In this paper we calculate the kinematical quantities possessed by Raychaudhuri equations, to characterize a congruence of time-like integral curves, according to the vacuum radial solution of Weyl theory of gravity. Also the corresponding flows are plotted for definite values of constants.

I. INTRODUCTION

An important and notable feature of Einstein gravity solutions, such as Schwarzschild spacetime or the cosmological Robertson-Walker solution, is that they all have apparent singularities. The question was what would be their physical implications? It was Raychaudhuri who tried to investigate these solutions in both cosmological [1] and gravitational contexts [1]. Later, in 1955, he proposed his famous equations [3] which are known as Raychaudhuri equations.

These equations appeared to be of great importance in describing gravitational focusing and spacetime singularities. The Focusing Theorem is based on Raychaudhuri equations Assuming the Einstein’s equations and using energy conditions it is established that time-like and null geodesics if initially converging will focus until zero size in a finite time. One of the most important notions about singularities, as pointed out by Landau and Lifshitz [7], is that a singularity would always imply focusing of geodesics, while focusing itself can not imply a singularity. Therefore in their work, the concept of geodesic focusing (although not explicitly stated the same) was worked out. However, they did not introduce shear and rotation which are inseparable ingredients of Raychaudhuri equations.

Ever since the equations were published, they have been discussed and analyzed in numerous frameworks of general relativity, quantum field theory, string theory and relativistic cosmology. One should note that the concept of a singularity was first defined in seminal works of Penrose and Hawking [4–6]. Therefore it was only then that Raychaudhuri equations received their deserved acclaim.

In addition to general relativity, the Raychaudhuri equations have also been discussed in the context of alternative theories of gravity, such as $f(R)$ theories [8]. In this paper as well, we consider characteristics of time-like flows in an alternative theory of gravity which as well has cosmological implications, namely the Weyl theory of gravity. The paper is organized as follows: in section 2 we briefly introduce the Raychaudhuri equations and its kinematical parameters; in section 3 we mention the Weyl field equations and obtain the kinematical evolution of time-like radial and rotational geodesic flows and see how they behave by plotting the congruences of the integral curves. Finally in section 4, we summarize the results.

II. RAYCHAUDHURI EQUATIONS

As it was mentioned, the Raychaudhuri equations are evolution equations for expansion, shear and rotation of a time-like geodesic congruence of integral curves, which is indeed pure geometrical and therefore, are independent of reference frames of Einstein equations. Being parameterized in terms of the affine parameter of the geodesics, $\tau$, These equations in 4-dimensional spacetimes are written as follows [9]:

$$\frac{d\Theta}{d\tau} + \frac{1}{3} \Theta^2 + \sigma^2 - \omega^2 = -R_{\mu\nu}v^\mu v^\nu,$$

$$\frac{d\sigma_{\mu\nu}}{d\tau} = -\frac{2}{3} \Theta \sigma_{\mu\nu} - \sigma_{\mu\lambda} \sigma^{\lambda\nu} - \omega_{\mu\lambda} \omega^{\lambda\nu} + \frac{1}{3} h_{\mu\nu} (\sigma^2 - \omega^2)$$

* m.fathi@shargh.tpnu.ac.ir; mohsen.fathi@gmail.com
\[ + C_{\lambda\mu\nu\rho} v^\lambda v^\rho + \frac{1}{2} h_{\mu\lambda} h_{\nu\rho} R^{\lambda\rho} - \frac{1}{3} h_{\mu\nu} h_{\lambda\rho} R^{\lambda\rho}, \]  
(2)

\[ \frac{d\omega_{\mu\nu}}{d\tau} = - \frac{2}{3} \Theta \omega_{\mu\nu} - 2 \sigma_{\lambda [\nu} \omega_{\mu]}^{\lambda}. \]
(3)

In (1)-(3), \( \Theta, \sigma_{\mu\nu} \) and \( \omega_{\mu\nu} \) are respectively the scalar expansion, the symmetric traceless shear tensor and the antisymmetric rotation tensor. Moreover \( \sigma^2 = \sigma_{\mu\nu} \sigma^{\mu\nu}, \omega^2 = \omega_{\mu\nu} \omega^{\mu\nu} \) and \( C_{\lambda\mu\nu\rho} \) is the Weyl conformal tensor. In (1), \( v^\mu \) denotes the tangential vector field on the geodesics and \( h_{\mu\nu} \) in (2) and (3) is the projection tensor which for time-like curves is defined by

\[ h_{\mu\nu} = g_{\mu\nu} + v^\mu v^\nu. \]
(4)

Generally speaking, the Raychaudhuri equations deal with the kinematics of flows which are generated by vector fields. Such flows are indeed congruences of integral curves which may or may not be geodesics. Actually in the context of these equations, we are interested in the evolution of the kinematical characteristics of the so-called flows, not the origin of them. These characteristics which are contained in the Raychaudhuri equations (1) to (3), may constitute one equation like [10]

\[ \nabla_\nu v_\mu = \sigma_{\mu\nu} + \omega_{\mu\nu} + \frac{1}{3} h_{\mu\nu} \Theta, \]
(5)

in which the traceless symmetric part is defined as

\[ \sigma_{\mu\nu} = \nabla_{(\nu} v_{\mu)} - \frac{1}{3} h_{\mu\nu} \Theta. \]
(6)

Also the scalar trace is

\[ \Theta = \nabla_\mu v^\mu, \]
(7)

and the antisymmetric part is

\[ \omega_{\mu\nu} = \nabla_{[\mu} v_{\nu]}, \]
(8)

Geometrically, these quantities are related to a cross-sectional area which encloses a definite number of integral curves and is orthogonal to them. Moving along the flow lines, this area may isotropically changes its size or being sheared or twisted, however it still holds the same number of flow lines. There are some analogies with elastic deformations which are discussed in [11]. Also one can find explicit discussions on these quantities in [12, 13].

Here we should note that the Raychaudhuri equations may be essentially regarded as identities, which become equations when they are for example used in spacetimes defined by Einstein field equations.

Moreover, the equations are of first order and non-linear. Also the expansion equation (1), is the same as Riccati equation in mathematical regards [14, 15]. The expansion is indeed the change of the cross-sectional area which is orthogonal to the geodesic bundle.

In the next section, we will find the mentioned kinematical characteristics, for curve bundles on a definite spacetime background.

### III. TIME-LIKE GEODESIC CONGRUENCES IN WEYL GRAVITY

The Weyl theory of gravity has had an interesting background and had received a great deal of attention from those who believe that the dark matter/dark energy scenario could be well-treated by altering general theory of gravity. This became more elaborated after arguing that the extraordinary behavior of the galactic rotation curves could be extracted from Weyl gravity as a natural consequence of its vacuum solutions [16–18]. There were subsequently more attempts to make relations between the theory’s anticipations and observational evidences [19–21] and as the main course, proposing gravitational alternatives to dark matter/dark energy [23–25]. Some good information about this 4th order theory of gravity can be found in Ref. [22]. Another important feature of the Weyl theory of gravity, is its conformal invariance which, as it is stated in the literature, could be considered as a tool in unification with the standard model by creating the desired mass during the symmetry breaking [26].
The Weyl theory of gravity is a theory of fourth order with respect to the metric. Weyl gravity is characterized by the Bach action

\[ I_B = -\alpha \int d^4x \sqrt{-g} C^2, \]  

(9)

where \( C^2 = C_{\mu\nu\rho\lambda} C^{\mu\nu\rho\lambda} \) is the Weyl invariant and \( \alpha \) is a coupling constant. The action (9) in principle, could be rewritten as

\[ I_B = -\alpha \int d^4x \sqrt{-g} \left( R^{\mu\nu\rho\lambda} R_{\mu\nu\rho\lambda} - 2R^{\mu\nu} R_{\mu\nu} + \frac{1}{3} R^2 \right), \]  

(10)

from which, using the total divergency of the Gauss-Bonnet term \( \sqrt{-g} \left( R^{\mu\nu\rho\lambda} R_{\mu\nu\rho\lambda} - 4R^{\mu\nu} R_{\mu\nu} + R^2 \right) \), we have

\[ I_B = -\alpha \int d^4x \sqrt{-g} \left( R^{\mu\nu} R_{\mu\nu} - \frac{1}{3} R^2 \right). \]  

(11)

Varying (11) with respect to \( g_{\mu\nu} \) one obtains the Bach tensor as

\[ W_{\mu\nu} = \frac{1}{4\alpha} T_{\mu\nu}, \]  

(13)

where \( T_{\mu\nu} \) is the matter/energy tensor. Also the vacuum field equations \( (W_{\mu\nu} = 0) \) have been explicitly solved. The solution constructs a spherically symmetric spacetime defined by the line element

\[ ds^2 = -B(r) dt^2 + B^{-1}(r) dr^2 + r^2 d\Omega^2, \]  

(14)

in which

\[ B(r) = -\frac{\beta(2-3\beta\gamma)}{r} + (1-3\beta\gamma) + \gamma r - kr^2. \]  

(15)

This solution has three important constants, \( \beta, \gamma \) and \( k \), by which the Schwarzschild-de Sitter metric could be regenerated. Also \( \gamma \) and \( k \) are respectively related to the dark matter and dark energy constituents of the cosmic fluid. Now let us inspect that how time-like flows evolve in the spacetime defined in (14). To do this, we separately consider radial and rotational flows, and obtain the kinematical parameters in the Raychaudhuri equations.

### A. Radial Flows

Some features of pure radial time-like flows has been discussed in Ref. [27]. Firstly, for the spacetime coordinates on a parametric integral curve

\[ x^\mu = (t(\tau), r(\tau), \theta(\tau), \phi(\tau)), \]  

(16)

we define the 4-velocity vector field

\[ u^\mu = \left( \dot{t}(\tau), \dot{r}(\tau), \dot{\theta}(\tau), \dot{\phi}(\tau) \right), \]  

(17)

which are supposed to be tangential to any integral curve in the spacetime and for time-like congruences one must have \( u_\mu u^\mu = -1 \). Also \( \dot{x}^\mu \) denotes \( \frac{dx^\mu}{d\tau} \). To have purely radial flows on equatorial plane, we take \( \dot{\theta} = \frac{\pi}{2} \) and \( \dot{\phi} = 0 \). Therefore for such flows in the spacetime defined in (14) and (15), the time-like condition

\[ g_{\mu\nu} u^\mu u^\nu = -1, \]  

(18)
and the geodesic equations
\[ \dot{v}^\mu + \Gamma_{\nu\lambda}^\mu v^\nu v^\lambda = 0, \] (19)
are respectively
\[ \frac{r\dot{t}^2}{\beta(3\beta\gamma - 2) - kr^3 + \gamma r^2 - 3\beta\gamma r + r} + \frac{i(2\beta + kr^3 - \gamma(3\beta^2 + r^2 - 3\beta r) - r)}{r} + r = 0, \] (20)
\[ \frac{i\dot{t}(\beta(3\beta\gamma - 2) + 2kr^3 - \gamma r^2)}{r(\beta(2 - 3\beta\gamma) + kr^3 - \gamma r^2 + r(3\beta\gamma - 1))} + \dot{r} = 0, \] (21)
\[ \frac{(\beta(3\beta\gamma - 2) + 2kr^3 - \gamma r^2) (\dot{t}^2(\beta(3\beta\gamma - 2) - kr^3 + \gamma r^2 - 3\beta\gamma r + r)^2 - r^2\dot{r}^2)}{2r^3(\beta(2 - 3\beta\gamma) + kr^3 - \gamma r^2 + r(3\beta\gamma - 1))} + \dot{r} = 0. \] (22)
Integrating (21) we obtain
\[ i = -\frac{r}{-3\beta^2\gamma + 2\beta + kr^3 - \gamma r^2 + 3\beta\gamma r - r}, \] (23)
using which in (20) gives
\[ \dot{r} = \pm \sqrt{-\frac{-3\beta^2\gamma + 2\beta + kr^3 + 3\beta\gamma r - \gamma r^2}{r}}. \] (24)
Taking the positive part, the tangential vector field (17) for pure radial flows would be
\[ v^\mu = \left( \frac{r}{-3\beta^2\gamma + 2\beta + kr^3 - \gamma r^2 + 3\beta\gamma r - r}, \sqrt{-\frac{-3\beta^2\gamma + 2\beta + kr^3 + 3\beta\gamma r - \gamma r^2}{r}}, 0, 0 \right). \] (25)
The flows which are formed by this vector field, are expanding by the following factor which is obtained by use of (7):
\[ \Theta = \frac{6kr^3 - 5\gamma r^2 + 3\beta(-3\beta\gamma + 4\gamma r + 2)}{2r^{3/2} \sqrt{kr^3 - \gamma r^2 + \beta(-3\beta\gamma + 3\gamma r + 2)}}. \] (26)
The vector field (25) is orthogonal to hypersurface of the field crests, therefore it is of zero rotation [11]. However the shear tensor is non-zero. From (4), (6) and (26) we have
\[ \sigma_{ut} = \frac{(9\beta^2\gamma + \gamma r^2 - 6\beta(\gamma r + 1)) \sqrt{-3\beta^2\gamma + kr^3 - \gamma r^2 + \beta(3\gamma r + 2)}}{3r^{5/2}}, \]
\[ \sigma_{ur} = \sigma_{ru} = -\frac{9\beta^2\gamma + \gamma r^2 - 6\beta(\gamma r + 1)}{3r(\beta(2 - 3\beta\gamma) + kr^3 - \gamma r^2 + r(3\beta\gamma - 1))}, \]
\[ \sigma_{rr} = \frac{\sqrt{7} (9\beta^2\gamma + \gamma r^2 - 6\beta(\gamma r + 1))}{3\sqrt{-3\beta^2\gamma + kr^3 - \gamma r^2 + \beta(3\gamma r + 2)(\beta(3\beta\gamma - 2) - kr^3 + \gamma r^2 - 3\beta\gamma r + r)^2}}, \]
\[ \sigma_{\theta\theta} = \sigma_{\phi\phi} = -\frac{\sqrt{7} (9\beta^2\gamma + \gamma r^2 - 6\beta(\gamma r + 1))}{6\sqrt{-3\beta^2\gamma + kr^3 - \gamma r^2 + \beta(3\gamma r + 2)}}. \] (27)
To obtain a pictorial viewpoint of how radial flows will behave in a Weyl field, we should find an expression for \( r(\tau) \).

Using (23), the geodesic equation (22) gives

\[
\ddot{r} - \frac{(\dot{r}^2 - 1) \left( \beta(3\beta\gamma - 2) + 2kr^3 - \gamma r^2 \right)}{2r \left( \beta(2 - 3\beta\gamma) + kr^3 - \gamma r^2 + r(3\beta\gamma - 1) \right)} = 0. 
\]

Unfortunately this is non-linear second order equation. Even the first order equation (24) could not be explicitly solved. Therefore we consider a simpler case of \( \gamma = 0 \) which is in accordance to the de Sitter solution. In this case (24) results in

\[
r(\tau) = \pm \frac{e^{-\sqrt{k}(c+\tau)} \left( e^{3\sqrt{k}(c+\tau)} - 2\beta k \right)^{2/3}}{2^{2/3}k^{2/3}},
\]

with

\[
c = \frac{1}{3} \ln \left( \frac{2 \sqrt{k^3r_0^3 (2\beta + kr_0^3)} + k^2r_0^3 + \beta k}{\sqrt{k}} \right),
\]

where \( r_0 \) is the point of closest approach. The radial flows are shown in figure 1. One can note that how the expansion will make cross-section area to change its size.

1. Focusing

If spacetime singularities are concerned, equation (1) for the expansion receives the most central attention. As it was shown above (and also in figure 1), the expansion changes the cross-sectional area along the geodesic bundle. It is noted that if the expansion approaches the negative infinity, the congruences will converge, whereas they diverge if the expansion goes to positive infinity. The converges is what we regard as the focusing of the geodesic bundles according to the singularities. However, to clarify whether any convergence occurs for a peculiar flow, one should examine the expansion equation. It has been put in the literature that convergence occurs if

\[
R_{\mu\nu}v^\mu v^\nu + \sigma^2 - \omega^2 \geq 0,
\]

or equivalently

\[
\frac{d\Theta}{d\tau} + \frac{1}{3} \Theta^2 \leq 0.
\]
Therefore one can observe that shear acts in favor of convergence while rotation opposes it. However for zero rotations, the condition (30) reduces to [10]

$$R_{\mu\nu}v^\mu v^\nu \geq 0.$$  \hfill (32)

Now for the zero-rotation flow defined by the vector field (25), the condition (32) gives

$$\frac{\gamma}{r} - 3k \geq 0.$$  \hfill (33)

This provides us a maximum for $r$ according to which one must have $r \leq \frac{\gamma}{3k}$. We should note that in the metric potential (15), includes a Newtonian term which is dominant at small distances. Increasing $r$, it would be the term $\gamma r$ as the dominant one. Such distances are about galactic scales. For a typical galaxy of of radius $r \sim 10^{10}$m, $\gamma$ is of order $10^{-26}$m$^{-1}$ [16]. Finally at cosmological distances, the term $kr^2$ is of the greatest importance. For a universe of constant curvature, $k$ may be regarded as the cosmological constant $\Lambda$ which is of order $10^{-52}$m$^{-2}$ [28]. Therefore if galactic scales are of interest, equation (33) implies that for $r \lesssim 3.3 \times 10^{25}$m we may expect the convergence of the flow.

### B. Rotational Flows

Pure rotational flows in equatorial plane, could be obtained by letting $\theta = \frac{\pi}{2}$ and $r = \text{const.}$, according to the vector field in (17). Accordingly the time-like condition (18) and the geodesic equations (19) are respectively

$$\ddot{t}^2 \left( \beta(2 - 3\beta \gamma) + kr^3 - \gamma r^2 + r(3\beta \gamma - 1) \right) + r^2 \dot{\phi}^2 + r = 0,$$  \hfill (34)

$$\dot{t} = 0,$$  \hfill (35)

$$\ddot{t}^2 \left( \beta(3\beta \gamma - 2) + 2kr^3 - \gamma r^2 \right) + 2r^3 \dot{\phi}^2 = 0,$$  \hfill (36)

$$\ddot{\phi} = 0.$$  \hfill (37)

Equation (35) implies $\dot{t} = 1$. Applying this to (34) gives

$$\dot{\phi} = \pm \frac{\sqrt{3\beta^2 \gamma - 2\beta - kr^3 + \gamma r^2 - 3\beta \gamma r}}{r^{3/2}}.$$  \hfill (38)

Therefore the tangential vector field can be written as

$$v^\mu = \left( 1, 0, 0, \frac{\sqrt{3\beta^2 \gamma - 2\beta - kr^3 + \gamma r^2 - 3\beta \gamma r}}{r^{3/2}} \right).$$  \hfill (39)

Together with (7), one can see that $\Theta = 0$, implying that the flows which are formed by (39), are free of expansion. Therefore we can not expect any focusing for this rotational flow, since the cross-sectional area does not change. Also the non-zero components of the shear tensor would be

$$\sigma_{t\phi} = \sigma_{\phi t} = \frac{-9\beta^2 \gamma - \gamma r^2 + 6\beta(\gamma r + 1)}{4r \sqrt{3\beta^2 \gamma - kr^3 + \gamma r^2 - \beta(3\gamma r + 2)}}.$$  \hfill (40)

Moreover using (8), one can obtain the rotation of the flow which is characterized by the following non-zero components of the antisymmetric part of Raychaudhuri kinematical parameters:

$$\omega_{tr} = -\omega_{rt} = kr - \frac{3\beta^2 \gamma + 2\beta + \gamma r^2}{2r^2},$$

$$\omega_{\phi r} = \omega_{r\phi} = \frac{3\beta^2 \gamma - 2\beta - kr^3 + \gamma r^2 + 3\beta \gamma r}{r^{3/2}}.$$
The purely rotational flows in a Weyl field.

\[ \omega_{r\phi} = -\omega_{\phi r} = \frac{-3\beta^2\gamma + 4kr^3 - 3\gamma r^2 + \beta(6\gamma r + 2)}{4\sqrt{r}\sqrt{3\beta^2\gamma - kr^3 + \gamma r^2 - \beta(3\gamma r + 2)}} \]

(41)

The constant radial distance can be obtained from (36) and (38). We have

\[ r = \frac{3\beta\sqrt{r} \pm \sqrt{6\sqrt{r}}}{\sqrt{3}}. \]

(42)

According to this, the pure rotational flow can be obtained which has been depicted in figure 2. One can note that the cross-sectional area will suffer a twist while holding the same number of integral curves. However for each curve, the radial distance is a constant and the shear gradually will make the congruence bundle to become compressed.

C. Radial-Directional Flow

Now let us consider a geodesic flow, for which both radial and angular components of the tangent vector field on the congruence are supposed to be affine variables. We are still on the equatorial plane, so the time-like condition (18) and the geodesic equations (19) read as

\[ \dot{t}^2 \left( \frac{kr^3 - \gamma r^2 + \beta(-3\beta\gamma + 3\gamma r + 2)}{r} \right) - 1 + \frac{r\dot{r}^2}{\beta(3\beta\gamma - 2) - kr^3 + \gamma r^2 - 3\beta\gamma r + r + r^2\dot{\phi}^2} = -1, \]

(43)

\[ \dot{t} + \frac{1}{2r^3 (\beta(2 - 3\beta\gamma) + kr^3 - \gamma r^2 + r(3\beta\gamma - 1))} \times \left[ (\beta(3\beta\gamma - 2) - kr^3 + \gamma r^2 - 3\beta\gamma r + r)^2 \left( \dot{t}^2 (\beta(3\beta\gamma - 2) + 2kr^3 - \gamma r^2) + 2r^3\dot{\phi}^2 \right) + r^2\dot{r}^2 (\beta(2 - 3\beta\gamma) - 2kr^3 + \gamma r^2) \right] = 0. \]

The temporal geodesic equation and consequently \( \dot{t} \) are the same as (21) and (23). Also direct integration of \( \dot{\phi} \) equation in (44) gives

\[ \dot{\phi} = \left( \frac{1}{r} \right)^2. \]

(45)
Using (23) and (45) in (43) to obtain \( \dot{r} \), the tangential vector field for the geodesic congruence becomes

\[
\nu^\mu = \left( -3\beta^2 \gamma + 2 \beta + kr^3 - \gamma r^2 + 3 \beta \gamma r - r, \sqrt{\beta(3\beta \gamma - 2) - kr^3 + \gamma r^2 - 3 \beta \gamma r + r \sqrt{\beta(3\beta \gamma - 2) - kr^3 + \gamma r^2 - 3 \beta \gamma r + r} - \frac{1}{r^2} - 1 \right) \left( 1 - \frac{1}{r} \right)^2. \tag{46}
\]

According to (46) one can obtain the kinematical characteristics of a Radial-Directional flow in a Weyl field. The expansion is

\[
\Theta = \frac{1}{2r^{7/2} A} \left[ \beta(2 - 3\beta \gamma) + 6kr^5 + 4r^3(3\beta \gamma + k) - 5\gamma r^4 - 3r^2(\beta(3\beta \gamma - 2) + \gamma) + r(6\beta \gamma - 2) \right], \tag{47}
\]

where

\[
A = \sqrt{\beta(3\beta \gamma - 2) - kr^3 + \gamma r^2 - 3 \beta \gamma r + r} \sqrt{\beta(3\beta \gamma - 2) - kr^3 + \gamma r^2 - 3 \beta \gamma r + r} - \frac{1}{r^2} - 1.
\]

Moreover the non-zero components of the shear tensor become

\[
\sigma_{tt} = \frac{1}{6r^{9/2} A} \times \left[ -4\beta^2(2 - 3\beta \gamma)^2 + 2k^2 r^6 + 2kr^3 \left( \beta(3\beta \gamma - 2) + \gamma r^4 - 6 \beta \gamma r^3 + r^2 \left( 9\beta^2 \gamma - 6 \beta - \gamma \right) - 2r \right) \right.
\]
\[
-2\gamma^2 r^6 + 18 \beta^2 \gamma r^5 + 4 \beta \gamma r^4(4 - 15 \beta \gamma) + \gamma r^3 \left( 90 \beta^3 \gamma - 60 \beta^2 + 6 \beta \gamma + 1 \right)
\]
\[
-2\beta r^2 \left( 27 \beta^3 \gamma^2 - 36 \beta^2 \gamma + 3 \beta \left( 5 \gamma^2 + 4 \right) - 7 \gamma \right) + \beta r \left( 54 \beta^2 \gamma^2 - 51 \beta \gamma + 10 \right) \right],
\]

\[
\sigma_{tr} = \sigma_{rt} = \frac{\beta(2 - 3\beta \gamma) + 4r^3(3\beta \gamma + k) - 2\gamma r^4 - 3r^2(6 \beta^2 \gamma - 4 \beta + \gamma) + r(6\beta \gamma - 2)}{6r^3(\beta(2 - 3\beta \gamma) + kr^3 - \gamma r^2 + r(3 \beta \gamma - 1))},
\]

\[
\sigma_{t\phi} = \sigma_{\phi t} = -\frac{1}{6r^{7/2} A} \left[ \beta(2 - 3\beta \gamma) + 6kr^5 + 4r^3(3\beta \gamma + k) - 5\gamma r^4 - 3r^2(\beta(3\beta \gamma - 2) + \gamma) + r(6\beta \gamma - 2) \right],
\]

\[
\sigma_{rr} = \frac{1}{6r^{9/2}(\beta(3\beta \gamma - 2) - kr^3 + \gamma r^2 - 3 \beta \gamma r + r)} \times \left[ -\beta^2(2 - 3 \beta \gamma)^2 + r^6 \left( \gamma(\gamma - 12 \beta) - 4k^2 + 2k(3 \beta \gamma - 5) \right) - \gamma(k - 2)r^7 \right.
\]
\[
+ r^5 \left( -9 \beta^2 \gamma(k - 2) + 3\beta \left( -3\gamma^2 + 2k - 4 \right) + \gamma(7k + 10) \right) + r^4 \left( 30 \beta^2 \gamma^2 - 38 \beta \gamma - 3\gamma^2 + k(6 - 18 \beta \gamma) + 8 \right)
\]
\[
-5r^3 \left( 9\beta^3 \gamma^2 + \gamma - 3 \beta \gamma^2(k + 4) + \beta \left( -3 \gamma^2 + 2k + 4 \right) \right)
\]
\[
+ r^2 \left( 27 \beta^4 \gamma^2 - 36 \beta^3 \gamma - 6 \beta^2 \gamma(5 \gamma^2 - 2) + 20 \beta \gamma - 2 \right) + 3 \beta r \left( 9 \beta^2 \gamma^2 - 9 \beta \gamma + 2 \right) \right],
\]
\[ \sigma_{\phi \phi} = \sigma_{\phi r} = \frac{\beta (2 - 3 \beta \gamma) + r^3 (-6 \beta \gamma + 4 k + 6) + \gamma r^4 + r^2 \left( 9 \beta^2 \gamma - 6 \beta - 3 \gamma \right) + r (6 \beta \gamma - 2)}{6 r^3 \left( \beta (2 - 3 \beta \gamma) + k r^3 - \gamma r^2 + r (3 \beta \gamma - 1) \right)}. \]

\[ \sigma_{\theta \theta} = \frac{1}{6 r^{3/2} A} \left[ 5 \beta (2 - 3 \beta \gamma) + 2 r^3 (3 \beta \gamma + k) - \gamma r^4 - 3 r^2 \left( 3 \beta^2 \gamma - 2 \beta + \gamma \right) + 4 r (3 \beta \gamma - 1) \right], \]

\[ \sigma_{\phi \theta} = \frac{1}{6 r^{3/2} A} \times \left[ \beta (3 \beta \gamma - 2) - 3 k r^7 - r^5 (3 \beta \gamma + 7 k) - r^3 (9 \beta \gamma + 4 k + 1) 
+ 3 r^2 \left( \beta (2 - 3 \beta \gamma) + k r^5 + r^3 (3 \beta \gamma + k) - \gamma r^4 - r^2 \left( 3 \beta^2 \gamma - 2 \beta + \gamma \right) + r (3 \beta \gamma - 1) \right) 
+ 2 \gamma r^6 + 5 \gamma r^4 + r^2 \left( 3 \beta^2 \gamma - 2 \beta + 3 \gamma \right) + r (2 - 6 \beta \gamma) \right]. \]  

(48)

Surprisingly the rotation tensor vanishes; \( \omega_{\mu \nu} = 0 \). Therefore if one is interested in focusing, it is sufficient examining equation (32). For (46) this gives the condition

\[ 3 \beta \gamma - (r^2 + 1) r (3 kr - \gamma) + 3 kr^2 - 2 \gamma r \geq 0. \]  

(49)

Once again, dealing with a typical galaxy, the dimension-less term \( \beta \gamma \) would be of order \( 10^{-12} \) [16]. Counting on our previous values for \( \gamma \) and \( k \), then the only non-zero solution for \( r \) is

\[ r = 3.33333 \times 10^{25} \text{m}. \]  

(50)

Note also that, this is in agreement with the convergence condition for the purely radial flows which was discussed above.

1. Capture Zone

One might even obtain the region in which there would be a possible capturing of the flow, by use of an effective potential. To proceed with this method, let us use the time-like condition (43), exploiting the total energy definition \( E = g_{00} t \) and also equation (45). Rearrangement yields

\[ \dot{r}^2 = E^2 - V_{\text{eff}}(r)^2, \]  

(51)

where

\[ V_{\text{eff}}(r) = \sqrt{\frac{(r^2 + 1) (\beta (3 \beta \gamma - 2) - k r^3 + \gamma r^2 - 3 \beta \gamma r + r)}{r^3}}. \]  

(52)

This potential has been plotted in figure 3. However in order to capture a time-like flow, it is pretty useful to take care about the potential maximums. Such maximums may represent unstable circular orbits. Hence if the energy of a particle is supposed to be the same as the potential maximum, it will be inevitably captured and the corresponding time-like geodesics will ultimately terminated where the potential is originated from. The potential in (52) has a maximum at \( r = 5 \times 10^{25} \text{m} \), where the derivatives of \( V_{\text{eff}}(r) \) vanish. So for this maximum and higher energies, one can expect geodesic focusing.
IV. SUMMARY

In this paper we dealt with characterizing time-like geodesic flows in Weyl filed and we supposed that such field is formed in vacuum spacetime, obtained from vacuum Weyl field equations. We distinctly considered radial and rotational flows and obtained their corresponding expansion, shear and vorticity (i.e. the rotation tensor). We noted that for radial flows, only it is expansion and shear which are contributing in characterization and as it is obvious in figure 1, the expansion is isotropic, however the shear makes the formation of the curve bundle an-isotropic. Moreover, for the peculiar rotational flows we considered, we found that although it is not usual, however the expansion vanishes. Therefore we are left with a simple shear tensor and of course a non-vanishing vorticity. This may provide us a circular flow, which is gradually getting compact. For further considerations, one may concern about null-like geodesics in Weyl fields. Also it is possible to take both rotation and radial motion in same flows. In the context of cosmology, this may help us to discover how real cosmic flows will behave in Weyl conformal gravity.
