ by ‘forgetting’ $R_\ell$ for $\ell \not\in \pi$. As before, there are two ways to define a set classified over $L$ when given a set classified over $L - \pi$.

The first one is given by the functor
\[ \Delta_\pi : \text{CSet}_{L-\pi} \longrightarrow \text{CSet}_L \]
$\Delta_\pi X$ has the same carrier as $X$, and the same relations $R_\ell$ for $\ell \not\in \pi$. But, if $\ell \in \pi$, then $R_\ell$ of $\Delta_\pi X$ is the diagonal relation. We let $\Delta_\pi$ be the identity on morphisms: all the relations not in $\pi$
are preserved by $\Delta_\pi f$, and the rest are diagonal so they are also trivially preserved. So for each classified set $X$ over $L - \pi$, we have a classified set $\Delta_\pi X$ over $L$ which is transparent at $\pi$. It is easy to see that $\Delta_\pi$ is full and faithful, and that

**Proposition 13.** $\Delta_\pi \dashv U_\pi$

The second one is given by the functor

$$\nabla_\pi : \mathbf{CSet}_{L-\pi} \to \mathbf{CSet}_L$$

which, this time, adds the complete relation as $R_\ell$ for each $\ell \in \pi$, and is also the identity on morphisms. Thus, for each classified set $X$ over $L - \pi$, we have a classified set $\nabla_\pi X$ over $L$ which is opaque at $\pi$. It is also easy to see that it $\nabla_\pi$ is full and faithful, and that

**Proposition 14.** $U_\pi \dashv \nabla_\pi$

It remains to consider connected components. Suppose we have a morphism $f : X \to \Delta_\pi Y$. For each $\ell \in \pi$, the relation $\Delta_\pi Y$ is reflexivity. Hence, for $\ell \in \pi$,

$$x R_\ell x' \ (in \ X) \implies f(x) \ R_\ell \ f(x') \ (in \ \Delta_\pi Y) \implies f(x) = f(x')$$

Thus, if $x$ and $x'$ are indistinguishable at level $\ell \in \pi$, then $f$ collapses them to a single element. As before, we would also like to phrase this in terms of quotients. Let $R_\pi^*$ to be the reflexive, symmetric, transitive closure of $\bigcup_{\ell \in \pi} R_\ell$. The construction of the quotient set $|X|/R_\pi^*$ extends to a functor

$$C_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_{L-\pi}$$

by letting $C_\pi(X)$ be the classified set with carrier $|X|/R_\pi^*$, and, for $\ell \in L - \pi$,

$$[b] \ R_\ell \ [b'] \ in \ C_\pi(X) \iff \exists x \in [b]. \ \exists y \in [b']. \ x R_\ell y \ in \ X$$

We let $C_\pi f \overset{\text{def}}{=} f_\pi^* : |X|/R_\pi^* \to |Y|/R_\pi^*$, where

$$f_\pi^*(|[x]|) \overset{\text{def}}{=} [f(x)]$$

$f_\pi^*$ is well-defined, as—by the same argument as in §3—$f$ preserves $R_\pi^*$. If $[b] \ R_\ell \ [b']$, there exist $x$ and $y$ such that $x R_\pi^* b$, $y R_\pi^* b'$, and $x R_\ell y$. But $f$ preserves all of these relations, so $[f(b)] \ R_\ell \ [f(b')]$. So $f_\pi^*$ is actually a morphism $C_\pi(X) \to C_\pi(Y)$. A similar argument to the one in §3 takes $f : X \to \Delta_\pi Y$ to a unique $\hat{f} : C_\pi X \to Y$, and hence

**Proposition 15.** $C_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_{L-\pi}$ is left adjoint to $\Delta_\pi : \mathbf{CSet}_{L-\pi} \to \mathbf{CSet}_L$.

It is easy to see that this preserves products, and that the nullstellensatz holds as before (the natural isomorphisms showing $\Delta_\pi \dashv U_\pi \dashv \nabla_\pi$ are identitites on the hom-sets). In total:

**Theorem 6.** $\mathbf{CSet}_L$ is pre-cohesive relative to $\mathbf{CSet}_{L-\pi}$.

It is worth reiterating some of the things that we automatically learn from this fact:

**Corollary 2.** For a given $\pi \subseteq L$,

1. $U_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_{L-\pi}$ preserves (co)limits.
2. $\Delta_\pi : \mathbf{CSet}_{L-\pi} \to \mathbf{CSet}_L$ preserves (co)limits.
3. $\nabla_\pi : \mathbf{CSet}_{L-\pi} \to \mathbf{CSet}_L$ preserves limits.
4. $\square_\pi \overset{\text{def}}{=} \Delta_\pi U_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_L$ is an idempotent comonad that preserves finite (co)limits.
5. $\nabla_\pi U_\pi \overset{\text{def}}{=} \nabla_\pi \Omega_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_L$ is an idempotent monad that preserves finite limits.
6. $\bigcirc_\pi \overset{\text{def}}{=} \Delta_\pi C_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_L$ is an idempotent monad, preserves products and colimits.
7. $\Psi_\pi \overset{\text{def}}{=} \nabla_\pi C_\pi : \mathbf{CSet}_L \to \mathbf{CSet}_L$ is an idempotent monad, preserves products and colimits.
5.1 Redaction is a strong monad

We record here a fact that we have already used and will use again, namely that

\[ \diamondsuit_\pi \text{ is a strong monad: that is, there exists a natural transformation} \]
\[ t_{A,B} : A \times \diamondsuit_\pi B \to \diamondsuit_\pi (A \times B) \]

such that the following diagrams commute:

\[ \begin{array}{ccc}
1 \times \diamondsuit_\pi A & \xrightarrow{t_{L,A}} & \diamondsuit_\pi (1 \times A) \\
\downarrow{\pi_1} & & \downarrow{\pi_1} \\
\diamondsuit_\pi A & \xrightarrow{\pi_2} & \diamondsuit_\pi (A \times B) \\
\end{array} \]
\[ \begin{array}{ccc}
(1 \times \diamondsuit_\pi A) \times \diamondsuit_\pi C & \xrightarrow{t_{A,B,C}} & \diamondsuit_\pi ((A \times B) \times C) \\
\downarrow{\pi_1 \times \pi_2} & & \downarrow{\pi_1 \times \pi_2} \\
A \times (B \times \diamondsuit_\pi C) & \xrightarrow{id_{A \times B,C}} & A \times \diamondsuit_\pi (B \times C) \\
\downarrow{\pi_B} & & \downarrow{\pi_B} \\
A \times B & \xrightarrow{t_{A,B,B}} & \diamondsuit_\pi (A \times B) \\
\end{array} \]

**Proof.** The components \( t_{A,B} \) are identity functions on \( |A \times \diamondsuit_\pi B| = |A| \times |B| = |\diamondsuit_\pi (A \times B)| \). These preserve all the relations at \( \ell \in \pi \), as \( \diamondsuit_\pi (A \times B) \) is protected at \( \pi \). If \( \ell \notin \pi \), then \( (a,b) R_\ell (a',b') \) in \( A \times \diamondsuit_\pi B \) means that \( a R_\ell a' \) in \( A \) and \( b R_\ell b' \) in \( B \), so \( (a,b) R_\ell (a',b') \) in \( A \times B \) and hence in \( \diamondsuit_\pi (A \times B) \). The diagrams commute as all the arrows excluding projections and associativities (but including components of \( t, \eta \) and \( \mu \) and products thereof) are identities on carrier sets. \( \square \)

5.2 (Co)reflective subcategories

In cohesive settings, we have a string of adjoints \( \Delta + U + \nabla \), where \( \Delta \) and \( \nabla \) are full and faithful. This is to say that both \( \Delta \) and \( \nabla \) are a kind of ‘inclusion,’ and that—up to equivalence—they exhibit certain subcategories of \( \mathcal{E} \). In particular, \( \nabla \) exhibits a reflective subcategory of objects \( \mathcal{Y} \) such that \( \nabla \mathcal{Y} \equiv \mathcal{Y} \). On the other hand, \( \Delta \) exhibits a coreflective subcategory of \( \mathcal{E} \), which is the full subcategory consisting of objects \( X \) such that \( \square X \equiv X \). It is illuminating to look at each of these cases for the pre-cohesion of \( \text{CSet}_L \) relative to \( \text{CSet}_{L-\pi} \).

5.2.1 Reflection. If \( X \) is a classified set such that \( X \equiv \diamondsuit_\pi X \), then \( R_\ell \) is the complete relation at all \( \ell \in \pi \). This leads us to the following definition:

**Definition 5 (Protection).** Let \( \pi \subseteq L \) be a set of labels. A classified set \( X \) is protected at \( \pi \) just if \( R_\ell = |X| \times |X| \) for all \( \ell \in \pi \).

Thus the monad \( \diamondsuit_\pi \) induces a reflective subcategory \( \text{CSet}_{L,p,\pi} \) of classified sets protected at \( \pi \). In other words, there is a functor \( R_\pi : \text{CSet}_L \to \text{CSet}_{L,p,\pi} \) that is left adjoint to the inclusion \( \text{CSet}_{L,p,\pi} \to \text{CSet}_L \):

\[ \begin{array}{ccc}
\text{CSet}_{L,p,\pi} & \xleftarrow{\sim} & \text{CSet}_L \\
\downarrow{R_\pi} & & \downarrow{i} \\
\text{CSet}_L & \xrightarrow{i} & \text{CSet}_{L-\pi} \\
\end{array} \]

\( R_\pi \) maps each classified set \( X \) to one with the same carrier, but with \( R_\ell \) replaced with the complete relation for every \( \ell \in \pi \). Moreover, we have that \( \diamondsuit_\pi = i \circ R_\pi \). Interestingly,
Proposition 17. \( R_\pi : \text{CSet}_L \to \text{CSet}_{L,p,\pi} \) preserves finite products.

This is because \( \text{CSet}_{L,p,\pi} \equiv \text{CSet}_{L,\pi} \), and up to that equivalence, \( R_\pi \) is just \( U_\pi \), and \( i \) is just \( \nabla_\pi \).

By a theorem of category theory—see e.g. [Johnstone 2003, §A4.3.1]—if a reflector preserves finite products, as \( R_\pi \) does, then the reflective subcategory is an exponential ideal. That is,

**Corollary 3.** If \( A \) is a classified set, and \( B \) is protected at \( \pi \), then \( B^A \) is protected at \( \pi \).

This is what underlies the definition of codiscrete objects we gave in §4, and which was introduced as a unmotivated definition in [Abadi et al. 1999].

5.2.2 Coreflection. Dually, the second subcategory consists of classified sets \( X \) over \( L \) such that \( X \equiv \Box_\pi X \). Each \( R_\ell \) in \( X \) for \( \ell \in \pi \) is the diagonal relation. The corresponding definition is:

**Definition 6 (Visibility).** Let \( \pi \subseteq L \) be a set of labels. A classified set \( X \) is visible at \( \pi \) just if \( R_\ell = \{ (x, x) \mid x \in |X| \} \) for every \( \ell \in \pi \).

This full subcategory induced \( \Box_\pi \) is notated \( \text{CSet}_{L,v,\pi} \), and its objects are those classified sets that are visible at \( \pi \). There is a functor

\[ D_\pi : \text{CSet}_L \to \text{CSet}_{L,v,\pi} \]

which, for each classified set \( X \) yields the classified \( D_\pi X \) that has the same carrier, but if \( \ell \in \pi \) then \( R_\ell \) is the diagonal relation. It is also the identity on morphisms. This functor is right adjoint to the inclusion:

\[ \text{CSet}_{L,v,\pi} \xrightarrow{\perp} \text{CSet}_L \]

and of course \( \Box_\pi = i \circ D_\pi \).

5.3 Stacking pre-cohesions and inter-level reasoning

In fact, it is not hard to generalise the results in the above section to the fact that we can 'stack' such pre-cohesions on top of one another. For example, by applying Theorem 6 twice, if \( \pi' \subseteq \pi \subseteq L \), we can obtain two pre-cohesions:

\[ \text{CSet}_L \]

\[ \text{CSet}_\pi \]

\[ \text{CSet}_{\pi'} \]

which compose to what we previously denoted \( \text{CSet}_{L,\pi'} \circ \Delta_{L,\pi'} \circ U_{L,\pi'} \circ \nabla_{L,\pi'} \). For example,

\[ U_{L,\pi'} = U_{\pi' \subseteq \pi} \circ U_{\pi' \subseteq L} : \text{CSet}_L \to \text{CSet}_{\pi'} \]

\[ \nabla_{L,\pi'} = \nabla_{\pi \subseteq L} \circ \nabla_{\pi' \subseteq \pi} : \text{CSet}_{\pi'} \to \text{CSet}_L \]

and so forth. This forms a functor

\[ \mathcal{P}(L)^{op} \to \text{Precoh} \]

from the opposite powerset lattice of \( L \) to \( \text{Precoh} \), which has strings of adjoints \( (C, \Delta, U, \nabla) : \mathcal{E} \to \mathcal{S} \) that exhibit \( \mathcal{E} \) to be pre-cohesive over \( \mathcal{S} \) for morphisms. The functor maps the unique arrow
α : π ⊆ π’ to a pre-cohesion \((C_\alpha, \Delta_\alpha, U_\alpha, \nabla_\alpha) : \text{CSet}_{\pi'} \rightarrow \text{CSet}_{\pi}\). Thus, each \(\alpha : \pi \subseteq \pi'\) induces modalities \(\Box_\alpha, \Diamond_\alpha : \text{CSet}_{\pi'} \rightarrow \text{CSet}_{\pi}\), and we previously wrote \(\Box_\pi\) for \(\Box_{\alpha : \pi' \subseteq \pi}\).

This functorial structure satisfies a number of strange-looking—yet very intuitive in terms of information flow—properties. To begin, we recall the isomorphism \(U_\alpha \Delta_\alpha \cong U_\alpha \nabla_\alpha \cong \text{Id}\), which was a consequence of pre-cohesion (Proposition 1), and holds on-the-nose in classified sets. This has the following consequences regarding the induced modalities.

**Proposition 18.** If \(\gamma : \pi'' \subseteq \pi'\) and \(\alpha : \pi' \subseteq \pi\), then:

1. \(\Diamond_{\alpha \circ \gamma} \Box_\alpha = \Diamond_{\alpha \circ \gamma} : \text{CSet}_{\pi} \rightarrow \text{CSet}_{\pi}\)
2. \(\Box_{\alpha \circ \gamma} \Diamond_\alpha = \Box_{\alpha \circ \gamma} : \text{CSet}_{\pi} \rightarrow \text{CSet}_{\pi}\)

**Proof.**

\[
\Diamond_{\alpha \circ \gamma} \circ \Box_\alpha = \Diamond_{\alpha \circ \gamma} U_{\alpha \circ \gamma} \Delta_\alpha U_\alpha = \Diamond_{\alpha \circ \gamma} U_\gamma U_\alpha \Delta_\alpha U_\alpha = \Diamond_{\alpha \circ \gamma} U_\gamma U_\alpha = \Diamond_{\alpha \circ \gamma} U_{\alpha \circ \gamma} = \Diamond_{\alpha \circ \gamma}
\]

(1) by definition

by functoriality and contravariance of \(U\)

by the fundamental corollary

by definition

(2) Similar to (1).

Intuitively, the first of these results says that declassifying things at some levels, and then redacting more than what was declassified is exactly the same as redacting all at once. Please note that we used no particular properties about the model of classified sets, apart from the strictness of \(U\Delta = U\nabla = \text{Id}\).

Next, the forgetful functor \(U\) and the discretisation functor \(\Delta\) sometimes commute. More specifically, if we have a pullback diagram in \(P(\mathcal{L})\)

\[
\begin{array}{ccc}
\pi_1 & \overset{\alpha}{\rightarrow} & \pi \\
\gamma \downarrow & & \downarrow \beta \\
\pi_1 \cap \pi_2 & \overset{\delta}{\rightarrow} & \pi_2
\end{array}
\]

then it is easy to check that the following functor diagram commutes on-the-nose:

\[
\begin{array}{ccc}
\text{CSet}_{\pi} & \overset{\Delta_\beta}{\leftarrow} & \text{CSet}_{\pi_2} \\
\text{CSet}_{\pi_1} & \overset{U_\beta}{\leftarrow} & \text{CSet}_{\pi_1 \cap \pi_2} \\
\Delta_\gamma & \downarrow & \downarrow U_\delta \\
\text{CSet}_{\pi_1} & \overset{U_\gamma}{\leftarrow} & \text{CSet}_{\pi_2}
\end{array}
\]

That is: if, starting from \(\pi_2\), we equip the extra labels with discrete cohesion, and then forget everything down to \(\pi_1\), we have not changed any of the labels of \(\pi_1 \cap \pi_2\). Thus, we might first
forget, and then discretise up to \( \pi_1 \). The same holds of codiscretisation, so we obtain

\[
U_\alpha \nabla_\beta = \nabla_\gamma U_\delta
\]

A sufficient condition for the above is that the components of the pasting diagram

\[
\begin{array}{ccc}
\text{CSet}_{\pi_1} & \xrightarrow{\epsilon} & \text{CSet}_{\pi_1} \\
\downarrow U_\delta & & \downarrow \Delta_\delta \\
\text{CSet}_{\pi_1 \cap \pi_2} & \xleftarrow{\Delta_\gamma} & \text{CSet}_{\pi_1 \cap \pi_2} \\
\downarrow \Delta_\gamma & & \downarrow U_\delta \\
\text{CSet}_\pi & \xrightarrow{U_\alpha} & \text{CSet}_\pi \\
\end{array}
\]

are identities—and they indeed are in our case: the components of \( \eta \) and \( \epsilon \) are identity functions, so this reduces to simply checking \( \Delta_\gamma U_\delta = U_\alpha \Delta_\beta \) again.

Secondly, if we discretise and codiscretise in disjoint regions, then these operations can be swapped. Namely, given a pullback diagram like above, we also have that

\[
\begin{array}{ccc}
\text{CSet}_\pi & \xleftarrow{\Delta_\alpha} & \text{CSet}_\pi \\
\downarrow \nabla_\beta & & \downarrow \Delta_\delta \\
\text{CSet}_{\pi_1} & \xleftarrow{\nabla_\gamma} & \text{CSet}_{\pi_2} \\
\downarrow \Delta_\gamma & & \downarrow \Delta_\delta \\
\text{CSet}_{\pi_1 \cap \pi_2} & \xleftarrow{\nabla_\gamma} & \text{CSet}_{\pi_1 \cap \pi_2} \\
\end{array}
\]

commutes. Again, it suffices that the following pasting diagram composes to an identity:

\[
\begin{array}{ccc}
\text{CSet}_{\pi_1 \cap \pi_2} & \xleftarrow{\Delta_\delta} & \text{CSet}_{\pi_1 \cap \pi_2} \\
\downarrow \equiv \downarrow U_\delta & & \downarrow \equiv \downarrow U_\delta \\
\text{CSet}_{\pi_1} & \xleftarrow{\nabla_\gamma} & \text{CSet}_{\pi_1} \\
\downarrow \nabla_\beta & & \downarrow \nabla_\beta \\
\text{CSet}_\pi & \xleftarrow{U_\alpha} & \text{CSet}_\pi \\
\end{array}
\]

where \( \xi \) is the preceding pasting diagram for \( \nabla \).

These “basic laws” allow us to prove many more that relate the different cohesive structures.

**Proposition 19.** Let \( \pi_1 \) be a pullback diagram. Then,

1. \( \square_\gamma U_\alpha = U_\alpha \square_\beta \)
2. \( \lozenge_\gamma U_\alpha = U_\alpha \lozenge_\beta \)
3. \( \square_\alpha \lozenge_\gamma = \square_\alpha \square_\beta \)
4. \( \lozenge_\alpha \lozenge_\gamma = \lozenge_\alpha \lozenge_\beta \)
5. \( \square_\alpha \square_\beta = \square_\beta \square_\alpha \)
6. \( \lozenge_\alpha \lozenge_\beta = \lozenge_\beta \lozenge_\alpha \)
**Proof.**

(1)  
\[ \square_y U_\alpha = \Delta_y U_y U_\alpha \]
\[ = \Delta_y U_\delta U_\beta \] by definition
\[ = U_\alpha \Delta_\beta U_\beta \] by functoriality of \( U \)
\[ = U_\alpha \Box_\beta \] by the first basic law above

(2) Similar to (1), but with \( \nabla \).

(3)  
\[ \Box_{\alpha \circ y} = \Delta_\alpha \Delta_y U_y U_\alpha \]
\[ = \Delta_\alpha \Box_y U_\alpha \] by definition (\( U \) contravariant)
\[ = \Delta_\alpha U_\alpha \Box_\beta \] by (1)
\[ = \Box_\alpha \Box_\beta \] by definition

(4) Similar to (3), but with \( \nabla \).

(5) By applying (3) twice:
\[ \Box_\alpha \Box_\beta = \Box_\alpha \Box_\gamma = \Box_\beta \Box_\delta = \Box_\alpha \Box_\beta \]

(6) Similar to (5).

All this structure allows us to show things about the original modalities \( \Box_\pi, \lozenge_\pi : \text{CSet}_L \to \text{CSet}_L \).

**Proposition 20.**

1. If \( \pi \cap \pi' = \emptyset \), then \( \Box_\pi \Box_\pi' = \Box_{\pi \cup \pi'} \).
2. If \( \pi \cap \pi' = \emptyset \), then \( \lozenge_\pi \lozenge_\pi' = \lozenge_{\pi \cup \pi'} \).
3. \( \Box_\pi \Box_\pi' = \Box_{\pi \cap \pi'} \)
4. \( \lozenge_\pi \lozenge_\pi' = \lozenge_{\pi \cap \pi'} \)
5. If \( \pi \subseteq \pi' \), then \( \Box_\pi \Box_\pi' = \Box_\pi \).
6. If \( \pi \subseteq \pi' \), then \( \lozenge_\pi \lozenge_\pi' = \lozenge_\pi' \).
7. If \( \pi \cap \pi' = \emptyset \), then \( \Box_\pi \Box_\pi' = \Box_{\pi' \cap \pi} \).
8. \( \Box_\pi \Box_\pi' = \lozenge_{\pi' \cap \pi} \Box_\pi \).

**Proof.** Notice that \( \pi \cap \pi' = \emptyset \) implies that \( L - \pi \)
\[ \xrightarrow{\alpha} L \leftarrow L - \pi' \]
\[ \xrightarrow{\beta} L - (\pi \cup \pi') \]
\[ \xrightarrow{\delta} \]

is a pullback diagram.

We can hence use Prop. 19: for (1), we have
\[ \Box_{\pi \cup \pi'} = \Box_{\alpha \circ y} = \Box_\alpha \Box_\beta = \Box_\pi \Box_\pi' \]

by definition and Prop. 19(3), and very similarly for (2). (3) follows by writing \( \pi = \pi_1 \cup (\pi \cap \pi') \) and \( \pi' = \pi_2 \cup (\pi \cap \pi') \) as disjoint unions, and then using (1) and (strict) idempotence to compute
\[ \Box_\pi \Box_\pi' = \Box_{\pi_1} \Box_{\pi \cap \pi'} \Box_{\pi_2} = \Box_{\pi_1} \Box_{\pi \cap \pi'} \Box_{\pi_2} = \Box_{\pi_1 \cap (\pi \cap \pi')} \cup \pi_2 \]

which is by definition equal to \( \Box_{\pi \cup \pi'} \). Again, a similar story for (4).

(5) and (6) follow from Prop. 18 (with \( \gamma : L - \pi' \subseteq L - \pi \) and \( \alpha : L - \pi \subseteq L \)).
For (7), we calculate:
\[
\Box_{\pi'} \downarrow_{\pi} = \Box_{\alpha} \downarrow_{\beta}
\]
by definition
\[
= \Delta_{\alpha} U_{\alpha} \bigtriangledown_{\beta} U_{\beta}
\]
by definition
\[
= \Delta_{\alpha} \bigtriangledown_{\gamma} U_{\delta} U_{\beta}
\]
by the first basic law
\[
= \bigtriangledown_{\beta} \Delta_{\delta} U_{\delta} U_{\beta}
\]
by the second basic law
\[
= \bigtriangledown_{\beta} U_{\delta} \Box_{\alpha}
\]
by Prop. 19(1)
\[
= \downarrow_{\beta} \downarrow_{\alpha}
\]
by definition

Finally, (8) follows easily by writing \( \pi = (\pi \cap \pi') \cup (\pi - \pi') \) and \( \pi' = (\pi \cap \pi') \cup (\pi' - \pi) \), and then using (3), (5), and (7).

All of the above equational laws express very intuitive properties. For example, (3) says that if we erase all the relations at security levels \( \pi \cup \pi' \), we could have done that in two steps, with either \( \pi \) or \( \pi' \) first. (5) can be understood to mean that protecting everything at levels \( \pi \) and then declassifying everything at a larger set of levels \( \pi' \) is exactly the same as declassifying \( \pi' \) in one go. (7) allows us to switch redaction and declassification if they act on disjoint sets of labels. Finally, (8) shows how to switch them even when there is overlap.

We have therefore developed an armory of results about information flow. But notice that we have used no relational reasoning at all! We have only relied on a functor \( C^{\text{op}} \to \text{Precoh} \), and the three equations
\[
U_{\alpha} \Delta_{\beta} = \Delta_{\gamma} U_{\delta} \quad (1)
\]
\[
U_{\alpha} \bigtriangledown_{\beta} = \bigtriangledown_{\gamma} U_{\delta} \quad (2)
\]
\[
\Delta_{\alpha} \bigtriangledown_{\beta} = \bigtriangledown_{\gamma} \Delta_{\delta} \quad (3)
\]
for each pullback diagram \( \delta \downarrow_{\beta} \bigtriangledown_{\gamma} \to \alpha \) in \( C \). It is conceivable that these equations could have a more general standing, especially if we replace equality with natural isomorphism. All the results in this section would then hold, but only up to natural isomorphism.

6 NONINTERFERENCE II: MULTI-MODAL INFORMATION FLOW

The theory developed in the previous section enables us to model multi-modal information flow calculi, which feature modalities that are indexed in some way. The usual way to do so is to index them over a poset \( (\mathcal{L}, \sqsubseteq) \) of security levels, and which is often (but not always) a lattice. We will focus on two main examples: the dependency core calculus (DCC) of [Abadi et al. 1999], and the sealing calculus of [Shikuma and Igarashi 2008].

We have now moved on to levelled cohesion over an arbitrary set \( L \) of labels. The first thing we want to note is that codiscrete contractibility is still satisfied, as long as \( \pi \neq \emptyset \): that is, if we redact something for some security levels \( \pi \) and then take the 'view from \( \pi \)' we end up with almost nothing, namely a single connected component:
\[
C_{\pi}(\downarrow_{\pi} X) \cong 1
\]

For that reason, a levelled version of Prop. 12 from §4 holds:
Proposition 21. If $\pi \neq \emptyset$, morphisms $\diamond_{\pi} A \to \Delta_{\pi} B$ naturally correspond to points $1 \to B$, and are hence constant functions in $\mathsf{CSet}_{\mathcal{L}}$.

The proof is the same as before.

6.1 Dependency Core Calculus

The dependency core calculus of [Abadi et al. 1999] is at its core a version of Moggi’s computational metalanguage with multiple monads $T_\ell$, indexed over $\ell \in \mathcal{L}$, where $(\mathcal{L}, \sqsubseteq)$ is a lattice, also called an information flow lattice. If we limit ourselves to the terminating fragment—as the original presentation also included fixpoints—all we need to interpret the DCC is a strong monad for each $\ell \in \mathcal{L}$.

Hence, given Prop. 16, we can interpret these in classified sets as

$$T_\ell \overset{\text{def}}{=} \downarrow \ell$$

where $\downarrow \ell \overset{\text{def}}{=} \{ \ell' \in \mathcal{L} \mid \ell' \sqsubseteq \ell \}$ is the principal lower set of $\ell$. Thus, $T_\ell A$ is protected at $\ell$ and all levels below it. The introduction rule is exactly that of Moggi’s monadic metalanguage:

$$\Gamma \vdash M : A \quad \Gamma \vdash [M]_\ell : T_\ell A$$

The elimination rule is modified slightly:

$$\Gamma \vdash M : T_\ell A \quad \Gamma, x : A \vdash N : B \quad B \text{ is protected at and below } \ell$$

$\Gamma \vdash \text{let } x = M \text{ in } N : B$

We can use the value produced by a term of type $T_\ell A$ in a term of type $B$, as long as $B$ is protected below $\ell$, which is to say $B$ is isomorphic to $T_\ell B$. [Abadi et al. 1999] gave an explicit definition of which types are protected, which coincides with the reflective subcategory we presented in §5.2.1: protected types are generated by unit, $T_\ell (A)$, are closed under products, and constitute an exponential ideal. It is easy to see that our levelled structure from §5 is a model of the DCC.

There is no explicit noninterference theorem stated for DCC itself in [Abadi et al. 1999]. Instead, there are six translations from various calculi into DCC, which are used to prove noninterference for each of these ‘source’ calculi. The technique is always the same: first, show that the translation $(-)^\downarrow$ is adequate, in the sense that $E$ has a canonical form in the source calculus if and only if the semantics of the translation satisfies $\llbracket E \rrbracket^\downarrow \neq \bot$. Then, some argument similar to our Prop. 21 is used to show constancy of the DCC-induced semantics $\llbracket E \rrbracket^\downarrow$ of a term $E : \mathsf{Bool}$ with a single free variable of an appropriately ‘secure’ type. Then $\llbracket (E[M/x])^\downarrow \rrbracket = \llbracket (E[M'/x])^\downarrow \rrbracket$ for all $M, M'$, and a single use of adequacy suffices to complete the argument.

We will attempt to capture the essence common to these proofs by the following proposition.

Proposition 22. If $\pi - \pi' \neq \emptyset$ and $B$ is visible at $\pi - \pi'$, then all morphisms

$\diamond_{\pi} A \to \diamond_{\pi'} B$

are constant functions.

Proof. If $B$ is visible at $\pi - \pi'$, then $B \cong \square_{\pi - \pi'} B = \Delta_{\pi - \pi'} U_{\pi - \pi'} B$. We also have a natural isomorphism between morphisms $\diamond_{\pi} A \to \diamond_{\pi'} B$ and morphisms $\square_{\pi'} \diamond_{\pi} A \to B$. But, using Prop. 20(8), $\square_{\pi'} \diamond_{\pi} = \diamond_{\pi - \pi'} \square_{\pi'}$. If we also postcompose the isomorphism $B \cong \Delta_{\pi - \pi'} U_{\pi - \pi'} B$, our original morphism corresponds to a morphism $\diamond_{\pi - \pi'} \square_{\pi} A \to \Delta_{\pi - \pi'} U_{\pi - \pi'} B$, and each hom-set

---

4It is worth noting that, curiously, the meet and join operations are never used in the study of the DCC.

5Recall that, unlike our work, [Abadi et al. 1999] is about calculi with recursion.
natural isomorphism we used was actually the identity (only the types changed.) But \( \pi - \pi' \neq \emptyset \), so Prop. 21 applies. \( \square \)

We have an analogue of Lemmas 1 and 2.

**Lemma 3 (DCC Adequacy).** Suppose we have a sound categorical semantics for the DCC, along the lines of the interpretation of the monadic metalanguage defined by Moggi [1991], such that—again according to op. cit—each monad \( T_\ell \) satisfies the mono requirement, i.e. each component \( A \rightarrow T_\ell A \) of the unit is mono. Let \( G \) be a ground type with an injective interpretation, so that

\[
\llbracket \ c_i : G \rrbracket = \llbracket \ c_j : G \rrbracket \quad \implies \quad c_i \equiv c_j
\]

Then this interpretation is adequate for \( T_\ell G \), in the sense that

\[
\llbracket \ M : T_\ell G \rrbracket = \llbracket \ [c_i]_\ell : T_\ell G \rrbracket \implies \ M = [c_i]_\ell : T_\ell G
\]

**Proof.** The canonical forms at \( T_\ell G \) are exactly \([c_i]_\ell\). Let \( M \) normalise to \([c_j]_\ell\). Then

\[
\eta_G \circ [c_j] = \llbracket [c_j]_\ell \rrbracket = \llbracket M \rrbracket = \llbracket [c_i]_\ell \rrbracket = \eta_G \circ [c_i]
\]

As \( \eta_G \) is mono, \([c_j] = [c_i] \), and hence \( c_j \equiv c_i \). \( \square \)

We can now interpret DCC+booleans into \( CSet \_\ell \), with \( \llbracket \text{Bool} \rrbracket \overset{\text{def}}{=} \Delta \mathbb{B} \). Then:

**Theorem 7 (Noninterference for DCC).** Let \( x : T_\ell A + M : T_\ell \text{Bool} \) with \( \ell \nsubseteq \ell' \). Then, for any \( \vdash E, E' : T_\ell \), we have

\[
\vdash M[x/E] = M[E'/x] : T_\ell \text{Bool}
\]

**Proof.** First, notice that the aforementioned interpretation into \( CSet \_\ell \) satisfies all the requirements of Lemma 3, so it is adequate. \( \Delta \mathbb{B} \) is a ground type and the unit \( A \rightarrow \diamond_x A \) is a mono, so our interpretation is adequate. We have

\[
\llbracket \ M[F/x] : T_\ell \text{Bool} \rrbracket = \llbracket x : T_\ell A + M : T_\ell \text{Bool} \rrbracket \circ \llbracket F : T_\ell A \rrbracket : 1 \rightarrow \Delta \mathbb{B}
\]

for any \( \vdash F : T_\ell A \). But we have that

\[
\ell \nsubseteq \ell' \iff \downarrow \ell \nsubseteq \downarrow \ell'
\]

Hence \( \downarrow \ell - \downarrow \ell' \neq \emptyset \). If we notice that \( \Delta \mathbb{B} \) is visible everywhere, it follows by Proposition 21 that \( \llbracket M \rrbracket : \diamond_\ell \llbracket A \rrbracket \rightarrow \diamond_\ell \Delta \mathbb{B} \) is a constant function, so \( \llbracket M[x/E] \rrbracket = \llbracket M[E'/x] \rrbracket \) for any \( \vdash E, E' : T_\ell A \). By adequacy, it follows that \( \vdash M[x/E] = M[E'/x] : T_\ell \text{Bool} \). \( \square \)

### 6.2 The sealing calculus

The sealing calculus was introduced by Shikuma and Igarashi [2008]. Its history is complicated: it is a simplification of a calculus introduced by Tse and Zdancewic [2004] as a (weak) refinement of DCC, whose authors hoped to prove noninterference for DCC not through denotational methods—as in [Abadi et al. 1999]—but by translating it to System F and using parametricity. However, there was a technical issue in their work. Shikuma and Igarashi [2008] carried out a similar programme by translating their sealing calculus to simple types, and thus proving noninterference through parametricity for simple types. Subsequently, Bowman and Ahmed [2015] carried out the original programme to completion, by translating DCC itself to System F\( \omega \).

The sealing calculus is also based on a partial order \( (\mathcal{L}, \sqsubseteq) \) of security levels. It augments the context of the simply typed \( \lambda \)-calculus with a finite set \( \pi \) of observer levels. Typing judgments are of the form

\[
\Gamma \mid \pi \vdash M : A
\]
The idea is that an observer can only read data whose classification is below his observer status. We write $\ell \sqsubseteq \pi$ to mean that $\ell$ is below some level in $\pi$.

The introduction rule specifies that, a term obtained using observer access $\ell$ can be sealed, thus becoming a term that can be handled possibly without (but not necessarily without) access $\ell$:

$$\Gamma \mid \pi \cup \{\ell\} \vdash M : A$$

$$\Gamma \mid \pi \vdash [M]_\ell : [A]_\ell$$

$[A]_\ell$ is a type sealed at $\ell$. Conversely, if the observer level dominates $\ell$, terms can be unsealed:

$$\Gamma \mid \pi \vdash M : [A]_\ell \quad \ell \sqsubseteq \pi$$

$$\Gamma \mid \pi \vdash M^\ell : A$$

and, naturally, $(M)_{\ell} = M$. The rest of the system is just that of simple types.

Our levelled cohesion can be used quite directly to provide semantics for the sealing calculus. To do so, notice that the only rules that interact with the observer context $\pi$ are the modal/sealing rules: if we forget those for a moment, everything else is simply-typed $\lambda$-calculus. Thus, we can interpret the sealing-free/'constant part of the calculus in any cartesian closed category. We will choose to do so in the co-Kleisli category $\coKl(\square_\pi)$ of $\square_\pi$, which has the same objects as $\CSet_\ell$, but whose morphisms $A \to B$ are the morphisms $\square_\pi A \to B$ of $\CSet_\ell$. This is standard, see e.g. [Awodey 2010, Ex. 11, §10.6]. Also standard is the following theorem, which is considered “folk” by Brookes and Geva [1992], and mentioned in passing by Uustalu and Vene [2008]:

**Theorem 8.** If $Q : C \longrightarrow C$ is a product-preserving comonad on a cartesian closed category $C$, then its co-Kleisli category $\coKl(Q)$ is also cartesian closed.

Thus, a sequent $x_1 : A_1, \ldots, x_n : A_n \mid \pi \vdash M : A$ is interpreted as an arrow

$$\square_\pi ([A_1] \times \cdots \times [A_n]) \to [A]$$

The idea is that the observer context $\pi$ declassifies everything at levels $\downarrow \pi$. But recall that $\square_\pi$ is product-preserving, and that in the particular example of $\CSet_\ell$ it is strictly product preserving. Thus, morphisms of the above type are naturally isomorphic (or equal to, in $\CSet_\ell$) to morphisms

$$\square_\pi [A_1] \times \cdots \times \square_\pi [A_n] \to [A]$$

Sealing is uniformly interpreted on types by the redaction functors:

$$[[A]_\ell] \overset{\text{def}}{=} \Diamond^\ell [A]$$

On terms, the sealing and unsealing rules will be interpreted by using the adjunction $\square_\pi \dashv \Diamond_\pi$ to move between the different co-Kleisli categories of the comonads $\square_\pi$. For simplicity we explain the case $\ell \notin \pi$ which discards $\ell$ from the observer levels. Recall that, by Prop. 20, we have

$$\square_{\pi(\pi \cup \ell)} = \square_{\pi \cup \ell} = \square_{\pi} \square_\ell = \square_\ell \square_{\pi}$$

So the interpretation of a term $\Gamma \mid \pi \cup \{\ell\} \vdash M : A$, which is a morphism $[[\Gamma]] \to [A]$ in the co-Kleisli category of $\square_{\pi \cup \ell}$, which—by the above—is really a morphism of type

$$\square_\ell ([A_1] \times \cdots \times \square_\pi [A_n]) \to [A]$$

in $\CSet_\ell$. Moving across the adjunction yields a morphism

$$\square_{\pi} [A_1] \times \cdots \times \square_\pi [A_n] \to \Diamond^\ell [A]$$
which is now a morphism in the co-Kleisli category of \(\Box_\pi\), and we take that to be the interpretation of \(\Gamma \vdash \pi \vdash M : [A]_\ell\). Unsealing is obtained by moving in the opposite direction: doing so, we obtain a morphism
\[
\Box_\ell \Box_\pi [A_1] \times \cdots \times \Box_\ell \Box_\pi [A_n] \to [A]
\]
But \(\ell \subseteq \pi\) implies \(\downarrow \pi = \downarrow \pi \cup \downarrow \ell\), and so \(\Box_\ell \Box_\pi\) is just \(\Box_\pi\). Again, it would suffice for these equalities of modalities to be mere natural isomorphisms. Soundness of the equations of the sealing calculus then follow from the fact the adjunction induces a natural isomorphism between the appropriate hom-sets.

Shikuma and Igarashi [2008] prove the following noninterference theorem. Say that terms \(\cdot \vdash \pi \vdash M, N : [A]_\ell\) and \(x : [A]_\ell \mid \pi \vdash E : \text{Bool}\) are contextually equivalent at \(\pi\): that is, if \(\cdot \vdash A \mid \pi \vdash N : \text{Bool}\), then \(N[M/x] = N[M/x]\). This defines an equivalence relation \(\approx\), which extends to substitutions \(\cdot \vdash \sigma : \Gamma\). The main theorem states that if \(\sigma \approx_\pi \sigma' : \Gamma\) and \(\Gamma \vdash E : A\), then \(E[\sigma] \approx_\pi E[\sigma']\). That is: substituting terms indistinguishable at \(\pi\) yields results indistinguishable at \(\pi\).

This is a particularly strong noninterference theorem, which takes many pages of very beautiful—but also painfully elaborate!—work to show. We will content ourselves with using the model to provide the following direct corollary:

**Theorem 9 (Noninterference for Sealing Calculus).** If \(\ell \nsubseteq \pi\), then for any \(\cdot \vdash \pi \vdash M, N : [A]_\ell\) and \(x : [A]_\ell \mid \pi \vdash E : \text{Bool}\), we have \(\cdot \vdash \pi \vdash E[M/x] = E[N/x] : \text{Bool}\).

First, we notice that our ‘generic’ adequacy lemma (Lemma 1) applies to the above interpretation of the sealing calculus, with Bool interpreted by \(\Delta B\). The domain of \([x : [A]_\ell \mid \pi \vdash E : \text{Bool}]\) is \(\Diamond_\ell [A]\) as an object of \(\text{CoKl}(\Box_\pi\)), and hence as an object of \(\text{CSet}_L\) it is
\[
\Box_\ell \Diamond_\ell [A] = \Diamond_\ell \Box_\pi [A]
\]
by Prop. 20, and its codomain is \(\Delta B\), which is visible everywhere. But, as \(\ell \nsubseteq \pi\), we have that \(\downarrow \ell - \downarrow \pi \neq \emptyset\), so Prop. 22 applies (with \(\pi' = \emptyset\)) to show that it is a constant function. Then,
\[
[E[M/x]] = [E] \circ_{\text{CoKl}} [M] = [E] \circ_{\text{CoKl}} [N] = [E[N/x]]
\]
where \(\circ_{\text{CoKl}}\) is composition \(\text{CoKl}(\Box_\pi\)), and by using adequacy the proof is complete.

7 CONCLUSION

To recapitulate: we have defined the model of classified sets, and shown that it forms a pre-cohesion. This led us to the generation of modalities \(\int + \Box + \Diamond\), and the proof of noninterference properties for Moggi’s monadic metalanguage and the Davies-Pfenning comonadic calculus. Next, we took a levelled view of cohesion, and showed that this generates a multimodal framework \(\int_\pi + \Box_\pi + \Diamond\). These modalities satisfy many algebraic laws, which we then used to prove noninterference for two multi-modal information flow calculi, the dependency core calculus, and the sealing calculus.

We discuss two aspects of our work that we believe may lead to interesting future developments. Finally, we discuss related work.

---

6It is easy to show that any \(M, N : [A]_\ell\) are contextually equivalent at \(\pi \nsubseteq \ell\) by a logical relations argument: see [Shikuma and Igarashi 2008, Theorem 2.18]. Then this result is the special case of the noninterference theorem, once we observe that equality and observational equivalence coincide at the ground type Bool.
**Modalities, Cohesion, and Information Flow**

(Pre)-cohesion as a theory of information flow. Our results demonstrate that the very general and abstract framework of pre-cohesion in fact has very concrete applications in analysing information flow. Our noninterference proofs rely on very general lemmas about pre-cohesion—in the case of §6, with some additional, slightly mysterious equations—which are then applied to each calculus by using some, usually very simple, form of adequacy. We believe these to be a simplification compared to previous work on noninterference, which required quite a bit of hard work in terms of fully abstract/fully complete translations, e.g. [Bowman and Ahmed 2015; Shikuma and Igarashi 2008].

However, we believe this to be the tip of the iceberg: cohesion can tell us much more about information flow. However, this cannot happen unless we replace adequacy, which is a very weak form of completeness, with something stronger. It would be very interesting to seek whether there are information flow calculi for which classified sets are **fully abstract**, in the sense that $M$ and $N$ are contextually equivalent if and only if $\llbracket M \rrbracket = \llbracket N \rrbracket$ in $\mathbb{CSet}_L$. That would grant us far more power to use ideas from and properties of cohesion to prove theorems about information flow.

Conversely, we can seek information flow calculi with likeness to cohesion-based models: we can look at what structure is available in the multi-modal setting of classified sets, and then try to formulate a calculus from that. This would most likely lead to a multi-modal version of the spatial type theory of Shulman [2018]. Such a calculus would probably also be informative in terms of resolving the debate between, for example, coarse-grained and fine-grained formulations, as discussed by Rajani and Garg [2018]. In a sense, its formulation would provide a mathematical justification for canonical, type-theoretic choices of modalities and constructs. (That is, if we of course accept classified sets as a canonical model of information flow.) Additionally, the calculus would include the shape at $\pi$ modality ($\int_\pi$), which has never appeared before in papers on information flow type systems, and which might have interesting applications as a ‘security quotient’ or ‘secure view’ type constructor. Finally, there seem to be close connections between this work and graded monads and comonads, which also have applications in information flow: see [Gaboardi et al. 2016].

Cohesion as a basis for multi-modal type theories. The other side of the coin in the present development is that information flow—which is a garden-variety application for multi-modal types—can be quite eloquently spoken about in this language of cohesion. In particular, the formulation of a functor $\mathcal{P}(\mathcal{L})^{op} \rightarrow \text{Precoh}$ enabled very short and conceptual proofs of results that would ordinarily require a lot of unintellectual reasoning. It is thus natural to ask whether there might be other functors $\mathcal{C}^{op} \rightarrow \text{Precoh}$ of Precoh-valued presheaves that yield interesting analyses of multi-modal logical systems. In fact, some of the notation we developed in §5 bears a striking similarity to the adjoint logic of Licata and Shulman [2016], and the framework of Licata et al. [2017]. Could there be a closer connection between these developments?

Related work. As mentioned in the introduction, the problem of information flow is almost as old as Computer Science itself, dating at least as far back as Bell and Padula’s report of 1973 [LaPadula and Bell 1996]. The notion of noninterference itself was introduced by Goguen and Meseguer [1982]. The use of types to guarantee information flow control, and hence some form of noninterference, appears to have begun in the 1990s, with the first work on higher-order functional programming being that of [Heintze and Riecke 1998] on the SLam calculus; see op. cit. for a useful list of references to approaches that preceded it. Rajani and Garg [2018] provide a good overview and a largely complete list of references to the literature thereafter.

Even the first higher-order noninterference results, such as those for SLam [Heintze and Riecke 1998], use some form of logical relations, who directly state that they are “borrowing ideas from Reynolds.” In particular, Heintze and Riecke [1998] use logical relations on top of a denotational
model, which then led to the *dependency category* of Abadi et al. [1999], which we have refined into classified sets. Other than that, there appears to be very little other work on denotational models of information flow; even if situated outside the higher-order functional setting, we ought to mention the work of Sabelfeld and Sands [2001].

Furthermore, we should note that this paper is the first *categorical* approach to information flow. Even though we mostly use the motivating example of classified sets, all our theorems are rather general, and apply to all pre-cohesive settings indexed over subsets of $L$ for which the equations 1, 2 and 3 apply. It is also worth noting that we did not use any particular structure on $L$, even though most of the related work cited above asks for some kind of lattice—even if they do not use it either: we merely made use of indexing over $P(L)$.

ACKNOWLEDGMENTS

Thanks are due to Mario Alvarez-Picallo and for discussions on the material of this paper, Amar Hadzihasanovic for the pasting diagrams, and the anonymous reviewers for their many useful suggestions. I would like to thank Dan Licata for numerous observations that led to the material in this paper. I would also like to thank his cat, Otto, for keeping me company while I was writing it.
