THE MOD-$p$ HOMOLOGY OF THE CLASSIFYING SPACES OF CERTAIN GAUGE GROUPS

DAISUKE KISHIMOTO AND STEPHEN THERIAULT

Abstract. Let $G$ be a simply-connected, simple compact Lie group of type $\{n_1, \ldots, n_\ell\}$, where $n_1 < \cdots < n_\ell$. Let $G_k$ be the gauge group of the principal $G$-bundle $P \to S^4$ whose isomorphism class is determined by the second Chern class having value $k \in \mathbb{Z}$. We calculate the mod-$p$ homology of the classifying space $BG_k$ provided that $n_\ell < p - 1$ and $p$ does not divide $k$.

1. Introduction

Let $G$ be a simply-connected, simple compact Lie group. Principal $G$-bundles over $S^4$ are classified by the value of the second Chern class, which can be any integer. Let $P_k \to S^4$ represent the equivalence class of principal $G$-bundles with second Chern class equal to $k$. The gauge group of $P_k$ is the group of $G$-equivariant automorphisms of $P_k$ which fix $S^4$; we denote this group by $G_k$. The classifying space of $G_k$ is denoted by $BG_k$.

Gauge groups are fundamental in modern physics and geometry. The topology of gauge groups and their classifying spaces has proved to be of immense value in studying diffeomorphism structures on 4-manifolds [D], Yang-Mills theory [AJ], and invariants of 3-manifolds [F]. An important problem is to calculate the mod-$p$ homology of $BG_k$ for a prime $p$, as this would give rise to characteristic classes that could be used in geometric and physical contexts. When $G = SU(2)$ the mod-2 cohomology of $BG_k$ was determined by Masbaum [M] but the mod-$p$ homology or cohomology for odd primes has proved to be elusive. Regarding $SU(2)$ as $Sp(1)$, Choi [C] has some partial results. Practically nothing was known to this point for $G \neq SU(2)$.

In this paper we calculate the mod-$p$ homology of $BG_k$ under certain conditions. To state our results, we need some notation. Let $\text{Map}_k(S^4, BG)$ be the component of the space of continuous (not necessarily pointed) maps from $S^4$ to $BG$ which are of degree $k$, and similarly define $\text{Map}_k^*(S^4, BG)$ with respect to pointed maps. There is a fibration $\text{Map}_k^*(S^4, BG) \to \text{Map}_k(S^4, BG) \xrightarrow{ev} BG$ where $ev$ evaluates a map at the basepoint of $S^4$. Let $G(3)$ be the three-connected cover of $G$. For each $k \in \mathbb{Z}$, the space $\text{Map}_k^*(S^4, BG)$ is homotopy equivalent to $\Omega^3 G(3)$. By [AB, Go], there is a homotopy equivalence $BG_k \simeq \text{Map}_k(S^4, BSG)$. Thus there is a homotopy fibration

$$\Omega^3 G(3) \to BG_k \xrightarrow{ev} BG.$$
The Lie group $G$ has type $\{n_1, \ldots, n_\ell\}$ if the rational cohomology of $G$ is generated by elements in degrees $\{2n_1 - 1, \ldots, 2n_\ell - 1\}$, where $n_1 < \cdots < n_\ell$. For two integers $a, b$, let $(a, b)$ be the greatest common divisor of $a$ and $b$. Unless otherwise indicated, homology is assumed to be with mod-$p$ coefficients.

**Theorem 1.1.** Let $G$ be a simply-connected, simple compact Lie group of type $\{n_1, \ldots, n_\ell\}$ and let $p$ be a prime. If $n_\ell < p - 1$ and $(p, k) = 1$ then there is an isomorphism of $\mathbb{Z}/p\mathbb{Z}$-vector spaces

$$H_*(BG_k) \cong H_*(\Omega^3G(3)) \otimes H_*(BG).$$

The approach is to consider the Serre spectral sequence applied to the $k = 1$ case of (1). Control is obtained over the differentials by showing that they are derivations, which is not obvious, and then atomicity-style arguments (c.f. [S]) are used to show the spectral sequence must collapse at the $E^2$-term. A $p$-local homotopy equivalence $BG_k \simeq BG_1$ when $(p, k) = 1$ then completes the picture.

A notable example is when $G = SU(2)$, a case of particular interest in Donaldson Theory and 3-manifold theory. Theorem 1.1 holds if $p \geq 5$. In Section 6 we go on to also calculate the mod-3 homology of $BG_k$ provided that $(3, k) = 1$. In this case it is the Serre spectral sequence for the homotopy fibration $S^3 \to \Omega^3SU(2)(3) \to BG_k$ that collapses at the $E^2$-term.

2. Delooping the evaluation fibration

Let $j: \Sigma G \to BG$ be the canonical inclusion. The aim of this section is to show that the differentials in the homology Serre spectral sequence for the evaluation fibration

$$\text{Map}_j^*(\Sigma G, BG) \to \text{Map}_j(\Sigma G, BG) \xrightarrow{\text{can}} BG$$

are derivations. To this end, we will use the following.

**Lemma 2.1** (cf. [MT] Theorem 2.18, Part I). The differentials in the homology Serre spectral sequence for a principal fibration are derivations.

We aim to show that the evaluation fibration (2) is principal. This was proved by Tsutaya [Ts] in a more general setting when the source space of the mapping space is the $n$-th projective space $B_nG$, where $B_1G \simeq \Sigma G$. The proof is a combination of the technique of Kono and the first author [KK] and Tsutaya’s technique on $A_n$-structures. In our case, the proof drastically simplifies since we do not need $A_n$-structures. So we give here a simple proof.

Let $ad$ denote the adjoint action of $G$ on $G$ itself and $Ad$ denote the action of $G$ on the classifying space $BG$ induced from $ad$. The action $Ad$ induces an action of $G$ on $\text{Map}_j^*(Z, BG)$ which we denote by $Ad_*$.

**Lemma 2.2** (Crabb and Sutherland [CS] Corollary 3.4). There is a fiberwise homotopy equivalence

$$EG \times_{Ad_*} \text{Map}_j^*(Z, BG) \simeq \text{Map}_j(Z, BG).$$
over $BG$, where $EG \times Ad$, $Map^*_f(Z, BG)$ and $Map_f(Z, BG)$ are regarded as fiberwise spaces over $BG$ by the projection onto the first factor and the evaluation map respectively.

On the other hand, the action $Ad$ of $G$ on $BG$ induces an action of $G$ on $\Omega BG$ which is, by definition, identified with $ad$ through the natural homotopy equivalence $G \simeq \Omega BG$. Let $ad_*$ denote the action of $G$ on $Map_f^*(Z, G)$ induced from the action $ad$, where $f: \Sigma Z \to BG$ is the adjoint of a map $f: Z \to G$. Then it follows that the action $ad_*$ on $Map_f^*(Z, G)$ is identified with the action $Ad_*$ on $Map_f^*(\Sigma Z, BG)$ through the natural homotopy equivalence $Map_f^*(\Sigma Z, BG) \simeq Map_f^*(Z, G)$.

**Lemma 2.3.** There is a fiberwise homotopy equivalence

$$EG \times Ad, Map^*_f(\Sigma Z, BG) \simeq EG \times ad, Map^*_f(Z, G)$$

over $BG$, where both spaces are regarded as fiberwise spaces over $BG$ by the projection onto the first factor.

Combining Lemmas 2.2 and 2.3 gives the following.

**Corollary 2.4.** There is a fiberwise homotopy equivalence

$$EG \times ad, Map^*_f(Z, G) \simeq Map_f(\Sigma G, BG)$$

over $BG$, where $EG \times ad, Map^*_f(Z, G)$ and $Map_f(\Sigma G, BG)$ are regarded as fibrewise spaces over $BG$ by the projection onto the first factor and the evaluation map respectively.

Now regard $Map^*_f(G, G)$ as a topological monoid by the composite of maps. Let $I: G \to Map^*_f(G, G)$ be the homomorphism of topological monoids given by $I(g)(h) = ghg^{-1}$ for $g, h \in G$. Notice that $I$ is the adjoint action $ad_*$ in this case, so $EG \times ad, Map^*_f(G, G)$ is the principal $Map^*_f(G, G)$-bundle over $BG$ induced from the homomorphism $I$. Hence we obtain the following.

**Lemma 2.5.** There is a homotopy fibration

$$EG \times ad, Map^*_f(G, G) \to BG \longrightarrow BMap^*_f(G, G).$$

By Corollary 2.4, there is a fibre homotopy equivalence $EG \times ad, Map^*_f(G, G) \simeq Map_f(\Sigma G, BG)$ over $BG$. Therefore Lemma 2.5 implies the following.

**Theorem 2.6.** There is a homotopy fibration

$$Map_f(\Sigma G, BG) \xrightarrow{ev} BG \longrightarrow BMap^*_f(G, G).$$

**Corollary 2.7.** The homotopy fibration $\xrightarrow{2}$ is principal.

**Corollary 2.8.** The differentials in the homology Serre spectral sequence for the evaluation fibration $\xrightarrow{2}$ are derivations.
3. Properties of $B\mathcal{G}_k$

Now we specialize to $G$ being a simply-connected, simple compact Lie group of type $\{n_1, \ldots, n_\ell\}$ and let $p$ be a prime. The Lie group $G$ is $p$-regular if there is a $p$-local homotopy equivalence

$$G \simeq \prod_{i=1}^\ell S^{2n_i-1}.$$ 

It is well known that $G$ is $p$-regular if and only if $n_\ell \leq p$.

In this section we show that if $G$ is $p$-regular then, in the mod-$p$ homology Serre spectral sequence for the homotopy fibration $\Omega^3G(3) \to B\mathcal{G}_1 \to BG$, the differentials are derivations. We also show that for any simply-connected, simple compact Lie group $G$ there is a $p$-local homotopy equivalence $B\mathcal{G}_k \simeq B\mathcal{G}_1$ provided that $(p, k) = 1$.

Since $G$ is a simply-connected, simple compact Lie group there is a $t : S^3 \to G$ which induces the inclusion of the degree 3 generator in homology. Let $i$ be the composite

$$i : S^4 \xrightarrow{\Sigma t} \Sigma G \xrightarrow{j} BG.$$ 

The map $\Sigma t$ induces a commutative diagram of evaluation fibrations

\[
\begin{array}{ccc}
\text{Map}^*_j(\Sigma G, BG) & \longrightarrow & \text{Map}^*\Sigma G, BG) \\
\downarrow^{(\Sigma t)_{ptd}^*} & & \downarrow^{(\Sigma t)_{free}^*} \\
\text{Map}^*_i(S^4, BG) & \longrightarrow & \text{Map}^*\Sigma G, BG) \\
\end{array}
\]

Consequently, $i$ induces a map of mod-$p$ homology Serre spectral sequences from the fibration along the top row to the fibration along the bottom row. If $G$ is $p$-regular then the map $S^3 \xrightarrow{t} G$ has a left homotopy inverse when localized at $p$, implying in particular that the map $(\Sigma t)_{ptd}^*$ has right homotopy inverse when localized at $p$. Thus the map $(\Sigma t)_{ptd}^*$ is a split epimorphism in mod-$p$ homology. Therefore the differentials in the mod-$p$ homology Serre spectral sequence for the fibration along the bottom row in $(3)$ are determined by the differentials in the mod-$p$ homology Serre spectral sequence for the fibration along the top row. In the latter case, by Corollary 2.8, the differentials are derivations. Thus we obtain the following.

**Lemma 3.1.** If $G$ is $p$-regular then, in the mod-$p$ homology Serre spectral sequence for the homotopy fibration $\text{Map}^*_i(S^4, BG) \to \text{Map}^*(S^4, BG) \xrightarrow{ev} BG$, the differentials are derivations. $\square$

By definition, $i = j \circ \Sigma t$. Observe that $t$ induces the identity map in degree 3 homology and we may choose the homotopy equivalence $G \xrightarrow{s} \Omega BG$ so that it does as well. Therefore $j$, the adjoint of $s$, induces the identity in degree 4 homology. Hence $i = j \circ \Sigma i$ induces the identity in degree 4 homology. Therefore, in the notation used in the Introduction, we may identify $\text{Map}^*_i(S^4, BG)$ and...
Map\_k(S^4, BG) as Map\_k^\ast(S^4, BG) and Map\_k(S^4, BG) respectively, and therefore further identify them as \(\Omega^3 G(3)\) and \(BG_1\). Thus, rewriting Lemma 3.1 in terms of gauge groups, we obtain the following.

**Lemma 3.2.** If \(G\) is \(p\)-regular then, in the mod-\(p\) homology Serre spectral sequence for the homotopy fibration \(\Omega^3 G(3) \to BG_1 \to BG\), the differentials are derivations.

Now turn to \(\text{Map}_k(S^4, BG)\), and we return to the general case of \(G\) being a simply-connected, simple compact Lie group. Observe that the degree \(k\) map \(S^4 \overset{k}{\to} S^4\) induces a fibration diagram

\[
\begin{array}{ccc}
\text{Map}_1^\ast(S^4, BG) & \overset{\text{ev}}{\longrightarrow} & \text{Map}_1(S^4, BG) \\
\; \downarrow (\underline{k}) \; & & \; \downarrow (\underline{k})_f \; \\
\text{Map}_k^\ast(S^4, BG) & \overset{\text{ev}}{\longrightarrow} & \text{Map}_k(S^4, BG)
\end{array}
\]

(4)

Write \(\text{Map}_k^\ast(S^4, BG)\) as \(\Omega^k \text{BG}\). Since \(k\) is the three-fold suspension of the standard degree \(k\) map on \(S^3\), the map \((\underline{k})_{\text{ptd}}\) is the three-fold loops of the \(k\)th-power map on \(\Omega BG\). Using the homotopy equivalence \(\Omega BG \simeq G\), each of the spaces \(\Omega^k \text{BG}\) is homotopy equivalent as an \(H\)-space to \(\Omega^3 G(3)\), so we may rewrite \((\underline{k})_{\text{ptd}}\) as \(\Omega^3 G(3) \overset{k}{\to} \Omega^3 G(3)\).

**Lemma 3.3.** Localize at a prime \(p \geq 3\). If \((p, k) = 1\) then the map \(\text{Map}_1^\ast(S^4, BG) \overset{(\underline{k})_f}{\longrightarrow} \text{Map}_k^\ast(S^4, BG)\) is a weak homotopy equivalence.

**Proof.** Observe that for any simply-connected, simple compact Lie group \(G\), after localization at \(p \geq 3\) the space \(\Omega^3 G(3)\) is simply-connected. As \(BG\) is 3-connected, the exact sequence of homotopy groups for the homotopy fibration \(\Omega^3 G(3) \to \text{Map}_k(S^4, BG) \overset{\text{ev}}{\to} BG\) implies that \(\text{Map}_k(S^4, BG)\) is simply-connected. In particular, the homotopy groups of \(\text{Map}_k(S^4, BG)\) are abelian. Next, since \(k\) is a unit in the \(p\)-local integers, the map \(\Omega^3 G(3) \overset{k}{\to} \Omega^3 G(3)\) is a homotopy equivalence. That is, in (4), the map \((\underline{k})_{\text{ptd}}\) is a homotopy equivalence. Therefore, as (4) is a fibration diagram, the Five-Lemma implies that \((\underline{k})_f\) induces an isomorphism in all homotopy groups.

Rewriting \(\text{Map}_k(S^4, BG)\) as \(BG_k\), Lemma 3.3 has an immediate corollary.

**Corollary 3.4.** Let \(G\) be a simply-connected, simple compact Lie group. Localized at a prime \(p \geq 3\), if \((p, k) = 1\) then there is a weak homotopy equivalence \(BG_k \simeq BG_1\). 

4. THE MOD-\(p\) HOMOLOGY OF \(\Omega^3 G(3)\) WHEN \(G\) IS \(p\)-REGULAR

Localize at an odd prime \(p\) and take homology with mod-\(p\) coefficients. If \(G\) is \(p\)-regular of type \(\{n_1, \ldots, n_\ell\}\) then there is a homotopy equivalence \(G \simeq \prod_{i=1}^\ell S^{2n_i - 1}\). Therefore

\[
\Omega^3 G(3) \simeq \Omega^3 S^{3(3)} \times \prod_{i=2}^\ell \Omega^3 S^{2n_i - 1}.
\]
This is an equivalence of $H$-spaces and so induces an isomorphism of Hopf algebras in homology. In this section we record a property of $H_*(\Omega^3 G(3))$ which will be important later. This begins with a general definition.

In general, for a path-connected space $X$ of finite type, let $PH_*(X)$ be the subspace of primitive elements in $H_*(X)$. Let

$$\mathcal{P}_n: H_q(X) \rightarrow H_{q-2(p-1)n}(X)$$

be the hom-dual of the Steenrod operation $\mathcal{P}_n$. Then from the mod-$p$ Steenrod algebra $A$ we obtain an opposite algebra $A^e$, which acts from the left on $H_*(X)$. For $r \geq 1$, let $\beta^r$ be the $r$th-Bockstein. Let $MH_*(X)$ be the subspace of $PH_*(X)$ defined by

$$MH_*(X) = \{ x \in PH_*(X) \mid \mathcal{P}_n^*(x) = 0 \text{ for all } n > 0 \text{ and } \beta^r(x) = 0 \text{ for all } r \geq 1 \}.$$

Since $MH_*(X)$ records information about the primitive elements in $H_*(X)$, if $X \simeq A \times B$ then

$$MH_*(X) = M(H_*(A) \otimes H_*(B)) = MH_*(A) \oplus MH_*(B).$$

Now consider $MH_*(\Omega^3 G(3))$. The product decomposition for $\Omega^3 G(3)$ implies that

$$MH_*(\Omega^3 G) = MH_*(\Omega^3 S^3(3)) \oplus \left( \bigoplus_{i=2}^\infty MH_*(\Omega^3 S^{2n_i-1}) \right).$$

By [CLM] there is an isomorphism of Hopf algebras

$$H_*(\Omega^3 S^{2n+1}) \cong \bigotimes_{k \geq 1, j \geq 0} A(\bar{a}_{2(np^k-1)p^j-1}) \otimes \bigotimes_{k \geq 1, j \geq 1} \mathbb{Z}/p\mathbb{Z}[b_{2(np^k-1)p^j-2}] \otimes \bigotimes_{k \geq 0} \mathbb{Z}/p\mathbb{Z}[c_{2n^k-2}].$$

Here, the generators are primitive and many are related by the action of the dual Steenrod algebra. Selick [S] determined $MH_*(\Omega^3 S^{2n+1})$ in full, we record only the subset of elements of odd degree.

**Lemma 4.1.** $MH_*(\Omega^3 S^{2n+1})_{\text{odd}} = \{ a_{2np-3} \}$. \qed

In the references that follow for $\Omega^3 S^3(3)$, the statements in [Th] are in terms of Anick spaces, but by [GT] the space $\Omega S^3(3)$ is homotopy equivalent to the Anick space $T^{2p+1}(p)$ for $p \geq 3$. By [Th Prop. 4.1], for $p$ odd there is an isomorphism of Hopf algebras

$$H_*(\Omega^3 S^3(3)) \cong H_*(\Omega^2 S^{2p-1}) \otimes H_*(\Omega^3 S^{2p+1}).$$

This can be phrased in terms of a generating set using the isomorphism of Hopf algebras

$$H_*(\Omega^2 S^{2p-1}) \cong \bigotimes_{k=0}^\infty A(\bar{a}_{(p-1)p^k-1}) \otimes \bigotimes_{k=1}^\infty \mathbb{Z}/p\mathbb{Z}[b_{2(p-1)p^k-2}]$$

proved in [CLM] and the $n = p$ case of [G]. Again, the generators are primitive and many are related by the action of the dual Steenrod algebra. A description of $MH_*(\Omega^3 S^3(3))$ in full was given in [Th Lemma 4.2], but again we need only record the subset of elements of odd degree.

**Lemma 4.2.** $MH_*(\Omega^3 S^3(3))_{\text{odd}} = \{ a_{2p-3} \}$. \qed
Combining (5), Lemmas 4.1 and 4.2 we obtain the following.

**Lemma 4.3.** If \( G \) is \( p \)-regular of type \( \{ n_1, \ldots, n_\ell \} \) then

\[
MH_*(\Omega^3 G(3))_{\text{odd}} = \{ \bar{a}_{2p-3}, a_{2n_{2p-3}}, \ldots, a_{2n_{p-3}} \}.
\]

\[\square\]

5. THE MOD-\( p \) HOMOLOGY OF \( BG_1 \) AND THE PROOF OF THEOREM 1.1

We continue to assume that all spaces and maps have been localized at an odd prime \( p \) and take homology with mod-\( p \) coefficients. Consider the homotopy fibration sequence

\[
G \xrightarrow{\partial_1} \Omega^3 G(3) \xrightarrow{g_1} BG_1 \xrightarrow{ev} BG
\]

where \( g_1 \) is simply a name for the map \( \Omega^3 G(3) \to BG_1 \), and \( \partial_1 \) is the fibration connecting map. After identifying when the map \( \partial_1 \) is null homotopic, we show that in those cases the map \( g_1 \) induces an injection in homology. This then leads to Theorem 1.1.

When \( G = SU(n) \) or \( Sp(n) \) the identification of when \( \partial_1 \) is null homotopic is easily deduced from results of Bott [B] and Lang [L]. The identification in general is due to Hasui, the first author, and Ohsita [HKO].

**Lemma 5.1.** Let \( G \) be a simply-connected, simple compact Lie group of type \( \{ n_1, \ldots, n_\ell \} \). Then \( \partial_1 \) is null homotopic if and only if \( n_\ell < p - 1 \).

\[\square\]

**Corollary 5.2.** There is a homotopy equivalence \( G_1 \simeq G \times \Omega^3 G(3) \) if and only if \( n_\ell < p - 1 \).

The condition \( n_\ell < p - 1 \) in Lemma 5.1 implies that \( G \) is \( p \)-regular, so \( g_1 \) may be regarded as a map

\[
\Omega^3 S^3(3) \times \prod_{i=2}^{\ell} \Omega^3 S^{2n_{i-1}} \xrightarrow{g_1} BG_1.
\]

By Lemma 4.3

\[
MH_*(\Omega^3 G(3))_{\text{odd}} = \{ \bar{a}_{2p-3}, a_{2n_{2p-3}}, \ldots, a_{2n_{p-3}} \},
\]

where \( \bar{a}_{2p-3} \in H_*(\Omega^3 S^3(3)) \).

**Lemma 5.3.** If \( n_\ell < p - 1 \) then the restriction of \( (g_1)_* \) to \( MH_*(\Omega^3 G(3)) \) is an injection.

**Proof.** First, for \( n \geq 2 \), consider the homotopy fibration \( \Omega^4 S^{2n+1} \to \ast \to \Omega^3 S^{2n+1} \). We claim that the element \( a_{2n_{p-3}} \in H_*(\Omega^4 S^{2n+1}) \) transgresses to a nonzero element in \( H_*(\Omega^5 S^{2n+1}) \). To see this, let \( E^2 : S^{2n-1} \to \Omega^2 S^{2n+1} \) be the double suspension. Let \( W_n \) be the homotopy fibre of \( E^2 \). Then there is a homotopy fibration \( \Omega S^{2n+1} \xrightarrow{E^2} \Omega^3 S^{2n+1} \to W_n \). By [CLM] this fibration induces an isomorphism of Hopf algebras

\[
H_*(\Omega^3 S^{2n+1}) \cong H_*(\Omega S^{2n+1}) \otimes H_*(W_n).
\]
In particular, the element \( a_{2np-3} \in H_\ast (\Omega^3 S^{2n+1}) \) corresponds to an element \( c \in H_{2np-3}(W_n) \). On the other hand, \( W_n \) is \((2np-4)\)-connected and has a single cell in dimension \( 2np-3 \), so \( c \) represents the inclusion of the bottom cell. Now consider the homotopy fibration diagram

\[
\begin{array}{ccc}
\Omega^2 S^{2n+1} & \xrightarrow{\Omega^2 E^2} & \Omega^4 S^{2n+1} \\
\downarrow & & \downarrow \\
\ast & \xrightarrow{} & \ast \\
\Omega S^{2n+1} & \xrightarrow{\Omega E^2} & \Omega^3 S^{2n+1} \\
\downarrow & & \downarrow \\
& & \ast \\
\end{array}
\]

As \( c \) represents the bottom cell in \( H_{2np-3}(W_n) \), it transgresses nontrivially to a class \( d \in H_{2np-4}(\Omega W_n) \). Since \( a_{2np-3} \) maps to \( c \), the naturality of the transgression implies that \( a_{2np-3} \) must transgress to a nontrivial class in \( H_{2np-4}(\Omega^4 S^{2n+1}) \).

Next, consider the homotopy fibration diagram

\[
\begin{array}{ccc}
\Omega^4 G(3) & \xrightarrow{\Omega g_1} & G_1 \xrightarrow{\Omega ev} G \\
\downarrow & & \downarrow \\
\ast & \xrightarrow{} & \ast \\
\Omega^3 G(3) & \xrightarrow{\Omega g_1} & BG_1 \xrightarrow{ev} G. \\
\end{array}
\]

Since \( n \leq p-1 \), by Corollary 5.2 the map \( \Omega g_1 \) has a left homotopy inverse. In particular, \( (\Omega g_1)_\ast \) is an injection. Since \( G \) is \( p \)-regular, the left column in the fibration diagram is a product of the path-loop fibrations \( \Omega^4 S^3(3) \to \ast \to \Omega^2 S^3(3) \) and, for \( 2 \leq i \leq n \), \( \Omega^4 S^{2n_i-1} \to \ast \to \Omega^3 S^{2n_i-1} \).

Therefore, by the argument in the first paragraph of the proof, the element \( a_{2n_i-1} \in MH_\ast (\Omega^3 G(3)) \) transgresses to a nontrivial element in \( H_{2np-4}(\Omega^4 G(3)) \). As this element injects into \( H_{2np-4}(G_1) \), the naturality of the transgression implies that \( (g_1)_\ast (a_{2n_i-3}) \) must be nontrivial.

Finally, consider the element \( \bar{a}_{2p-3} \in H_\ast (\Omega^3 G(3)) \). It comes from an element \( x \in H_{2np-3}(\Omega^3 S^3(3)) \). The description of \( H_\ast (\Omega^3 G(3)) \) in (7) implies that \( \Omega^3 S^3(3) \) is \((2p-4)\)-connected and has a single cell in dimension \( 2p-3 \). Thus \( x \) represents the inclusion of the bottom cell. Therefore, \( x \) transgresses to a nontrivial element in \( H_{2np-4}(\Omega^4 S^3(3)) \), and so \( \bar{a}_{2p-3} \) transgresses to a nontrivial element in \( H_{2p-4}(\Omega^4 G(3)) \). Since \( (\Omega g_1)_\ast \) is an injection, the naturality of the transgression in (8) implies that \( (g_1)_\ast (a_{2p-3}) \) is nontrivial.

Now we put things together to give a condition for when the map \( \Omega^3 G(3) \xrightarrow{g_1} BG_1 \) induces an injection in homology.

**Proposition 5.4.** Let \( G \) be a simply-connected, simple compact Lie group of type \( \{n_1, \ldots, n_\ell\} \) and let \( p \) be a prime. If \( n_\ell < p-1 \) then the map \( \Omega^3 G(3) \xrightarrow{g_1} BG_1 \) induces an injection in mod-\( p \) homology.
Proof. We aim for a contradiction by supposing that this is not the case. To simplify notation, write \( g \) for \( g_1 \). Let \( z \in H_m(\Omega^3G(3)) \) be an element in the kernel of \( g_* \) of least dimension. We begin by establishing some properties of \( z \).

**Property 1:** \( z \) is primitive. If not, then \( \Delta(z) = \Sigma_\alpha z'_\alpha \otimes z''_\alpha \) for some nontrivial elements \( z'_\alpha, z''_\alpha \) of degrees \( < m \), where \( \Delta \) is the reduced diagonal. The reduced diagonal is natural for any map of spaces, so \((g_* \otimes g_*) \circ \Delta = \Delta \circ g_* \). Now
\[
(g_* \otimes g_*) \circ \Delta(z) = (g_* \otimes g_*)(\Sigma_\alpha z'_\alpha \otimes z''_\alpha) = \Sigma_\alpha g_*(z'_\alpha) \otimes g_*(z''_\alpha)
\]
is a sum of nonzero elements since \( z'_\alpha, z''_\alpha \) are of degrees \( < m \) while the element of least degree in \( \text{Ker} \, g_* \) is of degree \( m \). On the other hand,
\[
\Delta \circ g_*(z) = \Delta(0) = 0.
\]
This contradiction implies that \( \Delta(z) \) must be 0; that is, \( z \) is primitive.

**Property 2:** \( P_*^I(z) = 0 \) for all sequences \( P_*^I \in \mathcal{A}_* \). Suppose \( P_*^I(z) = y \) for some \( I \), where \( I \) is not the identity operation and \( y \) is nonzero. The (dual) Steenrod operations are natural for any map of spaces, so \( g_* \circ P_*^I = P_*^I \circ g_* \). Now
\[
g_* \circ P_*^I(z) = g_*(y)
\]
is nonzero, since \(|y| < m \) while the element of least degree in \( \text{Ker} \, g_* \) is of degree \( m \). On the other hand,
\[
P_*^I \circ g_*(z) = P_*^I(0) = 0.
\]
This contradiction implies that \( P_*^I(z) = 0 \) for every \( I \).

**Property 3:** \( \beta^r(z) = 0 \) for every \( r \geq 1 \). The reasoning is exactly as in the proof of Property 2.

**Property 4:** \( z \) is in the transgression of the mod-\( p \) homology Serre spectral sequence for the homotopy fibration \( \Omega^3G(3) \xrightarrow{g} BG \xrightarrow{ev} BG \). Since \( n_\ell < p - 1 \), \( G \) is \( p \)-regular, so Lemma 3.2 implies that, in the mod-\( p \) homology Serre spectral sequence for the homotopy fibration \( \Omega^3G(3) \xrightarrow{g} BG \xrightarrow{ev} BG \), the differentials are derivations. In particular, the differentials are determined by how they act on the elements in \( H_*(BG) \).

The \( E^2 \)-term of the spectral sequence is \( H_*(\Omega^3G(3)) \otimes H_*(BG) \). Since \( z \) is an element of least degree in the kernel of \( g_* \) and is of degree \( m \), the map \( g_* \) an injection in degrees \( < m \). Thus the spectral sequence is totally non-homologous to zero in this degree range, implying that it collapses at \( E^2 \). In particular, any differential on an element of \( H_*(BG) \) of degree \( \leq m \) is zero, and so as the differentials are derivations, any differential on an element of the form \( x \otimes y \) is zero for \( x \in H_*(\Omega^3G(3)) \) and \( y \in H_*(BG) \) with \( t \leq m \). Hence, for degree reasons, if \( z \) is in the image of a differential then the only possibility is that \( z = d^{m+1}(y) \) for some \( y \in H_{m+1}(BG) \). That is, \( z \) is in
the transgression. On the other hand, as \( z \in \text{Ker} \ g_* \), it cannot survive the spectral sequence and so must be hit by some differential.

**Property 5: z has odd degree.** By Property 4, in the mod-\( p \) Serre spectral sequence for the homotopy fibration \( \Omega^3G(3) \to BG_1 \to BG \), we have \( z = d^{n+1}(y) \) for some \( y \in H_*(BG) \). As \( H_*(BG) \) is concentrated in even degrees, the degree of \( z \) must be odd.

Let’s examine the consequences of Properties 1 to 5. Collectively, Properties 1 to 3 imply that \( z \in MH_*(\Omega^3G(3)) \). Property 5 then implies that \( z \in MH_*(\Omega^3G(3))_{\text{odd}} \). By Lemma 4.3, \( MH_*(\Omega^3G(3))_{\text{odd}} = \{a_{2p-3}, a_{2n_2p-3}, \ldots, a_{2n_\ell p-3}\} \). But Lemma 5.3 implies that \( g_* \) is an injection on each of these elements, implying in turn that \( z \notin \text{Ker} \ g_* \), a contradiction. Thus the initial assumption that \( g_* \) is not an injection is false, and this completes the proof. □

**Theorem 5.5.** If \( G \) is a simply-connected simple compact Lie group of type \( \{n_1, \ldots, n_\ell\} \) and \( n_\ell < p-1 \) then there is an isomorphism of \( \mathbb{Z}/p\mathbb{Z} \)-vector spaces

\[
H_*(BG_1) \cong H_*(\Omega^3G(3)) \otimes H_*(BG).
\]

**Proof.** Consider the mod-\( p \) homology Serre spectral sequence for the homotopy fibration \( \Omega^3G(3) \to BG_1 \to BG \). By Proposition 5.4, \( (g_1)_* \) is an injection. Thus the Serre spectral sequence is totally non-homologous to zero, which implies that it collapses at the \( E^2 \)-term. □

Finally, we prove the main result of the paper.

**Proof of Theorem 1.1.** By Corollary 3.4 there is a \( p \)-local homotopy equivalence \( BG_k \simeq BG_1 \) if \( (p, k) = 1 \). Therefore, in mod-\( p \) homology, \( H_*(BG_k) \cong H_*(BG_1) \). The statement in the theorem now follows from Theorem 5.5. □

6. THE MOD-3 HOMOLOGY OF \( SU(2) \)-GAUGE GROUPS

The mod-\( p \) homology of \( BG_k \) for \( G = SU(2) \) and \( p \geq 5 \) is given by Theorem 1.1. Since \( SU(2) \)-gauge groups are pivotal in Donaldson Theory, in this section we expand beyond the statement of Theorem 1.1 by also calculating the mod-3 homology.

Since there is a homeomorphism \( SU(2) \cong S^3 \), we phrase what follows in terms of \( S^3 \). By 11 there is a homotopy fibration sequence

\[
S^3 \to \Omega^3S^3(3) \to BG_1 \to BS^3
\]

where \( g_1 \) is simply a name for the map \( \Omega^3S^3(3) \to BG_1 \), and \( \partial_1 \) is the fibration connecting map. By [K] we have the following.

**Lemma 6.1.** The map \( S^3 \to \Omega^3S^3(3) \) has order 12. □
In particular, if we localize at $p = 3$ then $\partial_1$ is nontrivial. Observe that for $p = 3$, the description of $H_*(\Omega^3 S^3(3))$ in [11] implies that $\Omega^3 S^3(3)$ is 2-connected with a single cell in dimension 3.

**Lemma 6.2.** If $p = 3$ then the map $S^3 \xrightarrow{\partial_1} \Omega^3 S^3(3)$ induces an injection in mod-3 homology.

**Proof.** By Lemma 6.1, $\partial_1$ is nontrivial. Thus it represents a nontrivial element in $\pi_3(\Omega^3 S^3(3)) \cong \pi_3(S^3) \cong \pi_6(S^3)$. By [10], the three-component of $\pi_6(S^3)$ is isomorphic to $\mathbb{Z}/3\mathbb{Z}$. Since this is the 3-torsion class of least dimension in $\pi_*$, the class is represented by the composite $S^6 \xrightarrow{\gamma} S^3(3) \rightarrow S^3$, where $\gamma$ is the inclusion of the bottom cell. Thus $\partial_1$ is homotopic to the three-fold adjoint of $\gamma$, up to multiplication by a unit in $\mathbb{Z}/3\mathbb{Z}$. But as $\gamma$ is the inclusion of the bottom cell, its three-fold adjoint $\gamma' : S^3 \rightarrow \Omega^3 S^3(3)$ is homotopic to the inclusion of the bottom cell. Thus $(\gamma')_*$ is an injection, implying that $(\partial_1)_*$ is an injection.

Next, by [11] and the descriptions of $H_*(\Omega^2 S^{2p-1})$ and $H_*(\Omega^3 S^{2p+1})$ in Section 4 if $x_3 \in H_3(\Omega^3 S^3(3))$ is the generator, then $\Lambda(x_3)$ is a tensor algebra factor of $H_*(\Omega^3 S^3(3))$.

**Proposition 6.3.** If $p = 3$ then there is an isomorphism of $\mathbb{Z}/3\mathbb{Z}$-vector spaces

$$H_*(BG_1) \cong H_*(\Omega^3 S^3(3))/(x_3)$$

where $(x_3)$ is the ideal generated by $x_3$.

**Proof.** Consider the homotopy fibration $S^3 \xrightarrow{\partial_1} \Omega^3 S^3(3) \xrightarrow{\pi_1} BG_1$. By Lemma 6.2, $(\partial_1)_*$ is an injection. Therefore the Serre spectral sequence for this fibration is totally non-homologous to zero, implying that it collapses at $E^2$, so $H_*(\Omega^3 S^3(3)) \cong H_*(S^3) \otimes H_*(BG_1)$. Since $H_*(S^3) \cong \Lambda(x_3)$ and $\Lambda(x_3)$ is a tensor algebra factor of $H_*(\Omega^3 S^3(3))$, we obtain the isomorphism asserted in the statement of the Proposition.

**Corollary 6.4.** If $(3, k) = 1$ then there is an isomorphism of $\mathbb{Z}/3\mathbb{Z}$-vector spaces

$$H_*(BG_k) \cong H_*(\Omega^3 S^3(3))/(x_3)$$

**Proof.** This follows immediately from the homotopy equivalence $BG_k \simeq BG_1$ in Corollary 3.3 and Proposition 6.3.
