received, revised, accepted.

In the geodetic convexity, a set of vertices $S$ of a graph $G$ is convex if all vertices belonging to any shortest path between two vertices of $S$ lie in $S$. The cardinality $\text{con}(G)$ of a maximum proper convex set $S$ of $G$ is the convexity number of $G$. The complementary prism $\overline{G}G$ of a graph $G$ arises from the disjoint union of the graph $G$ and $\overline{G}$ by adding the edges of a perfect matching between the corresponding vertices of $G$ and $\overline{G}$. In this work, we prove that the decision problem related to the convexity number is NP-complete even restricted to complementary prisms, we determine $\text{con}(\overline{G}G)$ when $G$ is disconnected or $G$ is a cograph, and we present a lower bound when $\text{diam}(G) \neq 3$.

Keywords: geodetic convexity, convex set, convexity number, complementary prism

1 Introduction

In this paper we consider finite, simple, and undirected graphs, and we use standard terminology. For a finite and simple graph $G$ with vertex set $V(G)$, a graph convexity on $V(G)$ is a collection $\mathcal{C}$ of subsets of $V(G)$ such that $\emptyset, V(G) \in \mathcal{C}$ and $\mathcal{C}$ is closed under intersections. The sets in $\mathcal{C}$ are called convex sets and the convex hull $H(S)$ in $\mathcal{C}$ of a set $S$ of vertices of $G$ is the smallest set in $\mathcal{C}$ containing $S$.

Convex sets in graphs emerged as an analogy to convex sets in the Euclidean plane. Such concepts have attracted attention on the last decades due to its versatility for modeling some disseminating processes between discrete entities. Graph convexities can model, for instance, contexts of distributed computing (Flocchini et al., 2004; Peleg, 2002). We can consider a network, where a fault on some computer data propagates to other computers, according to some rule of propagation. A problem raised on this context is determining the maximum number of computers in which can occur a fault in order to ensure that the entire network does not fail. Modeling the network as a graph $G$, that context is equivalent to determine the parameter known as convexity number of the graph $G$. We may cite other contexts that graph convexities can be applied, e.g. spread of disease and contamination (Balogh and Pete, 1998; Bollobás, 2006; Dreyer

and Roberts, 2009), marketing strategies (Domingos and Richardson, 2001; Kempe et al., 2003, 2005), and spread of opinion (Brunetti et al., 2012; Dreyer and Roberts, 2009).

We consider the geodetic convexity $\mathcal{C}$ on a graph $G$, which is defined by means of shortest paths in $G$. We say that set of vertices $S$ of a graph $G$ is convex if all vertices belonging to any shortest path between two vertices of $S$ lie in $S$. The cardinality $\text{con}(G)$ of a maximum proper convex set $S$ of $G$ is the convexity number of $G$.

One of the first works to introduce the convexity number was published by Chartrand et al. (2002). They determine the convexity number for complete graphs, paths, cycles, trees, and present bounds for general graphs. In the same year, Canoy and Garces (2002) show results on the convexity number for graph operations like join, composition and Cartesian product. Later on, Kim (2004) studies the parameter for $k$-regular graphs. Considering complexity aspects, Gimbel (2003) shows that determining the convexity number is NP-hard for general graphs, whereas, Dourado et al. (2012) refine Gimbel’s result showing the NP-hardness of the problem even restricted to bipartite graphs.

Motivated by the work of Canoy and Garces (2002), on the convexity number for graph operations, we study that parameter for a graph product called complementary prism. Such graph product was introduced by Haynes et al. (2007) as a variation of the well-known prism of a graph (Hammack et al., 2011). Let $G$ be a graph and $\overline{G}$ its complement. For every vertex $v \in V(G)$ we denote $\overline{v} \in V(\overline{G})$ as its corresponding vertex. The complementary prism $G\overline{G}$ of a graph $G$ arises from the disjoint union of the graph $G$ and $\overline{G}$ by adding the edges of a perfect matching between the corresponding vertices of $G$ and $\overline{G}$. A classic example of a complementary prism is the Petersen graph $C_5\overline{C}_5$.

In this paper we determine the convexity number for complementary prisms $G\overline{G}$ when $G$ is disconnected or $G$ is a cograph, and we present a lower bound of that parameter for complementary prisms of graphs with restricted diameter. Furthermore, given a complementary prism $H\overline{V}$, and an integer $k$, we prove that it is NP-complete to decide whether $\text{con}(H\overline{V}) \geq k$.

This paper is divided in more three sections. In Section 2 we define the fundamental concepts and terminology. In Section 3 we present our contributions. We close with the conclusions in Section 4.

2 Preliminaries

Let $G$ be a graph. Given a vertex $v \in V(G)$, its open neighborhood is denoted by $N_G(v)$, and its closed neighborhood, denoted by $N_G[v]$, is the set $N_G[v] = N_G(v) \cup \{v\}$. For a set $U \subseteq V(G)$, let $N_G(U) = \bigcup_{v \in U} N_G(v) \setminus U$, and $N_G[U] = N_G(U) \cup U$.

A clique (resp. independent set) is a set of pairwise adjacent (resp. nonadjacent) vertices. A vertex of a graph $G$ is simplicial in $G$ if its neighborhood induces a clique.

The distance $d_G(u, v)$ of two vertices $u$ and $v$ in $G$ is the minimum number of edges of a path in $G$ between $u$ and $v$. Let $A, B \subseteq V(G)$. The distance $d_G(A, B)$ between two vertex sets $A$ and $B$ in $G$ is the length of the shortest path between any vertex of $A$ and any vertex of $B$. A graph $G$ is called connected if any two of its vertices are linked by a path in $G$. Otherwise, $G$ is called disconnected. A maximal connected subgraph of $G$ is called a connected component or component of $G$. A component $G_i$ of a graph $G$ is trivial, if $|V(G_i)| = 1$, and non-trivial otherwise.

Let $G$ be a graph. For a set $X \subseteq V(G)$, we let $\overline{X}$ be the corresponding set of vertices in $V(\overline{G})$. We denote the set of positive integers $\{1, \ldots, k\}$ by $[k]$.

A convex set $S$ of a graph $G$ can be defined by a closed interval operation. The closed interval $I[u, v]$ of a pair $u, v \in V(G)$ consists of all vertices lying in any shortest $(u, v)$-path in $G$. For a set $S \subseteq V(G)$,
the closed interval $I[S]$ is the union of all sets $I[u, v]$ for $u, v \in S$. If $I[S] = S$, then $S$ is a convex set. To avoid ambiguity, sometimes a subscript can be added to the notation (e.g. $I_G[S]$, and $H_G(S)$) to indicate which graph $G$ is being considered.

3 Results

Chartrand et al. (2002) provide us two useful results. They proved that $\text{con}(K_n) = n - 1$, and for a noncomplete graph the result follows in Theorem 3.1.

**Theorem 3.1 (Chartrand et al. (2002))** Let $G$ be a noncomplete connected graph of order $n$. Then $\text{con}(G) = n - 1$ if and only if $G$ contains a simplicial vertex.

We begin our contributions by determining in Theorem 3.3 the convexity number for complementary prisms of disconnected graphs. We first show Proposition 3.2 that will be useful for the subsequent results.

**Proposition 3.2** Let $G$ be a graph, $S \subseteq V(G\overline{G})$, and $v_1 \ldots v_k$ be a path in $G$, for $k \geq 2$. If $\{v_1, \overline{v_2}, \ldots, \overline{v_k}\} \subseteq H(S)$, then $v_k \in H(S)$.

**Proof:** The proof is by induction on $k$. First, let $k = 2$. Since $v_1v_2 \in E(G)$ and $v_1, \overline{v_2} \in H(S)$, $v_2 \in I[v_1, \overline{v_2}]$. Now, let $k > 2$. Let $v_1 \ldots v_k$ be a path in $G$ and suppose that $\{v_1, \overline{v_2}, \ldots, \overline{v_{k-1}}, \overline{v_k}\} \subseteq H(S)$. By induction hypothesis $v_{k-1} \in H(S)$, which implies that $v_k \in I[v_{k-1}, \overline{v_k}]$. Therefore, it follows that $v_k \in H(S)$, for $k \geq 2$. □

**Theorem 3.3** Let $G$ be a disconnected graph of order $n$, and $k$ be the order of a minimum component of $G$. Then, $\text{con}(G\overline{G}) = 2n - k$.

**Proof:** Let $G_1, \ldots, G_\ell$ be the components of $G$, for $\ell \geq 2$. We can sort the components $G_1, \ldots, G_\ell$ of $G$ in non-decreasing order. Then, $G_1$ is a component of minimum order, say $|V(G_1)| = k$. If $k = 1$, then $G_1$ is a trivial component. Hence, the unique vertex $v \in V(G_1)$ is a simplicial vertex, and the result $\text{con}(G\overline{G}) = n - 1$ follows from Theorem 3.1. This way, we consider that $|V(G_i)| \geq 2$, for every $i \in [\ell]$.

Let $S = V(G\overline{G}) \setminus V(G_1)$. See Figure 1 for an illustration. We show that $S$ is a convex set of $G\overline{G}$.

Let $x, y \in V(G) \setminus V(G_1)$, and a path $P$ between $x$ and $y$ passing through $V(G_1)$. We have that $P$ has length at least $2$. Since $\text{diam}(G\overline{G}) = 3$, $P$ is not a shortest path. This implies that $I_G[x, y] \cap V(G_1) = \emptyset$.

Let $x \in V(G \setminus V(G_1))$, and $\overline{y} \in V(G\overline{G})$ (resp. $\overline{x} \overline{y} \in V(G\overline{G})$). We have that a shortest $(x, \overline{y})$-path (resp. $(\overline{x}, \overline{y})$-path) has length at most 2, hence $I_G[x, y] \cap V(G_1) = \emptyset$. Therefore, $S$ is a convex set of $G\overline{G}$.

Next, we show that $S$ is maximum. By contradiction, suppose that there exists a convex set $S' \subseteq V(G\overline{G})$ such that $|S'| > |S|$.

Since $|S'| > 2n - k$, we have that $S' \cap V(G_j) \neq \emptyset$, and $S' \cap V(G_j) \neq \emptyset$, for every $j \in [\ell]$. We divide the proof in two cases, considering that $S' \cap V(G)$ contains two nonadjacent vertices or not.

**Case 1** There exist $x, y \in S' \cap V(G\overline{G})$ such that $x \overline{y} \notin E(G\overline{G})$.

Let $x, y \in S' \cap V(G\overline{G})$ such that $x \overline{y} \notin E(G\overline{G})$. By the definition of complementary prism, every vertex in $V(G_i)$ is adjacent to every vertex in $V(G_j)$, for every $i, j \in [\ell], i \neq j$. This implies that $x, y \in V(G_i)$, for some $i \in [\ell]$, and $V(G_i) \setminus V(G_j) \subseteq I_G[x, y]$.

We know that $|V(G_k)| \geq 2$, for every $k \in [\ell]$. Let $j \in [\ell] \setminus \{i\}$. Since $G_j$ is a connected component, and $|V(G_j)| \geq 2$, there exists $u, v \in V(G_j)$ such that $uv \in E(G)$. Thus, $\overline{u} \overline{v} \notin E(G\overline{G})$. Since $\overline{u}, \overline{v} \in$
such that $S'$ is maximum, let $C_i = S' \cap V(G_i)$, for every $i \in [\ell]$. We know that $C_i$ is an independent set, and $C_i$ is a clique. We claim that $S' \cap (N_G(C_i) \cup N_G(C_i)) = \emptyset$, for every $i \in [\ell]$. On the other hand, we prove a stronger statement, $S' \cap (V(G_i \setminus (C_i \cup C_i)) = \emptyset$, for every $i \in [\ell]$. 

Claim 1 For every $i \in [\ell]$, $S_i \cap (V(G_i \setminus (C_i \cup C_i)) = \emptyset$. 

Proof of Claim 1 First, recall that $\pi, \pi \in I_{G_i}[u, v]$, for every $u \in V(G_i)$ and $v \in V(G_i)$, for every $i, j \in [\ell], i \neq j$. Let $i \in [\ell]$. By contradiction, suppose that there exists $v \in S_i \cap (V(G_i \setminus (C_i \cup C_i))$.

Since $C_i$ is maximum, if $v \in S_i \cap (V(G_i \setminus C_i)$, then $S_i \cap V(G)$ contains two nonadjacent vertices, a contradiction. Then, suppose that $v \in S_i \cap (V(G_i \setminus C_i)$. Since $S_i \cap V(G_j) \neq \emptyset$, for every $j \in [\ell]$, we have that $\pi, \pi \in I_{G_i}[u, v]$, for some $u \in S_i \cap V(G_j), i \neq j$. Since $C_i$ is maximum, there exists $\pi \in C_i$ such that $\pi \notin E(G)$. Consequently, $S_i \cap V(G)$ contains two nonadjacent vertices, a contradiction. \qed

Claim 2 For every $i \in [\ell]$, $|C_i \cap S_i| \leq |V(G_i) \setminus C_i|$. 

Proof of Claim 2 Let $i \in [\ell]$. By Claim 1, $S_i \cap (V(G_i \setminus C_i) = \emptyset$. Since $S_i \cap V(G_i) \neq \emptyset$, we have that $|C_i \cap S_i| \geq 1$. By contradiction, suppose that $|C_i \cap S_i| > |V(G_i) \setminus C_i|$. Let $|C_i \cap S_i| = p$.

If $p = 1$, then $|V(G_i) \setminus C_i| = 0$. Since $C_i$ is an independent set, it follows that $G_i$ is disconnected, a contradiction. Then, consider $p \geq 2$. Let $C_i \cap S_i = \{u_1, \ldots, u_p\}$, and $V(G_i) \setminus C_i = \{v_1, \ldots, v_{p-1}\}$.

Since $C_i$ is an independent set, and $G_i$ is connected, it follows that every vertex in $C_i \cap S_i$ is adjacent to at least one vertex in $V(G_i) \setminus C_i$. Since $|C_i \cap S_i| > |V(G_i) \setminus C_i|$, we have that there exist $j, j' \in [p], j \neq j'$, such that $u_j, v_q, u_j, v_q \in E(G)$, for some $q \in [p-1]$. Then, $v_q \in I_{G_i}[u_j, u_j']$. Since $S_i$ is convex, $v_q \in S_i$. But that is a contradiction, since $S_i \cap (V(G_i) \setminus C_i) = \emptyset$. \qed

To conclude the proof, we show that $|S| \leq n$. In view of the above statements, for every $i \in [\ell]$, it follows that 

$$|S_i \cap V(G_i)\| = |S_i \cap V(G_i)| + |S_i \setminus V(G_i)|$$

$$= |C_i \cap S_i| + |C_i| - |C_i|$$

$$\leq |V(G_i) \setminus C_i| + |V(G_i)| - |V(G_i) \setminus C_i|$$

(by Claim 2)

$$= |V(G_i)|.$$ 

Since $S_i \cap V(G_i)\| \leq |V(G_i)|$, for every $i \in [\ell]$, we obtain that 

$$|S| \leq \sum_{i=1}^{\ell} |V(G_i)| = n,$$ 

a contradiction. Therefore $S$ is a maximum convex set of $G_G$, and $con(G_G) \leq 2n - k$, which completes the proof. \qed
Figure 1: Example of a proper convex set of $G\overline{G}$.

Figure 1 shows an illustration of a proper convex set of $G\overline{G}$, represented by the black vertices. Consider $G_1$ the component of minimum order of $G$.

As a consequence of Theorem 3.3 we obtain the next result on cographs.

**Corollary 3.4** Let $G$ be a connected cograph of order $n$, and $k$ be the order of a minimum component of $G\overline{G}$. Then, $\text{con}(G\overline{G}) = 2n - k$.

**Proof:** Since a cograph $G$ is connected if and only if $\overline{G}$ is disconnected (Corneil et al., 1981), and $G\overline{G}$ is isomorphic to $\overline{G\overline{G}}$, the result follows from Theorem 3.3. \hfill $\square$

### 3.1 NP-Completeness

Next, we show a hardness result of the geodetic number for complementary prims. We first present Proposition 3.5, and we define the two decision problems to be considered.

**Proposition 3.5** Let $G$ be a graph, $S$ be a convex set of $G\overline{G}$, $S' = S \cap V(\overline{G})$. If $A = N_{G\overline{G}}(S') \setminus S'$, then $S \cap A = \emptyset$.

**Proof:** Suppose that $u \in S \cap A$. Since $\overline{u}\overline{v} \in E(\overline{G})$, for some $\overline{v} \in S'$, we have that $\overline{v} \in I_{G\overline{G}}[u, \overline{v}]$. We know that $S$ is convex, which implies that $\overline{v} \in S$. But that is a contradiction, since $\overline{v} \notin S \cap V(\overline{G})$. \hfill $\square$

**Problem 3.6** **CLIQUE** (Garey and Johnson, 1979).

**Instance:** A graph $G$ and an integer $k$.

**Question:** Does $G$ have a clique of order at least $k$?

**Problem 3.7** **CONVEXITY NUMBER** (Dourado et al., 2012).

**Instance:** A graph $G$ and an integer $k$.

**Question:** Does $G$ have a proper convex set of order at least $k$?

**Theorem 3.8** **CONVEXITY NUMBER** is **NP-complete** even restricted to complementary prisms.
By contradiction, suppose that there exists a proper convex set of order at least \( k \). Let \( S = C \cup U \cup X \cup Y \). We can show that \( S \) is a convex set of \( H \). Let \( w \in S \cap V(H) \). For every \( v \in V(G) \), we have that \( U \cup V(G) \cup \{ w, w' \} \subseteq I_{H \bar{P}}[w, w'] \), since \( \bar{V} \in \bar{E} \). Consequently, \( V(G) \cup \{ w, w' \} \subseteq I_{H \bar{P}}[w, w'] \). By symmetry, \( U \subseteq I_{H \bar{P}}[U \cup \{ w, w' \} \subseteq I_{H \bar{P}}[w, w'] \). This implies that \( \bar{U} \subseteq I_{H \bar{P}}[\bar{U} \cup \{ w, w' \} \subseteq I_{H \bar{P}}[w, w'] \). Consequently, \( \bar{U} \subseteq I_{H \bar{P}}[\bar{U} \cup \{ w, w' \} \subseteq I_{H \bar{P}}[w, w'] \). Since \( V(\bar{H}) \subseteq H_{H \bar{P}}(S) \), Proposition 3.2 implies that \( V(H) \subseteq H_{H \bar{P}}(S) \), a contradiction.

Claim 2 Let \( S \) be a proper convex set of \( H \). Then \( S \cap V(\bar{H}) \) is a clique.

Proof of Claim 2 By contradiction, suppose that there exists \( \bar{w}, \bar{w}' \in S \cap V(\bar{H}) \) such that \( \bar{w} \bar{w}' \notin E(\bar{H}) \). Then, we have the following cases.

Case 1.1 \( \bar{w}, \bar{w}' \in \bar{Z} \).

This implies that \( \bar{X} \cup \bar{Y} \subseteq I_{H \bar{P}}[\bar{w}, \bar{w}'] \). By symmetry, \( \bar{X} \cup \bar{Y} \subseteq I_{H \bar{P}}[\bar{w}, \bar{w}'] \). Consequently, \( V(G) \subseteq I_{H \bar{P}}[\bar{X}] \). Since \( d_{H \bar{P}}(\bar{V}, V(G)) = 3 \), by Claim 1, \( \bar{S} \) is not a proper convex set, a contradiction.

Case 1.2 \( \bar{w}, \bar{w}' \in \bar{X} \cup \bar{Y} \cup \bar{U} \).

In this case, \( \bar{Z} \subseteq I_{H \bar{P}}[\bar{w}, \bar{w}'] \), then the proof follows by Case 1.1.

Case 1.3 \( \bar{w}, \bar{w}' \in V(\bar{G}) \cup \bar{Z} \).

We have that \( \bar{X} \subseteq I_{H \bar{P}}[\bar{w}, \bar{w}'] \), then the proof follows by Case 1.2. \( \square \)
Convexity number for complementary prisms

Let $S$ be a proper convex set of $H\overline{H}$ of order at least $k + 5n + 3$. By Claim 2, we know that $S \cap V(\overline{H})$ is a clique. Let $\overline{C} = S \cap V(\overline{H})$. To proceed with the proof, we show that $\overline{C} \cap (V(G) \cup X \cup Y \cup Z) = \emptyset$. For that, we consider two cases, $\overline{C}$ does not contain vertices from $V(G) \cup Z$, and $\overline{C}$ does not contain vertices from $X \cup Y$.

**Case 2.1** $\overline{C} \cap (V(G) \cup Z) = \emptyset$.

Suppose, by contradiction, that $\overline{C}$ contains a vertex in $V(G)$ or in $Z$. If $\overline{C} \cup X = \emptyset$, then $X \subseteq N_H(\overline{C}) \setminus \overline{C}$. Otherwise, we have that $X \cup \{x_i\} \subseteq N_H(\overline{C}) \setminus \overline{C}$, for some $i \in [4n]$. In both cases, we have that $|N_H(\overline{C}) \setminus \overline{C}| \geq 4n - 1$. For $A = N_H(\overline{C}) \setminus \overline{C}$, Proposition 3.5 implies that $S \cap A = \emptyset$, then $|S \cap V(H)| = |V(H)| - |A| \leq 6n + 4 - (4n - 1) = 2n + 5$.

So far, we conclude that the number of vertices from $S$ in $H$ is at most $2n + 5$. Remains to show the maximum number of vertices from $S$ in $\overline{H}$. By the construction of $H$, a clique in $\overline{H}$ of maximum order is a proper subset of $V(G) \cup \overline{Y}$, hence $|S \cap V(\overline{H})| < n + 2$. Consequently, $|S| = |S \cap V(H)| + |S \cap V(\overline{H})| < 2n + 5 + n + 2 = 3n + 7$, a contradiction.

**Case 2.2** $\overline{C} \cap (X \cup Y) = \emptyset$.

We know by Case 2.1 that $\overline{C} \cap (V(G) \cup Z) = \emptyset$. By contradiction, suppose that $\overline{C}$ contains a vertex from $X$ or $Y$. Let $A = N_H(\overline{C}) \setminus \overline{C}$. In this case, we have that $V(G) \cup Z \subseteq A$. Hence, $|A| \geq n + 2$. It follows from Proposition 3.5 that $|S \cap V(H)| = |V(H)| - |A| \leq 6n + 4 - (n + 2) = 5n + 2$.

Since $\overline{C} \cap (V(G) \cup Z) = \emptyset$, and $U \cup X$ is an independent set, the maximum order of a clique in $V(\overline{H})$ is $|\overline{Y}| = 2$, then $|S \cap V(\overline{H})| \leq 2$. This implies that $|S| = |S \cap V(H)| + |S \cap V(\overline{H})| \leq 5n + 2 + 2 = 5n + 4$. Since $k \geq 3$, we have that $|S| \geq k + 5n + 3 = 5n + 6$, a contradiction.

By the Cases 2.1 and 2.2, we have that a proper convex set $S$ of $H\overline{H}$ of order at least $k + 5n + 3$ is such that $S \cap U \neq \emptyset$ or $S \cap V(\overline{H}) = \emptyset$. We show that, in both cases, the order of $S$ implies in $|S \cap V(G)| \geq k$.

**Case 3.1** $S \cap U \neq \emptyset$.

Since $U$ is an independent set, $|S \cap U| \leq 1$. So, let $i \in [n]$, and consider that $\pi_i \in S$. We have that $A = N_H(\pi_i) = Z$. By Proposition 3.5, $S \cap Z = \emptyset$. By the construction of $H$, we have that $|U \cup X \cup Y| = 5n + 2$. Since $|S \cap V(H)| = |S| - 1 = k + 5n + 2$, we have that $|S \cap V(G)| \geq k$.

**Case 3.2** $S \cap V(\overline{H}) = \emptyset$.

By Claim 1, we have that

\[
\begin{align*}
\text{either } & S \cap V(H) \subseteq (U \cup V(G) \cup X \cup Y) \quad (I) \\
\text{or } & S \cap V(H) \subseteq (U \cup V(G) \cup Z) \quad (II).
\end{align*}
\]

Condition II implies that the order of $S$ is at most $2n + 2$, a contradiction. Then, consider that $S \subseteq (U \cup V(G) \cup X \cup Y)$. Still by the construction of $H$, $|U \cup X \cup Y| = 5n + 2$. Since $|S \cap V(H)| = |S| = k + 5n + 3$, we obtain that $|S \cap V(G)| \geq k + 1$.

By Cases 3.1 and 3.2 we have that $|S \cap V(G)| \geq k$. Remains to show that $S \cap V(G)$ is a clique. Suppose, by contradiction, that $S \cap V(G)$ is not a clique. Then, there exists $v_1, v_2 \in V(G)$ such that $v_1v_2 \notin E(G)$. This implies that $Z \subseteq I_{H}(v_1, v_2)$. But, in both cases $S \cap U \neq \emptyset$ and $S \cap V(\overline{H}) = \emptyset$, we have that $S \cap Z = \emptyset$, a contradiction. Therefore $S \cap V(G)$ is a clique of order at least $k$, which completes the proof. \( \square \)
Figure 2 contains an example of graph $H\overline{H}$ constructed for Theorem 3.8. Every edge joining two rectangles $A$ and $B$ represents the set of all edges joining every pair of vertices $a \in A$ and $b \in B$. The black vertices correspond to the convex set $S$ except the vertices from $V(G)$. For convenience, the edges joining corresponding vertices from $G$ to $\overline{G}$ are not depicted in the figure.

Notice that the graph $H$ constructed for Theorem 3.8 has diameter 3. In view of the complexity result of that theorem, we finish by showing a lower bound of this parameter for graphs with restricted diameter.

**Theorem 3.9** Let $G$ be a graph of order $n$. If $diam(G) \neq 3$, then $con(G\overline{G}) \geq n$.

**Proof:** Consider first that $diam(G) \leq 2$. Let $u, v \in V(G)$. Since $diam(G) \leq 2$, and every $(u, v)$-path passing through $V(G)$ has length at least 3, we obtain that $I_{conv}(u, v) \cap V(G) = \emptyset$. Hence, $V(G)$ is a convex set of $G\overline{G}$. Since $V(G) \subset V(G\overline{G})$, it follows that $con(G\overline{G}) \geq |V(G)| = n$.

Now, let $diam(G) \geq 4$. According to Goddard and Oellermann (2011), $diam(G) > 3$ implies that $diam(G) \leq 2$. Since $G\overline{G}$ is isomorphic to $\overline{G}G$, the result follows from the above case. \qed

**4 Conclusions**

We have considered the convexity number in the geodetic convexity for complementary prisms $G\overline{G}$. When $G$ is disconnected or $G$ is a cograph we provided an equality. When $diam(G) \neq 3$ we have presented a lower bound. On the complexity point of view, we have proved that, given a complementary prism $H\overline{H}$, and an integer $k$, it is NP-complete to decide whether $con(H\overline{H}) \geq k$.
