ON THE LATTICE POINT COVERING PROBLEM IN
DIMENSION 2

FEI XUE

ABSTRACT. In this paper we study the lattice point covering property
of some regular polygons in dimension 2.

1. Introduction

Let $K^n$ be the set of all convex bodies, i.e., compact convex sets, in the
$n$-dimensional Euclidean space $\mathbb{R}^n$ with non-empty interior. We denote by
$K^n_{(o)} \subset K^n$ the set of all convex bodies, having the origin as an interior point,
i.e., $0 \in \text{int}(K)$, and by $K^n_{(s)} \subset K^n_{(o)}$ those bodies which are symmetric with
respect to $0$, i.e., $K = -K$.

We say that a convex body $K \in K^n$ has the lattice point covering property,
i.e., contains a lattice point of $\mathbb{Z}^n$ in any position, if each translation and
rotation of $K$ contains at least a lattice point of $\mathbb{Z}^n$.

There are several beautiful results about the lattice point covering prop-
erty.

Theorem 1.1 (Henk&Tsintsifas,[10]). Let $E \subset \mathbb{R}^n$ be an ellipsoid with semi-
axes $\alpha_i$, $1 \leq i \leq n$. The following statements are equivalent:

(i) $E$ contains a lattice point of $\mathbb{Z}^n$ in any position,

(ii) $\sum_{i=1}^{n} \frac{1}{\alpha_i^2} \leq 4$,

(iii) $E$ contains a cube of edge length 1.

Theorem 1.2 (Niven&Zuckerman,[12]). A triangle with sides of lengths
$a, b, c$, with $a \leq b \leq c$, has the lattice point covering property if and only if
$2\Delta(c-1) \geq c^2$ where $\Delta$ is the area of the triangle.

Theorem 1.3 (Niven&Zuckerman,[12]). Let $a$ and $b$ be the distances be-
tween the pairs of opposite sides, say with $a \leq b$, of a parallelogram $ABCD$
with an interior angle $\gamma \leq \pi/2$. The parallelogram has the lattice point cov-
ering property if and only if $a \geq 1$ and one of the following conditions holds:

(i) $b \geq \sqrt{2}$;

(ii) $b \leq \sqrt{2}$ and $\alpha + \beta + \gamma \leq \pi/2$, where $\alpha = \text{arccos}(a/\sqrt{2})$ and $\beta = \text{arccos}(b/\sqrt{2})$.

Let $K \in K^n$. Denote by $Z(K)$ the lattice point covering radius of $K$, i.e.,
the smallest positive number $r$, such that $rK$ has the lattice point covering
property.

The research of the author was supported by a PhD scholarship of the Berlin Mathem-
atical School.
We here concern the lattice point covering properties of regular polygons. Denote by
\[ H_n = \text{conv} \left\{ \left( \cos \left( \frac{2k\pi}{n} \right), \sin \left( \frac{2k\pi}{n} \right) \right) : k = 0, 1, \ldots, n-1 \right\} \]
the regular $n$-gon.

Our main result is:

**Theorem 1.4.** Let $t_i > 0$, $i \in \mathbb{Z}_+$. 

1. The following statements are equivalent:
   1. $t_{4n} \cdot H_{4n}$ contains a lattice point of $\mathbb{Z}^2$ in any position,
   2. $t_{4n} \cdot H_{4n}$ contains a ball with radius $\sqrt{\frac{2}{2}}$,
   3. $t_{4n} \geq Z(H_{4n}) = \sqrt{\frac{2}{2}} \cos \frac{\pi}{2} n$.

2. The following statements are equivalent for $n = 1, 2$:
   1. $t_{4n+2} \cdot H_{4n+2}$ contains a lattice point of $\mathbb{Z}^2$ in any position,
   2. $t_{4n+2} \cdot H_{4n+2}$ contains $\left[ -\frac{1}{2}, \frac{1}{2} \right]^2$,
   3. $t_6 \geq Z(H_6) = \frac{1}{3 - \sqrt{3}} \approx 0.788675 \ldots$,
   4. $t_{10} \geq Z(H_{10}) = \frac{\cos \frac{\pi}{5} - \sin \frac{\pi}{5} + \sin \frac{2\pi}{5} - \cos \frac{2\pi}{5}}{2 \sin \frac{\pi}{5}} \approx 0.734342 \ldots$.

This paper is organized as follows: in the Section 2 we will introduce the covering radius and gauge function; then we will give a necessary and a sufficient condition of the lattice point covering property in the Section 3 and the Section 4; the content of the Section 5 will be the proof of the main theorem.

2. COVERING RADIUS

The covering radius of $K \in \mathcal{K}_n^o$ with respect to $\mathbb{Z}^n$ is denoted by
\[ c(K) = c(K, \mathbb{Z}^n) = \min \{ \lambda > 0 : \lambda K + \mathbb{Z}^n = \mathbb{R}^n \} . \]

The gauge function $\| \|_K$ associated to a $K \in \mathcal{K}_n^o$ is the function
\[ \| \|_K : \mathbb{R}^n \to [0, \infty) \]
defined by
\[ \| v \|_K = \min \{ t > 0 : v \in tK \} . \]

**Theorem 2.1.** Let $K \in \mathcal{K}_n^o$. Then $K$ contains a lattice point of $\mathbb{Z}^n$ in any position if and only if, for any $o(K)$ rotation of $K$, $c(o(K)) \leq 1$.

**Proof.** If $c(o(K)) > 1$ for some rotation $o(K)$, then there exists a point $x \in \mathbb{R}^n$, such that for every $u \in \mathbb{Z}^2$,
\[ \| x - u \|_{o(K)} > 1 \iff \| u - x \|_{-o(K)} > 1 . \]
Therefore, $-o(K) + x$ does not contain a lattice point of $\mathbb{Z}^2$. 

\[ \]
If \( c(o(K)) \leq 1 \) for any rotation \( o(K) \), then for any point \( x \in \mathbb{R}^n \), since 
\( o(K) + \mathbb{Z}^n = \mathbb{R}^n \), there exists a lattice point \( u \in \mathbb{Z}^2 \), such that 
\[
\| x - u \|_{o(K)} \leq 1 \iff \| u - x \|_{-o(K)} \leq 1.
\]
So, \( -o(K) + x \) contain a lattice point \( u \). □

Therefore, the lattice point covering property of a convex body depends on the covering radius of all rotations of this convex body.

3. NECESSARY CONDITION

According to the knowledge of the lattice covering for a centrally symmetric convex body, we have:

**Theorem 3.1** (I. Fáry, [5]). Let \( K \in \mathcal{K}_2^{(s)} \), such that \( K + \mathbb{Z}^2 \) is a lattice covering. Then \( K \) contains a spacefiller \( L \), i.e., a parallelogram or a centrally symmetric hexagon, such that \( L + \mathbb{Z}^2 \) is a lattice tiling.

Since the lattice point covering property depends on the lattice covering of all rotations, we have:

**Theorem 3.2.** Let \( K \in \mathcal{K}_2^{(s)} \). Then \( K \) contains a lattice point of \( \mathbb{Z}^2 \) in any position, if and only if \( o(K) \) contains a spacefiller, i.e., parallelogram or a centrally symmetric hexagon, with respect to the lattice \( \mathbb{Z}^2 \) for any rotation \( o(K) \).

**Proof.** Cf. Theorem 2.1 and 3.1. □

We here call it a necessary condition of the lattice point covering property, because this condition has to hold, but is uneasy to check.

4. SUFFICIENT CONDITION

For a planar convex body, it is possible to check some inscribed parallelograms, i.e., by checking the Steiner symmetrization of the convex body. We will give a sufficient condition of the lattice point covering property in this way.

The Steiner symmetrization of \( K \in \mathcal{K}_2 \) with respect to \( \{ x \in \mathbb{R}^2 : x_2 = 0 \} \), denoted by \( \text{St}_1(K) \), is a convex body symmetric with respect to \( \{ x \in \mathbb{R}^2 : x_2 = 0 \} \), such that for each line \( l \) vertical to \( \{ x \in \mathbb{R}^2 : x_2 = 0 \} \),
\[
\text{vol}_1(K \cap l) = \text{vol}_1(\text{St}_1(K) \cap l).
\]
For more information on the Steiner symmetrization, we refer to [7, Section 9.1]. It is obvious that \( \text{St}_1(K) \subset \text{St}_1(L) \) for two convex bodies \( K \subset L \).

**Theorem 4.1.** Let \( K \in \mathcal{K}_2^{(s)} \). If for each rotation \( o(K) \) of \( K \), \( \text{St}_1(o(K)) \) contains \( [-\frac{1}{2}, \frac{1}{2}]^2 \), then \( K \) contains a lattice point of \( \mathbb{Z}^2 \) in any position.

**Proof.** Notice that if \( \text{St}_1(o(K)) \) contains \( [-\frac{1}{2}, \frac{1}{2}]^2 \), then \( o(K) \) contains a parallelogram in the form of \( L = \text{conv} \{(a, \frac{1}{2}), (a - 1, \frac{1}{2}), (-a, -\frac{1}{2}), (1 - a, -\frac{1}{2})\} \), which is a spacefiller with respect to \( \mathbb{Z}^2 \). Therefore \( K \) has the lattice point covering property (cf. Theorem 2.1).

Somehow, we also have the following proposition of lattice covering.
Proposition 4.2. Let $K \in K_2^{(s)}$. If $K$ is symmetric with respect to $\{x \in \mathbb{R}^2 : x_1 = 0\}$ and $\{x \in \mathbb{R}^2 : x_2 = 0\}$, then $K + \mathbb{Z}^2 = \mathbb{R}^2$ if and only if $K$ contains $[-\frac{1}{2}, \frac{1}{2}]^2$.

Proof. If $K$ contains $[-\frac{1}{2}, \frac{1}{2}]^2$, then $K + \mathbb{Z}^2$ is a lattice covering. Otherwise, if $K$ does not contain $[-\frac{1}{2}, \frac{1}{2}]^2$, then since $K$ is symmetric with respect to $\{x \in \mathbb{R}^2 : x_1 = 0\}$ and $\{x \in \mathbb{R}^2 : x_2 = 0\}$, $K$ does not contain any point of $(\frac{1}{2}, \frac{1}{2}) + \mathbb{Z}^2$, thus $K + \mathbb{Z}^2$ does not contain $(\frac{1}{2}, \frac{1}{2}) + \mathbb{Z}^2$. □

5. PROOF OF THE MAIN THEOREM

In this section we discuss the lattice point covering property of some regular polygons. The proofs are based on Theorem 4.1 and have the following steps:

1. Prove that the Steiner symmetrizations of all rotations of the convex body contain $[-\frac{1}{2}, \frac{1}{2}]^2$.
2. Prove that a smaller copy of the convex body does not have the lattice point covering property.

We first look at the regular $4n$-gon.

Theorem 5.1. Let $t > 0$. The following statements are equivalent:

i) $t \cdot H_{4n}$ contains a lattice point of $\mathbb{Z}^2$ in any position,

ii) $t \cdot H_{4n}$ contains a ball with radius $\frac{\sqrt{2}}{2}$,

iii) $t \geq Z(H_{4n}) = \frac{\sqrt{2}}{\cos \frac{\pi}{2n}}$.

Proof. If $t \cdot H_{4n}$ contains $B_2(\frac{\sqrt{2}}{2})$, then each rotation $o(t \cdot H_{4n})$ also contains $B_2(\frac{\sqrt{2}}{2})$. Notice that $B_2(\frac{\sqrt{2}}{2})$ contains $[-\frac{1}{2}, \frac{1}{2}]^2$, therefore $o(t \cdot H_{4n}) + \mathbb{Z}^2$ is always a lattice covering, thus $t \cdot H_{4n}$ has the lattice point covering property (cf. Theorem 2.1).

If $t \cdot H_{4n}$ does not contain $B_2(\frac{\sqrt{2}}{2})$, then $o(t \cdot H'_{4n}, \frac{\pi}{4}) + (\frac{1}{2}, \frac{1}{2})$, does not contain any lattice point of $\mathbb{Z}^2$, where $o(t \cdot H'_{4n}, \frac{\pi}{4})$ is the rotation of $t \cdot H'_{4n}$ by angle $\frac{\pi}{4}$.

Then we look at the regular hexagon.

Theorem 5.2. Let $t > 0$. The following statements are equivalent:

i) $t \cdot H_6$ contains a lattice point of $\mathbb{Z}^2$ in any position,

ii) $t \cdot H_6$ contains $[-\frac{1}{2}, \frac{1}{2}]^2$,

iii) $t \geq Z(H_6) = \frac{1}{3 - \sqrt{3}}$.

Proof. Denote by $o(K, \theta)$ the counterclockwise rotation of $K$ by angle $\theta$, i.e.,

$$o(H_n, \theta) = \text{conv} \{ (\cos(\frac{2k\pi}{n} + \theta), \sin(\frac{2k\pi}{n} + \theta)) : k = 0, 1, \cdots, n - 1 \}.$$
For the symmetric reason, the case $\frac{\pi}{12} \leq \theta \leq \frac{\pi}{6}$ is actually symmetric to the case $0 \leq \theta \leq \frac{\pi}{12}$ with respect to the line $\{x \in \mathbb{R}^2 : x_2 = x_1\}$. We are going to prove that $\text{St}_1(o(\frac{1}{3-\sqrt{3}}H_6, \theta))$ contains $[-\frac{1}{2}, \frac{1}{2}]^2$ for $0 \leq \theta \leq \frac{\pi}{12}$ (cf. Theorem 3.1).

By calculation,

$$\text{St}_1(o(H_6, \theta)) = \{(\pm \cos \theta, 0), (\pm \cos(\theta - \frac{\pi}{3}), \pm \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})}), (\pm \cos(\theta + \frac{\pi}{3}), \pm \frac{\sqrt{3}}{2 \cos \theta})\},$$

which by the way is also symmetric with respect to $\{x \in \mathbb{R}^2 : x_2 = 0\}$. In order to check whether $\text{St}_1(o(\frac{1}{3-\sqrt{3}}H_6, \theta))$ contains $[-\frac{1}{2}, \frac{1}{2}]^2$ for $0 \leq \theta \leq \frac{\pi}{12}$, notice that when $0 \leq \theta \leq \frac{\pi}{12}$, it holds

$$\cos(\theta + \frac{\pi}{3}) \leq \frac{\sqrt{3}}{2 \cos \theta}$$

(cf. Proposition A.1), therefore the line $\{x \in \mathbb{R}^2 : x_2 = x_1\}$ may intersects the boundary of $\text{St}_1(o(H_6, \theta))$ with the edge

$$\text{conv}\{(\cos \theta, 0), (\cos(\theta - \frac{\pi}{3}), \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})})\}$$

or the edge

$$\text{conv}\{(\cos(\theta - \frac{\pi}{3}), \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})}), (\cos(\theta + \frac{\pi}{3}), \frac{\sqrt{3}}{2 \cos \theta})\}.$$

Case 1: $\cos(\theta - \frac{\pi}{3}) \leq \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})}$, i.e., $0 \leq \theta \leq \arcsin\left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6}$.

In this case, the line $\{x \in \mathbb{R}^2 : x_2 = x_1\}$ intersects the edge

$$\text{conv}\{(\cos \theta, 0), (\cos(\theta - \frac{\pi}{3}), \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})})\}$$

with $(s(\theta), s(\theta))$, where

$$\frac{s(\theta)}{s(\theta) - \cos \theta} = \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})} \cos(\theta - \frac{\pi}{3}) - \cos \theta$$

thus

$$s(\theta) = \frac{\sin \frac{\pi}{3} \cos \theta}{\sin \frac{\pi}{3} - 2 \sin^2(\theta + \frac{\pi}{6}) + 2 \cos \theta \sin(\theta + \frac{\pi}{6})}.$$

This function $s(\theta)$ is increasing in $[0, \arcsin\left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6}]$ (cf. Proposition A.2), therefore,

$$s(\theta) \geq s(0) = \frac{\sqrt{3}}{\sqrt{3} + 1},$$

and

$$\frac{1}{3 - \sqrt{3}}s(\theta) \geq \frac{1}{2}.$$

So $\text{St}_1(o(\frac{1}{3-\sqrt{3}}H_6, \theta))$ always contains $[-\frac{1}{2}, \frac{1}{2}]^2$ when $\theta \in [0, \arcsin\left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6}].$

Case 2: $\cos(\theta - \frac{\pi}{3}) \geq \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})}$, i.e., $\arcsin\left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6} \leq \theta \leq \frac{\pi}{12}$. 
In this case, the line \( \{ x \in \mathbb{R}^2 : x_2 = x_1 \} \) intersects the edge
\[
\text{conv} \{ (\cos(\theta - \frac{\pi}{3}), \frac{\sin \frac{\pi}{3}}{2 \sin(\theta + \frac{\pi}{6})}), (\cos(\theta + \frac{\pi}{3}), \frac{\sqrt{3}}{2 \cos \theta}) \}.
\]
with \((t(\theta), t(\theta))\), where
\[
\frac{2t(\theta) - \frac{\sqrt{3}}{\cos \theta}}{t(\theta) - \cos (\theta + \frac{\pi}{3})} = \frac{\frac{\sin \frac{\pi}{3}}{\sin(\theta + \frac{\pi}{6})} - \frac{\sqrt{3}}{\cos \theta}}{\cos (\theta - \frac{\pi}{3}) - \cos (\theta + \frac{\pi}{3})},
\]
i.e.,
\[
t(\theta) = \frac{2\sqrt{3} \sin (\theta + \frac{\pi}{6}) + \sqrt{3} \cos (\theta + \frac{\pi}{6})}{4 \cos \theta \sin (\theta + \frac{\pi}{6}) + \sqrt{3}}.
\]
This function \(t(\theta)\) is decreasing in \([\arcsin \left( \frac{\sqrt{3}}{2} \right) - \frac{\pi}{6}, \frac{\pi}{12}]\), and in fact decreasing in \([\arcsin \left( \frac{\sqrt{3}}{2} \right) - \frac{\pi}{6}, \frac{\pi}{12}]\) (cf. Proposition A.3), therefore
\[
t(\theta) \geq t(\frac{\pi}{12}) > t(\frac{\pi}{6}) = \frac{\sqrt{3}}{\sqrt{3} + 1},
\]
and
\[
\frac{1}{3 - \sqrt{3}} t(\theta) > \frac{1}{2}.
\]
So \(\text{St}_1(o(\frac{1}{3 - \sqrt{3}} H_6, \theta))\) always contains \([-\frac{1}{2}, \frac{1}{2}]^2\) when \(\theta \in [\arcsin \left( \frac{\sqrt{3}}{2} \right) - \frac{\pi}{6}, \frac{\pi}{12}]\).

To see that \(\frac{1}{3 - \sqrt{3}}\) is the minimum number, we refer to Proposition 4.2. \(\Box\)

Now we look at the regular 10-gon.

**Theorem 5.3.** Let \(t > 0\). The following statements are equivalent:

i) \(t_{10} \cdot H_{10}\) contains a lattice point of \(\mathbb{Z}^2\) in any position,

ii) \(t_{10} \cdot H_{10}\) contains \([-\frac{1}{2}, \frac{1}{2}]^2\),

iii) \(t_{10} \geq Z(H_{10}) = \frac{\cos \frac{\pi}{9} - \sin \frac{\pi}{9} + \sin \frac{2\pi}{9} - \cos \frac{2\pi}{9}}{2 \sin \frac{\pi}{9}}\).

**Proof.** Denote by \(o(K, \theta)\) the counterclockwise rotation of \(K\) by angle \(\theta\), i.e.,
\[
o(H_n, \theta) = \text{conv} \{ (\cos(\frac{2k\pi}{n} + \theta), \sin(\frac{2k\pi}{n} + \theta)) : k = 0, 1, \cdots, n - 1 \}.
\]

For the symmetric reason, the case \(\frac{\pi}{20} \leq \theta \leq \frac{\pi}{10}\) is actually symmetric to the case \(0 \leq \theta \leq \frac{\pi}{20}\) with respect to the line \(\{ x \in \mathbb{R}^2 : x_2 = x_1 \}\). We are going to prove that \(\text{St}_1(o(\frac{\cos \frac{\pi}{9} - \sin \frac{\pi}{9} + \sin \frac{2\pi}{9} - \cos \frac{2\pi}{9}}{2 \sin \frac{\pi}{9}} H_{10}, \theta))\) contains \([-\frac{1}{2}, \frac{1}{2}]^2\) for \(0 \leq \theta \leq \frac{\pi}{20}\) (cf. Theorem 3.1).
By calculation, 
$$\text{St}_1(o(H_{10}, \theta)) = \{ \pm (\cos \theta, 0),$$
$$\left( \pm \cos(\theta - \pi/5), \frac{\sin \pi/10 \sin \pi/5}{\sin(\pi/10 + \theta)} \right), \left( \pm \cos(\theta + \pi/5), \frac{\sin \pi/10 \sin 3\pi/10}{\sin(\pi/10 - \theta)} \right),$$
$$\left( \pm \cos(\theta - 2\pi/5), \frac{\sin 3\pi/10 \sin 2\pi/5}{\sin(\pi/10 + \theta)} \right), \left( \pm \cos(\theta + 2\pi/5), \frac{\sin 3\pi/10 \sin 2\pi/5}{\cos \theta} \right) \}. $$

While $\theta \in [0, \pi/2]$, it holds
$$\cos(\theta - \pi/5) > \frac{\sin \pi/10 \sin \pi/5}{\sin(\pi/10 + \theta)} \quad \text{(cf. A.5)},$$
$$\cos(\theta + \pi/5) > \frac{\sin \pi/10 \sin 3\pi/10}{\sin(\pi/10 - \theta)} \quad \text{(cf. A.6)},$$
$$\cos(\theta - 2\pi/5) < \frac{\sin 3\pi/10 \sin 2\pi/5}{\sin(\pi/10 + \theta)} \quad \text{(cf. A.7)},$$
$$\cos(\theta + 2\pi/5) < \frac{\sin 3\pi/10 \sin 2\pi/5}{\cos \theta} \quad \text{(cf. A.8)}. $$

Therefore, the line $\{ x \in \mathbb{R}^2 : x_2 = x_1 \}$ intersects $\text{St}_1(o(H_{10}, \theta))$ with the edge
$$\text{conv} \left\{ \left( \cos(\theta + \pi/5), \frac{\sin \pi/10 \sin \pi/5}{\sin(\pi/10 - \theta)} \right), \left( \cos(\theta - 2\pi/5), \frac{\sin 3\pi/10 \sin 2\pi/5}{\sin(\pi/10 + \theta)} \right) \right\}$$
at the point $(t(\theta), t(\theta))$, where
$$\frac{t(\theta) - \sin \pi/10 \sin 2\pi/5}{t(\theta) - \cos \theta - 2\pi/5} = \frac{\sin \pi/10 \sin \pi/5}{\sin(\pi/10 - \theta)} - \frac{\sin 3\pi/10 \sin 2\pi/5}{\sin(\pi/10 + \theta)}. $$

The function $t(\theta)$ is increasing in $[0, \pi/20]$ (cf. Proposition A.4), therefore
$$t(\theta) \geq t(0) = \frac{\sin \pi/5}{\cos \pi/5 - \sin \pi/5 + \sin 2\pi/5 - \cos 2\pi/5},$$
and
$$\frac{\cos \pi/5 - \sin \pi/5 + \sin 2\pi/5 - \cos 2\pi/5}{2 \sin \pi/5} t(\theta) \geq \frac{1}{2}. $$

So $\text{St}_1(o(\cos \pi/5 - \sin \pi/5 + \sin 2\pi/5 - \cos 2\pi/5 H_{10}, \theta))$ always contains $[-\frac{1}{2}, \frac{1}{2}]$ when $\theta \in [0, \pi/20]$. 

To see that $\frac{\cos \pi/5 - \sin \pi/5 + \sin 2\pi/5 - \cos 2\pi/5}{2 \sin \pi/5}$ is the minimum number, we refer to Proposition 4.2. $\square$

**Remark 5.4.** $\text{St}_1(o(H_{2n}, \theta))$, $\theta \in [0, \pi/n]$, has the vertices
$$(\cos \theta, 0),$$
$$\left( \cos(\theta - \frac{2\pi}{n}), \frac{\sin \pi/n \sin \frac{2\pi}{n}}{\sin(\frac{\pi}{n} + \theta)} \right), \left( \cos(\theta + \frac{2\pi}{n}), \frac{\sin \frac{2\pi}{n} \sin \frac{3\pi}{n}}{\sin(\frac{2\pi}{n} - \theta)} \right),$$
$$\left( \cos(\theta - \frac{2\pi}{n}), \frac{\sin \pi/n \sin \frac{2\pi}{n}}{\sin(\frac{\pi}{n} + \theta)} \right), \left( \cos(\theta + \frac{2\pi}{n}), \frac{\sin \frac{2\pi}{n} \sin \frac{3\pi}{n}}{\sin(\frac{2\pi}{n} - \theta)} \right).$$
\[\left(\cos(\theta - \frac{4\pi}{n}), \frac{\sin \frac{3\pi}{n} \sin \frac{4\pi}{n}}{\sin(\frac{3\pi}{n} + \theta)}\right), \left(\cos(\theta + \frac{4\pi}{n}), \frac{\sin \frac{4\pi}{n} \sin \frac{5\pi}{n}}{\sin(\frac{4\pi}{n} - \theta)}\right)\]

We can deal with all regular \((4n+2)\)-gons similarly (cf. Theorem 5.2 and 5.3).

**Appendix A. Some inequalities**

**Proposition A.1.**

\[\cos(\theta + \frac{\pi}{3}) \leq \frac{\sqrt{3}}{2 \cos \theta}\]

for \(0 \leq \theta \leq \frac{\pi}{12}\).

*Proof.* It is equivalent to

\[
2 \cos \theta \cos(\theta + \frac{\pi}{3}) \leq \sqrt{3}
\]

\[
\iff \cos \frac{\pi}{3} + \cos(2\theta + \frac{\pi}{3}) \leq \sqrt{3}
\]

\[
\iff \cos(2\theta + \frac{\pi}{3}) \leq \sqrt{3} - \frac{1}{2}.
\]

\[\Box\]

**Proposition A.2.**

\[s(\theta) = \sin \frac{\pi}{3} \cos \theta \frac{\sin \frac{\pi}{3} - 2 \sin^2(\theta + \frac{\pi}{6}) + 2 \cos \theta \sin(\theta + \frac{\pi}{6})}{3 + \sqrt{3} + 4 \cos^2 \theta} \geq s(0)\]

for \(0 \leq \theta \leq \arcsin \left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6}\).

*Proof.* Notice that

\[s(\theta) = \frac{\sqrt{3} \cos \theta}{3 + \sqrt{3} + 4 \cos^2 \theta}.
\]

While \(\theta \in [0, \arcsin \left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6}]\) is increasing, \(\cos \theta > \sqrt{3 - \frac{\sqrt{3}}{4}}\) is decreasing and thus \(s(\theta)\) is increasing. \[\Box\]

**Proposition A.3.**

\[t(\theta) = \frac{2\sqrt{3} \sin \left(\theta + \frac{\pi}{6}\right) + \sqrt{3} \cos \left(\theta + \frac{\pi}{3}\right)}{4 \cos \theta \sin \left(\theta + \frac{\pi}{6}\right) + \sqrt{3}} \geq t\left(\frac{\pi}{6}\right)\]

for \(\arcsin \left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6} \leq \theta \leq \frac{\pi}{6}\).

*Proof.* Notice that

\[t(\theta) = \frac{3 \sin(\theta + \frac{\pi}{6})}{4 \sin^2(\theta + \frac{\pi}{6}) + \sqrt{3} - 1}.
\]

While \(\theta \in [\arcsin \left(\frac{\sqrt{3}}{2}\right) - \frac{\pi}{6}, \frac{\pi}{6}]\) is increasing, \(\sin(\theta + \frac{\pi}{6}) > \sqrt{\frac{3}{4} - 1}\) is increasing and thus \(t(\theta)\) is decreasing. \[\Box\]
Proposition A.4. \( t(\theta) \geq t(0) \) for \( 0 \leq \theta \leq \frac{\pi}{20} \) where
\[
\frac{t(\theta) - \sin \frac{3\pi}{10} \sin \frac{2\theta}{5}}{t(\theta) - \cos(\theta - \frac{2\pi}{5})} = \frac{\sin \frac{2\pi}{5} \sin \frac{4\pi}{10} - \sin \frac{3\pi}{10} \sin \frac{2\pi}{10}}{\cos(\theta + \frac{\pi}{5}) - \cos(\theta - \frac{2\pi}{5})}.
\]

Proof. Notice that
\[
t(\theta) = 2 \sin \frac{3\pi}{10} \cos \frac{\pi}{10} \cos \frac{\pi}{5} \sin(\frac{3\pi}{10} + \theta).
\]
While \( \theta \in [0, \frac{\pi}{20}] \), \( \cos \theta > \sqrt{1 - \sin \frac{2\pi}{5} + \cos \frac{3\pi}{10}} \) is decreasing and thus \( t(\theta) \) is increasing. \( \square \)

Proposition A.5. \( \cos(\theta - \frac{\pi}{5}) > \frac{\sin \frac{\pi}{10} \sin \frac{\pi}{5}}{\sin(\frac{\pi}{10} + \theta)} \) for \( 0 \leq \theta \leq \frac{\pi}{20} \).

Proof. It is equivalent to
\[
\sin(\frac{\pi}{10} + \theta) \cos(\theta - \frac{\pi}{5}) > \sin \frac{\pi}{10} \sin \frac{\pi}{5}
\]
\[
\Leftrightarrow \sin(2\theta - \frac{\pi}{10}) + \sin \frac{3\pi}{10} > 2 \sin \frac{\pi}{10} \sin \frac{\pi}{5}
\]
\[
\Leftrightarrow \sin(2\theta - \frac{\pi}{10}) > 2 \sin \frac{\pi}{10} \sin \frac{\pi}{5} - \sin \frac{3\pi}{10}.
\]
Since \( \sin(2\theta - \frac{\pi}{10}) \) is increasing for \( 0 \leq \theta \leq \frac{\pi}{20} \), and
\[
\sin \frac{3\pi}{10} - \sin \frac{\pi}{10} - 2 \sin \frac{\pi}{10} \sin \frac{\pi}{5} > 0,
\]
the inequality holds for \( 0 \leq \theta \leq \frac{\pi}{20} \). \( \square \)

Proposition A.6. \( \cos(\theta + \frac{\pi}{5}) > \frac{\sin \frac{\pi}{5} \sin \frac{3\pi}{10}}{\sin(\frac{3\pi}{10} - \theta)} \) for \( 0 \leq \theta \leq \frac{\pi}{20} \).

Proof. It is equivalent to
\[
\sin(\frac{3\pi}{10} - \theta) \cos(\theta + \frac{\pi}{5}) > \sin \frac{\pi}{5} \sin \frac{3\pi}{10}
\]
\[
\Leftrightarrow \sin \frac{\pi}{2} + \sin(\frac{\pi}{10} - 2\theta) > 2 \sin \frac{\pi}{5} \sin \frac{3\pi}{10}
\]
\[
\Leftrightarrow \sin(\frac{\pi}{10} - 2\theta) > 2 \sin \frac{\pi}{5} \sin \frac{3\pi}{10} - \sin \frac{\pi}{2}.
\]
Since \( \sin(\frac{\pi}{10} - 2\theta) \) is decreasing for \( 0 \leq \theta \leq \frac{\pi}{20} \), and
\[
0 > 2 \sin \frac{\pi}{5} \sin \frac{3\pi}{10} - \sin \frac{\pi}{2},
\]
the inequality holds for \( 0 \leq \theta \leq \frac{\pi}{20} \). \( \square \)
Proposition A.7.

\[
\cos(\theta - \frac{2\pi}{5}) < \frac{\sin\frac{3\pi}{10} \sin\frac{2\pi}{5}}{\sin\left(\frac{3\pi}{10} + \theta\right)}
\]

for \(0 \leq \theta \leq \frac{\pi}{20}\).

Proof. It is equivalent to

\[
\sin\left(\frac{3\pi}{10} + \theta\right) \cos(\theta - \frac{2\pi}{5}) < \sin\frac{3\pi}{10} \sin\frac{2\pi}{5}
\]

\[
\Leftrightarrow \sin(2\theta - \frac{\pi}{10}) + \sin\frac{7\pi}{10} < 2 \sin\frac{3\pi}{10} \sin\frac{2\pi}{5}
\]

\[
\Leftrightarrow \sin(2\theta - \frac{\pi}{10}) < 2 \sin\frac{3\pi}{10} \sin\frac{2\pi}{5} - \sin\frac{7\pi}{10}
\]

Since \(\sin(2\theta - \frac{\pi}{10})\) is increasing for \(0 \leq \theta \leq \frac{\pi}{20}\), and

\[
0 < 2 \sin\frac{3\pi}{10} \sin\frac{2\pi}{5} - \sin\frac{7\pi}{10},
\]

the inequality holds for \(0 \leq \theta \leq \frac{\pi}{20}\). \(\square\)

Proposition A.8.

\[
\cos(\theta + \frac{2\pi}{5}) < \frac{\sin\frac{2\pi}{5}}{\cos \theta}
\]

for \(0 \leq \theta \leq \frac{\pi}{20}\).

Proof. It is equivalent to

\[
\cos \theta \cos(\theta + \frac{2\pi}{5}) < \sin\frac{2\pi}{5}
\]

\[
\Leftrightarrow \cos(2\theta + \frac{2\pi}{5}) + \cos\frac{2\pi}{5} < 2 \sin\frac{2\pi}{5}
\]

\[
\Leftrightarrow \cos(2\theta + \frac{2\pi}{5}) < 2 \sin\frac{2\pi}{5} - \cos\frac{2\pi}{5}.
\]

Since \(\cos(2\theta + \frac{2\pi}{5})\) is decreasing for \(0 \leq \theta \leq \frac{\pi}{20}\), and

\[
\cos\frac{2\pi}{5} < 2 \sin\frac{2\pi}{5} - \cos\frac{2\pi}{5},
\]

the inequality holds for \(0 \leq \theta \leq \frac{\pi}{20}\). \(\square\)
