COMPRESSED ZERO-DIVISOR GRAPHS OF
NONCOMMUTATIVE RINGS

ALEN ĐURIČ, SARA JEVDENIĆ, AND NIK STOPAR

Abstract. We extend the notion of the compressed zero-divisor graph \( \Theta(R) \) to noncommutative rings in a way that still induces a product preserving functor \( \Theta \) from the category of finite unital rings to the category of directed graphs. For a finite field \( F \), we investigate the properties of \( \Theta(M_n(F)) \), the graph of the matrix ring over \( F \), and give a purely graph-theoretic characterization of this graph when \( n \neq 3 \). For \( n \neq 2 \) we prove that every graph automorphism of \( \Theta(M_n(F)) \) is induced by a ring automorphism of \( M_n(F) \). We also show that for finite unital rings \( R \) and \( S \), where \( S \) is semisimple and has no homomorphic image isomorphic to a field, if \( \Theta(R) \cong \Theta(S) \), then \( R \cong S \). In particular, this holds if \( S = M_n(F) \) with \( n \neq 1 \).

Key Words: zero-divisor, compressed zero-divisor graph, matrix ring

2010 Mathematics Subject Classification: 16U99, 15B33, 05C25, 05C50

1. Introduction

The zero-divisor graph of a unital commutative ring \( K \) was first introduced in 1988 by Beck [10] as a tool to study the structure of the ring. His graph \( G(K) \) is a simple graph with vertex set \( K \) where two distinct vertices are adjacent if and only if their product is equal to 0. Beck studied the chromatic number and the clique number of this graph. Later Anderson and Livingston [9] modified Beck’s definition and defined a simple graph \( \Gamma(K) \) by taking only nonzero zero-divisors of \( K \) as the vertex set and leaving the definition of edges the same. The properties of \( \Gamma(K) \) were subsequently studied by several authors [2, 3, 6, 9, 28]. In particular, the isomorphism problem for such graphs has been considered in [6] and solved for finite reduced rings. For more results on these graphs we refer the reader to a survey paper [1].

To further reduce the size of the graph, Mulay [24] introduced the graph of equivalence classes of zero-divisors \( \Gamma_E(K) \), which was later called compressed zero-divisor graph by Anderson and LaGrange [7]. The vertex set of \( \Gamma_E(K) \) is the set of all equivalence classes of nonzero zero-divisors of \( K \), where two zero-divisors are equivalent if and only they have the same annihilator in \( K \). Two equivalence classes \([x]\) and \([y]\) are adjacent in \( \Gamma_E(K) \) if and only if \( xy = 0 \). Thus \( \Gamma_E(K) \) is obtained from \( \Gamma(K) \) by compressing the vertices of \( \Gamma(K) \) with the same neighbourhood in \( \Gamma(K) \) into one vertex. Compressed zero-divisor graphs were extensively studied in [7, 8, 16, 29].
The advantage of $\Gamma_E(K)$ is that it may be much smaller than $\Gamma(K)$. In particular, $\Gamma_E(K)$ can be a finite graph even if $K$ is an infinite ring and $\Gamma(K)$ an infinite graph. However, the disadvantage of this type of compression is that $\Gamma_E$ cannot be extended in a natural way to a functor from the category of commutative unital rings to the category of graphs. There are two reasons for this. Firstly, only zero-divisors are included in the definition of $\Gamma_E(K)$, however a homomorphic image of a zero-divisor can easily be invertible. And secondly, the graph is compressed too much, since the homomorphic image of two equivalent zero-divisors need not be equivalent in general. To overcome this shortcoming, a new type of compressed zero-divisor graph $\Theta(K)$ of a commutative unital ring was recently introduced by the authors in [18].

We recall the definition of $\Theta(K)$ for finite rings, the definition for infinite rings can be found in [18, Definition 6.1]. The vertex set of $\Theta(K)$ is the set of associatedness classes of all elements of $K$. Recall that two elements $a, b \in K$ are associated, denoted $a \sim b$, if $a = bu$ for some invertible element $u \in K$. Two associatedness classes $[a]_\sim$ and $[b]_\sim$ (not necessarily distinct) are adjacent in $\Theta(K)$ if and only if $ab = 0$. It was proved in [18] that this construction extends to a product preserving functor $\Theta$ from the category of finite commutative unital rings to the category of graphs, and that the compression by associatedness relation is the optimal for this purpose. The graph structure of $\Theta(K)$ was used to characterize important classes of finite commutative rings, namely, local rings and principal ideal rings.

There are also several other graphs constructions over commutative rings related to the zero-divisor graph that appear in the literature, see [11, 17, 26].

In 2002 Redmond [25] extended the concept of zero-divisor graphs to noncommutative rings. For a general unital ring $R$ he defined a simple directed graph $\Gamma(R)$ and a simple undirected graph $\overline{\Gamma}(R)$ as follows. The vertex set of both graphs is the set of all nonzero zero-divisors of $R$. In $\Gamma(R)$ there is a directed edge $x \to y$ if and only if $x \neq y$ and $xy = 0$, while in $\overline{\Gamma}(R)$ there is undirected edge $x - y$ if and only if $x \neq y$ and either $xy = 0$ or $yx = 0$. Properties of these graphs have been studied in [4, 5, 14, 23, 27]. Most attention has been devoted to matrix rings either over fields or over general commutative unital rings, but other ring such as group rings, polynomial rings etc. have been considered as well.

Recently, Ma, Wang and Zhou [23, Definition 2.5] extended the notion of compressed zero-divisor graph $\Gamma_E(K)$ to noncommutative rings. For a noncommutative ring $R$ graph $\Gamma_E(R)$ is a compression of $\Gamma(R)$ by an equivalence relation where two zero-divisors are equivalent if and only if they have the same left annihilator and the same right annihilator in $R$. They described the connection between the automorphism groups of $\Gamma_E(M)$ and $\Gamma(M)$ where $M$ is the ring of $2 \times 2$ matrices over a finite field.

In this paper we extend the notion of the compressed zero-divisor graph $\Theta(K)$ to noncommutative unital rings (see Definitions [25] for finite rings and Definition [6, 1] for infinite rings) in order to obtain a functor $\Theta$ from the category of finite unital rings to the category of directed graphs. All
the relevant definitions are contained in Section 2, where we also show that functor \( \Theta \) enjoys similar properties as in the commutative case, namely, it preserves finite products in both directions (see Propositions 2.8 and 2.9).

In Section 3 we discuss the properties of the compressed zero-divisor graph \( \Theta(M_n(F)) \) of the ring of \( n \times n \) matrices over a finite field \( F \). We show that it can be described in terms of pairs of vector subspaces of \( F^n \), which makes it easier to work with and allows us to bring projective geometry into play later on. We determine the number of vertices of \( \Theta(M_n(F)) \), the sizes of their neighbourhoods, the existence of Hamiltonian paths and cycles in \( \Theta(M_n(F)) \), the size of largest directed cliques, and the size of smallest dominating sets. In Section 4 we give a purely graph-theoretic characterization of graph \( \Theta(M_n(F)) \) for \( n \neq 3 \), with no reference to the ring structure whatsoever (see Theorem 4.2). To the best of our knowledge this is the first result of this kind for matrix rings.

In Section 5 we study two standard questions; (1) Does \( \Theta(R) \cong \Theta(S) \) imply \( R \cong S \)? and (2) Is any graph automorphism of \( \Theta(R) \) induced by a ring automorphism of \( R \)? We answer question (1) positively when \( S = M_n(F) \), a matrix ring over a finite field \( F \), with \( n \neq 1 \), and more generally when \( S \) is a semisimple finite ring with no homomorphic image isomorphic to a field (see Theorems 5.2 and 5.4). We also give a positive answer to question (2) when \( R = M_n(F) \) with \( n \neq 2 \) (see Theorem 5.1). Lastly, in Section 6 we discuss the definition of \( \Theta(R) \) for infinite rings.

2. Definition and categorial properties of \( \Theta(R) \)

Throughout the paper, \( F \) will denote a general finite field, and for a prime power \( q > 1 \), \( F_q \) will denote the unique finite field with \( q \) elements. Unless specified otherwise, all rings will be finite unital rings, except in the last section, where we discuss the definition of \( \Theta(R) \) for infinite rings. In this section we will extend some of the categorial results obtained in [18] to noncommutative rings. We first need an appropriate equivalence relation to compress the zero divisor graph \( \Gamma(R) \). We remark that our graphs will primarily be directed graphs.

Let \( \sim \) denote a relation on a finite unital ring \( R \), defined by \( a \sim b \) if and only if \( a = bu = vb \) for some units \( u \) and \( v \). Observe that on a commutative ring, the relation \( \sim \) is just the associatedness relation, so there should be no confusion if we use the same notation for the relation as was used in the commutative setting in [18]. We claim that relation \( \sim \) is an equivalence relation. Reflexivity is obvious. The relation is symmetric since the equality \( x = yu = vy \), where \( u \) and \( v \) are units, implies \( y = xu^{-1} = v^{-1}x \). If \( x \sim y \) and \( y \sim z \), then \( x = yu = vy \) and \( y = zs = tz \) for some units \( u, v, s, t \), hence \( x = z(su) = (vt)z \). This implies \( x \sim z \), so the relation is also transitive. The equivalence class of an element \( a \) with respect to \( \sim \) will be denoted simply by \( [a] \), while the equivalence class with respect to any other equivalence relation \( \approx \) will be denoted by \( [a]_\approx \).
The following proposition shows that, at least on matrix rings over fields, the relation ∼ is the best possible equivalence relation to compress the zero-divisor graph because it will compress the graph as much as possible in a way that edges will be well-defined by zero products.

**Proposition 2.1.** Let ∼ be an equivalence relation on the ring $R = M_n(F)$ such that for all $x, y, z, w \in R$, $x \approx y$ and $y \approx w$ and $xy = 0$ imply $zw = 0$. Then for any $a, b \in R$, $a \approx b$ implies $a \sim b$.

**Proof.** Let $a \approx b$. Since the ring $M_n(F)$ is unit-regular, element $a$ can be written as $a = es$, where $e^2 = e$ and $s$ is a unit. Then $1 - e \approx 1 - e$, $a \approx b$ and $(1 - e)a = 0$ imply $(1 - e)b = 0$, so $b = eb = as^{-1}b \in aR$. Since ∼ is symmetric, we also have $a \in bR$, hence $aR = bR$. This means that matrices $a$ and $b$ have the same image, so there is an invertible matrix $u$ such that $a = bu$. Similarly, there is an invertible matrix $v$, such that $a = vb$. \[\square\]

Next we show that if we want to obtain a functor, the relation ∼ is the best possible also on products of finite unital algebras over fields. This partially generalizes [18, Proposition 3.1]. Before we can state the result, we need the following auxiliary proposition. We denote by $\text{ann}_L a$ and $\text{ann}_R a$ the left and right annihilator of $a$ respectively.

**Proposition 2.2.** Let $R$ be a finite unital ring and $a, b \in R$. Then $aR = bR$ if and only if $a = bu$ for some invertible element $u \in R$.

**Proof.** The if part of the claim is obvious. To prove the only if part, assume that $aR = bR$. Choose $x, y \in R$ such that $a = bx$ and $b = ay$. Then $b(1 - xy) = 0$, so $1 - xy$ is an element of $\text{ann}_R b$, which is a right ideal of $R$. This implies that $1 \in xR + \text{ann}_R b$, hence $xR + \text{ann}_R b = R$. Every finite unital ring is (left) artinian and hence semilocal, so by Bass’ Theorem (see [22, Theorem 20.9]), the coset $x + \text{ann}_R b$ contains an invertible element of $R$, say $u = x + z$, where $z \in \text{ann}_R b$. Multiplying from the left by $b$ we obtain $bu = bx = a$. \[\square\]

In what follows, the category of finite unital rings and unital ring homomorphisms will be denoted by $\text{FinRing}$ and the category of directed graphs and graph homomorphisms will be denoted by $\text{Digraph}$.

**Proposition 2.3.** For every $R \in \text{obj} \text{FinRing}$ let $\approx_R$ be an equivalence relation on $R$, such that the family $\{\approx_R\}_{R \in \text{obj} \text{FinRing}}$ induces a well-defined functor $T : \text{FinRing} \rightarrow \text{Digraph}$ in the following way.

(i) For $R \in \text{obj} \text{FinRing}$, the vertices of $T(R)$ are equivalence classes of $\approx_R$, and there is an edge $[a]_{\approx_R} \rightarrow [b]_{\approx_R}$ if and only if $ab = 0$.

(ii) For $f \in \text{FinRing}(R, S)$, we have $T(f)([a]_{\approx_R}) = [f(a)]_{\approx_S}$.

If $A \in \text{obj} \text{FinRing}$ is a direct product of finite unital algebras over possibly different fields, then $a \approx_A b$ implies $a \sim b$. 

Proof. First, suppose $A$ is an algebra over a field $F$. Let $\text{End}_F(A)$ denote the algebra of all $F$-linear maps $A \to A$. Let $L : A \to \text{End}_F(A)$ be the left regular representation of $A$, i.e. $L(r) = L_r$, where $L_r$ denotes left multiplication by $r$. Suppose $a \approx_A b$. Then $L_a \approx_{\text{End}_F(A)} L_b$ by $(ii)$. Since $A$ is finite dimensional vector space over $F$, the algebra $\text{End}_F(A)$ is isomorphic to a matrix algebra. By $(i)$ the conditions of Proposition 2.3 are satisfied. Using $(ii)\text{[(ii)]}$ we thus conclude that $L_a \sim L_b$, i.e. $L_a = L_b \circ U = V \circ L_b$ for some invertible $U, V \in \text{End}_F(A)$. Applying these maps to $1 \in A$, we get $a = b \cdot U(1) = V(b)$. This implies $a \in bA$. Since $\approx_A$ is symmetric, we also have $b \in aA$. Therefore, $aA = bA$ and Proposition 2.2 implies $a = bu$ for some invertible element $u$. Similarly, using right regular representation $R : A \to \text{End}_F(A)^{\text{op}}$, where $\text{End}_F(A)^{\text{op}}$ denotes the opposite algebra of $\text{End}_F(A)$, we obtain $Aa = Ab$. By a left-hand sided version of Proposition 2.2 we get $a = vb$ for some invertible element $v$. This shows that $a \sim b$.

Now, suppose $A \cong \bigoplus_{i=1}^n A_i$, where each $A_i$ is an algebra over some field. Let $a = (a_i)_i$ and $b = (b_i)_i$ be elements of $A$, such that $a \approx_A b$. Applying $(ii)$ to canonical projection $A \to A_i$, we get $a_i \approx_{A_i} b_i$, hence $a_i \sim b_i$ by the first part of the proof. It is easy to see that this implies $a \sim b$. \hfill $\square$

Regarding Proposition 2.3 we pose the following open question.

**Question 2.4.** Does the conclusion of Proposition 2.3 hold for any finite unital ring $A$?

To answer Question 2.4 it would suffice to consider the endomorphism ring $\text{End}_\mathbb{Z}(H_p)$ of a finite abelian $p$-group $H_p$ (where $p$ is a prime), i.e. a group of the form

$$H_p = \mathbb{Z}/p^{k_1} \mathbb{Z} \times \mathbb{Z}/p^{k_2} \mathbb{Z} \times \ldots \times \mathbb{Z}/p^{k_m} \mathbb{Z}$$

for some positive integers $k_1 \geq k_2 \geq \ldots \geq k_m$. Indeed, if $A$ is an arbitrary finite unital ring, then by the classification of finite abelian groups, the additive group of $A$ is isomorphic to a direct product

$$H_{p_1} \times H_{p_2} \times \ldots \times H_{p_n},$$

where $p_1, p_2, \ldots, p_n$ are distinct prime numbers and each $H_{p_i}$ is a finite abelian $p_i$-group. Since $p_i$ are distinct, it follows that

$$\text{End}_\mathbb{Z}(A) \cong \text{End}_\mathbb{Z}(H_{p_1}) \times \text{End}_\mathbb{Z}(H_{p_2}) \times \ldots \times \text{End}_\mathbb{Z}(H_{p_n}).$$

If every $\text{End}_\mathbb{Z}(H_{p_i})$ satisfies the conclusion of Proposition 2.3 then so does their direct product $\text{End}_\mathbb{Z}(A)$ (see the end of the proof of Proposition 2.3). Hence, a similar argument as in the proof of Proposition 2.3 would show that $A$ also satisfies the conclusion of Proposition 2.3.

We remark that the structure of $\text{End}_\mathbb{Z}(H_p)$ and the invertible elements of $\text{End}_\mathbb{Z}(H_p)$ were described by Hillar and Rhea in [20].

Propositions 2.1 and 2.3 motivate us to define a compressed zero-divisor graph of finite unital rings in the following way.
**Definition 2.5.** For a finite unital ring $R$, $\Theta (R)$ is a directed graph whose vertices are equivalence classes $[a] = [a]_\sim$ of elements of $R$, where $a \sim b$ if and only if $a = bu = vb$ for some units $u$ and $v$, and there is a directed edge $[x] \rightarrow [y]$ in $\Theta (R)$ ($[x]$ and $[y]$ not necessarily distinct) if and only if $xy = 0$. We also define $\overline{\Theta} (R)$ to be an undirected graph whose vertices are equivalence classes $[a] = [a]_\sim$ of elements of $R$ and there is an edge joining $[x]$ and $[y]$ (not necessarily distinct) if and only if either $xy = 0$ or $yx = 0$.

Observe that edges in $\Theta (R)$ and $\overline{\Theta} (R)$ are well-defined because if $x_1 \sim y_1$, $x_2 \sim y_2$, and $x_1x_2 = 0$, then $y_1 = vx_1$ and $y_2 = x_2u$ for some units $u, v$, so $y_1y_2 = (vx_1)(x_2u) = v(x_1x_2)u = 0$. However, unlike in the commutative setting, the equivalence classes do not naturally form a monoid, because the operation $[x] \cdot [y] = [xy]$ is not well-defined in general.

**Remark 2.6.** Let $K$ be a commutative ring. If we ignore the directions of edges in the directed graph $\Theta (K)$ and then replace every double edge by a single edge, we obtain the undirected graph $\overline{\Theta} (K)$, which is actually equal to the undirected compressed zero-divisor graph of $K$ as defined in [18].

**Proposition 2.7.** The mapping $R \mapsto \Theta (R)$ extends to a functor $\Theta : \text{FinRing} \rightarrow \text{Digraph}$.

**Proof.** Let $f : R \rightarrow S$ be a unital ring homomorphism, where $R$ and $S$ are finite unital rings. Define $\Theta (f) : \Theta (R) \rightarrow \Theta (S)$ by $\Theta (f) ([x]) = [f(x)]$. Observe that $\Theta (f)$ is well-defined since $f$ preserves units, and it is easy to verify that $\Theta (f)$ is a graph homomorphism. Clearly, $\Theta (id_R) = id_{\Theta (R)}$ and $\Theta (g \circ f) = \Theta (g) \circ \Theta (f)$ for $f : R \rightarrow S$ and $g : S \rightarrow T$. So $\Theta : \text{FinRing} \rightarrow \text{Digraph}$ is a functor. \qed

Observe that both categories involved have all finite products. Binary product in the category $\text{FinRing}$ is the direct product of rings, while binary product in category $\text{Digraph}$ is the tensor product of graphs (see [19]). Recall that for graphs $G$ and $H$, their tensor product $G \times H$ is defined as follows. The set of vertices of $G \times H$ is the Cartesian product $V (G) \times V (H)$ and there is an edge $(g,h) \rightarrow (g',h')$ if and only if there are edges $g \rightarrow g'$ and $h \rightarrow h'$ in $G$ and $H$ respectively. Final object in the category $\text{FinRing}$ is the zero ring $0$ and final object in the category $\text{Digraph}$ is the graph with precisely one vertex and one directed loop.

**Proposition 2.8.** The functor $\Theta : \text{FinRing} \rightarrow \text{Digraph}$ preserves finite products.

**Proof.** It is sufficient to show that functor $\Theta$ preserves binary products and final object. Let $R,S \in \text{obj} \text{FinRing}$. Since operations in $R \times S$ are defined coordinate-wise, we have that $[(x,y)] = [(x',y')]$ in $R \times S$ if and only if both $[x] = [x']$ and $[y] = [y']$. This shows that $V (\Theta (R \times S)) = V (\Theta (R)) \times V (\Theta (S))$. There is an edge $[(x,y)] \rightarrow [(z,w)]$ in $\Theta (R \times S)$ if and only if there are edges $[x] \rightarrow [z]$ and $[y] \rightarrow [w]$ in $\Theta (R)$ and $\Theta (S)$ respectively.
Hence, \( \Theta (R \times S) \) is isomorphic to the tensor product of graphs \( \Theta (R) \) and \( \Theta (S) \), where the isomorphism is given by \( [(x, y)] \mapsto ([x], [y]) \). Clearly, \( \Theta (0) \), the graph of the zero ring, is the graph with precisely one vertex and one loop.

\[ \square \]

Given an edge \( a \to b \) in a directed graph \( G \), we will say that vertex \( a \) is a pre-neighbour of vertex \( b \), and vertex \( b \) a post-neighbour of vertex \( a \). For a given set \( X \subseteq V (G) \), let \( N^+ (X) \) denote the set of all common post-neighbours of all vertices in \( X \). Similarly, \( N^- (X) \) will denote the set of all common pre-neighbours of all vertices in \( X \). For convenience we will simply write \( N^+ (v) \) (respectively \( N^- (v) \)) instead of \( N^+ (\{v\}) \) (respectively \( N^- (\{v\}) \)), where \( v \in V (G) \). We remark that \( N^- (\{v\}) \) and \( N^+ (\{v\}) \) may or may not contain \( v \) depending on whether there is a loop on \( v \). Observe that in a graph \( G \) with no equally oriented multiple edges we have \( |N^+ (v)| = \deg^+ (v) \) and \( |N^- (v)| = \deg^- (v) \), where \( \deg^+ (v) \) and \( \deg^- (v) \) denote the outdegree and the indegree of \( v \) respectively. All graphs considered in this paper have this property.

Next proposition generalizes [LS Theorem 3.6]. The proof is essentially the same except that extra care is needed due to the lack of commutativity.

**Proposition 2.9.** Suppose \( K, L_1, L_2 \in \text{objFinRing} \) such that \( \Theta (K) \cong \Theta (L_1) \times \Theta (L_2) \). Then \( K = K_1 \times K_2 \) for some subrings \( K_1, K_2 \subseteq K \) with \( \Theta (K_1) \cong \Theta (L_1) \) and \( \Theta (K_2) \cong \Theta (L_2) \).

**Proof.** If \( \Theta (L_1) \cong \Theta (0) \), then \( \Theta (L_1) \times \Theta (L_2) \cong \Theta (L_2) \) so we may take \( K_1 = 0 \) and \( K_2 = K \). We argue similarly if \( \Theta (L_2) \cong \Theta (0) \). So assume \( \Theta (L_1) \not\cong \Theta (0) \) and \( \Theta (L_2) \not\cong \Theta (0) \).

Let \( f : \Theta (L_1) \times \Theta (L_2) \rightarrow \Theta (K) \) be any isomorphism. Choose \( k_1, k_2 \in K \) such that \( f ([1], [0]) = [k_1] \) and \( f ([0], [1]) = [k_2] \). Observe that \( N^+ ([1], [0]) = N^- ([1], [0]) \), hence \( N^+ ([k_1]) = N^- ([k_1]) \). This implies that \( \text{ann}_r (k_1) = \text{ann}_l (k_1) \). Similarly, \( \text{ann}_r (k_2) = \text{ann}_l (k_2) \). Define

\[
(1) \quad K_1 = \text{ann}_r (k_2) = \text{ann}_l (k_2) \quad \text{and} \quad K_2 = \text{ann}_r (k_1) = \text{ann}_l (k_1).
\]

Clearly, \( K_1 \) and \( K_2 \) are two-sided ideals of \( K \). If \( x \in K_1 \cap K_2 \), then

\[
[x] \in N^+ ([k_1]) \cap N^+ ([k_2]) = f (N^+ ([1], [0])) \cap N^+ ([0], [1])) =
\]

\[
= f ([0], [0]) = \{0\}.
\]

Thus, \( K_1 \cap K_2 = 0 \).

Observe that the subgraph of \( \Theta (L_1) \times \Theta (L_2) \), induced by \( N^+ ([0], [1]) \), is isomorphic to \( \Theta (L_1) \). Hence, the subgraph \( G_1 \) of \( \Theta (K) \), induced by \( N^+ ([k_2]) \), is also isomorphic to \( \Theta (L_1) \). By definition of \( K_1 \) we clearly have \( V (G_1) = \{x \in V (\Theta (K)) : x \in K_1\} \) and \( k_1 \in K_1 \). Since \( K_1 \) is an ideal, it thus follows that \( k_1^2 \in V (G_1) \). Observe that \( k_1^2 \neq [0] \), since \( k_1 \) has no loop due to the fact that \( L_1 \neq 0 \). Suppose \( k_1^2 \neq [k_1] \). Then \( [k_1^2] \in V (G_1) \setminus \{[0], [k_1]\} \). Since \( G_1 \cong \Theta (L_1) \), the neighbourhood \( N_{G_1}^+(V (G_1)) \) contains only one vertex, i.e. \( [0] \), and there is only one vertex in \( G_1 \) whose
only post-neighbour in $G_1$ is $[0]$, i.e. $f([1,0]) = [k_1]$. This implies that $[k_1^2]$ has a post-neighbour in $G_1$ different from $[0]$, say $[a]$, where $a \in K_1$. Hence, $k_1^2 a = 0$ because $G_1$ is an induced subgraph of $\Theta(K)$. This implies that $[k_1a]$ is a post-neighbour of $[k_1]$ in $\Theta(K)$, and since $K_1$ is an ideal, $[k_1a] \in V(G_1)$. Therefore, $k_1a = 0$ by the above. Similarly, this implies that $[a]$ is a post-neighbour of $[k_1]$, hence $a = 0$, a contradiction. We have thus shown that $[k_1^2] = [k_1]$. In particular, $k_1 = k_1^2 u_1$ for some unit $u_1 \in K$.

Observe that $k_1(1 - k_1 u_1) = 0$, hence $1 - k_1 u_1 \in K_2$ by (1). If $1 - k_1 u_1 = 0$, then $k_1$ is a unit in $K$, hence $[k_1] = [1]$. But this would imply that $[0]$ is the only post-neighbour of $[k_1]$ in $\Theta(K)$, which would further imply $K_2 = 0$. In this case, $\Theta(L_2) \cong \Theta(0)$, a contradiction. So $1 - k_1 u_1 \neq 0$.

Suppose $[1 - k_1 u_1] \neq [k_2]$. Let $G_2$ be the subgraph of $\Theta(K)$, induced by $N^+([k_1])$. Then the same argument as above shows that $[1 - k_1 u_1] \in V(G_2) \setminus \{[0],[k_2]\}$ has a post-neighbour in $G_2$ different from $[0]$, say $[b]$, where $0 \neq b \in K_2$. Hence,

\begin{equation}
(1 - k_1 u_1)b = 0
\end{equation}

because $G_2$ is an induced subgraph of $\Theta(K)$. Since $k_2 k_1 = 0$, we have $k_2 = k_2 (1 - k_1 u_1)$. Hence, $k_2 b = 0$ by (2). This implies $b \in K_1$, so $b \in K_1 \cap K_2 = 0$, a contradiction. Thus, $[1 - k_1 u_1] = [k_2]$, and consequently $1 = k_1 u_1 + k_2 u_2$ for some unit $u_2 \in K$. This shows that $K = K_1 + K_2$. Since we already know that $K_1 \cap K_2 = 0$, we conclude that $K = K_1 \times K_2$.

Observe that if $x \in K_1$ and $x \sim y$ in $K$, then $y \in K_1$ and $x \sim y$ in $K_1$. Hence, $\Theta(K_1) \cong G_1 \cong \Theta(L_1)$ and similarly $\Theta(K_2) \cong \Theta(L_2)$. \hfill \Box

It follows from Remark 2.6 and [18, Example 3.5] that functor $\Theta$ does not preserve limits.

3. Rings of Matrices over Finite Fields

We now investigate the graph of the matrix ring $M_n(F)$, where $F$ is a finite field. In particular, we determine the number of vertices, their degrees, existence of Hamiltonian paths and cycles, directed cliques of maximal size, and dominating sets of minimal size.

Below we first establish a bijective correspondence between the set of vertices of $\Theta(M_n(F))$ and the set of ordered pairs $(V,W)$ of subspaces of $F^n$ such that $\dim V + \dim W = n$. This correspondence is given by the map $[A] \mapsto (\text{im}A, \text{ker}A)$, where $\text{im}A$ and $\text{ker}A$ denote respectively the image and the kernel of the linear transformation $x \mapsto Ax$.

Assume $A \sim B$ in $M_n(F)$. Then $A = BP = QB$ for some invertible matrices $P$ and $Q$. The invertibility of $P$ clearly implies that $\text{im} A = \text{im} B$ and the invertibility of $Q$ implies that $\text{ker} A = \text{ker} B$. So for $[A] \in V(\Theta(M_n(F)))$, there is a well-defined ordered pair $(\text{im} A, \text{ker} A)$ of subspaces of $F^n$ whose dimensions add up to $n$.

Conversely, given a pair $(V,W)$ of subspaces of $F^n$ such that $\dim V + \dim W = n$, fix some bases of $V$ and $W$, say $B_V$ and $B_W$. Let $B$ be some
basis of $F^n$ that contains $B_W$. Let $A$ be a matrix that represents (in the standard basis) a linear transformation which maps $B \setminus B_W$ bijectively onto $B_V$ and maps $B_W$ to 0. Clearly, $(\text{im} A, \ker A) = (V, W)$. If $B$ is another matrix with $(\text{im} B, \ker B) = (V, W)$, then the equality $\text{im} A = \text{im} B$ implies $A = BP$ for some invertible matrix $P$ and the equality $\ker A = \ker B$ implies $A = QB$ for some invertible matrix $Q$. This establishes the aforementioned bijective correspondence.

We will use the above correspondence throughout the paper. Observe also that, by the this correspondence, there is an edge $(V_1, W_1) \rightarrow (V_2, W_2)$ if and only if $W_1 \supseteq V_2$.

Let $q > 1$ be a prime power. We will denote the number of $k$-dimensional subspaces of $F^n_q$ by $\binom{n}{k}_q$. This is usually called a $q$-binomial coefficient. In particular, $\binom{n}{k}_q = 0$ if $k > n$ or $k < 0$. For a detailed treatment of $q$-binomial coefficients we refer the reader to Stanley's book [30, §7.1], where, in particular, it is shown that the $q$-binomial coefficients satisfy the following equalities

\begin{align*}
(3) \quad & \binom{n}{k}_q = \frac{(q^n - 1)(q^n - q) \cdots (q^n - q^{k-1})}{(q^k - 1)(q^k - q) \cdots (q^k - q^{k-1})}, \\
(4) \quad & \binom{n}{k} = \binom{n}{n-k}_q, \\
(5) \quad & \binom{n}{k}_q = \binom{n-1}{k}_q + q^{n-k} \binom{n-1}{k-1}_q.
\end{align*}

We remark that Stanley’s book also gives a generating function for $\binom{n}{k}_q$.

We begin by counting the vertices in $\Theta(M_n(F_q))$ and determining their degrees.

**Proposition 3.1.** If $R = M_n(F_q)$, then

$$|V(\Theta(R))| = \sum_{i=0}^{n} \binom{n}{i}_q^2$$

and

$$\deg^+((V, W)) = \deg^-((V, W)) = \sum_{i=0}^{\dim W} \binom{\dim W}{i}_q \binom{n}{i}_q.$$

**Proof.** The number of pairs $(V, W)$ of subspaces of $F^n_q$, where $\dim V + \dim W = n$ and $\dim V = i$ equals $\binom{n}{i}_q \binom{n-i}{i}_q = \binom{n}{i}_q^2$. Summing over all $i$ gives the formula for the number of vertices.

A vertex $(V', W')$ is a post-neighbour of $(V, W)$ if and only if $V' \subseteq W$. There are $\binom{\dim W}{i}_q$ subspaces of $W$ with dimension equal to $i$ and for each such subspace $X$ there are $\binom{n}{n-i}_q = \binom{n}{i}_q$ vertices of the form $(X, \ast)$. Hence,
(V, W) has \( \binom{\dim W}{i} q^i \) post-neighbours \( (V', W') \) with \( \dim V' = i \). Summing over all \( 0 \leq i \leq \dim W \) gives
\[
\deg^+ ((V, W)) = \sum_{i=0}^{\dim W} \binom{\dim W}{i} q^i .
\]

A vertex \( (V', W') \) is a pre-neighbour of \( (V, W) \) if and only if \( W' \supseteq V \). The number of spaces of \( F_q^n \) with dimension \( j \) that contain \( V \), is equal to the number of subspaces of \( F_q^n / V \cong F_q^{n-\dim V} \) with dimension \( j - \dim V \), and this equals \( \binom{n-\dim V}{j-\dim V} q \). For each subspace \( Y \) of the former kind there are \( \binom{n}{n-j} q \) vertices of the form \((*, Y)\). Hence, \( (V, W) \) has \( \binom{n-\dim V}{n-j} q \) pre-neighbours \( (V', W') \) with \( \dim W' = j \). Summing over all \( \dim V \leq j \leq n \) gives
\[
\deg^- ((V, W)) = \sum_{j=\dim V}^{n} \binom{n-\dim V}{n-j} q \left( \binom{n}{n-j} q \right) .
\]
If we substitute \( j = n - i \) into this sum we obtain
\[
\deg^- ((V, W)) = \sum_{i=0}^{n-\dim V} \binom{n-\dim V}{i} q \left( \binom{n}{i} q \right) = \sum_{i=0}^{\dim W} \binom{\dim W}{i} q \left( \binom{n}{i} q \right) .
\]

This already enables us to show that non-isomorphic matrix rings have non-isomorphic graphs.

**Proposition 3.2.** If \( \Theta(M_n(F)) \cong \Theta(M_m(E)) \), where \( n > 1 \) and \( F \) and \( E \) are finite fields, then \( n = m \) and \( F \cong E \).

**Proof.** Let \( G = \Theta(M_n(F)) \) and \( F \cong F_q, E \cong F_{q'} \). Observe that, by Proposition 3.1, \( \deg^+ ((V, W)) \) only depends on \( \dim W \), and as a function of \( \dim W \) it is strictly increasing. Hence, the number of different outdegrees in \( G \) is equal to the number of different dimensions of subspaces of \( F^n_q \) which is \( n + 1 \). This implies \( n = m \). In addition, the least outdegree in \( G \) different from 1 is equal to
\[
d = \sum_{i=0}^{1} \binom{1}{i} q^{i} = 1 + \binom{n}{1} q = 1 + q^n - 1 q - 1 =
q^n - q + q - 1 + q^n - 2 q + 2 + \cdots + q + 2.
\]
Every term \( q^i, i \geq 1 \), is an increasing function of \( q \in \mathbb{N} \). Given that \( n > 1 \), this implies that \( d \) is an increasing function of \( q \), so it is injective. Since \( n = m \), this implies \( q = q' \), hence \( F \cong E \).

In the next few results we discuss Hamiltonian cycles and paths in graph \( \Theta(M_q(F)) \). Recall that a cycle in a directed graph is called simple if no vertex in this cycle is repeated. A cycle of length 1 is a vertex with a loop.
Lemma 3.3. Let $V$ be a nontrivial proper subspace of $F^n$ and $\mathcal{S}$ a set of subspaces of $F^n$, such that $V \notin \mathcal{S}$. Then, there is a simple (possibly empty) cycle in $\Theta(M_n(F)) \setminus \{[0], [1]\}$ that contains all the vertices of the form $(V, W)$ or $(W, V)$ where $W \notin \mathcal{S}$, and every edge in this cycle is of the form $(X_1, X_2) \rightarrow (X_2, X_3)$.

Proof. Let $\mathcal{W} = \{W : W \text{ is subspace of } F^n, \dim W + \dim V = n, W \notin \mathcal{S}\}$. Since $\mathcal{W}$ is a finite set, we can enumerate all of its elements, say $\mathcal{W} = \{W_1, W_2, \ldots, W_k\}$. Then the cycle

$$(V, W_1) \rightarrow (W_1, V) \rightarrow (V, W_2) \rightarrow (W_2, V) \rightarrow \cdots$$

$$(\cdots \rightarrow (V, W_k) \rightarrow (W_k, V) \rightarrow (V, W_1))$$

has all the desired properties except that it might not be simple. Observe that it is simple unless $n$ is even and $\dim V = \frac{n}{2}$, in which case $V$ is an element of $\mathcal{W}$, say $V = W_1$. In this case, we replace $(V, W_1) \rightarrow (W_1, V) \rightarrow (V, W_2)$ by $(V, V) \rightarrow (V, W_2)$ to make the cycle simple. \qed

In what follows, we denote $S_{k,m} = \{(V, W) : V, W \text{ are subspaces of } F^n, \dim V = k, \dim W = m\}$.

Lemma 3.4. Let $n = k + m$ be a partition of $n$, where $k, m \neq 0$. Then there is a simple cycle in $\Theta(M_n(F)) \setminus \{[0], [1]\}$ that contains all the vertices in $S_{k,m} \cup S_{m,k}$, and every edge in this cycle is of the form $(X_1, X_2) \rightarrow (X_2, X_3)$.

Proof. Let $\mathcal{V} = \{V_1, V_2, \ldots, V_s\}$ be the set of all subspaces of $F^n$ whose dimension is $k$.

Suppose that $k \neq m$. By Lemma 3.3 for every $i \in \{1, 2, \ldots, s\}$ there is a simple cycle $C_i$ in $\Theta(M_n(F)) \setminus \{[0], [1]\}$ containing all the vertices of the form $(V_i, W)$ or $(W, V_i)$, where $W$ is an arbitrary subspace of dimension $m$. Fix a subspace $X$ whose dimension is $m$. Then $X \neq V_i$ since $m \neq k$, so there is an edge in $C_i$ of the form $(V_i, X) \rightarrow (X, V_i)$. Remove this edge from $C_i$ to obtain a simple path. We denote this path by $(X, V_i) \rightarrow P_i \rightarrow (V_i, X)$. Observe that these paths for different $i$ are disjoint since $k \neq m$, and their union contains all the vertices in $S_{k,m} \cup S_{m,k}$. In this case, the cycle

$$(X, V_1) \rightarrow P_1 \rightarrow (V_1, X) \rightarrow (X, V_2) \rightarrow P_2 \rightarrow (V_2, X) \rightarrow \cdots$$

$$(\cdots \rightarrow (X, V_s) \rightarrow P_s \rightarrow (V_s, X) \rightarrow (X, V_1))$$

has the desired property.

Now suppose $k = m$. For every $i \in \{1, 2, \ldots, s\}$, by Lemma 3.3 (with $\mathcal{S} = \{V_1, V_2, \ldots, V_{i-1}\}$), there is a simple cycle $D_i$ in $\Theta(M_n(F)) \setminus \{[0], [1]\}$ that contains all the vertices of the form $(V_i, W)$ or $(W, V_i)$, where $W \notin \{V_1, V_2, \ldots, V_{i-1}\}$. The cycle $D_i$ contains the edge $(V_i, V_s) \rightarrow (V_s, V_i)$. Remove this edge from $D_i$ to obtain a simple path and denote this path by $(V_i, V_s) \rightarrow R_i \rightarrow (V_i, V_s)$ (when $i = s$, this path is just one vertex $(V_s, V_s)$). Observe that these paths for different $i$ are disjoint and their union contains
all the vertices in $S_{k,k}$. In this case, the cycle
\[(V_s, V_1) \rightarrow R_1 \rightarrow (V_1, V_s) \rightarrow (V_s, V_2) \rightarrow R_2 \rightarrow (V_2, V_s) \rightarrow \cdots \]
\[\cdots \rightarrow (V_s, V_{s-1}) \rightarrow R_{s-1} \rightarrow (V_{s-1}, V_s) \rightarrow (V_s, V_s) \rightarrow (V_s, V_1)\]
has the desired property.

We are now ready to describe Hamiltonian paths and cycles in the zero-
divisor graph of a matrix ring.

**Theorem 3.5.** Let $F$ be a finite field.

(i) If $n \in \{2, 3\}$ then $\Theta(M_n(F)) \setminus \{[0], [1]\}$ contains a Hamiltonian cycle.

(ii) If $n \geq 4$ then $\Theta(M_n(F)) \setminus \{[0], [1]\}$ contains a Hamiltonian path but $\overline{\Theta}(M_n(F)) \setminus \{[0], [1]\}$ does not contain a Hamiltonian cycle.

**Proof.** If $(V, W)$ is a vertex in $\Theta(M_n(F)) \setminus \{[0], [1]\}$, then $n = \dim V + \dim W$ is a partition of $n$ with nonzero parts. There is only one partition of 2 with nonzero parts, namely $2 = 1 + 1$, and only one partition of 3 with nonzero parts, namely $3 = 1 + 2$. Hence, (i) follows directly from Lemma 3.4.

Let $n \geq 4$ and denote $G = \Theta(M_n(F)) \setminus \{[0], [1]\}$ and $\overline{G} = \overline{\Theta}(M_n(F)) \setminus \{[0], [1]\}$. Observe that in $\overline{G} \setminus S_{1,n-1}$ there is no edge incident with any vertex in $S_{n-1,1}$. Hence, every element of $S_{n-1,1}$ is an isolated vertex of $\overline{G} \setminus S_{1,n-1}$ and since $n \geq 4$ there is at least one vertex in $\overline{G} \setminus (S_{1,n-1} \cup S_{n-1,1})$. Hence, there are at least $|S_{n-1,1}| + 1 = |S_{1,n-1}| + 1$ connected components in $\overline{G} \setminus S_{1,n-1}$, therefore $\overline{G}$ does not contain a Hamiltonian cycle by [13, Theorem 4.2]).

By Lemma 3.4 there is a simple cycle $E_k$ in $G$ containing all vertices in $S_{k,m} \cup S_{m,k}$, where $k + m = n$. Observe that cycles $E_1, E_2, \ldots, E_{\frac{n}{2}}$ are disjoint and their union contains all the vertices of $G$. Choose a chain of subspaces $Y_1 \subseteq Y_2 \subseteq \cdots \subseteq Y_{\frac{n}{2}}$, where $\dim Y_k = k$. Then there is an edge in $E_k$ of the form $(X_k, Y_k) \rightarrow (Y_k, Z_k)$ for some $X_k, Z_k$. Remove this edge from $E_k$ to obtain a path, which we denote by $(Y_k, Z_k) \rightarrow Q_k \rightarrow (X_k, Y_k)$. Then the path
\[
(Y_{\frac{n}{2}}, Z_{\frac{n}{2}}) \rightarrow Q_{\frac{n}{2}} \rightarrow (X_{\frac{n}{2}}, Y_{\frac{n}{2}}) \rightarrow \cdots \rightarrow (Y_2, Z_2) \rightarrow Q_2 \rightarrow (X_2, Y_2) \rightarrow (Y_1, Z_1) \rightarrow Q_1 \rightarrow (X_1, Y_1)
\]
is a Hamiltonian path in $G$. □

Next we determine the size of the largest directed clique in $\Theta(M_n(F))$. By a directed clique, we mean a subgraph in which for any two (not necessarily distinct) vertices $u$ and $v$, there is a directed edge from $u$ to $v$. For a
subspace $U \subseteq F^n$, let
\[ K(U) = \{ (V, W) \in V(\Theta(M_n(F))) : V \subseteq U \subseteq W \}. \]

It is easily checked that $K(U)$ is a directed clique in $\Theta(M_n(F))$.

**Lemma 3.6.** Every directed clique in $\Theta(M_n(F))$ is contained in $K(U)$ for some subspace $U \subseteq F^n$.

**Proof.** Let $K = \{ (V_i, W_i) : 1 \leq i \leq k \}$ be any directed clique in $\Theta(M_n(F))$. Take $U = \bigcap_{i=1}^k W_i$. Since $K$ is a directed clique, we have $V_j \subseteq W_i$ for all $i, j \in \{1, 2, \ldots, k\}$. This implies $V_j \subseteq U \subseteq W_j$ for every $j \in \{1, 2, \ldots, k\}$. We conclude that $K \subseteq K(U)$. \hfill $\square$

**Proposition 3.7.** The size of the largest directed clique in $\Theta(M_n(F_q))$ is
\[ \sum_{i=0}^{\lfloor \frac{n}{2} \rfloor} \binom{\lfloor \frac{n}{q} \rfloor}{i} \binom{\lfloor \frac{n}{q} \rfloor}{i} \]
and any directed clique of this size is of the form $K(U)$, where $\dim U$ is equal to $\lfloor \frac{n}{2} \rfloor$ or $\lfloor \frac{n}{q} \rfloor$.

**Proof.** By Lemma 3.6 it suffices to determine the maximum of $|K(U)|$, where $U$ is a subspace of $F_q^n$. Let $u = \dim U$. Subspaces containing $U$ are in a bijective correspondence with the subspaces of $F_q^n/U$, hence
\[ |K(U)| = \sum_{i=0}^{\min\{u, n-u\}} \binom{u}{i} \binom{n-u}{i}. \]

Due to the symmetry in the formula for $|K(U)|$ we may assume $u \leq \lfloor \frac{n}{2} \rfloor$. In this case $\min\{u, n-u\} = u \leq \lfloor \frac{n}{2} \rfloor$. Since $q$-binomial coefficients are nonnegative, it thus suffices to show that
\[ \binom{u}{i} \binom{n-u}{i} \leq \binom{\lfloor \frac{n}{q} \rfloor}{i} \binom{\lfloor \frac{n}{q} \rfloor}{i} \]
for all $i \in \{0, 1, \ldots, u\}$. Writing out $q$-binomial coefficients as in (3) and multiplying the inequality by $\prod_{r=0}^{i-1} (q^r - q^r)^2$, we get
\[ \prod_{r=0}^{i-1} (q^u - q^r) (q^{n-u} - q^r) \leq \prod_{r=0}^{i-1} \left( q^{\lfloor \frac{n}{q} \rfloor} - q^r \right) \left( q^{n-\lfloor \frac{n}{q} \rfloor} - q^r \right). \]

So it suffices to show that
\[ (q^u - q^r) (q^{n-u} - q^r) \leq \left( q^{\lfloor \frac{n}{q} \rfloor} - q^r \right) \left( q^{n-\lfloor \frac{n}{q} \rfloor} - q^r \right) \]
for all $r \in \{0, 1, \ldots, u-1\}$. Multiplying out both sides of the last inequality and simplifying, we get
\[ q^{n-u+r} + q^{u+r} \geq q^{n-\lfloor \frac{n}{q} \rfloor+r} + q^{\lfloor \frac{n}{q} \rfloor+r}. \]
We thus need to determine the minimum on the set of integers of the function $f: \mathbb{R} \to \mathbb{R}$ defined by $f(x) = q^{n-x+r} + q^{x+r}$. Observe that $f'(x) = (q^{x+r} - q^{n-x+r}) \ln q$. From this, it is easy to see that $f$ has a local minimum at $x = \frac{n}{2}$. In addition, $f'(x) < 0$ for $x < \frac{n}{2}$ and $f'(x) > 0$ for $x > \frac{n}{2}$. Hence, if we restrict the domain of $f$ to integers, then its global minimum is equal to $f\left(\floor{\frac{n}{2}}\right) = f\left(\ceil{\frac{n}{2}}\right)$ as required. □

The following question remains open.

**Question 3.8.** What is the size of the largest clique in $\overline{\Theta}(M_n(F_q))$?

Recall that a dominating set in an undirected graph $G$ is a subset $D \subseteq V(G)$ such that every vertex of $G$ is either in $D$ or is adjacent to at least one vertex in $D$. The least possible size of a dominating set is called the domination number of $G$. In next two propositions we determine the domination number of graph $\overline{\Theta}(M_n(F_q))$ as well as what could be called the “directed domination number” of $\Theta(M_n(F_q))$.

**Proposition 3.9.** Let $n \geq 3$ and $R = M_n(F_q)$. There is a subset $D \subseteq V(\Theta(R))$ with $(\binom{n}{1})_q$ elements such that:

(i) $D$ is a dominating set for $\overline{\Theta}(R) \setminus \{[0], [1]\}$ of the least possible size,

(ii) for every vertex $v \in V(\Theta(R)) \setminus D$ there is an edge in $\Theta(R)$ with source $v$ and target in $D$,

(iii) for every vertex $v \in V(\Theta(R)) \setminus D$ there is an edge in $\Theta(R)$ with target $v$ and source in $D$.

**Proof.** Let $\mathcal{Y} = \{V_1, V_2, \ldots, V_k\}$ be the set of all 1-dimensional subspaces of $F_q^n$ and let $\mathcal{W} = \{W_1, W_2, \ldots, W_k\}$ be the set of all $(n-1)$-dimensional subspaces of $F_q^n$. These sets indeed have the same size $k = \binom{n}{1}_q$.

Let $D$ be any dominating set for $\overline{\Theta}(R) \setminus \{[0], [1]\}$. We will say that a subspace $X \subseteq F_q^n$ is an image in $D$ (respectively a kernel in $D$) if $(X, Y) \in D$ (respectively $(Y, X) \in D$) for some subspace $Y \subseteq F_q^n$.

Fix some $i \in \{1, 2, \ldots, k\}$. Suppose first that for some $i \in \{1, 2, \ldots, k\}$, $W_i$ is not a kernel in $D$. We claim that, in this case, for every $j \in \{1, 2, \ldots, k\}$, $V_j$ is either an image or a kernel in $D$. To see this, suppose $W_i$ is not a kernel in $D$. If $(W_i, V_j) \in D$ then $V_j$ is a kernel in $D$, otherwise $(W_i, V_j)$ is adjacent to some vertex $(X, Y) \in D$. There is no edge $(X, Y) \to (W_i, V_j)$ since this would imply $W_i \subseteq Y$ and hence $W_i = Y$ due to dimension of $W_i$ being $n-1$. This would contradict the assumption that $W_i$ is not a kernel in $D$. Hence, there is an edge $(W_i, V_j) \to (X, Y)$ which implies $X \subseteq V_j$ and thus $X = V_j$ due to the dimension of $V_j$ being 1. This means that $V_j$ is an image in $D$, which proves our claim. We conclude that in this case $|D| \geq k = \binom{n}{1}_q'$ because vertices $(W_s, V_t), (V_t, W_s)$ for $s, t \in \{1, 2, \ldots, k\}$ are all distinct due to our assumption $n \geq 3$. On the other hand, if $W_i$ is a kernel in $D$ for all $i \in \{1, 2, \ldots, k\}$, then clearly $|D| \geq k = \binom{n}{1}_q$.

To finish the proof, we construct a set $D$ with $(\binom{n}{1})_q$ vertices that satisfies (ii) and (iii), and hence also (i). Let $D = \{(V_i, W_i) : i \in \{1, 2, \ldots, k\}\}$. If
Let $V = \{V_i : i \in \{1, 2, \ldots, k\}\}$ be the set of all 1-dimensional subspaces of $F^n_q$. Since $n = 2$, every vertex in $\Theta (R) \setminus \{[0], [1]\}$ is of the form $(V_i, V_j)$ for some $i, j \in \{1, 2, \ldots, k\}$.

Let $D'$ be any subset satisfying condition (iii). Using terminology from the proof of Proposition 3.9, if for some $i \in \{1, 2, \ldots, k\}$, $V_i$ is not a kernel in $D'$ then for every $j \in \{1, 2, \ldots, k\}$ there is no edge from $D'$ to $(V_i, V_j)$. Hence, $(V_i, V_j) \in D'$ by assumption. In this case, $|D'| \geq \binom{n}{1}_q$. On the other hand, if $V_i$ is a kernel in $D'$ for all $i \in \{1, 2, \ldots, k\}$, then $|D'| \geq \binom{n}{1}_q$ as well. This establishes the bound for the size of the set in (iii). Similar argument works for (ii).

Let $D$ be any dominating set in $\Theta (R) \setminus \{[0], [1]\}$. If $V_i$ is a kernel in $D$ for all $i \in \{1, 2, \ldots, k\}$ then $|D| \geq \binom{n}{1}_q$. So suppose $V_i$ is not a kernel in $D$ for some $i$. As in the proof of Proposition 3.9, for every $j \neq i$, either $(V_i, V_j) \in D$ or $(V_j, V_i) \in D$ for some $l \in \{1, 2, \ldots, k\}$. Since the sets \{$(V_i, V_j), (V_j, V_i)$\}, $j \in \{1, 2, \ldots, k\} \setminus \{i\}$, are disjoint, we conclude that $|D| \geq k - 1 \geq \binom{n}{1}_q - 1$.

Now, we construct $D$ and $d$ that satisfy all the conditions. Observe that $k = \binom{n}{1}_q \geq 3$. Hence, we can take $D = \{(V_1, V_2)\} \cup \{(V_i, V_i) : i \in \{3, 4, \ldots, k\}\}$ and $d = (V_2, V_1)$. Only $V_1$ is not a kernel in $D$ and only $V_2$ is not an image in $D$. Hence, $(V_1, V_2)$ is the only vertex not adjacent (in any direction) to any vertex in $D$. But $(V_1, V_2) \in D$, so $D$ is a dominating set. Every element of $\mathcal{V}$ is a kernel as well as an image in $D' = D \cup \{d\}$, hence $D'$ satisfies (ii) and (iii).

4. Graph-theoretic characterization of $\Theta (M_n (F_q))$

Motivated by [18, Propositions 4.1 and 4.2], the aim of this section is to give a purely graph-theoretic characterization of the graph $\Theta (M_n (F_q))$.

For a set $X \subseteq V(G)$, where $G$ is a directed graph, define $\text{cl}_t (X) = N^+(N^- (X))$ and $\text{cl}_s (X) = N^- (N^+(X))$. 

(X,Y) is a vertex distinct from [0] and [1], then X is a proper subspace of $F^n_q$ and Y is a nonzero subspace of $F^n_q$. Hence, $X \subseteq W_i$ for some $i$ and $V_j \subseteq Y$ for some $j$, so we have a path $(V_i, W_i) \rightarrow (X, Y) \rightarrow (V_j, W_j)$. □

**Proposition 3.10.** Let $n = 2$ and $R = M_n (F_q)$. There is a subset $D \subseteq V (\Theta (R))$, with $\binom{n}{1}_q - 1$ elements and a vertex $d \in V (\Theta (R)) \setminus D$ such that:

(i) $D$ is a dominating set for $\overline{\Theta} (R) \setminus \{[0], [1]\}$ of the least possible size,

(ii) $D' = D \cup \{d\}$ is a subset of $V (\Theta (R))$ of the least possible size such that for every vertex $v \in V (\Theta (R)) \setminus D'$ there is an edge in $\Theta (R)$ with source $v$ and target in $D'$,

(iii) $D' = D \cup \{d\}$ is a subset of $V (\Theta (R))$ of the least possible size such that for every vertex $v \in V (\Theta (R)) \setminus D'$ there is an edge in $\Theta (R)$ with target $v$ and source in $D'$.

Proof. Let $\mathcal{V} = \{V_1, V_2, \ldots, V_k\}, k = \binom{n}{1}_q$ be the set of all 1-dimensional subspaces of $F^n_q$. Since $n = 2$, every vertex in $\Theta (R) \setminus \{[0], [1]\}$ is of the form $(V_i, V_j)$ for some $i, j \in \{1, 2, \ldots, k\}$.

Let $D'$ be any subset satisfying condition (iii). Using terminology from the proof of Proposition 3.9, if for some $i \in \{1, 2, \ldots, k\}$, $V_i$ is not a kernel in $D'$ then for every $j \in \{1, 2, \ldots, k\}$ there is no edge from $D'$ to $(V_i, V_j)$. Hence, $(V_i, V_j) \in D'$ by assumption. In this case, $|D'| \geq \binom{n}{1}_q$. On the other hand, if $V_i$ is a kernel in $D'$ for all $i \in \{1, 2, \ldots, k\}$, then $|D'| \geq \binom{n}{1}_q$ as well. This establishes the bound for the size of the set in (iii). Similar argument works for (ii).

Let $D$ be any dominating set for $\overline{\Theta} (R) \setminus \{[0], [1]\}$. If $V_i$ is a kernel in $D$ for all $i \in \{1, 2, \ldots, k\}$ then $|D| \geq \binom{n}{1}_q$. So suppose $V_i$ is not a kernel in $D$ for some $i$. As in the proof of Proposition 3.9, for every $j \neq i$, either $(V_i, V_j) \in D$ or $(V_j, V_i) \in D$ for some $l_j \in \{1, 2, \ldots, k\}$. Since the sets \{$(V_i, V_j), (V_j, V_i)$\}, $j \in \{1, 2, \ldots, k\} \setminus \{i\}$, are disjoint, we conclude that $|D| \geq k - 1 \geq \binom{n}{1}_q - 1$.

Now, we construct $D$ and $d$ that satisfy all the conditions. Observe that $k = \binom{n}{1}_q \geq 3$. Hence, we can take $D = \{(V_1, V_2)\} \cup \{(V_i, V_i) : i \in \{3, 4, \ldots, k\}\}$ and $d = (V_2, V_1)$. Only $V_1$ is not a kernel in $D$ and only $V_2$ is not an image in $D$. Hence, $(V_1, V_2)$ is the only vertex not adjacent (in any direction) to any vertex in $D$. But $(V_1, V_2) \in D$, so $D$ is a dominating set. Every element of $\mathcal{V}$ is a kernel as well as an image in $D' = D \cup \{d\}$, hence $D'$ satisfies (ii) and (iii). □
Lemma 4.1. For a given directed graph \( G \), \( \text{cl}_t \) (respectively \( \text{cl}_s \)) is a closure operator on \( V(G) \), i.e. it satisfies the following properties for all subsets \( X, Y \subseteq V(G) \):

(i) \( X \subseteq \text{cl}_t(X) \),
(ii) \( X \subseteq Y \) implies \( \text{cl}_t(X) \subseteq \text{cl}_t(Y) \),
(iii) \( \text{cl}_t(\text{cl}_t(X)) = \text{cl}_t(X) \).

We will call \( \text{cl}_t(X) \) the target closure of \( X \) and \( \text{cl}_s(X) \) the source closure of \( X \).

Proof. \([i]\) The inclusion \( X \subseteq \text{cl}_t(X) \) follows directly from the definition of closure.

\([ii]\) \( X \subseteq Y \) implies \( N^-(X) \supseteq N^-(Y) \) which further implies \( N^+(N^-(X)) \subseteq N^+(N^-(Y)) \).

\([iii]\) By property \([i]\), we have \( X \subseteq \text{cl}_t(X) \) and consequently \( N^-(X) \supseteq N^-(\text{cl}_t(X)) \). By definition of \( \text{cl}_t(X) \), every vertex in \( N^-(X) \) is a common pre-neighbour of all vertices in \( \text{cl}_t(X) \). Hence, \( N^-(X) \subseteq N^-(\text{cl}_t(X)) \). We conclude that \( N^-(X) = N^-(\text{cl}_t(X)) \) which implies \( N^+(N^-(X)) = N^+(N^-(\text{cl}_t(X))) \). \( \square \)

We will use these properties of closure operators without further reference. A set \( X \) will be called target-closed (respectively source-closed) if \( \text{cl}_t(X) = X \) (respectively \( \text{cl}_s(X) = X \)). Observe that an arbitrary intersection of target-closed sets is again a target-closed set. Indeed, for two target-closed sets \( A \) and \( B \), properties \([ii]\) and \([iii]\) in Lemma 4.1 imply \( \text{cl}_t(A \cap B) \subseteq \text{cl}_t(A) = A \) and similarly for \( B \). Hence, \( \text{cl}_t(A \cap B) \subseteq A \cap B \) which implies that \( \text{cl}_t(A \cap B) = A \cap B \) by property \([i]\). The proof for arbitrary intersections is similar.

Given a directed graph \( G \), let \( d_0 > d_1 > d_2 > \cdots > d_n \) be all the possible outdegrees of vertices of \( G \). We will denote by \( V_k(G) \) the set of all vertices of \( G \) whose outdegree equals \( d_k \). Clearly, the sets \( V_k(G) \) form a partition of \( V(G) \). For \( x \in V_k(G) \), we will say that the type of vertex \( x \), denoted by \( T(x) \), is equal to \( k \).

In the next theorem we give a purely graph-theoretic characterization of the graph \( \Theta(M_n(F_q)) \). In the proof we will need the notion of projective spaces over finite fields. We denote the \((n-1)\)-dimensional projective space over \( F_q \) by \( PG(n-1, q) \). The points of \( PG(n-1, q) \) are 1-dimensional vector subspaces of \( F_q^n \). A subspace of \( PG(n-1, q) \) is the set of points whose union is a vector subspace of \( F_q^n \). For further information on \( PG(n-1, q) \) we refer the reader to Hirschfeld \([21]\) and Casse \([15]\).

Theorem 4.2. Let \( n \neq 3 \) be a positive integer and \( q > 1 \) a prime power. Up to a graph isomorphism, there is a unique directed graph \( G \) with no multiple edges that satisfies the following five properties:

(i) \( V(G) = \bigcup_{k=0}^n V_k(G) \), i.e. the number of different outdegrees in \( G \) is \( n + 1 \).
Similarly, define there exists $z \in y$ for all $j, k \in \{0, 1, \ldots, n\}$.

(iii) $|N^+(x) \cap V_j(G)| = |N^-(x) \cap V_j(G)| = \binom{n}{j} \binom{n-k}{j} \forall x \in V_k(G)$ and all $j, k \in \{0, 1, \ldots, n\}$.

(iv) Every target-closed set is a target closure of a single vertex. Every source-closed set is a source closure of a single vertex.

(v) $|cl_t(x) \cap cl_s(y) \cap V_k(G)| = 1$ for all $x, y \in V_k(G)$ and all $k \in \{0, 1, \ldots, n\}$.

The graph $G$ is isomorphic to $\Theta(M_n(F_q))$.

We remark that property (iii) implies $\text{deg}^+(x) = \text{deg}^-(x)$ for every $x \in V(G)$, so the conditions (i)–(v) are symmetric with respect to indegree and outdegree.

Proof. We divide the proof into several steps.

Step 1. For all $x, y \in V_k(G)$, $cl_t(x) \cap cl_t(y) \cap V_k(G) \neq \emptyset$ implies $cl_t(x) = cl_t(y)$, and $cl_s(x) \cap cl_s(y) \cap V_k(G) \neq \emptyset$ implies $cl_s(x) = cl_s(y)$.

Suppose $z \in cl_t(x) \cap cl_t(y) \cap V_k(G)$. Then, by definition of $cl_t$, $N^-(z) \supseteq N^-(x) \cup N^-(y)$. This gives us

$$N^-(z) \cap V_j(G) \supseteq (N^-(x) \cap V_j(G)) \cup (N^-(y) \cap V_j(G))$$

for all $j \in \{0, 1, \ldots, n\}$. Property (iii) implies that $|N^-(z) \cap V_j(G)| = |N^-(x) \cap V_j(G)| = |N^-(y) \cap V_j(G)|$. Hence, $N^-(z) \cap V_j(G) = N^-(x) \cap V_j(G) = N^-(y) \cap V_j(G)$. Since this holds for all $j$, we have $N^-(x) = N^-(y)$ and consequently $cl_t(x) = cl_t(y)$.

Step 2. $T(y) \leq T(x)$ for all $y \in cl_t(x)$.

By property (iii), $|N^-(z) \cap V_{n-T(x)}(G)| = \binom{n}{n-T(x)} \binom{n-T(x)}{n-T(x)} \neq 0$, hence there exists $z \in N^-(x) \cap V_{n-T(x)}(G)$. Since $y \in N^+(N^-(x))$, we have $y \in N^+(z)$. Therefore, $|N^+(z) \cap V_{T(y)}(G)| \neq 0$. By property (iii) we have $|N^+(z) \cap V_{T(y)}(G)| = \binom{n}{T(y)} \binom{n-T(z)}{T(y)}$. The second factor is equal to $\binom{T(x)}{T(y)} q$ by definition of $z$ and has to be nonzero. So, by definition of $q$-binomial coefficients, we obtain $T(y) \leq T(x)$.

Step 3. $y \in N^+(x)$ (equivalently, $x \in N^-(y)$) implies $cl_t(y) \subseteq N^+(x)$ and $cl_s(x) \subseteq N^-(y)$.

By definition, $y \in N^+(x)$ implies $x \in N^-(y)$, which further implies $N^+(x) \supseteq N^+(N^-(y)) = cl_t(y)$. The proof for source closure is similar.

Step 4. $|cl_t(x) \cap V_k(G)| = |cl_t(y) \cap V_k(G)|$ for all $x, y \in V_k(G)$.

Define a map $f : cl_t(x) \cap V_k(G) \rightarrow cl_t(y) \cap V_k(G)$ as follows. For $z \in cl_t(x) \cap V_k(G)$, we use property (v) to define $f(z)$ uniquely by the condition

$$\{f(z)\} = cl_t(y) \cap cl_s(z) \cap V_k(G).$$

Similarly, define $g : cl_t(y) \cap V_k(G) \rightarrow cl_t(x) \cap V_k(G)$ by

$$\{g(w)\} = cl_t(x) \cap cl_s(w) \cap V_k(G).$$
It suffices to prove that maps \( f \) and \( g \) are inverses of each other. Choose any \( z \in \text{cl}_t (x) \cap V_k (G) \). Since \( f (z) \in \text{cl}_s (f (z)) \cap \text{cl}_s (z) \cap V_k (G) \), Step 1 implies \( \text{cl}_s (f (z)) = \text{cl}_s (z) \). Hence \( z \in \text{cl}_t (x) \cap \text{cl}_s (f (z)) \cap V_k (G) = \{ g (f (z)) \} \). We conclude that \( g (f (z)) = z \). Similarly, \( f (g (w)) = w \).

**Step 5.** \( |\text{cl}_t (x) \cap V_k (G)| = |\text{cl}_s (x) \cap V_k (G)| = \binom{n}{k} q \) for all \( x \in V_k (G) \).

Let \( z \in V_{n-k} (G) \). If \( y \in N^+ (z) \cap V_k (G) \), then \( \text{cl}_t (y) \cap V_k (G) \subseteq N^+ (z) \cap V_k (G) \) by Step 3, so \( N^+ (z) \cap V_k (G) \) is a union of sets of the form \( \text{cl}_t (y) \cap V_k (G) \) where \( y \in N^+ (z) \cap V_k (G) \). By Step 1, two sets of this form are either disjoint or equal and, by Step 4, they all have the same size. Hence, \( |\text{cl}_t (x) \cap V_k (G)| \) divides \( |N^+ (z) \cap V_k (G)| \), which is equal to \( \binom{n}{k} q (\binom{k}{q} q = \binom{n}{k} q \) by property \( [iii] \). Similarly, \( |\text{cl}_s (x) \cap V_k (G)| \) divides \( \binom{n}{k} q \).

By Step 1, the set \( V_k (G) \) is a disjoint union of some number of sets of the form \( \text{cl}_t (w) \cap V_k (G) \), where \( w \in V_k (G) \). Since each set of this form intersects \( \text{cl}_s (x) \cap V_k (G) \) in precisely one element by property \( [ii] \), \( V_k (G) \) is a disjoint union of \( |\text{cl}_s (x) \cap V_k (G)| \) sets of the form \( \text{cl}_t (w) \cap V_k (G) \). Using Step 4 and property \( [ii] \), we obtain \( |\text{cl}_t (x) \cap V_k (G)| \cdot |\text{cl}_s (x) \cap V_k (G)| = |V_k (G)| = \binom{n}{k} q \).

Both factors on the left-hand side divide \( \binom{n}{k} q \), hence \( |\text{cl}_t (x) \cap V_k (G)| = \binom{n}{k} q \).

**Step 6.** \( |N^+ (x) \cap N^-(y) \cap V_{n-k} (G)| = 1 \) for all \( x, y \in V_k (G) \).

By property \( [iii] \), there are \( x', y' \in V_{n-k} (G) \) such that \( x' \in N^+ (x) \) and \( y' \in N^- (y) \). Using property \( [iv] \) let

\[
\{z\} = \text{cl}_t (x') \cap \text{cl}_s (y') \cap V_{n-k} (G).
\]

By definition of closures, it follows that \( z \in N^+ (x) \cap N^- (y) \). To prove uniqueness of \( z \), suppose \( w \in N^+ (x) \cap N^- (y) \cap V_{n-k} (G) \). By Step 3, we have \( \text{cl}_t (w) \cap V_{n-k} (G) \subseteq N^+ (x) \cap V_{n-k} (G) \). But, using Step 5 and property \( [iii] \), we get \( |\text{cl}_t (w) \cap V_{n-k} (G)| = \binom{n}{n-k} q = |N^+ (x) \cap V_{n-k} (G)| \).

Thus
\[
\text{cl}_t (w) \cap V_{n-k} (G) = N^+ (x) \cap V_{n-k} (G).
\]

Similarly \( \text{cl}_s (w) \cap V_{n-k} (G) = N^- (y) \cap V_{n-k} (G) \). By replacing \( w \) with \( z \) in the last two equations, we deduce \( \text{cl}_t (z) \cap V_{n-k} (G) = \text{cl}_t (w) \cap V_{n-k} (G) \) and \( \text{cl}_s (z) \cap V_{n-k} (G) = \text{cl}_s (w) \cap V_{n-k} (G) \). By property \( [v] \), we conclude

\[
\{z\} = \text{cl}_t (z) \cap \text{cl}_s (z) \cap V_{n-k} (G) = \text{cl}_t (w) \cap \text{cl}_s (w) \cap V_{n-k} (G) = \{w\},
\]

which completes the proof of Step 6.

For any \( v \in V_k (G) \), Step 6 allows us to define \( v^{\text{op}} \), the *opposite vertex* of \( v \), by the condition

\[
\{v^{\text{op}}\} = N^+ (v) \cap N^- (v) \cap V_{n-k} (G).
\]

Observe that \( (v^{\text{op}})^{\text{op}} = v \) since \( v \in N^+ (v^{\text{op}}) \cap N^- (v^{\text{op}}) \cap V_k (G) \). In addition, the proof of Step 6 shows that

\[
\text{cl}_t (v^{\text{op}}) \cap V_{n-k} (G) = N^+ (v) \cap V_{n-k} (G).
\]
Replacing $v$ by $v^\text{op}$, we obtain

\[(7) \quad \text{cl}_t(v) \cap V_k(G) = N^+(v^\text{op}) \cap V_k(G).\]

**Step 7**. $\text{cl}_t(x) = N^+(x^\text{op})$ and $\text{cl}_s(x) = N^-(x^\text{op})$ for all $x \in V(G)$.

Let $x \in V_k(G)$. By Step 3 and the definition of $x^\text{op}$, $\text{cl}_t(x) \subseteq N^+(x^\text{op})$.

To prove the opposite inclusion, let $z \in N^+(x^\text{op})$. By property (iii), we have $\text{cl}_t(\{x,z\}) = \text{cl}_t(u)$ for some $u \in V_j(G)$, $j \in \{0,1,\ldots,n\}$. Since $x^\text{op} \in N^-(\{x,z\})$ and $u \in \text{cl}_t(u) = N^+(N^-(\{x,z\}))$, we have $u \in N^+(x^\text{op})$.

By property (iii) (using similar argument as in Step 2), we obtain $j \leq k$. Since $x \in \text{cl}_t(u)$, Step 2 implies $k \leq j$. Hence, $j = k$. By (7), we have

\[
\text{cl}_t(x) \cap V_k(G) = N^+(x^\text{op}) \cap V_k(G) \ni u.
\]

This implies $u \subseteq \text{cl}_t(x)$, hence $\text{cl}_t(x) = \text{cl}_t(u) \ni z$. We conclude that $N^+(x^\text{op}) \subseteq \text{cl}_t(x)$.

In the next few steps, we will prove several properties of the target-closed sets which will enable us to introduce a projective space isomorphic to $PG(n - 1, q)$. We will make use of the characterization given in [21] p. 39.

Let $\mathcal{P}_k$ be the set of all $\text{cl}_t(x)$, where $x \in V_k(G)$. By Step 2, the sets $\mathcal{P}_k$ for different indices $k$ are disjoint. Elements of $\mathcal{P}_1$ will be called points, and elements of $\mathcal{P}_2$ will be called lines, and we will be using all the standard geometric terminology such as point lies on a line, two lines intersect, etc.

**Step 8**. Every element of $\mathcal{P}_m$ contains $\binom{m}{k}$ elements of $\mathcal{P}_k$ and is contained in $\binom{n-m}{n-m-k}$ elements of $\mathcal{P}_k$. In particular, $|\mathcal{P}_k| = \binom{n}{k}_q$.

Let $x \in V_m(G)$ and $y \in V_k(G)$. Then, by Step 7, $\text{cl}_t(y) \subseteq \text{cl}_t(x)$ is equivalent to $\text{cl}_t(y) \subseteq N^+(x^\text{op})$ which is, by Step 3, further equivalent to $y \in N^+(x^\text{op})$ and this is, again by Step 3, equivalent to $\text{cl}_t(y) \cap V_k(G) \subseteq N^+(x^\text{op}) \cap V_k(G)$. In addition, it follows from Step 1 and Step 3 that $N^+(x^\text{op}) \cap V_k(G)$ is a disjoint union of sets of the form $\text{cl}_t(z) \cap V_k(G)$, where $z \in N^+(x^\text{op}) \cap V_k(G)$. Hence, using Step 5 and property (iii) we see that $\text{cl}_t(x)$ contains

\[
\frac{|N^+(x^\text{op}) \cap V_k(G)|}{|\text{cl}_t(y) \cap V_k(G)|} = \binom{n}{k} \frac{\binom{m}{k}_q}{\binom{n}{k}_q} = \frac{m}{k}_q
\]

elements of $\mathcal{P}_k$. To prove the second part, observe that, by Step 7, $\text{cl}_t(x) \subseteq \text{cl}_t(y)$ is equivalent to $x \in N^+(y^\text{op})$ which is equivalent to $y^\text{op} \in N^-(x)$ and this is, again by Step 7, equivalent to $\text{cl}_s(y^\text{op}) \subseteq \text{cl}_s(x^\text{op})$. By symmetry with the above and the fact that $T(x^\text{op}) = n - m$ and $T(y^\text{op}) = n - k$, we conclude that $\text{cl}_t(x)$ is contained in $\binom{n-m}{n-m-k}_q$ elements of $\mathcal{P}_k$.

To prove $|\mathcal{P}_k| = \binom{n}{k}_q$, let $x \in V_n(G)$. By Step 7, we have $\text{cl}_t(x) = N^+(x^\text{op})$, where $x^\text{op} \in V_0(G)$. For every $j \in \{0,1,\ldots,n\}$, properties (ii)
and \((iii)\) give us
\[
|N^+ (x^{op}) \cap V_j (G)| = \left( \begin{array}{c} n \\ j \end{array} \right)_q = |V_j (G)|,
\]
which implies \(V_j (G) \subseteq N^+ (x^{op})\). By property \((i)\) \(cl_t (x) = V (G)\). Now, \(|\mathcal{P}_k| = \left( \begin{array}{c} n \\ k \end{array} \right)_q\) follows from the first part of Step 8.

Observe that in our situation, an element of \(\mathcal{P}_k\) is not a union of points it contains, but rather their closure, as we show next.

Step 9. \(cl_t (x) = cl_t (\cup \{ P \in \mathcal{P}_1 : P \subseteq cl_t (x) \})\) for all \(x \in V (G)\).

By property \((iv)\) \(cl_t (\cup \{ P \in \mathcal{P}_1 : P \subseteq cl_t (x) \}) = cl_t (u)\) for some \(u \in V (G)\). By Step 8, \(cl_t (x)\) contains \((T(x))_q\) points and \(cl_t (u)\) contains \((T(u))_q\) points. By construction, \(cl_t (x)\) contains all the points of \(cl_t (u)\), so \((T(u))_q \geq (T(x))_q\). On the other hand, \((T(u))_q \leq (T(x))_q\) since \(cl_t (u) \subseteq cl_t (x)\). Hence, \((T(u))_q = (T(x))_q\) and consequently \(T (u) = T (x)\). Thus, Step 1 implies \(cl_t (u) = cl_t (x)\).

Step 10. For \(X \in \mathcal{P}_k\) and \(Y \in \mathcal{P}_1\), where \(Y \not\subseteq X\), there is at most one \(Z \in \mathcal{P}_{k+1}\) such that \(X, Y \subseteq Z\).

Suppose \(Z, Z' \in \mathcal{P}_{k+1}\) both contain \(X\) and \(Y\). Then \(cl_t (X \cup Y) \subseteq Z \cap Z'\). Since \(Z \cap Z'\) is a target-closed set, we have \(Z \cap Z' = cl_t (u)\) for some \(u \in V_j (G)\) by property \((iv)\). By Step 2, we have \(k \leq j\) since \(X \subseteq cl_t (u)\). If \(k = j\), then \(X \subseteq cl_t (u)\) would imply \(X = cl_t (u) \supseteq Y\) by Step 1, a contradiction. Hence \(k < j\). By Step 2, we also have \(j \leq k + 1\) since \(u \in Z\). Thus, \(j = k + 1\). So, \(u \in Z \cap Z' \cap V_{k+1} (G)\) which implies \(Z = Z'\) by Step 1.

Step 11. For \(X \in \mathcal{P}_k\) and \(Y \in \mathcal{P}_1\), where \(Y \not\subseteq X\), there is precisely one \(Z \in \mathcal{P}_{k+1}\) such that \(X, Y \subseteq Z\).

First suppose \(k = 1\). Let us count the number of pairs \(\{X, Y\}\), where \(X \in \mathcal{P}_1\), \(Y \in \mathcal{P}_1\) and \(Y \not\subseteq X\), such that \(X, Y \subseteq Z\) for some \(Z \in \mathcal{P}_2\). For convenience, we will simply say that a pair \(\{X, Y\}\) is contained in \(Z\) if \(X, Y \subseteq Z\). Observe that, by Step 1, the condition \(Y \not\subseteq X\) is equivalent to \(Y \neq X\). By Step 8, every element of \(\mathcal{P}_2\) contains \(\binom{2}{1}_q\) elements of \(\mathcal{P}_1\).

Hence, every \(Z \in \mathcal{P}_2\) contains \(\binom{2}{1}_q\) such pairs \(\{X, Y\}\). But, by Step 10, two distinct elements of \(\mathcal{P}_2\) cannot contain the same pair \(\{X, Y\}\). Hence, by the equality \(|\mathcal{P}_2| = \binom{n}{2}_q\) in Step 8, there are exactly \(\binom{2}{1}_q \cdot \binom{n}{2}_q\) such pairs \(\{X, Y\}\). A short calculation shows that \(\binom{2}{1}_q \cdot \binom{n}{2}_q = \binom{n}{2}_q\), but, by Step 8, this is precisely the number of pairs of distinct elements of \(\mathcal{P}_1\). This shows that every pair of distinct elements of \(\mathcal{P}_1\) is contained in some \(Z \in \mathcal{P}_2\) and, by Step 10, this \(Z\) is unique.
Now suppose $k > 1$. First, let us count the number of pairs $\{X, Y\}$, where $X \in \mathcal{P}_k$, $Y \in \mathcal{P}_1$ and $Y \not\subseteq X$, such that $X, Y \subseteq Z$ for some $Z \in \mathcal{P}_{k+1}$. We fix some $Z \in \mathcal{P}_{k+1}$ and count such pairs contained in $Z$, as follows. By Step 8, we first choose $X$ in $\binom{k+1}{1} \cdot \binom{k}{1}$ ways and then $Y$ in $\binom{k+1}{1} - \binom{k}{1}$ ways (the number of points in $Z$ minus the number of points in $X$). Observe that no pair is counted twice since $k > 1$. So there are $\binom{k+1}{1} \cdot \left(\binom{k+1}{1} - \binom{k}{1}\right)$ such pairs in a given $Z \in \mathcal{P}_{k+1}$. By Step 10, each pair $\{X, Y\}$ is contained in only one $Z \in \mathcal{P}_{k+1}$. Hence, by the equality $|\mathcal{P}_{k+1}| = \binom{n}{k+1}$ in Step 8, there are exactly $\binom{k+1}{1} \cdot \left(\binom{k+1}{1} - \binom{k}{1}\right) \cdot \binom{n}{k+1} \cdot \binom{n}{k} \cdot \left(\binom{n}{k} - \binom{k}{1}\right) = \binom{n}{k} \cdot \left(\binom{n}{k} - \binom{k}{1}\right)$, which implies that each pair $\{X, Y\}$, where $X \in \mathcal{P}_k$, $Y \in \mathcal{P}_1$ and $Y \not\subseteq X$, that are contained in some $Z$.

Now, let us count the number of pairs $\{X, Y\}$, where $X \in \mathcal{P}_k$, $Y \in \mathcal{P}_1$ and $Y \not\subseteq X$ (here, we do not insist that $X$ and $Y$ should be contained in some $Z \in \mathcal{P}_{k+1}$). Similar as above, we first choose $X \in \mathcal{P}_k$ and then $Y \in \mathcal{P}_1$, $Y \not\subseteq X$, to count that there are exactly $\binom{n}{k} \cdot \left(\binom{n}{k} - \binom{k}{1}\right)$ such pairs $\{X, Y\}$. A short calculation shows that $\binom{k+1}{1} \cdot \left(\binom{k+1}{1} - \binom{k}{1}\right) \cdot \binom{n}{k+1} \cdot \binom{n}{k} = \binom{n}{k} \cdot \left(\binom{n}{k} - \binom{k}{1}\right)$, which implies that each pair $\{X, Y\}$, where $X \in \mathcal{P}_k$, $Y \in \mathcal{P}_1$ and $Y \not\subseteq X$, is in fact contained in some $Z \in \mathcal{P}_{k+1}$.

**Step 12.** If $X \in \mathcal{P}_k$ and $Y \in \mathcal{P}_1$, where $Y \not\subseteq X$, then $cl_t(X \cup Y) \in \mathcal{P}_{k+1}$.

By property (iv) $cl_t(X \cup Y) = cl_t(u)$ for some $u \in V_j(G)$ where $j \in \{0, 1, \ldots, n\}$. By Step 11, $cl_t(u) \subseteq cl_t(v)$ for some $v \in V_{k+1}(G)$. By Step 2, we have $k \leq j \leq k + 1$. If $j = k$, then the inclusion $X \subseteq cl_t(u)$ implies $X = cl_t(u) \supseteq Y$ by Step 1, a contradiction. Hence, $j = k + 1$.

**Step 13.** For all $X \in \mathcal{P}_k$, $Y \in \mathcal{P}_2$ and $Z \in \mathcal{P}_{k+1}$, where $X, Y \subseteq Z$, there exists $W \in \mathcal{P}_1$ such that $W \subseteq X \cap Y$.

We count the number of lines that are contained in $Z$ and contain a common point with $X$. Step 8 implies that every line contains $\binom{2}{1} \cdot q \geq 3$ distinct points. Step 11 says, in particular, that a line is determined uniquely by two distinct points it contains. We will use this fact implicitly in our counting. We first count those lines contained in $Z$, that have only one common point with $X$, as follows. We choose a point contained in $X$ in $\binom{k}{1}$ ways and then a point contained in $Z \setminus X$ in $\binom{k+1}{1} - \binom{k}{1}$ ways. These two points determine a line that has only one common point with $X$ (if a line contained two distinct points in $X$, then the whole line would be contained in $X$), but this way every line is counted $\binom{2}{1} - 1$ times (this is the number of points on the line, that are not contained in $X$). So there are

\[
\frac{\binom{k}{1} \cdot \left(\binom{k+1}{1} - \binom{k}{1}\right)}{\binom{2}{1} - 1} = q^{k-1} \cdot \binom{k}{1}.
\]
lines that are contained in $Z$ and have only one common point with $X$. Any line that has more than one common point with $X$, is contained in $X$, and there are $\binom{k}{2}q$ such lines by Step 8. So, using the recursion formula \[5\] for $q$-binomial coefficients, we see that altogether there are $\binom{k}{2}q + q^{k-1} \cdot \binom{1}{q} = \binom{k+1}{2}q$ lines contained in $Z$ that have a common point with $X$. However, by Step 8, there are only $\binom{k+1}{2}q$ lines contained in $Z$ altogether, so every line contained in $Z$ has a common point with $X$.

**Step 14.** If $\text{cl}_t\{(x, y)\} = \text{cl}_t\{(z)\}$ and $\text{cl}_t\{(x)\} \cap \text{cl}_t\{(y)\} = \text{cl}_t\{(w)\}$ then $T(x) + T(y) + T(z) = T(x) + T(w)$.

It follows from Step 2 that $T(w) \leq T(y)$. Suppose $T(w) = T(y)$. Then $\text{cl}_t\{(w)\} = \text{cl}_t\{(y)\}$ by Step 1. Consequently, $\text{cl}_t\{(x)\} \subseteq \text{cl}_t\{(x, y)\}$, hence $\text{cl}_t\{(x, y)\} = \text{cl}_t\{(x)\}$ and $T(x) = T(z)$. In this case, the claim holds.

We continue by induction on $T(y) - T(w)$. So suppose $T(y) - T(w) \geq 1$. Then, by Step 8, $\text{cl}_t\{(y)\}$ contains more points than $\text{cl}_t\{(w)\}$, so we can choose a vertex $p \in V_1(G)$, such that $p \notin \text{cl}_t\{(y)\} \setminus \text{cl}_t\{(w)\}$. By Step 12, we have

- $\text{cl}_t\{(x, p)\} = \text{cl}_t\{(x)\} \cup \text{cl}_t\{(p)\} = \text{cl}_t\{(x')\}$
- $\text{cl}_t\{(w, p)\} = \text{cl}_t\{(w)\} \cup \text{cl}_t\{(p)\} = \text{cl}_t\{(w')\}$

where $T(x') = T(x) + 1$ and $T(w') = T(w) + 1$. We will show that

- $\text{cl}_t\{(x', y)\} = \text{cl}_t\{(z)\}$
- $\text{cl}_t\{(x')\} \cap \text{cl}_t\{(y)\} = \text{cl}_t\{(w')\}$

Clearly, we have $\text{cl}_t\{(x', y)\} \subseteq \text{cl}_t\{(z)\}$, and in addition, $\text{cl}_t\{(x')\} = \text{cl}_t\{(x, y)\} \subseteq \text{cl}_t\{(x')\}$. So, $\text{cl}_t\{(x', y)\} = \text{cl}_t\{(z)\}$. Take any $r \in \text{cl}_t\{(x')\} \cap \text{cl}_t\{(y)\}$ such that $r \notin \text{cl}_t\{(p)\}$. Then $\text{cl}_t\{(p, r)\} \in \mathcal{P}_2$ by Step 12. Since $\text{cl}_t\{(x)\}$ and $\text{cl}_t\{(p, r)\}$ are subsets of $\text{cl}_t\{(x')\}$, by Step 13, there is $s \in V_1(G)$ such that $\text{cl}_t\{(s)\} \subseteq \text{cl}_t\{(p, r)\} \cap \text{cl}_t\{(x)\}$. Since $p, r \in \text{cl}_t\{(y)\}$, we have $\text{cl}_t\{(s)\} \subseteq \text{cl}_t\{(w)\} \subseteq \text{cl}_t\{(w')\}$. In particular, $p \notin \text{cl}_t\{(s)\}$ since $p \notin \text{cl}_t\{(w)\}$. Hence, $\text{cl}_t\{(p, s)\} \in \mathcal{P}_2$ by Step 12. But $\text{cl}_t\{(p, s)\} \subseteq \text{cl}_t\{(p, r)\}$, and thus $\text{cl}_t\{(p, s)\} = \text{cl}_t\{(p, r)\}$ by Step 1. This implies $r \in \text{cl}_t\{(p, s)\} \subseteq \text{cl}_t\{(w')\}$ by the above. Since $\text{cl}_t\{(p)\} \subseteq \text{cl}_t\{(w')\}$, we have thus shown that $\text{cl}_t\{(x')\} \cap \text{cl}_t\{(y)\} \subseteq \text{cl}_t\{(w')\}$. On the other hand, $\text{cl}_t\{(w')\} = \text{cl}_t\{(w, p)\} \subseteq \text{cl}_t\{(x')\} \cap \text{cl}_t\{(y)\}$, hence $\text{cl}_t\{(x')\} \cap \text{cl}_t\{(y)\} = \text{cl}_t\{(w')\}$.

Since $T(y) - T(w) = T(y) - T(w) - 1 < T(y) - T(w)$, it follows by induction that $T(x') + T(y) = T(z) + T(w)$ and thus $T(x) + T(y) = T(z) + T(w)$.

Now, we introduce a projective space $\mathcal{P}_{n-1}$ following a characterization in \[21\] p. 39 (see also \[15\]). The set of points of our projective space $\mathcal{P}_{n-1}$ will be $\mathcal{P}_1$. For any $X \in \mathcal{P}_k$, $k \in \{0, 1, \ldots, n\}$, we introduce a subspace

$$S(X) = \{P \in \mathcal{P}_1 : P \subseteq X\}$$

and define its (projective) dimension to be $\dim(S(X)) = k - 1$. Note that, by Step 9, $S$ is a bijection from the set of all target-closed sets to the set of all subspaces of $\mathcal{P}_1$, and since the sets $\mathcal{P}_k$ for different indices $k$ are disjoint, the dimension is well-defined.
Step 15. For \( n \geq 4 \), \( \mathcal{J}_{n-1} \) is a projective space isomorphic to \( PG(n-1, q) \).

We will show that the space \( \mathcal{J}_{n-1} \) satisfies the axioms for projective space \( PG(n-1, q) \) given in [21] p. 39. Clearly, the set of all possible dimensions of subspaces is \( \{-1, 0, \ldots, n-1\} \). By property \( (\text{iii}) \) there is unique subspace of dimension \(-1\), and by Step 2, it is precisely the empty set. Observe that subspaces of dimension 0 are precisely points. By property \( (\text{ii}) \) there is a unique subspace of dimension \( n-1 \), and by the proof of Step 8, it is precisely the whole \( \mathcal{J}_1 \). If \( S(X) \subseteq S(Y) \) then \( X \subseteq Y \) by Step 9, which implies \( \dim(S(X)) \leq \dim(S(Y)) \) by Step 2. Here, \( S(X) = S(Y) \) if and only if \( X = Y \) which is equivalent to \( \dim(S(X)) = \dim(S(Y)) \) by Step 1. The intersection of two subspaces is again a subspace. This follows from the fact that target-closed sets are closed for intersections and from property \( (\text{iv}) \).

Given two subspaces \( S(X) \) and \( S(Y) \), the span of \( S(X) \) and \( S(Y) \), i.e. the intersection of all the subspaces containing both, is clearly \( S(cl_t(X \cup Y)) \) by Step 9. Step 14 easily implies

\[
\dim S(X) + \dim S(Y) = \dim (S(X) \cap S(Y)) + \dim S(cl_t(X \cup Y))
\]

because \( S(X) \cap S(Y) = S(X \cap Y) \). Finally, by Step 8, every subspace of dimension 1 contains \( \binom{2}{1}q = q + 1 \geq 3 \) points.

Step 16. For \( n \leq 2 \), \( \mathcal{J}_{n-1} \) is a projective space isomorphic to \( PG(n-1, q) \).

If \( n = 1 \), then the projective space \( \mathcal{J}_{n-1} \) contains only one point, so the claim trivially holds. If \( n = 2 \), then the projective space \( \mathcal{J}_{n-1} \) consists of one projective line, i.e. 1-dimensional subspace, with \( q + 1 \) points. Hence, it is trivially isomorphic to \( PG(n-1, q) \).

Step 17. Graph \( \Theta(M_n(F_q)) \) satisfies properties \((i)-(v)\).

Let \( G = \Theta(M_n(F_q)) \). Properties \((i)-(iii)\) follow from the proof of Propositions \( 3.1 \) and \( 3.2 \) upon noticing that

\[
V_k(G) = \{(V, W) \in V(G) : \dim_{F_q} V = k, \ \dim_{F_q} W = n - k\}.
\]

Let \( X \) be set of vertices of \( G \), say \( X = \{(V_\alpha, W_\alpha) : \alpha \in A\} \). It is easy to check that

\[
cl_t(X) = \{(V, W) \in V(G) : V \subseteq \bigcup_{\alpha \in A} V_\alpha\}
\]

and

\[
cl_s(X) = \{(V, W) \in V(G) : \bigcap_{\alpha \in A} W_\alpha \subseteq W\}.
\]

Hence, \( cl_t(X) = cl_t(V', W') \) where \( V' \) is the linear span of \( \bigcup_{\alpha \in A} V_\alpha \) and \( W' \) is any linear subspace of \( F_q^n \) such that \( \dim_{F_q} V' + \dim_{F_q} W' = n \). Similarly, \( cl_s(X) = cl_s(V'', W'') \) where \( W'' = \bigcap_{\alpha \in A} W_\alpha \) and \( V'' \) is any linear subspace of \( F_q^n \) such that \( \dim_{F_q} V'' + \dim_{F_q} W'' = n \). This proves property \((iv)\). To prove property \((v)\), let \( x = (V_x, W_x) \) and \( y = (V_y, W_y) \) be elements of \( V_k(G) \) for some \( k \) and suppose \( (V, W) \in cl_t(x) \cap cl_s(y) \cap V_k(G) \). Equivalences \( (8), (9) \) and \( (10) \) then imply \( V \subseteq V_x \) and \( \dim_{F_q} V = \dim_{F_q} V_x = k \), hence \( V = V_x \).
Similarly we get $W = W_y$. Therefore, we clearly have
\[ \text{cl}_t(x) \cap \text{cl}_s(y) \cap V_k(G) = \{(V_x, W_y)\}, \]
which proves (v).

To finish the proof, we need to show that $G$ is isomorphic to $\Theta (M_n (F_q))$. By Steps 15 and 16, there is a collineation $\varphi : \mathcal{S}_{n-1} \to PG (n - 1, q)$. By [12] §9 Theorem 5 and §8 Theorem 17, this collineation extends uniquely to a lattice isomorphism $\hat{\varphi}$ between the lattices of subspaces of the projective spaces involved. Observe that for any $x \in V(G)$, the element $\hat{\varphi}(S(\text{cl}_t(x)))$ corresponds to vector subspace of $F_q^n$ and will be henceforth viewed as such. With this in mind, we can define a map $\psi : V(G) \to V(\Theta (M_n (F_q)))$ by the rule

\[ \psi (x) = (\hat{\varphi}(S(\text{cl}_t(x))) , \hat{\varphi}(S(\text{cl}_t(x^{op})))). \]

Observe that $T(x) + T(x^{op}) = n$, so $\dim(S(\text{cl}_t(x))) + \dim(S(\text{cl}_t(x^{op}))) = n - 2$ and hence $\dim_{F_q}(\hat{\varphi}(S(\text{cl}_t(x)))) + \dim_{F_q}(\hat{\varphi}(S(\text{cl}_t(x^{op})))) = n$. This shows that $\psi(x)$ is indeed a vertex of $\Theta (M_n (F_q))$.

**Step 18.** $\psi$ is injective.

Suppose $\psi(x) = \psi(y)$. The injectivity of $\hat{\varphi}$ implies $S(\text{cl}_t(x)) = S(\text{cl}_t(y))$ and $S(\text{cl}_t(x^{op})) = S(\text{cl}_t(y^{op}))$. By Step 9, this further implies $\text{cl}_t(x) = \text{cl}_t(y)$ and $\text{cl}_t(x^{op}) = \text{cl}_t(y^{op})$. By Step 7, the last equality implies $N^+(x) = N^+(y)$ and hence $\text{cl}_s(x) = \text{cl}_s(y)$. In addition, $T(x) = T(y)$ by Step 2. By property [v] we obtain

\[ \{x\} = \text{cl}_t(x) \cap \text{cl}_s(x) \cap V_{T(x)}(G) = \text{cl}_t(y) \cap \text{cl}_s(y) \cap V_{T(y)}(G) = \{y\}. \]

Hence, $\psi$ is injective.

**Step 19.** $\psi$ is surjective.

Let $(V, W)$ be a vertex of $\Theta (M_n (F_q))$. Then $\dim_{F_q} V + \dim_{F_q} W = n$. By property [iv] we have $\text{cl}_t(\hat{\varphi}^{-1}(V)) = \text{cl}_t(v)$ for some $v \in V(G)$. Observe that, by Step 9,

\[ (11) \quad \hat{\varphi}^{-1}(V) = S(\text{cl}_t(v)) \]

which implies that $T(v) = \dim \hat{\varphi}^{-1}(V) + 1 = \dim_{F_q} V$ since $\hat{\varphi}$ is a lattice isomorphism. Similarly, $\text{cl}_t(\hat{\varphi}^{-1}(W)) = \text{cl}_t(w)$ where $T(w) = \dim_{F_q} W$. In particular, $T(v) = T(w^{op})$, hence by property [v] there is a vertex $x \in V(G)$ such that $\{x\} = \text{cl}_t(v) \cap \text{cl}_s(w^{op}) \cap V_{T(v)}(G)$. By Step 1, we have $\text{cl}_t(x) = \text{cl}_t(v)$ and, by equality [iii], $\hat{\varphi}(S(\text{cl}_t(x))) = V$. Similarly, $\text{cl}_s(x) = \text{cl}_s(w)$. As in the proof of Step 18, this implies that $\text{cl}_t(x^{op}) = \text{cl}_t(w)$. As before, this implies $\hat{\varphi}(S(\text{cl}_t(x^{op}))) = W$. We conclude that $\psi(x) = (V, W)$, so $\psi$ is surjective.

**Step 20.** $\psi$ is a graph isomorphism.

Let $x \to y$ be an edge in $G$. In other words, $y \in N^+(x)$. Then, by Step 7, $y \in \text{cl}_t(x^{op})$, which implies $\text{cl}_t(y) \subseteq \text{cl}_t(x^{op})$. Since $\hat{\varphi}$ is a lattice isomorphism, we deduce $\hat{\varphi}(S(\text{cl}_t(y))) \subseteq \hat{\varphi}(S(\text{cl}_t(x^{op})))$. Hence, there is an edge $\psi(x) \to \psi(y)$ in $\Theta (M_n (F_q))$. On the other hand, if there is an edge
ψ(x) → ψ(y) in Θ(M_n(F_q)), then ̂ϕ(S(cl_k(y))) ⊆ ̂ϕ(S(cl_k(x^op))). The fact that ̂ϕ is a lattice isomorphism, and Step 9 imply cl_k(y) ⊆ cl_k(x^op).

Hence, y ∈ N^+(x) by Step 7, so there is an edge x → y in G. Since graphs involved have no multiple edges, this shows that ψ is a graph isomorphism. □

**Remark 4.3.** If n = 3, then the graph Θ(M_n(F_q)) still has the properties described in Theorem 4.2 but it is not the only graph that satisfies those properties, essentially because there exist non-Desarguesian projective planes. Every projective plane, Desarguesian or not, induces a graph with properties described in Theorem 4.2. We simply take the vertices of those properties, essentially because there exist non-Desarguesian projective planes.

5. **Structural connections between M_n(F_q) and Θ(M_n(F_q))**

In this section we prove two strong connections between the ring M_n(F_q) and the graph Θ(M_n(F_q)), namely

(i) for n ≠ 2, every graph automorphism of Θ(M_n(F_q)) is induced by a ring automorphism of M_n(F_q) (see Theorem 5.1), and

(ii) for n ≠ 1, the graph structure of Θ(M_n(F_q)) uniquely determines the ring structure of M_n(F_q) (see Theorem 5.2).

For an automorphism σ of a field F and a matrix X = (x_{ij})_{i,j} ∈ M_{m,n}(F), written in the standard basis, we denote X^σ = (σ(x_{ij}))_{i,j}. For a subset A ⊆ M_{m,n}(F), we denote A^σ = {X^σ : X ∈ A}. Recall that the group of automorphisms of a finite field F_q, where q = p^m, is a cyclic group of order m, generated by the automorphism τ(λ) = λ^p.

**Theorem 5.1.** Let n ≠ 2 be a positive integer and f a graph automorphism of Θ(M_n(F_q)). Then there is an invertible matrix A ∈ M_n(F_q) and an automorphism σ of F_q such that f([X]) = [AX^σA^{-1}] for all X ∈ M_n(F_q).

**Proof.** Case n = 1 is clear because Θ(M_1(F_q)) has only one vertex with one loop. So, suppose n ≥ 3. Let (V_1, W_1), (V_2, W_2), (V_1', W_1'), (V_2', W_2') be vertices of Θ(M_n(F_q)) such that f((V_1, W_1)) = (V_1', W_1') and f((V_2, W_2)) = (V_2', W_2'). Observe that V_1 ⊆ V_2 if and only if V_1' ⊆ V_2', and V_1 = V_2 if and only if V_1' = V_2'. Indeed, by definition of edges, inclusion V_1 ⊆ V_2 is equivalent to N^-((V_1, W_1)) ⊇ N^-((V_2, W_2)) which is further equivalent to N^-((V_1', W_1')) ⊇ N^-((V_2', W_2'))), i.e. V_1' ⊆ V_2'. Equivalence of equalities is proved similarly. In the same manner, it can be shown that W_1 = W_2 if and only if W_1' = W_2'.

This allows us to define maps ϕ, ϕ' : L → L, where L is the lattice of subspaces of the projective space PG(n - 1, q), by the condition

\[(12) \quad f((V, W)) = (ϕ(V), ϕ'(W))\]
for all \((V, W) \in V(\Theta(M_n(F_q)))\). It is clear that \(\varphi\) is a bijective map. Also, observe that, by the above, we have that \(V_1 \subseteq V_2\) if and only if \(\varphi(V_1) \subseteq \varphi(V_2)\). Hence, \(\varphi\) is a lattice isomorphism. By the Fundamental theorem of projective geometry, \(\varphi\) is induced by a bijective semilinear map \(S\) on \(F_q^{n}\). Let \(\sigma\) be the corresponding automorphism of the field \(F_q\). We now prove that \(\varphi = \varphi'\). We borrow the notion of the opposite vertex from the proof of Theorem 4.2. Observe that opposite vertex is defined in terms of neighbourhoods and degrees, hence the relation of being opposite is preserved by graph automorphism. From the proof of Proposition 3.2, it follows that \((V, W) \in V_k(\Theta(M_n(F_q)))\), where \(k = \dim V\). Hence, it is easy to see that \((V, W)^{\text{op}} = (W, V)\). Therefore,

\[
(\varphi(V), \varphi'(W)) = f((V, W)) = f((W, V)^{\text{op}}) = f((W, V))^{\text{op}} = (\varphi(W), \varphi'(V))^{\text{op}} = (\varphi'(V), \varphi(W)),
\]

which shows that \(\varphi = \varphi'\).

Now, define a map \(L : F_q^n \to F_q^n\) by \(L(x) = S(x^{\sigma^{-1}})\), where \(x \in F_q^n\) is written in the standard basis. It is easy to see that \(L\) is a bijective linear map. Let \(A\) be its matrix in the standard basis. Then \(A\) is an invertible matrix and \(S(x) = AX^\sigma\) for all \(x \in F_q^n\). Let \([X] = (V, W)\) be a vertex of \(\Theta(M_n(F_q))\), where \(X \in M_n(F_q)\), \(V = \text{im } X\) and \(W = \text{ker } X\). By the above, we have

\[
\varphi(V) = \{S(v) : v \in V\} = \{Av^\sigma : v \in V\}.
\]

On the other hand, \(\text{im } (AX^\sigma A^{-1}) = A \cdot \text{im } (X^\sigma) = A \cdot (\text{im } X)^\sigma\) since \(\sigma\) is a field automorphism. Hence, \(\varphi(V) = \text{im } (AX^\sigma A^{-1})\). Similarly, \(\varphi'(W) = \text{im } (AX^\sigma A^{-1}) = A \cdot (\text{im } X^\sigma) = A \cdot (\text{im } X)^\sigma = \varphi'(W)\). By (12), we thus have

\[
f([X]) = (\text{im } (AX^\sigma A^{-1}), \ker (AX^\sigma A^{-1})) = [AX^\sigma A^{-1}].
\]

For \(n = 2\), Theorem 5.1 fails. Observe that vertices in \(\Theta(M_2(F_q))\) distinct from \((0, F_q^2)\) and \((F_q^2, 0)\) are all of the form \((V, W)\), where \(V\) and \(W\) are 1-dimensional subspaces of \(F_q^2\). Let \(\pi\) be any permutation of 1-dimensional subspaces of \(F_q^2\). Then the map \(\varphi\) defined by

\[
\varphi((0, F_q^2)) = (0, F_q^2), \\
\varphi((F_q^2, 0)) = (F_q^2, 0), \\
\varphi((V, W)) = (\pi(V), \pi(W)), \quad \dim_{F_q} V = \dim_{F_q} W = 1,
\]

is a graph automorphism of \(\Theta(M_2(F_q))\). However, not all such maps are of the form as described in Theorem 5.1.

We remark that for the compressed zero-divisor graph \(\Gamma_E\), the group of automorphisms of \(\Gamma_E(M_2(F_q))\) was described in [28].
Theorem 5.2. If \( \Theta (R) \cong \Theta (M_n (F_q)) \) where \( n \neq 1 \) and \( R \) is a finite unital ring, then \( R \cong M_n (F_q) \).

Proof. We will be using some notions introduced in the proof of Theorem 4.2 and some results obtained there. For each \( x \in R \), define \( U_x = \{ r \in R : [r] \in cl_s ([x]) \} \). Choose any representative \( \overline{x} \in R \) of the class \([x]^{op}\).

Since \( cl_s ([x]) = N^- ([\overline{x}]) \) by Step 9 of the proof of Theorem 4.2 it follows that \( U_x = \text{ann}_s (\overline{x}) \). In particular, \( U_x \) is a left ideal in \( R \), hence \( Rx \subseteq U_x \).

We will show that for every \( a \in R \) such that \([a] \in V_1 (\Theta (R)) \), we have in fact \( U_a = Ra \). So, fix \( a \in R \) such that \([a] \in V_1 (\Theta (R)) \). Observe that, by Proposition 3.1, we have \((V(W) \in V_1 (\Theta (M_n (F_q))) \) if and only if \( \dim_{F_q} V = 1 \). In addition, it is easy to verify that for such a vertex, we have \( N^+ (cl_t ((V(W))) = \{0\} \) since

\[
cl_t ((V(W)) = N^+ ((V(W))^{op}) = N^+ ((W,V)) = \\
= \{ (X,Y) : X \subseteq V, \dim_{F_q} Y = n - \dim_{F_q} X \}.
\]

Consequently, if \([r] \in V_1 (\Theta (R)) \), then \( N^+ (cl_t ([r])) = \{0\} \neq [a] \). Hence, there exists \([r'] \in cl_t ([r]) \) such that \( r'a \neq 0 \). So, for each \( cl_t ([r]) \in P_1 \), we can fix such an \( r' \). Since \( U_a \) is a left ideal, we have \([r'a] \in cl_s ([a]) \). In a similar way we can show that \([r'a] \in cl_t ([r]) \). In particular, this implies that \([r'a] \in V_1 (\Theta (R)) \) by Step 2 of the proof of Theorem 4.2. Hence, \([r'a] \in cl_s ([a]) \cap V_1 (\Theta (R)) \).

Therefore, we can define a map

\[
\tau : P_1 \to cl_s ([a]) \cap V_1 (\Theta (R))
\]

by setting \( \tau (cl_t ([r])) = [r'a] \), where \( cl_t ([r]) \in P_1 \). Since \([r'a] \in cl_t ([r]) \) and \([r'a] \in V_1 (\Theta (R)) \), we have \( cl_t ([r'a]) = cl_t ([r]) \) by Step 1 of the proof of Theorem 4.2. This easily implies that \( \tau \) is injective. Observe that, by the proof of Theorem 4.2 we have \( |cl_s ([a]) \cap V_1 (\Theta (R))| = |N^- ([a]^{op}) \cap V_1 (\Theta (R))| = \binom{n}{q} = |P_1| \). Thus, \( \tau \) is also surjective, which implies that \( U_a \subseteq Ra \) since \( cl_s ([a]) = (cl_s ([a]) \cap V_1 (\Theta (R))) \cup \{0\} \). We conclude that \( U_a = Ra \).

Next, we show that \( R \) is a prime ring. Let \( x,y \neq 0 \) be elements of \( R \), where \([y] \in V_j (\Theta (R)) \), \( j > 0 \). Then, \( |N^- ([y]) \cap V_1 (\Theta (R))| = \binom{n}{1} \binom{n-j}{q} < \binom{n}{q} = |V_1 (\Theta (R))| \), hence there exists \( r \in R \) such that \([r] \in V_1 (\Theta (R)) \) and \( ry \neq 0 \). It follows that \([ry] \in V_1 (\Theta (R)) \). So, by the above, \( U_{ry} = Rry \). Similar argument as before shows that \( N^- (cl_s ([ry])) = \{0\} \neq [x] \), hence there exists \([s] \in cl_s ([ry]) \) such that \( xs \neq 0 \). This implies that \( s \in U_{ry} = Rry \). We conclude that \( xRy \neq 0 \), which shows that \( R \) is a prime ring.

As a finite ring, \( R \) is also artinian, so it follows from Wedderburn-Artin Theorem that \( R \) is isomorphic to \( M_{n'} (D) \) for some division ring \( D \) and nonnegative integer \( n' \). Clearly, \( D \) has to be finite, hence it is commutative by Wedderburn’s little theorem. Any finite commutative division ring is isomorphic to some Galois field. Hence, \( R \cong M_{n'} (F_{q'}) \) for some prime power \( q' \). By Proposition 3.2 we have \( n' = n \) and \( q' = q \). \( \square \)
We remark that a version of Theorem 5.2 for the uncompressed zero-divisor graph $\Gamma(R)$ was proved in [4] and generalized to matrix rings over commutative rings in [5].

As a corollary to Theorems 4.2 and 5.2 we obtain a graph-theoretic characterization of finite semisimple rings.

**Theorem 5.3.** A finite unital ring $R$ is semisimple if and only if

$$\Theta(R) \cong \bigoplus_{i=1}^{m} \Theta(M_{n_i}(F_{q_i}))$$

for some positive integers $n_i$ and prime powers $q_i$.

**Proof.** If $R$ is semisimple, then it is a direct product of matrix rings over finite division rings. Since every finite division ring is a field, the conclusion follows from Proposition 2.8.

Conversely, suppose $\Theta(R) \cong \bigoplus_{i=1}^{m} \Theta(M_{n_i}(F_{q_i}))$. By Proposition 2.8, we have $\Theta(R) \cong \Theta(M_{n_1}(F_{q_1})) \times \Theta(\prod_{i=2}^{m} M_{n_i}(F_{q_i}))$. Proposition 2.9 implies that $R \cong R_1 \times R_1'$, where $\Theta(R_1) \cong \Theta(M_{n_1}(F_{q_1}))$ and $\Theta(R_1') \cong \prod_{i=2}^{m} \Theta(M_{n_i}(F_{q_i}))$. By induction we get $R \cong \prod_{i=1}^{m} R_i$, where $\Theta(R_i) \cong \Theta(M_{n_i}(F_{q_i}))$. If $n_i = 1$ for some $i \in \{1, 2, \ldots, m\}$, then $\Theta(R_i)$ has only two vertices, so every nonzero element of $R_i$ is invertible. Thus, being finite, $R_i$ is a field. If $n_i > 1$ for some $i \in \{1, 2, \ldots, m\}$, then $R_i \cong M_{n_i}(F_{q_i})$ by Theorem 5.2. Hence, $R$ is semisimple. \qed

**Theorem 5.4.** Let $R$ and $S$ be finite unital rings, where $S$ is semisimple and has no nonzero homomorphic image isomorphic to a field. If $\Theta(R) \cong \Theta(S)$, then $R \cong S$.

**Proof.** The assumptions imply $S \cong \prod_{i=1}^{m} M_{n_i}(F_{q_i})$, where $n_i > 1$ for all $i \in \{1, 2, \ldots, m\}$. Hence, the conclusion follows from the proof of Theorem 5.3. \qed

### 6. Infinite rings

In analogy with the commutative case (see [18, Definition 6.1]), the following is a possible extension of Definition 2.5 to infinite rings.

**Definition 6.1.** For an arbitrary unital ring $R$, $\Theta(R)$ is a graph whose vertex set is the set of equivalence classes of elements of $R$, where two elements $a, b \in R$ are equivalent if and only if $aR = bR$ and $Ra = Rb$. There is a directed edge $[x] \to [y]$ in $\Theta(R)$ ([$x$] and [y] not necessarily distinct) if and only if $xy = 0$.

Proposition 2.2 and its left-hand sided version ensures that for finite rings (and even for artinian rings) Definitions 6.1 is equivalent to Definition 6.1.
