In this paper, we show that in two dimensions quantum mechanics can be mapped onto classical mechanics, by transforming the Schrödinger equation into system of \( n \) linear equations known as Kirchhoff equations. These Kirchhoff equations equations satisfy the a poison bracket relationship in phase space which is identical to the Heisenberg uncertainty relationship. Therefore, we conclude that quantum mechanics is consistent with classical mechanics atleast in two dimensions. This allows us to address the wave particle duality in terms of relative phase. As an illustration we show that the equation for optical vortices can be derived as Kirchhoff equation admit a paraxial wave equation in presence of real constant background.

I. INTRODUCTION

The fractional quantum Hall effect ground state evolution is described by Laughlin wave function \[1\], which is an ansatz, and is modeled in terms of Kirchhoff equations \[2–5\]. The Kirchhoff equations are given by

\[
\frac{d\bar{z}_i}{dt} = \sum_{1 \leq i \leq n, i \neq j} \frac{i\Gamma_j}{z_i - z_j} + iW(z_i)
\]

(1)

which describe the evolution of \( n \) point vortices in incompressible fluid \[6\], where \( z_i = x_i + iy_i \) are position of vortices, \( \Gamma_i \) the circulation strength, \( W(z_i) \) is background flow and \( \bar{z}_i = x_i - iy_i \). This study of fractional quantum Hall effect in terms of Kirchhoff equations has allowed to rewrite the Schrödinger equation as Kirchhoff equations \[7\]. These Kirchhoff equations \[1\] are in phase space and admit a poison bracket relationship \[6\] in terms of the complex coordinates is given by

\[
\{z_i, \bar{z}_j\} = -2i\delta_{ij}\Gamma_i.
\]

(2)

For more details, refer to \[6\]. The identification of \( \bar{z} = \partial_{z_i} = P_z \) with canonical momenta \[2\] allows one to replace Poison bracket with commutator

\[
[z_i, \partial_{z_i}] = i\hbar,
\]

(3)

where \( \Gamma_i = \hbar \) is the Heisenberg uncertainty relation.

One of the major differences between classical mechanics and quantum mechanics is Heisenberg uncertainty principle in terms of position and momentum given by equation \[49\]. It is widely accepted that Heisenberg
uncertainty relationship is a restatement of wave particle duality. Wave particle duality is the cornerstone of quantum mechanics. It states that quantum particles are both particles and waves. There are several theories based on wave particle duality, of which the most widely accepted one is the principle of complementarity. The essence of this principle is that quantum systems exhibit both wave and particle nature. However, the outcome of an event is dependent purely on an experiment. Either the wave or the particle nature is observed but both will not be observed simultaneously in a given experiment. The equation \( \text{(2)} \) is the Heisenberg uncertainty relation in phase space. Therefore, in this paper, we show that the quantum mechanics in two dimensions is mapped to classical mechanics in two dimensional point vortices.

The mapping of quantum mechanics to classical mechanics is of central importance to the philosophy of physics, and also the interpretation of quantum mechanics. There are several attempts made in this direction and one such well known is the Phase space formalism \[8\]. The Phase space formulation, where Wigner quasi-probability distribution \[8\] is defined such that it links the wave function that appears in Schrödinger equation to a probability distribution in phase space but this formalism has a drawback of negative probabilities.

One of the first attempts to find a classical relationship is given by Erwin Madelung known as Madelung quantum hydrodynamics \[9\] and the Madelung equations

\[
\partial_t \rho_m + \nabla \cdot (\rho_m \mathbf{u}) = 0, \quad (4)
\]

and

\[
\frac{d\mathbf{u}}{dt} = \partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} = -\frac{1}{m} \nabla (Q + V) \quad (5)
\]

where \( \mathbf{u} \) is the flow velocity, \( \rho_m = m \rho = m |\psi|^2 \) is the mass density, \( Q = -\frac{\hbar^2}{2m} \frac{\nabla^2 \sqrt{\rho}}{\sqrt{\rho}} \) is the Bohm quantum potential, and \( V \) is the potential from the Schrödinger equation. The Kirchhoff equations \[1\] are derived from Euler equations \[1\] and \[5\], for the complex velocity \[13\]. Readers should note that in deriving Kirchhoff equations quantum potential \( Q \) is not considered.

This Madelung quantum hydrodynamics formalism is later modified by Bohm known as the pilot wave formulation \[11, 12\]. de Broglie first proposed the pilot wave theory of double solution \[10\], to explain wave particle duality. In this theory, the Schrödinger equation has two solutions one the regular wave function \( \psi(x, y, z) = ae^{i\phi(x, y, z)} \) where \( a \) is a constant, and the other is a physical wave solution \( u(x, y, z) = f(x, y, z)e^{i\phi(x, y, z)} \). The two solutions are related by the phase \( \phi(x, y, z) \). The singularities in \( u(x, y, z) \) due to presence of singularities in \( f(x, y, z) \) give rise to particle-like nature. These are moving singularities. The drawback of the theory is that it explains only for single particle case. This theory was further developed by Bohm \[11, 12\] for a system of many particles. In this theory, the wave particle duality vanishes, quantum system behaves like a particle and a wave, simultaneously, in the same experimental setup. Then the particles are directed by the pilot wave which will guide them to areas of interference. The classical mechanics structure of the Kirchhoff equations allows us to address the wave particle duality as interference or in terms of relative phase. As an illustration we show that the equation for optical vortices can be derived as Kirchhoff equation admit a paraxial wave equation in presence of real constant background.
A. Derivation of Kirchhoff equations from Schrödinger equation

It is quite well known in mathematics literature \[13\] that the Kirchhoff equations (1) can be derived from time dependent with potential \(V(x) = 0\)

\[
i\frac{\partial}{\partial t}\psi(x,t) = \nu \frac{\partial^2}{\partial x^2}\psi(x,t),
\]

(6)

where \(\nu = -\frac{\hbar^2}{2m}\), by introducing a polynomial

\[
\psi(x,t) = (x - x_1(t))(x - x_2(t)) \cdots (x - x_n(t))
\]

(7)

for \(n = 2\), substituting equation (7) in time dependent Schrödinger equation (6) gives

\[
-i\dot{x}_1(x - x_2(t)) - i\dot{x}_2(x - x_1(t)) = 2\nu.
\]

(8)

The equations considered at \(x = x_1\) and \(x = x_2\)

\[
\dot{x}_1 = \frac{2\nu i}{(x_1 - x_2)}, \quad \dot{x}_2 = \frac{2\nu i}{(x_2 - x_1)}.
\]

(9)

Similarly for \(n = 3\), the equations at points \(x = x_1\), \(x = x_2\) and \(x = x_3\) are given by

\[
\dot{x}_1 = 2\nu i \left[ \frac{1}{(x_1 - x_2)} + \frac{1}{(x_1 - x_3)} \right]
\]

\[
\dot{x}_2 = 2\nu i \left[ \frac{1}{(x_2 - x_1)} + \frac{1}{(x_2 - x_3)} \right]
\]

\[
\dot{x}_3 = 2\nu i \left[ \frac{1}{(x_3 - x_1)} + \frac{1}{(x_3 - x_2)} \right]
\]

The same procedure for \(n\) zeros gives

\[
\dot{x}_i = 2\nu i \sum_{j \neq i} \frac{1}{(x_i - x_j)}.
\]

(10)

The equation (10) are known as the Kirchhoff equation which describe the evolution of \(n\) point vortices in Hydrodynamics. Therefore, Schrödinger equation can be written in the form of system of \(n\) linear equations (10). The Kirchhoff equation (10) with the background flow \(W(x)\) are given by

\[
\dot{x}_i = 2\nu i \sum_{j \neq i} \frac{1}{(x_i - x_j)} + iW(x),
\]

(11)

where the background flow \(W(x)\) is identified with the superpotential of super symmetric quantum mechanics.

When \(\dot{x}_i = 0\) are known as stationary Kirchhoff equations, reads as

\[
\nu i \sum_{j \neq i} \frac{1}{(x_i - x_j)} + iW(x_i) = 0.
\]

(12)

Integrating the equation (12) with respect to \(x_i\) one gets

\[
H = m\Gamma \sum_{i \neq j} log(|x_i - x_j|) + iQ(x_i),
\]

(13)
where \( \Gamma = \hbar \) and the background potential \( Q(x_i) = \int dx_i \mathcal{W}(x_i) \). In mathematics literature \[15, 16\] and also in \( n \) point vortices literature \[2\] the equation (13) is the Hamiltonian. In mathematics literature these functions are known as pseudo Harmonic functions \[14\]. It is clear that the equation (13) is complex, if the equation (13) is real then this known as Hamiltonian for \( n \) moving charges between the two fixed charges known as Steiljes electrostatic model \[15, 16\]. In Stieltjes electrostatic model, there are \( n \) unit moving charges between two fixed charges \( p \) and \( q \) at \(-1\) and \(1\) respectively on a real line and it is shown by Stieltjes that system attains equilibrium at the zeros of the Jacobi polynomials. It has been shown by the author, Stieltjes electrostatic model is analogous to the the quantum momentum function of quantum Hamilton Jacobi \[18\].

By exponentiation of equation (13) is known by wave function

\[
\psi(x_j) = \prod_{N \geq k \geq j \geq 1} (x_k - x_j)^{\frac{N}{j = 1}} \exp \left( -i \int \mathcal{W}(x_i) dx_j \right) .
\] (14)

The well known wave function in this form is the Laughlin wave function. In case of fractional quantum Hall effect, Robert Laughlin proposed the following wave function as an ansatz for the ground state wave function \[1\]

\[
\psi = \prod_{N \geq i \geq j \geq 1} (z_i - z_j)^n \exp \left( -\frac{1}{4l_B^2} \sum_i |z_i|^2 \right)
\] (15)

where \( \mathcal{W}(x_i) = \bar{z} \) gives \( i \int \mathcal{W}(z_j) dz_j = \frac{1}{4l_B^2} \sum_i |z_i|^2 \), \( z_i = x_i + iy_i \), \( N \) is number of electrons, \( l_B = \sqrt{\frac{\hbar}{eB}} \) is magnetic length, \( \hbar \) is Planck constant, \( e \) is electric charge, \( B \) is magnetic field, \( \omega_B \) is cyclotron frequency \( \omega_B = \frac{eB}{m} \), \( z_i \) and \( z_j \) are the position electrons for the ground state of a two-dimensional electron gas with the lowest Landau level, where \( n \) is written in terms \( \nu = 1/n \) and \( n \) is an odd positive integer are filling numbers. For details ref \[7\]. It has been shown by author that the logarithm of Laughlin wave function is a Hamiltonian and it is Berry connection by transforming the Schrödinger equation to Kirchhoff equations \[7\]. Thus, the Schrödinger equation as Berry connection allows us to formulate the problem of quantisation in terms of topology, as the quantum numbers are topological invariant which arise due to singularities in the Kirchhoff equations. Quantisation arises as it continuously connects the topologically inequivalent Hamiltonians in the Hilbert space.

II. WAVE PARTICLE DUALITY

Consider Kirchhoff equations \[11\] with identical say \( \Gamma \) are given by

\[
\frac{d\bar{x}_i}{dt} = \sum_{1 \leq i \leq n, i \neq j} \frac{i\Gamma}{x_i - x_j} + i\mathcal{W}(x_i).
\] (16)

By using the following identity \[17\]

\[
\sum_{1 \leq j \leq n, j \neq k} \frac{1}{x_j - x_k} = \lim_{x \to x_j} \left[ \frac{f''(x)}{f(x)} - \frac{1}{x - x_j} \right] = \lim_{x \to x_j} \frac{(x - x_j)f'(x) - f(x)}{(x - x_j)f(x)} = \frac{f''(x_j)}{2f'(x_j)}.
\] (17)
By substituting equation (17) in Kirchhoff equations (1) one gets
\[ f''(x_j) + W(x_i)f'(x_j) = u(x_i) + iv(x_i) = 0. \] (18)
where \( u(x_i) \) and \( v(x_i) \) are real valued function. If a relative phase in the Kirchhoff equations (18) is developed and \( v(x_i) \) is not a constant, gives rise to wave particle duality. As an illustration, we consider the case \( v(x_i) \) is constant, which gives rise to optical vortices.

The optical vortex which are defined as phase dislocation on the beam axis, the quantised orbital angular momentum, of a Laguerre-Gaussian laser mode [19]. Optical vortex beams are described in terms of Laguerre-Gaussian modes which are good approximation to the vortex modes created from Hermite-Gaussian laser modes [20, 21]. It is well known that the Laguerre-Gaussian vortex beam state arises as a solution of the paraxial approximation of the Helmholtz equation for light or Schrödinger equation for electrons in free space. The vortex states are solutions to the Schrödinger equation, Klein-Gordon equation and Dirac equations [22–25]. The connection between the optical vortices and Hydrodynamics is studied in ref [26].

When \( v(x_i) = P \) is a constant under paraxial approximation admit a wave equation which describes the optical vortices. consider the the Kirchhoff equations (1) in the stationary case \( \frac{dz}{dt} = 0 \), constant imaginary background field \( W(z_i) = iP \) will read as
\[ \sum_{1 \leq i \leq n, i \neq j} \frac{\Gamma}{z_i - z_j} + iP = 0. \] (19)
Using the identity [17]
\[ \sum_{1 \leq j \leq n, j \neq i} \frac{1}{z_j - z_i} = \frac{f''(z_i)}{2f'(z_i)}, \] (20)
and substituting equation (20) into equation (19) we obtain
\[ \frac{\partial^2 u}{\partial z_i^2} + 2ik \frac{\partial u}{\partial z_i} = 0, \] (21)
where \( k = P/\Gamma \). Writing equation (21) in terms of coordinates \( x_i \) and \( y_i \), the position of \( N \) vortices \( z_\alpha = x_i + iy_i \), gives
\[ \frac{\partial^2 u}{\partial x_i^2} + \frac{\partial^2 u}{\partial y_i^2} + 2ik \frac{\partial u}{\partial z_i} = 0. \] (22)
In optics the wave equation (22) is called paraxial wave equation and Gaussian beams of any beam waist \( w_0 \) satisfy this wave equation [27]. In paraxial approximation the term \( \frac{\partial^2 u}{\partial z_i^2} \) is neglected. Substituting, the term \( \frac{\partial^2 u}{\partial z_i^2} \) back into the equation (22) gives
\[ \frac{\partial^2 u}{\partial x_i^2} + \frac{\partial^2 u}{\partial y_i^2} + \frac{\partial^2 u}{\partial z_i^2} + 2ik \frac{\partial u}{\partial z_i} = 0, \] (23)
The equation (23) is derived from the Helmholtz equation:
\[ \nabla^2 \psi(x_i, y_i, z_i) + k^2 \psi(x_i, y_i, z_i) = 0 \] (24)
with
\[ \psi(x_i, y_i, z) = u(x_i, y_i, z_i) e^{ikz_i}. \] (25)
Therefore, two dimensional $N$ point vortices with the identical circulation strength under the constant imaginary background flow will admit a wave equation and under paraxial approximation.

In optics, relative phase gives rise to interference. It is well known, the particle nature of electrons passing through Young’s double slit experiment one observe interference pattern on screen which is a wave nature of electrons. It should be noted, the Kirchhoff equations (10) are one dimensional and Kirchhoff equations for the vortices (11) are two dimensional. But Kirchhoff equations written in differential form (18) can always be written as complex form. Therefore, we claim, if Kirchhoff equations in differential form (18) admits a relative phase then it gives rise to wave particle duality.

III. DISCUSSION

The mapping of quantum mechanics to classical mechanics allows us to draw the following conclusions. The $n$ point vortices are integrable unto three vortices [6]. If vortices circulation strength are identical, then the $n$ point vortices, can be solved with Stieltjes electrostatic model and their solutions are classical orthogonal polynomials [28]. The $n$ point vortices with identical circulation strength corresponds to Schrödinger equation and the solutions are classical orthogonal polynomials and they are basis in Hilbert space. Hence, the first postulate: The state of a quantum mechanical system is completely specified by a function $\Psi(r,t)$ is a vector in complex Hilbert space. The complex Hilbert space arise because the Kirchhoff equations are solved using Stieltjes electrostatic model with imaginary charges [18]. Stieltjes electrostatic model gives the equilibrium distribution of $n$ moving charges between the two fixed charges is solved, hence, it is the statistical distribution of these charges is given in terms of probability distribution. The probability distribution in terms of wave function is given by

$$\int_{-\infty}^{\infty} \Psi^*(r,t)\Psi(r,t)d\tau = 1.$$ (26)

The Kirchhoff equations allows us to study wave particle duality as relative phase which gives rise to interference. As an illustration we shown that the equation for optical vortices can be derived as Kirchhoff equation admit a paraxial wave equation in presence of real constant background. Quantum mechanics connection to geometry arise with the existence two dimensional topological system such as quantum Hall effect and optical vortices. The Schrödinger equation written in terms Kirchhoff equations is a Berry connection [7]. This allowed us the problem of quantisation in terms of topology, as the quantum numbers are topological invariant which arise due to singularities in the Kirchhoff equations [18]. Quantisation arises as it continuously connects the topologically inequivalent Hamiltonians in the Hilbert space.

IV. CONCLUSION

In this paper, we shown that in two dimensions quantum mechanics can be mapped onto classical mechanics, by transforming the Schrödinger equation into system of $n$ linear equations known as Kirchhoff equations. These Kirchhoff equations equations satisfy the a poison bracket relationship in phase space which is identical to the Heisenberg uncertainty relationship. Therefore, we conclude that quantum mechanics is consistent
with classical mechanics at least in two dimensions. This allows us to address the wave particle duality in terms of relative phase. As an illustration we shown that the equation for optical vortices can be derived as Kirchhoff equation admit a paraxial wave equation in presence of real constant background.
