Abstract

We express the Newton spectrum of a polynomial in terms of twisted degrees of reduced cohomology groups of toric varieties. We also define the toric Newton spectrum, which have a natural orbifold flavor.

1 Introduction

Let $f$ be a convenient and Newton nondegenerate polynomial in the sense of Kouchnirenko [11], defined on $\mathbb{C}^n$ (we recall the definitions in Section 2). The Newton spectrum of $f$ is the Hilbert-Poincaré series $P_{B^*}(z)$ of its Jacobi ring $\mathbb{C}[u_1, \ldots, u_n]/(\frac{\partial f}{\partial u_1}, \ldots, \frac{\partial f}{\partial u_n})$, graded by a twisted version of the Newton filtration. This Newton spectrum appears in the construction of Frobenius manifolds associated with polynomials because it gives the homogeneity constants of the structure [7], [8], [9]. It is closely related to the spectrum at infinity of a tame polynomial defined in [12] and has all the characteristic properties of a singularity spectrum. In particular, it satisfies the relation $z^n P_{B^*}(z^{-1}) = P_{B^*}(z)$ (Poincaré duality), which is classically provided by microlocal Poincaré duality, see for instance [12, Sec. II. 11]. Motivated by mirror symmetry, one aim of this text is to express this Newton spectrum as a sequence of ”orbifold” degrees (see [6] for convenient and nondegenerate Laurent polynomials: the main difference is that we deal now with non complete toric varieties) and to recover the previous symmetry result using Poincaré duality for toric varieties.

We first give in Theorem 4.6 a description of the Newton spectrum with the help of the toric Newton spectrum $P_{\mathbb{Z}^n, B^*}(z)$ of the ring $\mathbb{Z}^n := \mathbb{C}[u_1, \ldots, u_n]/(u_1 \frac{\partial f}{\partial u_1}, \ldots, u_n \frac{\partial f}{\partial u_n})$ graded by the Newton filtration. This toric Newton spectrum fits very well with the Newton filtration and can be computed using a Koszul complex provided by [11], see Theorem 3.2.

Then we show that these Newton spectra can be expressed with the help of (twisted) Hilbert-Poincaré series of toric varieties. More precisely, let $f$ be a convenient and nondegenerate polynomial on $\mathbb{C}^n$ and let $P$ be its Newton polytope (we will denote its vertices different from the origin by $b_1, \ldots, b_r$). Let $\Sigma$ be the fan in $\mathbb{R}^n$ obtained by taking the cones over the proper faces of $P$ not containing the origin and let $X_{\Sigma}$ be the toric variety associated with the fan $\Sigma$. Following [2], we will call the triple $\Sigma = (\mathbb{Z}^n, \Sigma, \{b_i\})$ the stacky fan of $P$. We associate to the stacky fan $\Sigma$ two graded vector spaces whose Hilbert-Poincaré series are the spectra alluded to.
We first consider the toric Newton spectrum. For a face $\Delta$ of $P$ with vertices $b_{i_1}, \cdots, b_{i_k}$, we define $\Box(\Delta) := \{\sum_{\ell=1}^k q_{\ell} b_{i_\ell}, \ q_{\ell} \in [0,1[, \ \ell = 1, \cdots, k\}$ and $\Box(P) = \bigcup_{\Delta \in \mathcal{F}(P)} \Box(\Delta)$ where $\mathcal{F}(P)$ is the union of the closed faces of $P$ not contained in the union of the hyperplane coordinates. For $\alpha \in \mathbb{Q}$, let

$$H_{K,\text{tor}}^{2\alpha}(\Sigma, \mathbb{Q}) := \bigoplus_{v \in \Box(P) \cap \mathbb{N}^n} H^2(\alpha - \nu(v))(X_{\Sigma/\sigma(v)}, \mathbb{Q})$$

where $\sigma(v)$ is the smallest cone of $\Sigma$ containing $v$, $X_{\Sigma/\sigma(v)}$ is the toric variety associated with the quotient fan $\Sigma/\sigma(v)$ and $\nu(v)$ is the Newton order of $v$. We get (see Theorem 6.6):

**Theorem 1.1** Let $f$ be a convenient and nondegenerate polynomial on $\mathbb{C}^n$. Assume that $\Sigma$ is simplicial. Then $P_{B^*}(\mathbb{F})_m = \sum_{\alpha \in \mathbb{Q}} \dim_{\mathbb{Q}} H_{K,\text{tor}}^{2\alpha}(\Sigma, \mathbb{Q})z^\alpha$. \hfill \Box

The decomposition of the vector space $H_{K,\text{tor}}^{2\alpha}$ matches with the description of the orbifold cohomology of the $\mathcal{X}$ associated with the stacky fan $\Sigma$ given in [2, Proposition 4.7], see Corollary 6.7 we will say that the polynomial $f$ and $\mathcal{X}$ are mirror partners if there is an isomorphism of $\mathbb{Q}$-graded rings $H_{\text{orb}}^2(\mathcal{X}, \mathbb{Q}) \longrightarrow \text{Gr}(\mathbb{F})$, see Section 8.

Then, we consider the Newton spectrum: for a face $\Delta$ of the Newton polytope with vertices $b_{i_1}, \cdots, b_{i_k}$, let $\text{Box}(\Delta) := \{\sum_{\ell=1}^k q_{\ell} b_{i_\ell}, \ q_{\ell} \in [0,1[, \ \ell = 1, \cdots, k\}$ and let $\text{Box}(P) := \bigcup_{\Delta \in \mathcal{F}(P)} \text{Box}(\Delta)$. For $\alpha \in \mathbb{Q}$, we define (we denote by $H$ the union of the hyperplane coordinates)

$$H_K^{2\alpha}(\Sigma, \mathbb{Q}) := \bigoplus_{v \in \text{Box}(P) \cap \mathbb{N}^n} H^2(\alpha - \nu(v))(X_{\Sigma/\sigma(v)}, \mathbb{Q}) \bigoplus_{v \in P \cap H \cap \mathbb{N}^n} \vec{H}^2(\alpha - \nu(v))(X_{\Sigma/\sigma(v)}, \mathbb{Q})$$

where $\vec{H}^2(X_{\Sigma/\sigma(v)}, \mathbb{Q}) = H^{2\beta}(X_{\Sigma/\sigma(v)}, \mathbb{Q})$ if $\beta \neq 0$ and $\vec{H}^0(X_{\Sigma/\sigma(v)}, \mathbb{Q}) = 0$. We get (see Theorem 6.3):

**Theorem 1.2** Let $f$ be a convenient and nondegenerate polynomial on $\mathbb{C}^n$. Assume that its Newton polytope $P$ is simplicial. Then $P_{B^*}(z) = \sum_{\alpha \in \mathbb{Q}} \dim_{\mathbb{Q}} H_K^{2\alpha}(\Sigma, \mathbb{Q})z^\alpha$. \hfill \Box

The relation $z^n P_{B^*}(z^{-1}) = P_{B^*}(z)$ can now be proven using Poincaré duality for the simplicial toric varieties $X_{\Sigma/\sigma(v)}$, see Corollary 6.2 We get also an explanation of integral shifts in the Newton spectrum, and this is related to the size of the Jordan blocks of the monodromy of $f$ at infinity, see Remark 6.4.

Last, it should be emphasized that the previous results have a straightforward local version: this is discussed in Section 7.

**Conventions.** Let $n$ be a positive integer. In this text, $\mathcal{B}$ will denote the polynomial ring $\mathbb{C}[u_1, \cdots, u_n]$ and we will write $u^m := u_1^{m_1} \cdots u_n^{m_n}$ if $m = (m_1, \cdots, m_n) \in \mathbb{N}^n$.

## 2 Kouchnirenko’s setting

In this section, we set the framework and the notations. We follow [11]. The support of $g = \sum_{m \in \mathbb{N}^n} a_m u^m \in \mathcal{B}$ is $\text{supp}(g) = \{m \in \mathbb{N}^n, \ a_m \neq 0\}$ and the Newton polytope of $g$ is the convex hull of $\{0\} \cup \text{supp}(g)$ in $\mathbb{R}^n_+$. The Newton boundary of a Newton polytope is the union of its closed faces that do not contain the origin. The polynomial $f$ is convenient if, for each $i = 1, \cdots, n$, there exists an integer $n_i \geq 1$ such that the monomial $u_i^{n_i}$ appears in $f$ with a non-zero coefficient. The
polynomial \( f \) is Newton nondegenerate (for short in this text: nondegenerate) if, for each closed face \( \Delta \) of the Newton boundary, the system

\[
(u_1 \frac{\partial f}{\partial u_1})_\Delta = \cdots = (u_n \frac{\partial f}{\partial u_n})_\Delta = 0
\]

has no solutions on \((\mathbb{C}^*)^n\) (we define here \( g_\Delta = \sum_{m \in \mathbb{N}^n \cap \Delta} b_m u^m \) if \( g = \sum_{m \in \mathbb{N}^n} b_m u^m \in B \)).

Let \( f \in B \) and let \( P \) be its Newton polytope. If \( f \) is a facet (face of dimension \( n-1 \)) of the Newton boundary of \( P \), let \( u_F \in \mathbb{Q}^n \) be such that

\[
F = P \cap \{ n \in \mathbb{R}^n, \langle u_F, n \rangle = 1 \}
\]

The Newton function \( \nu : \mathbb{N}^n \to \mathbb{Q} \) of \( P \) is defined by \( \nu(a) := \max_B \langle u_F, a \rangle \), where the maximum is taken over the facets of the Newton boundary of \( P \). We have \( \nu(a + b) \leq \nu(a) + \nu(b) \) with equality if and only if \( a \) and \( b \) belong to the same cone (by a cone, we mean a cone spanned by the faces of the Newton boundary of \( P \)). For \( \alpha \in \mathbb{Q} \), let

\[
B_\alpha = \{ g \in B, \ \text{supp}(g) \in \nu^{-1}([-\infty; \alpha]) \}.
\]

We get an increasing filtration \( N_\bullet \) of the ring \( B \), indexed by \( \mathbb{Q} \), by setting \( N_\alpha B := B_\alpha \); this is the Newton filtration of \( B \). We put \( B_{\leq \alpha} = \bigcup_{\beta < \alpha} B_\beta \), \( B_\alpha = \frac{B}{B_{<\alpha}} \) and \( B = \oplus_\alpha B_\alpha/B_{<\alpha} \). The product in \( B \) is described as follows: for \( u^m \in B \), let

\[
\delta_m = u^m + B_{<\nu(m)} \in B_{\nu(m)}/B_{<\nu(m)} = B_{\nu(m)};
\]

then,

\[
\delta_{m_1} \circ \delta_{m_2} = \begin{cases} 
\delta_{m_1 + m_2} & \text{if } m_1 \text{ and } m_2 \text{ belong to the same cone}, \\
0 & \text{otherwise}.
\end{cases}
\]

We will denote by \( P_B(z) = \sum_{\alpha \in \mathbb{Q}} \dim B_\alpha z^\alpha \) the Hilbert-Poincaré series of the graded ring \( B \).

Let \( f : \mathbb{C}^n \to \mathbb{C} \) be a convenient and nondegenerate polynomial. By [11], \( f \) has only isolated critical points and its global Milnor number \( \mu_f := \dim_{\mathbb{C}} \mathcal{B}/(\partial f/\partial u_1, \ldots, \partial f/\partial u_n) \) is finite. In this text, a geometric spectrum \( \text{Spec}_f \) of \( f \) is an ordered sequence of rational numbers \( \alpha_1 \leq \cdots \leq \alpha_{\mu_f} \) that we will identify with the generating function \( \text{Spec}_f(z) := \sum_{i=1}^{\mu_f} z^{\alpha_i} \). The specifications are the following: the \( \alpha_i \)’s are positive numbers (positivity) and \( \text{Spec}_f(z) = z^n \text{Spec}_f(z^{-1}) \) (Poincaré duality: a geometric spectrum is symmetric about \( n/2 \)). We can ask moreover that the multiplicity of \( \alpha_1 \) in \( \text{Spec}_f \) is equal to one (normalization): this normalization is not automatic, see Section 4.3, and appears in the construction of “canonical” Frobenius manifolds in the sense of [9].

3 The toric Newton spectrum of a convenient and nondegenerate polynomial

Let \( f \) be a convenient and nondegenerate polynomial on \( \mathbb{C}^n \). In what follows, \( \mathcal{L} \) will denote the ideal generated by the partial derivative \( u_1 \frac{\partial f}{\partial u_1}, \ldots, u_n \frac{\partial f}{\partial u_n} \) of \( f \). By projection, the Newton filtration \( N_\bullet \) on \( B \) induces the Newton filtration \( N_\bullet \) on \( \frac{\mathcal{B}}{\mathcal{L}} \) and we get the graded ring \( \text{gr}^N(\frac{\mathcal{B}}{\mathcal{L}}) = \oplus_\alpha \text{gr}_{\alpha}^N(\frac{\mathcal{B}}{\mathcal{L}}) \).

**Definition 3.1** The toric Newton spectrum of a convenient and nondegenerate polynomial \( f \) is the Hilbert-Poincaré series \( P_{\text{gr}^N(\frac{\mathcal{B}}{\mathcal{L}})}(z) := \sum_{\alpha \in \mathbb{Q}} \dim \text{gr}_{\alpha}^N(\frac{\mathcal{B}}{\mathcal{L}}) z^\alpha \).
We will also see the toric Newton spectrum as the sequence of rational numbers \( \alpha \), where each \( \alpha \) is counted \( \dim \gr_{\alpha}(B) \)-times.

**Theorem 3.2** Let \( f \) be a convenient and nondegenerate polynomial on \( \mathbb{C}^n \). Then

\[
P_{\gr N}(B)(z) = (1 - z)^n \sum_{v \in \mathbb{N}^n} z^{\nu(v)}. \tag{3}
\]

In particular, the toric Newton spectrum of \( f \) depends only on its Newton polytope.

**Proof.** Let \( F_i \) be the class of \( x_i \frac{\partial f}{\partial x_i} \) in \( B_1 = \frac{B}{B_{<1}} \) and let \( F \) be the ideal generated by \( F_1, \ldots, F_n \) in \( B \). By [11, Théorème 2.8], and because \( f \) is nondegenerate, the sequence

\[
0 \to B(n) \to B(n-1) \to \cdots \to B(1) \xrightarrow{d} B \to B/F \to 0 \tag{4}
\]

that we get from the Koszul complex of the elements \( F_1, \ldots, F_n \) in the ring \( B \) is exact. It follows that the map

\[
\partial : B^n \to B \tag{5}
\]

defined by \( \partial(b_1, \ldots, b_n) = b_1 u_1 \frac{\partial f}{\partial u_1} + \cdots + b_n u_n \frac{\partial f}{\partial u_n} \) is strict with respect to the Newton filtration, see [11, Théorème 4.1]. Hence \( \gr N(B) \cong \frac{B}{F} \) and

\[
P_{\gr N}(B)(z) = P_{B/F}(z). \tag{6}
\]

Now, by [11], we have also

\[
P_{B/F}(z) = (1 - z)^n P_B(z) \tag{7}
\]

where \( P_B(z) \) denotes the Hilbert-Poincaré series of the graded ring \( B \).

For \( \Delta \) a closed face of \( P \) whose vertices are \( b_{i_1}, \ldots, b_{i_k} \), let us define

\[
\square(\Delta) := \{\sum_{\ell=1}^k q_\ell b_{i_\ell} : q_\ell \in [0,1[, \; \ell = 1, \ldots, k\}. \tag{8}
\]

Let \( \mathcal{F}(P) \) be the set of the closed faces of \( P \) not contained in the union of the hyperplane coordinates.

**Proposition 3.3** Let \( f \) be a convenient and nondegenerate polynomial on \( \mathbb{C}^n \) and let \( P \) be its Newton polytope. Assume that the faces of \( \mathcal{F}(P) \) are simplices. Then

\[
P_{\gr N}(B)(z) = \sum_{q=0}^{n-1} \sum_{\dim \Delta = q} (z - 1)^{n-1-q} \sum_{v \in \square(\Delta) \cap \mathbb{N}^n} z^{\nu(v)}
\]

where \( \Delta \in \mathcal{F}(P) \).

**Proof.** For \( \Delta \) a closed face of \( P \), let \( \text{Cone}(\Delta) \) be the union of the half straight lines starting from the origin and passing through \( \Delta \) and \( B_\Delta = \{g \in B, \; \text{supp}(g) \in \mathbb{N}^n \cap \text{Cone}(\Delta)\} \). Because the polynomial \( f \) is convenient, there is by [11, Proposition 2.6] an exact sequence of graded \( B \)-modules

\[
0 \to B \to C_{n-1} \to C_{n-2} \to \cdots \to C_0 \to 0
\]
where \( C_q = \oplus_{\dim \Delta = q} B_{\Delta} \) for \( \Delta \in \mathcal{F}(P) \). It follows that

\[
P_B(z) = \sum_{q=0}^{n-1} \sum_{\dim \Delta = q} (-1)^{n-1-q} P_{B_{\Delta}}(z)
\]

where \( \Delta \in \mathcal{F}(P) \). Using (7), we get

\[
P_{B/F}(z) = \sum_{q=0}^{n-1} \sum_{\dim \Delta = q} (-1)^{n-1-q}(1-z)^{n-1-q}(1-z)^{q+1} P_{B_{\Delta}}(z).
\]

Last,

\[
(1-z)^{q+1} P_{B_{\Delta}}(z) = (1-z)^{q+1} \sum_{v \in \text{Cone}(\Delta) \cap \mathbb{N}^n} z^{\nu(v)} = \sum_{v \in \text{Cone}(\Delta) \cap \mathbb{N}^n} z^{\nu(v)}
\]

if \( \Delta \in \mathcal{F}(P) \) is a simplex and \( \dim \Delta = q \). Now the assertion follows from (6).

\[\square\]

**Remark 3.4** We get \( \dim_{\mathbb{C}} \frac{\mathbb{R}}{Z} = \mu_P \) where \( \mu_P := n! \text{vol}(P) \), the volume \( \text{vol}(P) \) of the Newton polytope \( P \) being normalized such that the volume of the cube is equal to one. See also [11, Théorème A.1 and Section 5].

Last, we give some expected consequences of the previous results (in particular we will get a complete description of the toric Newton spectrum for \( n = 2 \), compare with [9, Example 4.17] and [14, Lemma 3.13]). If \( I \) is an interval of \( \mathbb{R} \) and \( P_C(z) = \sum_{\alpha \in \mathbb{Q}} \dim C_\alpha z^\alpha \) we define \( P^I_C(z) = \sum_{\alpha \in I} \dim C_\alpha z^\alpha \).

**Corollary 3.5** Let \( f \) be a convenient and nondegenerate polynomial on \( \mathbb{C}^n \) and let \( P \) be its Newton polytope. Then,

1. \( P_{\text{gr}^{\mathbb{N}}(\frac{\mathbb{R}}{Z})}(z) = P^{[0,n]}_{\text{gr}^{\mathbb{N}}(\frac{\mathbb{R}}{Z})}(z) \) if \( P \) is simplicial,

2. \( P^{[0,1]}_{\text{gr}^{\mathbb{N}}(\frac{\mathbb{R}}{Z})}(z) = \sum_{v \in \mathbb{N}, \nu(v) < 1} z^{\nu(v)} \),

3. the multiplicity \( \mu_1 \) of 1 in \( P_{\text{gr}^{\mathbb{N}}(\frac{\mathbb{R}}{Z})}(z) \) is \( \mu_1 = \text{Card}(NB(P) \cap \mathbb{N}^n) - n \) where \( NB(P) \) denotes the Newton boundary of \( P \).

**Proof.** The first assertion follows from Proposition 3.3 because \( \nu(v) < q + 1 \) if \( v \) belongs to a \( q \)-dimensional face of \( P \). Because the map (5) is strict with respect to the Newton filtration, we have \( \mathcal{L}(f) \cap \mathcal{N}_\alpha B = \text{im} \partial \cap \mathcal{N}_\alpha B = \partial(\mathcal{N}_{\alpha-1}(B^n)) \) and because \( \mathcal{N}_\beta B = 0 \) if \( \beta < 0 \), we get

\[
\frac{\mathcal{N}_\alpha B}{\mathcal{L}(f) \cap \mathcal{N}_\alpha B + \mathcal{N}_{<\alpha} B} = \frac{\mathcal{N}_\alpha B}{\mathcal{N}_{<\alpha} B}
\]

for \( \alpha < 1 \). Thus, \( P^{[0,1]}_{\text{gr}^{\mathbb{N}}(\frac{\mathbb{R}}{Z})}(z) = \sum_{\alpha < 1} \dim B_\alpha z^\alpha \) and this shows the second assertion. The third one follows from the computation of the coefficient of \( z \) in the formula of Theorem 3.2. \[\square\]

**Remark 3.6** By Corollary 3.5 and because \( \nu(v) = 0 \) if and only if \( v = (0, \ldots, 0) \), the value 0 appears in the toric Newton spectrum with multiplicity one. In particular, the toric Newton spectrum is not symmetric about \( \frac{n}{2} \).
4 The Newton spectrum of a convenient and nondegenerate polynomial

In the first part of this section, we define the Newton spectrum and in the second part we explain how to compute it from the toric Newton spectrum. In this section, $f$ is a convenient and nondegenerate polynomial on $\mathbb{C}^n$ with Newton polytope $P$, $\mathcal{I}$ is the ideal generated by the partial derivative $\frac{\partial f}{\partial u_1}, \ldots, \frac{\partial f}{\partial u_n}$ of $f$ and $\mu_f := \dim_{\mathbb{C}} \mathbb{B}^f$ is the Milnor number of $f$.

4.1 The Newton spectrum

We define an increasing filtration, indexed by $\mathbb{Q}$, $W_\bullet$ on $\mathcal{B} := \mathbb{C}[u_1, \ldots, u_n]$ by

$$W_\alpha \mathcal{B} := \{ g \in \mathcal{B} : \text{supp}(gu_1 \cdots u_n) \in \nu^{-1}([-\infty; \alpha]) \}.$$  

By projection, we get a filtration on $\mathbb{B}^f$. We set $B_\alpha^* := \text{gr}_{\alpha}^W \mathbb{B}^f$ and $B^* := \bigoplus_\alpha B_\alpha^*$.

**Definition 4.1** The Newton spectrum of the convenient and nondegenerate polynomial $f$ is the Hilbert-Poincaré series $P_{B^*}(z) = \sum_{\alpha \in \mathbb{Q}} \dim B_\alpha^* z^\alpha$.

The Newton spectrum can be seen as a sequence of rational numbers with the following property: the frequency of $\alpha$ in the sequence is equal to $\dim B_\alpha^*$.

In order to justify this definition (in particular to explain the twist by $u_1 \cdots u_n$), we recall the definition of the spectrum at infinity of a convenient and nondegenerate polynomial $f$ defined on $U = \mathbb{C}^n$ (we use the notations of [9, 2.c]). Let $G$ be the Fourier-Laplace transform of the Gauss-Manin system of $f$ and let $G_0$ be its Brieskorn lattice. Because $f$ is convenient and nondegenerate, $G_0$ is indeed a free $\mathbb{C}[\theta]$-module of rank $\mu_f$ and $G = \mathbb{C}[\theta, \theta^{-1}] \otimes G_0$: this follows for instance from the strictness of the map [5], see [9, Remark 4.8]. Last, let $V_\bullet$ be the $V$-filtration of $G$ at infinity, that is along $\theta^{-1} = 0$. It provides, by projection, a $V$-filtration on the $\mu_f$-dimensional vector space $\Omega_f := \Omega^n(U)/df \wedge \Omega^{n-1}(U) = G_0/\theta G_0$.

**Definition 4.2** The spectrum at infinity of a convenient and nondegenerate polynomial $f$ is the sequence $\alpha_1, \alpha_2, \ldots, \alpha_{\mu_f}$ of rational numbers with the following property: the frequency of $\alpha$ in the sequence is equal to $\dim \text{gr}_{\alpha}^V \Omega_f$.

By [12], the spectrum at infinity is a geometric spectrum. Notice however that it does not satisfy the normalization condition in general, see Example [13]

In order to define a Newton filtration on $\Omega^n(U)$, we decrete that the Newton order of the volume form $\frac{du_1}{u_1} \wedge \cdots \wedge \frac{du_n}{u_n}$ is zero: the Newton filtration $N_\bullet$ on $\Omega^n(U)$ is thus the increasing filtration $N_\bullet$ indexed by $\mathbb{Q}$ such that

$$N_\alpha \Omega^n(U) := \{ \omega \in \Omega^n(U), \text{supp}(\omega) \in \nu^{-1}([-\infty; \alpha]) \}$$

where $\text{supp}(\omega) = \{ m + (1, \cdots, 1) \in \mathbb{N}^n, a_m \neq 0 \}$ if $\omega = \sum_{m \in \mathbb{Z}^n} a_m u^m du_1 \wedge \cdots \wedge du_n$. This filtration induces a filtration on $\Omega_f$ and the Newton spectrum is equal to the spectrum of this Newton filtration on $\Omega_f$. This normalization is explained by the following result:

**Theorem 4.3** [12] The Newton spectrum of a convenient and nondegenerate polynomial $f$ is equal to its spectrum at infinity.

In the local case (that is if $f$ is the germ of a holomorphic function with an isolated critical point at the origin) a similar result is given in [10] and [13].
4.2 Newton spectrum vs. toric Newton spectrum

We show in this section that the Newton spectrum can be computed from the toric Newton spectrum. The first step is given by the following counterpart of [3, Proposition B.1.2.3]:

**Proposition 4.4** Let \( f \) be a convenient and nondegenerate polynomial on \( \mathbb{C}^n \). Then the multiplication by \( u_1 \cdots u_n \) induces isomorphisms

\[
\lambda_\alpha : \text{gr}^W_\alpha \frac{B}{T} \longrightarrow \text{gr}^N_\alpha \frac{B u_1 \cdots u_n + L(f)}{L(f)} \subset \text{gr}^N_\alpha \frac{B + L(f)}{L(f)}
\]

for \( \alpha \in \mathbb{Q} \).

**Proof.** Let \( g \in B \) such that \( gu_1 \cdots u_n \in L(f) \cap N_\alpha B \cap Bu_1 \cdots u_n \). Then, as in [3, Appendix 1], there exists \( g_1, \ldots, g_n \in B \) such that

\[
gu_1 \cdots u_n = u_1 \frac{\partial f}{\partial u_1} u_2 \cdots u_n g_1 + \cdots + u_n \frac{\partial f}{\partial u_n} u_1 \cdots u_{n-1} g_n
\]

and \( \nu(u_2 \cdots u_n g_1) \leq \alpha - 1, \ldots, \nu(u_1 \cdots u_{n-1} g_n) \leq \alpha - 1 \). Thus, the multiplication by \( u_1 \cdots u_n \)

induces \( \lambda : \frac{B}{T} \rightarrow \frac{B u_1 \cdots u_n}{L(f) \cap Bu_1 \cdots u_n} \) and injective maps

\[
\lambda_\alpha : \frac{W_\alpha B}{T \cap W_\alpha B + W_{<\alpha} B} \rightarrow \frac{N_\alpha B \cap Bu_1 \cdots u_n}{L(f) \cap N_\alpha B \cap Bu_1 \cdots u_n + N_{<\alpha} B \cap Bu_1 \cdots u_n}.
\]

\( \square \)

**Corollary 4.5** Assume that the Newton polytope \( P \) of \( f \) is simplicial. Then the Newton spectrum of \( f \) is contained in \([0, n]\).

**Proof.** By Corollary 3.5 and Proposition 4.4, \( \text{gr}^W_\beta \frac{B}{T} = 0 \) for all \( \beta \geq n \). And \( \text{gr}^W_0 \frac{B}{T} = 0 \) because \( W_0(\frac{B}{T}) = 0 \).

For \( 1 \leq p \leq n \), let \( I_p = \{(i_1, \cdots, i_p), \ 1 \leq i_1 < \cdots < i_p \leq n\} \) and let \( P^{(i_1, \cdots, i_p)}_{\text{gr}^N(\frac{B}{T})}(z) \) be the toric Newton spectrum of the restriction \( f_{(i_1, \cdots, i_p)} \) of \( f \) at \( u_{i_1} = \cdots = u_{i_p} = 0 \), with the convention \( P^{(1, \cdots, n)}_{\text{gr}^N(\frac{B}{T})}(z) = 1 \). The restrictions \( f_{(i_1, \cdots, i_p)} \) are convenient and nondegenerate if \( f \) is so.

**Theorem 4.6** Let \( f \) be a convenient and nondegenerate polynomial with Newton polytope \( P \). Then

\[
P_B^*(z) = P^{(1, \cdots, n)}_{\text{gr}^N(\frac{B}{T})}(z) + \sum_{p=1}^{n-1} (-1)^p \sum_{(i_1, \cdots, i_p) \in I_p} P^{(i_1, \cdots, i_p)}_{\text{gr}^N(\frac{B}{T})}(z) + (-1)^n.
\]

**Proof.** Assume that \( gu_1 \cdots u_{n-1} \in L(f) \cap N_\alpha C[u_1, \ldots, u_n]u_1 \cdots u_{n-1} \). Then, by [3, Appendix 1], there exists \( g_1, \ldots, g_n \in B \) such that

\[
gu_1 \cdots u_{n-1} = u_1 \frac{\partial f}{\partial u_1} u_2 \cdots u_{n-1} g_1 + \cdots + u_{n-1} \frac{\partial f}{\partial u_{n-1}} u_2 \cdots u_{n-2} g_{n-1} + u_n \frac{\partial f}{\partial u_n} u_1 \cdots u_{n-1} g_n
\]
Hence \( g = \frac{\partial f}{\partial u_1} g_1 + \cdots + \frac{\partial f}{\partial u_n} g_n \). We deduce the isomorphisms (put \( u_n = 0 \) in the previous formula), induced by the multiplication by \( u_1 \cdots u_{n-1} \) as in proposition 4.4

\[
\text{gr}_a^W \frac{\mathbb{C}[u'_1]}{\langle \frac{\partial f}{\partial u_1}(u'_1,0), \ldots, \frac{\partial f}{\partial u_n}(u'_1,0) \rangle} \cong \text{gr}_a^N \frac{\mathbb{C}[u_1, \ldots, u_{n-1} | u_1 \cdots u_{n-1}]}{L(f) \cap \mathbb{C}[u_1, \ldots, u_{n-1} | u_1 \cdots u_{n-1}]} \tag{10}
\]

where \( u' = (u_1, \ldots, u_{n-1}) \). We also have \( P_{B^*}(1) = \mu_f \) because the filtration \( W_\bullet \) is exhaustive and finite on \( B \). By [11, Théorème 1.15], it follows that

\[
P_{B^*}(1) = n!V_n - (n-1)!V_{n-1} + \cdots + (-1)^{n-1}V_1 + (-1)^n
\]

where, for \( 1 \leq q \leq n-1 \), \( V_q \) is the sum of the \( q \)-dimensional volumes of the intersection of \( P \) with the hyperplane coordinates of dimension \( q \). Because \( P_{\text{gr}^N(B)}(1) = n!V_n \), a dimension argument, proposition 4.4 and equation (10) yield

\[
P_{\text{gr}^N(B)}(z) = P_{B^*}(z) + \sum_{p=1}^n \sum_{(i_1, \ldots, i_p) \in I_p} P_{B^*}^{(i_1, \ldots, i_p)}(z)
\]

where \( P_{B^*}^{(i_1, \ldots, i_p)}(z) \) is the Newton spectrum of \( f_{(i_1, \ldots, i_p)} \), and \( P_{B^*}^{(1, \ldots, n)}(z) = 1 \). Now we are done by induction because \( P_{B^*}(z) = P_{\text{gr}^N(B)}(z) - 1 \) if \( n = 1 \) by Proposition 3.3 and Proposition 4.4.

It follows from Theorem 3.2 that the Newton spectrum of \( f \) depends only on its Newton polytope.

### 4.3 Examples

In the following examples, the toric Newton spectrum is computed using Proposition 3.3 and the Newton spectrum is computed using Theorem 4.6.

1. Let \( f(u, v) = u^2 + u^2 v^2 + v^2 \). Then \( \mu_P = 8 \) and \( \mu_f = 5 \). We get

\[
P_{\text{gr}^N(B)}(z) = 1 + 3z + 3z^{1/2} + z^{3/2}
\]

and

\[
P_{B^*}(z) = P_{\text{gr}^N(B)}(z) - (1 + z^{1/2}) - (1 + z^{1/2}) + 1 = z^{1/2} + 3z + z^{3/2}.
\]
2. Let \( g(u,v) = u + v + u^2v^4 \) on \( \mathbb{C}^2 \). Then \( \mu_g = 5 \) and \( \mu_P = 6 \). We get
\[
P_{B^*}(z) = z^{1/2} + z^{3/4} + z + z^{3/2} + z^{5/4}
\]
and
\[
P_{gr^N}^{P}(z) = 1 + z^{1/2} + z^{3/4} + z + z^{3/2} + z^{5/4}.
\]
Because the linear forms supporting the facets of the Newton boundary of \( g \) have equations \( u - \frac{1}{4}v \) and \( -\frac{2}{3}u + v \), the Newton order of the volume form \( du \wedge dv \) is \( 3/4 \) and the Newton order of the form \( vdu \wedge dv \) is \( 1/2 \); the Newton order of the standard volume form \( du \wedge dv \) is not necessarily the smallest element in the Newton spectrum.

3. Let \( f(u,v,w) = u + v + w + u^2v^2w^2 + v^2w^2 \). Then \( \mu_P = 12 \) and \( \mu_f = 8 \). We first analyze the contributions of \( v \in \Delta(\Delta), \Delta \in \mathcal{F}(P) \):

- the contribution of \( v = (0,0,0) \) is \( 4 + 4(z-1) + (z-1)^2 = z^2 + 2z + 1 \),
- the contribution of \( v = (1,1,1) \) is \( 4 + 4(z-1) + (z-1)^2)z^{1/2} = (z^2 + 2z + 1)z^{1/2} \),
- the contribution of \( v = (1,2,2) \) is \( (2 + (z-1))z = (z+1)z = z + z^2 \),
- the contribution of \( v = (0,1,1) \) is \( (2 + (z-1))z^{1/2} = (z+1)z^{1/2} = z^{1/2} + z^{3/2} \).

Thus,
\[
P_{gr^N}^{P}(z) = 1 + 2z^{1/2} + 3z^{3/2} + 3z + 2z^2 + z^{5/2}
\]
and
\[
P_{B^*}(z) = P_{gr^N}^{P}(z) - (3 + z^{1/2} + z + z^{3/2}) + 3 - 1 = z^{1/2} + 2z^{3/2} + 2z + 2z^2 + z^{5/2}.
\]

5 Interlude: Hodge-Deligne polynomials of non-complete toric varieties

In this section, \( f \) is a convenient and nondegenerate polynomial defined on \( \mathbb{C}^n \) with Newton polytope \( P \). We define here some Hodge-Deligne polynomials that we will use in Section 6.

Let \( \Sigma \) be the fan in \( \mathbb{R}^n \) obtained by taking the cones over the faces of the Newton boundary of \( P \) and let \( X_{\Sigma} \) be the toric variety associated with the fan \( \Sigma \). We will call \( \Sigma \) the fan of \( P \) and \( X_{\Sigma} \) the toric variety of \( P \). We will denote by \( \Sigma^* \) the set of the cones of \( \Sigma \) not contained in the hyperplane coordinates.

**Definition 5.1** Let \( v \in \mathbb{N}^n \) and let \( \sigma(v) \) be the smallest cone of \( \Sigma \) containing \( v \). Then,

1. \( E_v(z) := \sum_{\tau \in \Sigma, \sigma(v) \subseteq \tau} (z-1)^{n-\dim \tau} \) is the Hodge-Deligne polynomial of \( v \),
2. \( E_v^*(z) := \sum_{\tau \in \Sigma^*, \sigma(v) \subseteq \tau} (z-1)^{n-\dim \tau} \) is the relative Hodge-Deligne polynomial of \( v \).

The case \( v = 0 \) deserves a special attention: we will call \( E_0(z) \) the Hodge-Deligne polynomial of the toric variety \( X_{\Sigma} \) and \( E_0^*(z) \) the relative Hodge-Deligne polynomial of \( X_{\Sigma} \).

Let \( \Sigma_i \) be the trace of \( \Sigma \) on the hyperplane coordinates of dimension \( i \) and let \( \Sigma_i^* \) be the set of cones of \( \Sigma_i \) not contained in the hyperplane coordinates of dimension less than \( i \).
Definition 5.2 Let $v \in \mathbb{N}^n$. The polynomial
\[
E_v^\circ(z) := \sum_{\sigma(v) \subseteq \tau, \tau \in \Sigma^*} (z - 1)^{n - \dim \tau} + \sum_{q=1}^{n-1} (-1)^q \sum_{\sigma(v) \subseteq \tau, \tau \in \Sigma^*_{n-q}} (z - 1)^{n-q - \dim \tau}
\]
is the Kouchnirenko-Hodge-Deligne polynomial of $v$.

We will call the polynomial $E_0^\circ(z)$ the Kouchnirenko-Hodge-Deligne polynomial of $X_{\Sigma}$.

Proposition 5.3 Assume that $P$ is simplicial. Then $E_0^\circ(z) = E_0^*(z) - 1 = E_0(z) - z^n$.

Proof. We have
\[
E_0^\circ(z) = E_0^*(z) + \sum_{q=1}^{n-1} (-1)^q \sum_{\tau \in \Sigma^*_{n-q}} (z - 1)^{n-q - \dim \tau} + (-1)^n
\]
and this is equal to $E_0^*(z) - 1$ by the simpliciality condition. Thanks again to the simpliciality assumption, we have
\[
E_0(z) = E_0^\circ(z) + \sum_{i=0}^{n-1} \binom{n}{i} (z - 1)^{n-i} = E_0^*(z) + z^n - 1
\]
and the second equality follows. \hfill \Box

Example 5.4 Assume that $n = 2$. Then $E_0(z) = z^2 + cz$, $E_0^*(z) = cz + 1$, and $E_0^\circ(z) = cz$ where $c$ is the number of vertices of $P$ not contained in the hyperplane coordinates.

Theorem 5.5 Let $f$ be a convenient and nondegenerate polynomial on $\mathbb{C}^n$ and let $P$ be its Newton polytope. Assume that $\Sigma$ is simplicial. Then:

1. $X_\Sigma$ has no odd cohomology and
\[
E_0(z) = \sum_{k=0}^{n} \dim H^k_c(X_\Sigma, \mathbb{Q}) z^k.
\] (11)

2. We have
\[
z^n E_0(z^{-1}) = E_0^*(z).
\] (12)

3. We have
\[
z^n E_0^\circ(z^{-1}) = E_0^\circ(z)
\] (13)
if $P$ is moreover simplicial.

Proof. For the first point we follow closely [14, Lemma 4.1]: let us denote by $\rho$ the ray in $-|\Sigma|$ whose primitive generator is $v_\rho = (-1, \cdots, -1) \in \mathbb{Z}^n$ and let $\Sigma'$ (resp. $\Sigma'_\rho$) be the fan given by the cones of $\Sigma$ and the cones generated by $\rho$ and the cones of $\Sigma$ contained in the hyperplane coordinates (resp. be the quotient fan $\Sigma'/\rho$, see also Section 6.2). By the proof of loc. cit., we have an exact sequence of cohomology with compact support
\[
0 \rightarrow H^{2i}_c(X_\Sigma, \mathbb{Q}) \rightarrow H^{2i}_c(X_{\Sigma'}, \mathbb{Q}) \rightarrow H^{2i}_c(X_{\Sigma'_\rho}, \mathbb{Q}) \rightarrow 0.
\]

10
Because $X_{\Sigma'}$ and $X_{\Sigma''}$ are complete and simplicial, formula (14) holds for $X_{\Sigma'}$ and $X_{\Sigma''}$ (see for instance [5, Section 14]) and we get

$$
\sum_{k=0}^{n} \dim H^{2k}_{c}(X_{\Sigma}, \mathbb{Q}) z^{k} = E^{\Sigma'}_{0}(z) = E^{\Sigma''}_{0}(z)
$$

where $E^{\Sigma'}_{0}(z)$ (resp. $E^{\Sigma''}_{0}(z)$) denotes the Hodge-Deligne polynomial of $X_{\Sigma'}$ (resp. $X_{\Sigma''}$). In order to get the second equality, we have used two facts: first, the orbit closure $V(\varphi) = \cup_{\varphi \leq \tau} O(\tau)$ of the orbit $O(\varphi)$ and the toric variety $X_{\Sigma/\varphi}$ are isomorphic, see for instance [4, Proposition 3.2.7]; second, the Hodge-Deligne polynomial of $\mathbb{C}^*$ is $z - 1$ and $O(\tau) \cong (\mathbb{C}^*)^{n - \dim \tau}$, see [4, Section 3.2]. This shows the first point.

By Poincaré duality for the complete and simplicial toric varieties $X_{\Sigma'}$ and $X_{\Sigma''}$, we have $z^{n}E^{\Sigma'}_{0}(z^{-1}) = E^{\Sigma'}_{0}(z)$ and $z^{n-1}E^{\Sigma''}_{0}(z^{-1}) = E^{\Sigma''}_{0}(z)$. Using (14), we get

$$
z^{n}E_{0}(z^{-1}) - E_{0}(z) = (1 - z)E^{\Sigma''}_{0}(z)
$$

thus

$$
z^{n}E_{0}(z^{-1}) = E_{0}(z) - (z - 1)E^{\Sigma''}_{0}(z) = E^{\Sigma''}_{0}(z).
$$

This gives the second point. If $P$ is simplicial, we deduce, using proposition [5, 3] that $z^{n}E_{0}(z^{-1}) = z^{n}E_{0}(z^{-1}) - 1 = E^{\Sigma}_{0}(z) = E_{0}(z)$.

\textbf{Corollary 5.6} Assume that $\Sigma$ is simplicial. Then $E_{0}(z) = \sum_{i=0}^{n} \dim H^{2i}(X_{\Sigma}, \mathbb{Q}) z^{i}$.

\textbf{Proof.} Follows from (11), (12) and Poincaré duality for the simplicial toric variety $X_{\Sigma}$.

These Hodge-Deligne polynomials are also related with the $h$-vector of $P$: let $f_{i}$ be the number of the faces of $P$ of dimension $i$ (we set $f_{-1} = 1$). The $h$-vector of $P$ is $h_{P} = (h_{0}, \cdots, h_{n})$ where

$$
h_{p} = \sum_{i=p}^{n} (-1)^{i-p} \binom{i}{p} f_{n-i-1}
$$

for $p = 0, \cdots, n$.

\textbf{Proposition 5.7} Assume that $P$ is simplicial. Then

$$
E_{0}(z) = \sum_{i=0}^{n} (h_{i} - 1) z^{i} + z^{n}, \quad E^{\Sigma}_{0}(z) = \sum_{i=1}^{n} (h_{i} - 1) z^{i} + 1 \quad \text{and} \quad E^{\Sigma'}_{0}(z) = \sum_{i=0}^{n} (h_{i} - 1) z^{i}
$$

where $(h_{0}, \cdots, h_{n})$ is the $h$-vector of $P$.
Proof. We keep the notations of the proof of Theorem 5.5. Let \( P' \) be the convex hull of the vertices of \( P \) and \( v_p \). Because \( X_\Sigma \) is complete and simplicial, we have \( E_{0}^{z'} (z) = \sum_{i=0}^{n} h_{i}^{'} z^i \) where \( h_{p}^{'} = (h_{1}^{'}, \ldots, h_{n}^{'}) \) is the \( h \)-vector of \( P' \), see for instance [5] Remark 10.9. Because \( P \) is simplicial, \( P' \) and \( P \) have the same number of faces, hence \( h_{p} = h_{p}^{'} \): we get \( E_{0}^{z'} (z) = \sum_{i=0}^{n} h_{i}^{'} z^i \) and \( E_{0} (z) = \sum_{i=0}^{n} h_{i} z^i - (1 + \cdots + z^{n-1}) \) by (11). By Proposition 5.3 we also have \( E_{0}^{z'} (z) = E_{0} (z) - z^{n} \) thus \( E_{0}^{z'} (z) = \sum_{i=0}^{n} (h_{i} - 1) z^i \).

Remark 5.8 If \( P \) is simplicial, \( z^{n} E_{0}^{z'} (z^{-1}) = E_{0}^{z'} (z) \) is thus equivalent to \( h_{p} = h_{n-p} \) for \( p = 0, \cdots, n \): these are the Dehn-Sommerville equations, see for instance [4] Exercise 9.4.10.

6 The Newton spectrum and orbifold cohomology

We now express the Newton spectrum of a convenient and nondegenerate polynomial \( f \) in terms of Hilbert-Poincaré series of toric varieties. We keep the notations of Section 5: \( f \) is a convenient and nondegenerate polynomial defined on \( \mathbb{C}^{n} \) with Newton polytope \( P \), \( \Sigma \) is the fan of \( P \), \( X_{\Sigma} \) is the (non complete) toric variety associated with the fan \( \Sigma \) and \( b_1, \cdots, b_r \) are the vertices of \( P \) different from the origin. Following [2], we will call the triple \( \Sigma = (\mathbb{Z}^{n}, \Sigma, \{b_i\}) \) the stacky fan of \( P \).

6.1 Spectra and Hodge-Deligne polynomials

Let us define, for \( \Delta \) a closed face of \( P \) whose vertices are \( b_{i_1}, \cdots, b_{i_k} \),

- \( \Box(\Delta) := \{ \sum_{\ell=1}^{k} q_{\ell} b_{i_\ell}, \ q_{\ell} \in [0,1], \ \ell = 1, \cdots, k \} \),
- \( \Box(P) := \bigcup_{\Delta \in \mathcal{F}(P)} \Box(\Delta) \),
- \( \Box(\Delta) := \bigcup_{\Delta \in \mathcal{F}(P)} \Box(\Delta) \)

(recall that \( \mathcal{F}(P) \) denotes the set of the closed faces of \( P \) not contained in the union of the hyperplane coordinates).

Theorem 6.1 Assume that \( \Sigma \) is simplicial. Then

\[
P_{g;-N_{\Sigma}}(z) = \sum_{v \in \Box(P) \cap \mathbb{N}^{n}} E_{v}^{*}(z) z^{\nu(v)}
\]

and

\[
P_{B}^{*}(z) = \sum_{v \in \Box(P) \cap \mathbb{N}^{n}} E_{v}^{*}(z) z^{\nu(v)} + \sum_{v \in P \cap H \cap \mathbb{N}^{n}} E_{v}^{0}(z) z^{\nu(v)}
\]

where \( H \) denotes the union of the hyperplane coordinates.

Proof. Equality (15) follows from Proposition 3.3 and (16) then follows from Theorem 4.6.
Proof. Let us first notice that $z^n P_B^*(z^{-1}) = P_{B^*}(z)$ if and only if
\[ z^n \sum_{v \in \text{Box}(P) \cap \mathbb{N}^n} E_v^\circ(z^{-1}) z^{-\nu(v)} = \sum_{v \in \text{Box}(P) \cap \mathbb{N}^n} E_v^\circ(z) z^{\nu(v)}. \tag{17} \]
Indeed, if $v$ doesn’t belong to the hyperplane coordinates, the polynomial $E_v^*(z)$ is the Hodge-Deligne polynomial of the orbit closure $V(\sigma(v))$ and we have $z^{n-\dim \sigma(v)} E_v^*(z^{-1}) = E_v^*(z)$ by Poincaré duality for the simplicial complete toric variety $V(\sigma(v))$. Thus
\[ z^n \sum_{v \in \text{Box}(P) \cap \mathbb{N}^n} E_v^*(z^{-1}) z^{-\nu(v)} = \sum_{v \in \text{Box}(P) \cap \mathbb{N}^n} E_v^*(z) z^{\dim \sigma(v)-\nu(v)} = \sum_{v \in \text{Box}(P) \cap \mathbb{N}^n} E_v^*(z) z^{\nu(v)} \]
and we get the assertion using (16). Now, (17) holds because $z^{n-\dim \sigma(v)} E_v^*(z^{-1}) = E_v^0(z)$ by Theorem 5.5 (by the simpliciality condition, the numbers $\nu(v)$ are symmetric about $\frac{\dim \sigma(v)}{2}$).

6.2 (Toric) Newton spectrum and (orbifold) cohomology
For $\sigma$ a cone in the fan $\Sigma$, we define the quotient fan $\Sigma/\sigma := \{ \tilde{\tau} = \tau + (L_\sigma)_\mathbb{R}, \, \tau \subseteq \tau, \, \tau \in \Sigma \}$ in $L(\sigma)_\mathbb{R}$, where $L_\sigma$ is the sublattice of $L := \mathbb{Z}^n$ generated by the points of $\sigma \cap L$ and $L(\sigma) := L/L_\sigma$. For $v \in \mathbb{N}^n$, let $\sigma(v)$ be the smallest cone of $\Sigma$ containing $v$ and let $X_{\Sigma/\sigma(v)}$ be the toric variety associated with the quotient fan $\Sigma/\sigma(v)$. We define, for $\alpha \in \mathbb{Q}$,
\[ H^2_{K^\sigma}(\Sigma, \mathbb{Q}) := \bigoplus_{v \in \text{Box}(P) \cap \mathbb{N}^n} H^{2(\alpha-\nu(v))}(X_{\Sigma/\sigma(v)}, \mathbb{Q}) \bigoplus \bigoplus_{v \in \text{Box}(P) \cap \mathbb{N}^n} \tilde{H}^{2(\alpha-\nu(v))}(X_{\Sigma/\sigma(v)}, \mathbb{Q}) \]
where $\tilde{H}^{2\beta}(X_{\Sigma/\sigma(v)}, \mathbb{Q}) = H^{23}(X_{\Sigma/\sigma(v)}, \mathbb{Q})$ if $\beta \neq 0$ and $\tilde{H}^0(X_{\Sigma/\sigma(v)}, \mathbb{Q}) = 0$ (recall that $H$ denotes the union of the hyperplane coordinates).

Theorem 6.3 Let $f$ be a convenient and nondegenerate polynomial. Assume that its Newton polytope $P$ is simplicial. Then
\[ P_{B^*}(z) = \sum_{\alpha \in \mathbb{Q}} \dim H^{2\alpha}_{K^\sigma}(\Sigma, \mathbb{Q}) z^{\alpha}. \]

Proof. If $v \in \text{Box}(P)$, $E_v^*(z)$ is the Hodge-Deligne polynomial of the orbit closure $V(\sigma(v))$ and the first summand in the definition of $H^{2\alpha}_{K^\sigma}(\Sigma, \mathbb{Q})$ corresponds to the first term on the right hand side of the equality (16) in Theorem 6.1. The second summand corresponds to the second term on the right hand side of the equality (16) in Theorem 6.1 because $E_v^0(z) = \sum_{i \geq 1} \dim \tilde{H}^{2i}(X_{\Sigma/\sigma(v)}, \mathbb{Q}) z^i$ by proposition 5.4 and corollary 5.6.

Remark 6.4 Theorem 6.3 explains integral shifts in the Newton spectrum: if $v \in \text{Box}(P) \cap N$ then the sequence $\nu(v), \nu(v)+1, \ldots, \nu(v)+n-\dim \sigma(v)$ is a part of the Newton spectrum. This is closely related with the size of the Jordan blocks of the monodromy of $f$ at infinity: such a $v$ produces a block of size $n - \dim \sigma(v) + 1$ for the eigenvalue $\exp(2i\pi \nu(v))$.

Example 6.5 Assume that $n = 2$. If $v \in P \cap H \cap \mathbb{N}^2$ and $v \neq 0$, we have $\tilde{H}^{2i}(X_{\Sigma/\sigma(v)}, \mathbb{Q}) = 0$ for all $i$. If $v = 0$, $\dim \tilde{H}^{2i}(X_{\Sigma}, \mathbb{Q}) = c$ if $i = 1$ (where $c$ denotes the number of vertices of $P$ not contained in the hyperplane coordinates), 0 otherwise.
For $\alpha \in \mathbb{Q}$, let us now define
\[ H_{K,\text{tor}}^{2\alpha}(\Sigma, \mathbb{Q}) := \bigoplus_{v \in \square(P) \cap N} H^{2(\alpha - \nu(v))}(X_{\Sigma/\sigma(v)}, \mathbb{Q}). \]
In the same way, we get (and this is Theorem 1 in the introduction):

**Theorem 6.6** Let $f$ be a convenient and nondegenerate polynomial on $\mathbb{C}^n$. Assume that $\Sigma$ is simplicial. Then
\[ P_{\text{gr}^\mathcal{N}(\frac{\partial f}{\partial n})}(z) = \sum_{\alpha \in \mathbb{Q}} \dim \mathbb{Q} H_{\text{orb}}^{2\alpha}(\mathcal{X}, \mathbb{Q}) z^\alpha. \]

If $X_{\Sigma}$ is simplicial, one associates to the stacky fan $\Sigma$ a Deligne-Mumford stack $\mathcal{X}$ whose coarse moduli space is $X_{\Sigma}$, see [2]. We get a geometric interpretation of the toric Newton spectrum in terms of the orbifold cohomology of $\mathcal{X}$ (see for instance [1] Definition 4.8):

**Corollary 6.7** Let $f$ be a convenient and nondegenerate polynomial on $\mathbb{C}^n$. Assume that $\Sigma$ is simplicial. Then
\[ P_{\text{gr}^\mathcal{N}(\frac{\partial f}{\partial n})}(z) = \sum_{\alpha \in \mathbb{Q}} \dim \mathbb{Q} H_{\text{orb}}^{2\alpha}(\mathcal{X}, \mathbb{Q}) z^\alpha. \]

**Proof.** By [2] Proposition 4.7, $H_{\text{orb}}^{2\alpha}(\mathcal{X}, \mathbb{Q}) = \bigoplus_{v \in \square(P) \cap N} H^{2(\alpha - \nu(v))}(X_{\Sigma/\sigma(v)}, \mathbb{Q})$. \qed

**Remark 6.8** By Theorem 7.2, the Hilbert-Poincaré series $P_{\text{gr}^\mathcal{N}(\frac{\partial f}{\partial n})}(z)$ is equal to the weighted $\delta$-vector denoted by $\delta^0(t)$ in [13] and Corollary 6.7 could also be deduced from [13, Theorem 4.3].

**7 Local case**

Analogous results hold in the local case: let now $f$ be a power series with an isolated critical point at the origin, and let $\mu_0 := \dim \mathbb{C} \mathbb{C}\{u_1, \cdots, u_n\}/(\partial u_1 f, \cdots, \partial u_n f)$ be its Milnor number at the origin. Let $\Gamma_+(f)$ be the convex hull of $\bigcup_{a \in \text{supp}(f)-0}(a + \mathbb{R}_+^n)$ in $\mathbb{R}_+^n$, let $\Gamma(f)$ be the union of the compact faces of $\Gamma_+(f)$ and let $P$ be the union of all the segments starting from the origin and ending on $\Gamma(f)$: this is the Newton polyhedron of $f$.

A Newton function $\nu_0$ is defined as in Section 2 putting $\nu_0(a) = \min_F < u_F, a >$ for $a \in \mathbb{N}^n$, see [11] Section 2.1. It now satisfies $\nu_0(a + b) \geq \nu_0(a) + \nu_0(b)$ for $a, b \in \mathbb{N}^n$, with equality if $a$ and $b$ belong to the same cone. This provides a decreasing Newton filtration $\mathcal{N}_0$ on $\mathcal{A} := \mathbb{C}\{u_1, \cdots, u_n\}$, a local toric Newton spectrum $P_{\text{gr}^\mathcal{L}(\frac{\partial f}{\partial n})}(z)$ (where $\mathcal{L}$ still denotes the ideal generated by the partial derivative $u_1 \frac{\partial f}{\partial u_1}, \cdots, u_n \frac{\partial f}{\partial u_n}$ of $f$) and a local Newton spectrum. Theorem 5.2 Proposition 3.3, Theorem 4.6 and their consequences, Theorem 6.3 and Theorem 6.6 still hold with minor modifications.

Let $\Sigma$ be the fan built over the faces of the Newton boundary of $P$ (the union of the closed faces of $P$ that do not contain the origin), and let $X_{\Sigma}$ be the toric variety associated with the fan $\Sigma$. Assume that $X_{\Sigma}$ is simplicial and let $\mathcal{X}$ be the Deligne-Mumford stack associated with the stacky fan $\Sigma = (\mathbb{C}^n, \Sigma, \{b_i\})$ where the $b_i$’s are the vertices of $P$ different from the origin (see [2]).

**Theorem 7.1** Let $f \in \mathcal{A}$ be a convenient and nondegenerate power series. Assume that the fan $\Sigma$ of its Newton polyhedron is simplicial. Then
\[ P_{\text{gr}^\mathcal{N}(\frac{\partial f}{\partial n})}(z) = \sum_{\alpha \in \mathbb{Q}} \dim \mathbb{Q} H_{\text{orb}}^{2\alpha}(\mathcal{X}, \mathbb{Q}) z^\alpha. \]
8 Concluding remarks: mirror symmetry and (toric) Newton spectrum

Let $f$ be a convenient and nondegenerate polynomial defined on $\mathbb{C}^n$ with Newton polytope $P$ and let $\mathcal{X}$ be the Deligne-Mumford stack associated with the stacky fan $\Sigma = (\mathbb{Z}^n, \Sigma, \{b_i\})$ of $P$ (we assume here that $X_\Sigma$ is simplicial) as in the beginning of Section 6. After Corollary 6.7, we will say that $f$ and $\mathcal{X}$ are mirror partners if there is an isomorphism of $\mathbb{Q}$-graded rings

$$H^*_{\text{orb}}(\mathcal{X}, \mathbb{Q}) \rightarrow \text{Gr}(\mathcal{B}/\mathcal{L}).$$

Because the map (5) is strict with respect to the Newton filtration, the graded ring $\text{Gr}(\mathcal{B}/\mathcal{L})$ looks like the ”Stanley-Reisner presentation” of $\mathcal{X}$ given by the right hand side of [2, Theorem 1.1] (but we can’t use directly this result because $X_\Sigma$ is not complete). The product on $\text{Gr}(\mathcal{B}/\mathcal{L})$ is in principle easy to compute and should give, with the help of such an isomorphism, a concrete description of the orbifold product on $H^{2*}_{\text{orb}}(\mathcal{X}, \mathbb{Q})$. On the other hand, Poincaré duality on $H^2(\mathcal{X}, \mathbb{Q})$ (see for instance [1, Proposition 4.11]) should be helpful in order to understand the pairing on $\text{Gr}(\mathcal{B}/\mathcal{L})$ and possible symmetries of the toric Newton spectrum.

In the same way, a product $\ast$ on $B^* := \text{gr}^* \left( \mathcal{B}/\mathcal{L} \right)$ is defined by

$$g \ast h := \lambda^{-1} (\lambda(g) \ast \lambda(h))$$

for $g, h \in B^*$, where $\lambda : \text{gr}^W \left( \mathcal{B}/\mathcal{L} \right) \rightarrow \text{gr}^N \left( \frac{\mathcal{B}a_{i1} \cdots a_{i\nu}}{\mathcal{L}(j) / \mathcal{B}a_{1} \cdots a_{n}} \right)$ is the isomorphism of Proposition 4.4. Equipped with the (commutative and associative, but without identity) product $\ast$, $B^*$ becomes a graded ring and this would give an ”orbifold cup-product” on the vector space $H^2_{\text{orb}}(\Sigma, \mathbb{Q})$ defined in Section 6.2.

Example 8.1 Let us return to the example $f(u, v) = u^2 + u^2 v^2 + v^2$. A basis of $\text{gr}^N \left( \mathcal{B}/\mathcal{L}(j) \right)$ is given by $1, uv, u^2 v^2, u^3 v^3, u, v, u^2 v, uv^2$, with respective grading $0, \frac{1}{2}, 1, \frac{3}{2}, \frac{1}{2}, \frac{1}{2}, 1, 1$, and we get the following table for the product $\bullet$ in $\text{gr}^N \left( \mathcal{B}/\mathcal{L}(j) \right)$:

<table>
<thead>
<tr>
<th>$\bullet$</th>
<th>1</th>
<th>$uv$</th>
<th>$u^2 v^2$</th>
<th>$u^3 v^3$</th>
<th>$u$</th>
<th>$v$</th>
<th>$u^2 v$</th>
<th>$uv^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$1$</td>
<td>1</td>
<td>$uv$</td>
<td>$u^2 v^2$</td>
<td>$u^3 v^3$</td>
<td>$u$</td>
<td>$v$</td>
<td>$u^2 v$</td>
<td>$uv^2$</td>
</tr>
<tr>
<td>$uv$</td>
<td>$uv$</td>
<td>$u^2 v^2$</td>
<td>$u^3 v^3$</td>
<td>$0$</td>
<td>$u^2 v$</td>
<td>$uv^2$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$u^2 v^2$</td>
<td>$u^2 v^2$</td>
<td>$u^3 v^3$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$u^3 v^3$</td>
<td>$u^3 v^3$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$u$</td>
<td>$u$</td>
<td>$u^2 v$</td>
<td>$0$</td>
<td>$0$</td>

<td>$-u^2 v^2$</td>
<td>$0$</td>
<td>$-u^3 v^3$</td>
<td>$0$</td>
</tr>
<tr>
<td>$u^2 v$</td>
<td>$u^2 v$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$uv^2$</td>
<td>$uv^2$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$-u^3 v^3$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
</tbody>
</table>

On the cohomology side, we define an isomorphism

$$H^2_{\text{orb}}(\mathcal{X}, \mathbb{Q}) \rightarrow \text{Gr}(\mathcal{B}/\mathcal{L})$$

by the assignments

$$1_{v_0} \mapsto 1, 1_{v_1} \mapsto u, 1_{v_2} \mapsto u^2 v, 1_{v_3} \mapsto uv, 1_{v_4} \mapsto uv^2, 1_{v_5} \mapsto v, 1_{v_0} p \mapsto u^2 v^2, 1_{v_3} p \mapsto u^3 v^3.$$
A basis of the orbifold cohomology is $1_{v_0}, 1_{v_0}p, 1_{v_1}, 1_{v_2}, 1_{v_3}, 1_{v_4}, 1_{v_5}$, with respective grading $0, 1, \frac{1}{2}, 1, \frac{1}{2}, 2, \frac{3}{2}, 1, \frac{1}{2}$ and we get the following table for an “orbifold” cup-product in $H^2_{orb}(X, \mathbb{Q})$:

<table>
<thead>
<tr>
<th>$\cup_{orb}$</th>
<th>$1_{v_0}$</th>
<th>$1_{v_1}$</th>
<th>$1_{v_2}$</th>
<th>$1_{v_3}$</th>
<th>$1_{v_4}$</th>
<th>$1_{v_5}$</th>
<th>$1_{v_0}p$</th>
<th>$1_{v_3}p$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$1_{v_0}$</td>
<td>$1_{v_0}$</td>
<td>$1_{v_1}$</td>
<td>$1_{v_2}$</td>
<td>$1_{v_3}$</td>
<td>$1_{v_4}$</td>
<td>$1_{v_5}$</td>
<td>$1_{v_0}p$</td>
<td>$1_{v_3}p$</td>
</tr>
<tr>
<td>$1_{v_1}$</td>
<td>$1_{v_1}$</td>
<td>$-1_{v_0}p$</td>
<td>$-1_{v_1}p$</td>
<td>$1_{v_2}$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$1_{v_2}$</td>
<td>$1_{v_2}$</td>
<td>$-1_{v_0}p$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td></td>
</tr>
<tr>
<td>$1_{v_3}$</td>
<td>$1_{v_3}$</td>
<td>$1_{v_2}$</td>
<td>$0$</td>
<td>$1_{v_0}p$</td>
<td>$0$</td>
<td>$1_{v_4}$</td>
<td>$1_{v_0}p$</td>
<td>$0$</td>
</tr>
<tr>
<td>$1_{v_4}$</td>
<td>$1_{v_4}$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$1_{v_0}p$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$1_{v_5}$</td>
<td>$1_{v_5}$</td>
<td>$0$</td>
<td>$0$</td>
<td>$1_{v_4}$</td>
<td>$1_{v_3}p$</td>
<td>$-1_{v_0}p$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$1_{v_0}p$</td>
<td>$1_{v_0}p$</td>
<td>$0$</td>
<td>$0$</td>
<td>$1_{v_3}p$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$1_{v_3}p$</td>
<td>$1_{v_3}p$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
</tbody>
</table>
