TRACE FUNCTIONS OF THE PARAFERMIOSN VERTEX OPERATOR ALGEBRAS

CHONGYING DONG, VICTOR KAC, AND LI REN

Abstract. The trace functions for the Parafermion vertex operator algebra associated to any finite dimensional simple Lie algebra $g$ and any positive integer $k$ are studied and an explicit modular transformation formula of the trace functions is obtained.

1. Introduction

This paper is a continuation of our study of the Parafermion vertex operator algebra $K(g, k)$ associated to any finite dimensional simple Lie algebra $g$ and positive integer $k$. In particular, we determine the modular transformation formula of the trace functions for the Parafermion vertex operator algebras.

The Parafermion vertex operator algebra $K(g, k)$ is the commutant of the Heisenberg vertex operator algebra $M_\hat{h}(k)$ in the affine vertex operator algebra $L_\hat{g}(k, 0)$, and can also be regarded as the commutant of the lattice vertex operator algebra $V_{\sqrt{k}Q_L}$ in $L_\hat{g}(k, 0)$ where $Q_L$ is the lattice spanned by the long roots of $g$. While the $C_2$-cofiniteness of the Parafermion vertex operator algebras was proved in [20] and [2], the rationality was established in [17] with the help of a result in [5] on the abelian orbifolds for rational and $C_2$-cofinite vertex operator algebras. The irreducible modules of $K(g, k)$ were classified in [1] for $g = sl_2$ and in [17], [1] for general $g$, and the fusion rules were computed in [22] for $sl_2$ and in [1] for general $g$ with the help of quantum dimensions. See recent work in [6], [7], [19], [22], [3] and [28] for other topics on Parafermion vertex operator algebras.

The trace functions $Z_M(v, \tau)$ are the main objects in this paper where $M$ is an irreducible $K(g, k)$-module and $v \in K(g, k)$. Since $K(g, k)$ is rational and $C_2$-cofinite, the space spanned by $Z_M(v, \tau)$ for the irreducible modules $M$ affords a representation of the modular group $SL_2(\mathbb{Z})$ [30]. Our goal is to determine this representation explicitly. The irreducible $K(g, k)$-modules are labeled by $M^{\Lambda, \lambda}$. Here $\Lambda$ is a dominant weight of $g$ such that $\langle \Lambda, \theta \rangle \leq k$, $\langle , \rangle$ is the normalized invariant bilinear form on $g$ so that the squared length of a long root is 2, $\theta$ is the maximal root, $\lambda \in \Lambda + Q$ modulo $kQ_L$ and $Q$ is the root lattice. In the case $v = 1$ the functions $\chi_{M^{\Lambda, \lambda}}(\tau)$ are a special kind of branching functions studied previously in [29], [30]. Moreover, $\chi_{M^{\Lambda, \lambda}}(\tau)/\eta(\tau)^l$ is the string function

The first author was supported by China NSF grant 11871351.

The third author was supported by China NSF grant 11671277.
in [29], [30] where \( l \) is the rank of \( \mathfrak{g} \). In fact, explicit modular transformation formulas for branching functions were obtained in [29]. Our main result in this paper is that the same transformation formula for the branching functions is valid for the trace function with \( 1 \) replaced by any \( v \in K(\mathfrak{g}, k) \).

The main idea is to use the modular transformation formulas for the affine vertex operator algebra \( \hat{L}_\mathfrak{g}(k, 0) \) and lattice vertex operator algebras \( V_{\sqrt{k}Q_L} \). There are two modular transformation formulas for the affine vertex operator algebra \( \hat{L}_\mathfrak{g}(k, 0) \) given in [29] explicitly and [35] abstractly. Using a transformation formula for the abstract theta functions studied in [31], [35], one can easily show that these two transformation formulas are the same. Unfortunately, this can only give the modular transformation formula for the character \( \chi_{M,\lambda}(\tau) \), not for the one point function \( Z_{M,\lambda}(v, \tau) \). Again, results in [31] on abstract theta functions including some vector \( w \) help us to solve the problem. To explain what kind of vector \( w \) is, we recall from [16] that if \( V = \oplus_{n \geq 0} V_n \) is a rational, \( C_2 \)-cofinite, simple vertex operator algebra of CFT type, then \( V_1 \) is a reductive Lie algebra whose rank (the dimension of a Cartan subalgebra) is less than or equal to the central charge. Fix a Cartan subalgebra \( \mathfrak{h} \) of \( V_1 \), vector \( w \) satisfies conditions \( h_n w = 0 \) for all \( h \in \mathfrak{h} \) and \( n \geq 0 \). In the case \( V = L_\mathfrak{g}(k, 0) \), the condition is exactly equivalent to \( w \in K(\mathfrak{g}, k) \). The rest of the proof is similar to that given in [29] for the branching functions.

The paper is organized as follows: We review basics on vertex operator algebras and their modules in Section 2 including rationality, \( C_2 \)-cofiniteness and modular transformation results on the trace functions associated to a rational and \( C_2 \)-cofinite vertex operator algebra \( V \). Following [35] and [31], we discuss Section 3 the modular transformation formula for generalized theta functions \( \chi_i(w, v, q) = \text{tr}_{M_i}(o(w) e^{2\pi i o(v)} q^{L(0) - c/24}) \) where \( M_i \) is an irreducible \( V \)-module and \( v \in \mathfrak{h} \) and \( w \) is defined as before. In Section 4 we discuss the affine vertex operator algebras \( L_\mathfrak{g}(k, 0) \) and the modular transformation formula of the specialized characters of the level \( k \) integrable highest weight modules for the the affine Kac-Moody algebra \( \hat{\mathfrak{g}} \). We recall the various known results on the Parafermion vertex operator algebra \( K(\mathfrak{g}, k) \) such as rationality and classification of irreducible modules. Section 6 deals with the modular transformation formula for the 1 point function \( Z_{M,\lambda}(v, \tau) \). The \( T \)-matrix is easy and the most effort is on the \( S \)-matrix. The idea and method for finding the \( S \)-matrix is similar to that in [29] and [30].

2. Basics

In this section we review the basic on vertex operator algebra. Let \( V = (V, Y, \mathbf{1}, \omega) \) be a vertex operator algebra (cf. [1] and [25]).

A vertex operator algebra \( V \) is of \textit{CFT type} if \( V \) is simple, with respect to \( L(0) \) one has \( V = \oplus_{n \geq 0} V_n \) and \( V_0 = \mathbb{C} \mathbf{1} \) [12].
A vertex operator algebra $V$ is called $C_2$-cofinite if $\dim V/C_2(V) < \infty$ where $C_2(V)$ is the subspace of $V$ spanned by $u_{-2}v$ for $u, v \in V$.

A weak $V$-module $M = (M, Y_M)$ is a vector space equipped with a linear map

$$Y_M : V \to (\text{End} M)[[z^{-1}, z]]$$

$$v \mapsto Y_M(v, z) = \sum_{n \in \mathbb{Z}} v_n z^{-n-1} \ (v_n \in \text{End} M) \text{ for } v \in V$$

satisfying the following conditions for $u, v \in V$, $w \in M$:

$$v_n w = 0 \text{ for } n \in \mathbb{Z} \text{ sufficiently large;}$$

$$Y_M(1, z) = 1;$$

$$z_0^{-1} \delta \left( \frac{z_1 - z_2}{z_0} \right) Y_M(u, z_1) Y_M(v, z_2) - z_0^{-1} \delta \left( \frac{z_2 - z_1}{z_0} \right) Y_M(v, z_2) Y_M(u, z_1)$$

$$= z_2^{-1} \delta \left( \frac{z_1 - z_0}{z_2} \right) Y_M(Y(u, z_0)v, z_2).$$

An (ordinary) $V$-module is a weak $V$-module $M$ which is $\mathbb{C}$-graded

$$M = \bigoplus_{\lambda \in \mathbb{C}} M_{\lambda}$$

such that $\dim M_{\lambda}$ is finite and $M_{\lambda+n} = 0$ for fixed $\lambda$ and $n \in \mathbb{Z}$ small enough, where $M_{\lambda}$ is the eigenspace for $L(0)$ with eigenvalue $\lambda$:

$$L(0)w = \lambda w, \ w \in M_{\lambda}.$$ 

Let $M$ be an ordinary $V$-module. We denote $v_{n-1}$ by $o(v)$ for $v \in V_n$ and extend to $V$ linearly. Then $o(v)M_{\lambda} \subset M_{\lambda}$ for all $\lambda \in \mathbb{C}$.

An admissible $V$-module is a weak $V$-module $M$ which carries a $\mathbb{Z}_+$-grading

$$M = \bigoplus_{n \in \mathbb{Z}_+} M(n)$$

($\mathbb{Z}_+$ is the set all nonnegative integers) such that if $r, m \in \mathbb{Z}, n \in \mathbb{Z}_+$ and $a \in V_r$ then

$$a_m M(n) \subseteq M(r + n - m - 1).$$

Note that any ordinary module is an admissible module.

A vertex operator algebra $V$ is called rational if any admissible module is a direct sum of irreducible admissible modules.

The following result is proved in [10] and [11].

**Theorem 2.1.** Assume that $V$ is rational.
(1) There are only finitely many inequivalent irreducible admissible modules $V = M^0, ..., M^p$ and each irreducible admissible module is an ordinary module. Each $M^i$ has weight space decomposition

$$M^i = \bigoplus_{n \geq 0} M^i_{\lambda_i + n}$$

where $\lambda_i \in \mathbb{C}$ is a complex number such that $M^i_{\lambda_i} \neq 0$ and $M^i_{\lambda_i + n}$ is the eigenspace of $L(0)$ with eigenvalue $\lambda_i + n$. The $\lambda_i$ is called the weight of $M^i$.

(2) If $V$ is both rational and $C_2$-cofinite, then $\lambda_i$ and central charge $c$ are rational numbers.

In the rest of this paper we assume that $V$ is a strong rational vertex operator algebra. That is $V$ satisfies the following:

(V1) $V = \oplus_{n \geq 0} V_n$ is a simple vertex operator algebra of CFT type,

(V2) $V$ is $C_2$-cofinite and rational,

(V3) The conformal weights $\lambda_i$ are nonnegative and $\lambda_i = 0$ if and only if $i = 0$.

Using the assumption (V3) we know that $V$ and its contragredient module $V'$ \cite{24} are isomorphic $V$-modules. From \cite{16} we know $V_1$ is a reductive Lie algebra with $[u, v] = u_0v$ for $u, v \in V_1$. Moreover, the rank $V_1$ is less than or equal to the central charge $c$ of $V$. For any $u \in V_1$, $u_0$ is a derivation of $V$ in the sense that $[u_0, Y(v, z)] = Y(u_0v, z)$ for any $v \in V$ and $u_0\omega = 0$. Furthermore, $e^{u_0}$ is an automorphism of $V$.

Recall from \cite{24} that a bilinear from $(\cdot, \cdot)$ on $V$ is called invariant if

$$(Y(u, z)v, w) = (u, Y(e^{zL(1)}(-z^{-2})L(0)v, z^{-1})w)$$

for $u, v, w \in V$. From our assumptions there is unique nondegenerate invariant bilinear form on $V$ \cite{33}. We shall fix a bilinear form $(\cdot, \cdot)$ on $V$ so that $(u, v) = u_1v$ for $u, v \in V_1$. It is clear from the definition that $(gu, gv) = (u, v)$ for any automorphism $g$ and $u, v \in V_1$.

The modular transformations of trace functions of irreducible modules of vertex operator algebras \cite{36} are of main importance in this paper. Another vertex operator algebra structure $(V, Y[\cdot, z], 1, \omega - c/24)$ is defined on $V$ in \cite{36} with grading

$$V = \bigoplus_{n \geq 0} V_{[n]}.$$ 

For $v \in V_{[n]}$ we write $\text{wt}[v] = n$. For $i = 0, ..., p$ we set

$$Z_i(v, q) = \text{tr}_{M^i}(v)q^{L(0) - c/24}$$

which is a formal power series in variable $q$. The $Z_i(1, q)$ which is also denoted by $\text{ch}_q M^i$ is called the $q$-character of $M^i$.

The series $Z_i(v, q)$ converges to a holomorphic function $Z_i(v, \tau)$ on $\mathbb{H} = \{ \tau \in \mathbb{C} \mid \text{Im} \tau > 0 \}$ where $q = e^{2\pi i \tau}$ with $\tau \in \mathbb{H}$ \cite{36}.
Recall the modular group $SL_2(\mathbb{Z})$ and let \( \gamma = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in SL_2(\mathbb{Z}) $.

**Theorem 2.2.** Let \( V \) be a strong rational vertex operator algebra.

1. There is a group homomorphism \( \rho : SL_2(\mathbb{Z}) \to GL_{p+1}(\mathbb{C}) \) with \( \rho(\gamma) = (\gamma_{ij}) \) such that for any \( 0 \leq i \leq p \) and \( v \in V \),
   \[
   Z_i(v, a\tau + b/c\tau + d) = (c\tau + d)^{\text{wt}[v]} \sum_{j=0}^{p} \gamma_{ij} Z_j(v, \tau).
   \]

2. Each \( Z_i(v, \tau) \) is a modular form of weight \( \text{wt}[v] \) over a congruence subgroup.

Part (1) of the Theorem was obtained in [36] and Part (2) was established in [13]. The matrices
\[
S = \rho_V \left( \begin{array}{cc} 0 & -1 \\ 1 & 0 \end{array} \right) \quad \text{and} \quad T = \rho_V \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right),
\]
are respectively called the genus one \( S \)- and \( T \)-matrices of \( V \).

3. **Modular invariance of the generalized theta functions**

We review the modular transformation formula of the theta functions defined on vertex operator algebra given in [35] and [31] for studying the modular invariance of trace functions for the parafermion vertex operator algebras.

Recall that \( V_1 \) is a reductive Lie algebra. We fix a Cartan subalgebra \( \mathfrak{h} \) of \( V_1 \). Then the abelian Lie algebra \( \mathfrak{h} \) acts on \( M^i \) semisimply for all \( i \). Following [35], we define the generalized theta functions as
\[
T_i(v, u, q) = \text{tr}_{M^i} e^{2\pi i(u_0 + (u, u)/2)} q^{L(0)+u_0+(u,u)/2-c/24}
\]
for \( u, v \in \mathfrak{h} \). The bilinear form on \( V_1 \) used in [35] is the negative of the bilinear form used in this paper. So our \( T_i(v, u, q) \) defined here is exactly the \( Z_{M^i}(v, u, q) \) in [35]. Based on Theorem 2.2, a modular transformation law was obtained in [35] with the convergence of \( Z_i(v, u, q) \) proved in [14].

**Theorem 3.1.** Let \( u, v \in \mathfrak{h} \) and \( \gamma = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in SL_2(\mathbb{Z}) \). Then \( T_i(v, u, q) \) converges to a holomorphic function in the upper half plane with \( q = e^{2\pi i\tau} \) and
\[
T_i(v, u, a\tau + b/c\tau + d) = \sum_{j=0}^{p} \gamma_{ij} T_j(du, bu, cv + au, \tau)
\]
where \( \gamma_{ij} \) is the same as in Theorem 2.2.

Set \( \chi_i(v, \tau) = T_i(v, 0, \tau) \). Using Theorem 3.1 one can easily show the following result [14].
Proposition 3.2. Assume that \( V \) is a strong rational vertex operator algebra. Then for \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}), v \in \mathfrak{h} \)

\[
\chi_s \left( \frac{v}{c+d}, \frac{a+c}{c+d}, \gamma \right) = e^{\frac{\pi i}{c+d}} \sum_{j=0}^{P} \gamma_{sj} \chi_j (v, \tau).
\]

As usual we set \( o(w) = w_{\text{wt}w-1} \) for homogeneous \( w \in V \) and extend to whole \( V \). Now take \( w \in V \) such that \( h_n w = 0 \) for all \( h \in \mathfrak{h} \) and \( n \geq 0 \). Also define

\[
\chi_i (w, v, q) = \text{tr}_{M(o(w))} e^{q L(0) - c/24}.
\]

The following result [31] generalizes Proposition 3.2.

Theorem 3.3. Let \( v \in \mathfrak{h} \). We assume that \( \chi_i (w, v, q) \) converges to a holomorphic function \( \chi_i (w, v, \tau) \) in \( \mathbb{H} \) with \( q = e^{2\pi i \tau} \) for any \( v \in \mathfrak{h} \). Then for \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}), \)

\[
\chi_i (w, \frac{v}{c+d}, \frac{a+c}{c+d}, \gamma) = (c+d)^{\text{wt}v} e^{\frac{\pi i}{c+d}} \sum_{j=0}^{P} \gamma_{ij} \chi_j (w, v, \tau).
\]

4. AFFINE VERTEX OPERATOR ALGEBRAS

In this section we discuss the affine vertex operator algebra \( \hat{L}_{\mathfrak{g}} (k, 0) \) associated to the level \( k \) integrable highest weight module for affine Kac-Moody algebra \( \hat{\mathfrak{g}} \) and its irreducible modules.

Let \( \mathfrak{g} \) be a finite dimensional simple Lie algebra with a Cartan subalgebra \( \mathfrak{h} \). We denote the corresponding root system by \( \Delta \) and the root lattice by \( Q \). Fix an invariant symmetric nondegenerate bilinear form \( \langle , \rangle \) on \( \mathfrak{g} \) such that \( \langle \alpha, \alpha \rangle = 2 \) if \( \alpha \) is a long root, where we have identified \( \mathfrak{h} \) with \( \mathfrak{h}^* \) via \( \langle \cdot, \cdot \rangle \). We denote the image of \( \alpha \in \mathfrak{h}^* \) in \( \mathfrak{h} \) by \( t_\alpha \). That is, \( \alpha (h) = \langle t_\alpha, h \rangle \) for any \( h \in \mathfrak{h} \). Fix simple roots \( \{ \alpha_1, ..., \alpha_l \} \) and let \( \Delta_+ \) be the set of corresponding positive roots. Denote the highest root by \( \theta \), and the Weyl group by \( W \). Also let \( \rho \) be the half sum of positive roots.

Recall that the weight lattice \( P \) of \( \mathfrak{g} \) consists of \( \lambda \in \mathfrak{h}^* \) such that \( 2 \langle \lambda, \alpha \rangle \in \mathbb{Z} \) for all \( \alpha \in \Delta \). It is well-known that \( P = \bigoplus_{i=1}^{l} \mathbb{Z} \Lambda_i \) where \( \Lambda_i \) are the fundamental weights defined by the equation \( 2 \langle \lambda, \alpha \rangle \in \mathbb{Z} \) for \( 1 \leq i, j \leq l \). Let \( P_+ \) be the subset of \( P \) consisting of the dominant weight \( \Lambda \in P \) in the sense that \( 2 \langle \lambda, \alpha \rangle \) is nonnegative for all \( j \). For any nonnegative integer \( k \) we also let \( P_+^k \) be the subset of \( P_+ \) consisting of \( \lambda \) satisfying \( \langle \Lambda, \theta \rangle \leq k \).

Let \( Q = \bigoplus_{i=1}^{l} \mathbb{Z} \alpha_i \) be the root lattice and \( Q_L \) be the sublattice of \( Q \) spanned by the long roots. Recall that the dual lattice \( \mathcal{Q}_L^\circ \) consists \( \lambda \in \mathfrak{h}^* \) such that \( \langle \lambda, \alpha \rangle \in \mathbb{Z} \) for all \( \alpha \in Q_L \). Then \( P \) is the dual lattice of \( Q_L \) [1].
Let $\widehat{g} = g \otimes \mathbb{C}[t, t^{-1}] \oplus CK$ be the affine Lie algebra. Fix a nonnegative integer $k$. For any $\Lambda \in P_k^+$ let $L(\Lambda)$ be the irreducible highest weight $g$-module with highest weight $\Lambda$ and $L(\Lambda)$ be the unique irreducible $\widehat{g}$-module such that $L(\Lambda)$ is generated by $L(\Lambda)$ and $g \otimes t^n L(\Lambda) = 0$ for $t > 0$ and $K$ acts as constant $k$. The following result is well known (cf. [26], [32]):

**Theorem 4.1.** The $L(\Lambda)$ is a simple, rational and $C_2$-cofinite vertex operator algebra with central charge $\frac{k \dim g}{k + h^\vee}$ and whose irreducible modules are $L(\Lambda)$ for $\Lambda \in P_k^+$ and the weight $n_\Lambda$ of $L(\Lambda)$ is $\langle \Lambda + 2\rho, \Lambda \rangle$ where $\rho = \sum_{i=1}^l \Lambda_i$ and $h^\vee$ is the dual Coxeter number.

Note that $L(\Lambda)$ has a decomposition with respect to the action of $h$:

$$L(\Lambda) = \bigoplus_{\lambda \in \Lambda^+} L(\lambda)$$

where $h(0)$ acts on $L(\Lambda)$ as constant $\lambda$ for $h \in \mathfrak{h}$. Following [29], define the character

$$\chi(\Lambda, h, \tau) = \text{tr}_{L(\Lambda)} e^{2\pi i h(0)} q^{L(0) - c/24}$$

for $h \in \mathfrak{h}$. Note that the character defined in [29] has an extra factor $e^{2\pi i ku}$ with $u$ being a complex number. This extra factor makes the modular transformation formula more beautiful. But from the point of view of vertex operator algebra, this extra factor is not necessary. From [29] we have

**Theorem 4.2.** Let $g$ and $k$ be as before.

1. $\{\chi(\Lambda, h, \tau)|\Lambda \in P_k^+\}$ are linearly independent functions on $\mathfrak{h} \times \mathbb{H}$.
2. For $\Lambda, \Lambda' \in P_k^+$, set

$$S_{\Lambda, \Lambda'} = i^{A_+ + |P/(k + h^\vee)|} Q_L^{1/2} \sum_{w \in W} (-1)^{l(w)} e^{-\frac{2\pi i}{k + h^\vee} \langle w(\Lambda + \rho), \Lambda' + \rho \rangle}$$

where $l(w)$ is the length of $w$. Then

$$\chi(\Lambda(h, -1, \tau)) = e^{\pi i k(h, h)/\tau} \sum_{\Lambda' \in P_k^+} S_{\Lambda, \Lambda'} \chi(\Lambda', h, \tau).$$

Recall Theorem 2.2 and Proposition 3.2.

**Lemma 4.3.** The $S$-matrices in Theorem 2.2 and Theorem 4.2 are the same.

**Proof.** Let $V = L(\Lambda(k, 0))$. Then $V$ satisfies the assumptions in Theorem 2.2. Recall that we have defined a bilinear form on $V_1$ such that $(u, v) = u_1 v$. Let $u = a(-1)1$ and $v = b(-1)1$ for $a, b \in g$. Then $(u, v) = a(1)b(-1)1 = k \langle a, b \rangle$. Identify Lie algebra $V_1$ with $g$ we see
that \((a, b) = k\langle a, b \rangle\). We denote the \(S\)-matrix in Theorem 2.2 by \((S_{L_{q(k, \Lambda)}, L_{q(k, \Lambda')}})\). Then from Proposition 3.2 we know

\[
\chi_{\Lambda}(\frac{h}{\tau}, \frac{-1}{\tau}) = e^{\pi ik(h, h)/\tau} \sum_{\Lambda' \in P^k} S_{L_{q(k, \Lambda)}, L_{q(k, \Lambda')}}(h, \tau).
\]

The result now is an immediate consequence of Theorem 4.2 (1). \(\square\)

5. Parafermion vertex operator algebras

In this section we recall the definition of a parafermion vertex operator algebra \(K(\mathfrak{g}, k)\) associated to any finite dimensional simple Lie algebra \(\mathfrak{g}\) and a positive integer \(k\). We also discuss some known results on \(K(\mathfrak{g}, k)\) from [17].

Let \(\lambda_i \in P\) such that \(\lambda_i = \frac{\langle \theta_i, \theta_i \rangle}{\langle \alpha_i, \alpha_i \rangle} \Lambda_i\) for \(i = 1, \ldots, l\). Then \(\langle \alpha_i, \lambda_j \rangle = \delta_{i,j}\) for all \(i, j\) and \(Q^o = \bigoplus_{i=1}^l \mathbb{Z} \lambda_i\). The following result is immediate from the relation between \(\Lambda_i\) and \(\lambda_i\).

**Lemma 5.1.** \(P/Q^o\) is a group of order

\[
|P/Q^o| = \begin{cases} 
1 & A_l, D_l, E_6, E_7, E_8 \\
2 & B_l \\
2^{l-1} & C_l \\
2^2 & F_4 \\
3 & G_2 
\end{cases}
\]

**Lemma 5.2.** For any simple Lie algebra \(\mathfrak{g}\) and any positive integer \(k\), \(\frac{1}{k} P/Q^o\) and \(Q/kQ_L\) are dual groups, so that for any \(\beta \in Q\), \(g_{\beta}(\alpha) = e^{2\pi i \langle \beta, \alpha \rangle}\) defines an irreducible character for \(\frac{1}{k} P/Q^o\). In particular, \(\frac{1}{k} P/Q^o\) and \(Q/kQ_L\) are isomorphic groups.

**Proof.** Clearly, \(g_{\beta}\) defines an irreducible character of \(\frac{1}{k} P/Q^o\) as \(Q^o_L = P\). Also, \(g_{\beta_1} = g_{\beta_2}\) for if and only if \(\beta_1 - \beta_2 \in kQ_L\). So \(Q/kQ_L\) is a subgroup of the dual group of \(\frac{1}{k} P/Q^o\). To finish the proof, it is enough to show that \(|P/Q^o| = |Q/Q_L|\). This is obvious if \(\mathfrak{g}\) is a Lie algebra of type \(A, D, E\). If \(\mathfrak{g}\) is a Lie algebra of other type, we verify the result case by case using the root systems given in [27]. We have already known \(|P/Q^o|\) from Lemma 5.1. So we only need to compute \(|Q/Q_L|\).

1. Type \(B_l\). Let \(E = \mathbb{R}^l\) with the standard orthonormal basis \(\{\epsilon_1, \ldots, \epsilon_l\}\). Then

\[
\Delta = \{\pm \epsilon_i, \pm (\epsilon_i \pm \epsilon_j) | i \neq j\}.
\]

Then \(Q = \sum_i \mathbb{Z} \epsilon_i\) and \(Q_L = \sum_{i \neq j} [\mathbb{Z} (\epsilon_i + \epsilon_j) + \mathbb{Z} (\epsilon_i - \epsilon_j)]\). It is evident that \(2Q \subset Q_L\) and \(|Q/Q_L| = 2\) with coset representatives 0 and \(\epsilon_1\).

2. Type \(C_l\). In this case,

\[
\Delta = \{\pm \sqrt{2} \epsilon_i, \pm \frac{1}{\sqrt{2}} (\epsilon_i \pm \epsilon_j) | i \neq j\}.
\]
Then $Q = \frac{1}{\sqrt{2}} \sum_{e \neq j} (\mathbb{Z}(\epsilon_i + \epsilon_j) + \mathbb{Z}(\epsilon_i - \epsilon_j))$ and $Q_L = \sqrt{2} \sum_{i=1}^{l} \mathbb{Z} \epsilon_i$. Thus $|Q/Q_L| = 2^{l-1}$ with coset representatives $a_1 \alpha_1 + a_2 \alpha_2 + \cdots + a_{l-1} \alpha_{l-1}$ for $a_i = 0, 1$ and $\alpha_i = \frac{1}{\sqrt{2}}(\epsilon_i - \epsilon_{i+1})$.

(3) Type $F_4$. Let $E = \mathbb{R}^4$. Then

$$
\Delta = \{ \pm \epsilon_i, \pm (\epsilon_i \pm \epsilon_j), \pm \frac{1}{2}(\epsilon_i \pm \epsilon_2 \pm \epsilon_3 \pm \epsilon_4) | i \neq j \}.
$$

Then $|Q/Q_L| = 2^2$ with coset representatives $a \epsilon_3 + b \frac{1}{2} (\epsilon_1 - \epsilon_2 - \epsilon_3 - \epsilon_4)$ for $a, b = 0, 1$.

(4) Type $G_2$. Let $E$ be the subspace of $\mathbb{R}^3$ orthogonal to $\epsilon_1 + \epsilon_2 + \epsilon_3$. Then

$$
\Delta = \pm \frac{1}{\sqrt{3}} \{ \epsilon_i - \epsilon_j, 2 \epsilon_1 - \epsilon_2 - \epsilon_3, 2 \epsilon_2 - \epsilon_1 - \epsilon_3, 2 \epsilon_3 - \epsilon_1 - \epsilon_2 | i \neq j \}.
$$

Then $|Q/Q_L| = 3$ with coset representatives $\frac{1}{\sqrt{3}} (\epsilon_1 - \epsilon_2)$ for $a = 0, 1, 2$. The proof is complete.

Let $M_{\hat{h}}(k)$ be the vertex operator subalgebra of $L_{\hat{g}}(k,0)$ generated by $h(-1)1$ for $h \in \mathfrak{h}$. For $\lambda \in \mathfrak{h}^*$, denote by $M_{\hat{h}}(k, \lambda)$ the irreducible highest weight module for $\mathfrak{g}$ with a highest weight vector $e^\lambda$ such that $h(0)e^\lambda = \lambda(h)e^\lambda$ for $h \in \mathfrak{h}$. The parafermion vertex operator algebra $K(g, k)$ is the commutant $[26]$ of $M_{\hat{h}}(k)$ in $L_{\hat{g}}(k,0)$. We have the following decomposition

$$
L_{\hat{g}}(k, \lambda) = \bigoplus_{\lambda \in Q + \Lambda} M_{\hat{h}}(k, \lambda) \otimes M^{\Lambda, \lambda} = \bigoplus_{\alpha \in Q} M_{\hat{g}}(k, \Lambda + \alpha) \otimes M^{\Lambda, \lambda + \alpha}
$$

as $M_{\hat{h}}(k) \otimes K(g, k)$-module. Moreover, $M^{0,0} = K(g, k)$ and $M^{\Lambda, \lambda}$ is an irreducible $K(g, k)$-module $[17]$. Recall equation (5.1). It is easy to see that

$$
L_{\hat{g}}(k, \Lambda)(\lambda) = M_{\hat{g}}(k, \lambda) \otimes M^{\Lambda, \lambda}.
$$

It is proved in $[21]$ that the lattice vertex operator algebra $V_{\sqrt{Q_L}}$ is a vertex operator subalgebra of $L_{\hat{g}}(k,0)$ and the parafermion vertex operator algebra $K(g, k)$ is also a commutant of $V_{\sqrt{Q_L}}$ in $L_{\hat{g}}(k,0)$. This gives us another decomposition

$$
L_{\hat{g}}(k, \Lambda) = \bigoplus_{i \in Q/kQ_L} V_{\sqrt{Q_L} + \sqrt{Q}^i(\Lambda + \beta_i)} \otimes M^{\Lambda, \Lambda + \beta_i}
$$

as modules for $V_{\sqrt{Q_L}} \otimes K(g, k)$, where $M^{\Lambda, \lambda}$ is as before, $Q = \cup_{i \in Q/kQ_L} (kQ_L + \beta_i)$, and $\beta_i \in Q$ is a representative of $i$. Moreover, for any $i \in Q/kQ_L$, we have

$$
V_{\sqrt{Q_L} + \sqrt{Q}^i(\Lambda + \beta_i)} \otimes M^{\Lambda, \Lambda + \beta_i} = \bigoplus_{\alpha \in kQ_L} M_{\hat{g}}(k, \Lambda + \alpha + \beta_i) \otimes M^{\Lambda, \Lambda + \alpha + \beta_i}
$$

where we have used the isomorphism between $K(g, k)$-modules $M^{\Lambda, \Lambda + \alpha + \beta_i}$ and $M^{\Lambda, \Lambda + \beta_i}$ for any $\alpha \in kQ_L$ $[17]$. So for any $h \in \mathfrak{h}$, $h(0) \in \mathfrak{g}$ acts as $\sqrt{k}h(0)$ or $\langle h, k\Lambda + \Lambda + \beta_i \rangle$ on $e^{\sqrt{Q}^i(\Lambda + \beta_i)}$.

Let $\theta = \sum_{i=1}^{l} a_i \alpha_i$. According to $[33], [34]$, if $a_i = 1$ then $L_{\hat{g}}(k, k\Lambda_i)$ is a simple current and $L_{\hat{g}}(k, k\Lambda) \otimes L_{\hat{g}}(k, \Lambda) = L_{\hat{g}}(k, \Lambda^{(i)})$ for any $\Lambda \in P_+^k$ where $\Lambda^{(i)} \in P_+^k$ is uniquely
determined by $\Lambda$ and $i$. Then $L_{\mathfrak{g}}(k, \Lambda)$ and $L_{\mathfrak{g}}(k, \Lambda^{(i)})$ are isomorphic $K(\mathfrak{g}, k)$-modules \[17\].

Here are some main results on $K(\mathfrak{g}, k)$ from \([20, 2, 3, 17, 1]\).

**Theorem 5.3.** Let $\mathfrak{g}$ be a simple Lie algebra and $k$ a positive integer.

1. The $K(\mathfrak{g}, k)$ is a rational, simple and $C_2$-cofinite vertex operator algebra of CFT type.
2. For any $\Lambda \in P^k_+$, $\lambda \in \Lambda + Q$ and $\alpha \in Q_L$, $M^{\Lambda, \lambda} = M^{\Lambda, \lambda + k\alpha}$.
3. For each $i \in I$, $\Lambda \in P^k_+$ there exists a unique $\Lambda^{(i)} \in P^k_+$ such that for any $\lambda \in \Lambda + Q$, $M^{\Lambda, \lambda} = M^{\Lambda^{(i)}, \lambda + k\Lambda}$.
4. Any irreducible $K(\mathfrak{g}, k)$-module is isomorphic to $M^{\Lambda, \lambda}$ for some $\Lambda \in P^k_+$ and $\lambda \in \Lambda + Q$.
5. The $K(\mathfrak{g}, k)$ has exactly $|P^k_+|/|Q/Q_L|$ inequivalent irreducible modules.

6. **Trace functions for parafermion vertex operator algebras**

In this section we determine the $S$-matrix for parafermion vertex operator algebra $K(\mathfrak{g}, k)$ associated to any finite dimensional simple Lie algebra $\mathfrak{g}$ and positive integer $k$ from \([17]\).

From decomposition (5.1) we have

$$\chi_{L_{\mathfrak{g}}(k, \Lambda)}(\tau) = \sum_{\lambda \in Q + \Lambda} \chi_{M_{\mathfrak{g}}(k, \lambda)}(\tau) \chi_{M^{\Lambda, \lambda}}(\tau) = \sum_{\lambda \in Q + \Lambda} q^{(\lambda, \lambda)/2k} \eta(\tau)^{\Lambda} \chi_{M^{\Lambda, \lambda}}(\tau)$$

where $\eta(\tau) = q^{1/24} \prod_{n \geq 1} (1 - q^n)$. The

$$c^{\Lambda}_{\lambda}(\tau) = \eta(\tau)^{-1} \chi_{M^{\Lambda, \lambda}}(\tau)$$

is called the string function and $\chi_{M^{\Lambda, \lambda}}(\tau)$ is called the branching function denoted by $b^{\Lambda}_{\lambda}(\tau)$ in \([29]\). The modular transformation formulas of branching functions were also given in \([29]\):

**Theorem 6.1.** Let $\Lambda \in P^k_+$ and $i \in Q/kQ_L$. Then

1. $\chi_{M^{\Lambda, \lambda^{(i)}}}(\tau + 1) = e^{2\pi i((\Lambda + 2\pi \Lambda)/(2k + k^2))} \frac{(\lambda + \beta_i \Lambda + \beta_i)}{2k} \frac{\dim \mathfrak{g}}{24k + k^2 + 24} \chi_{M^{\Lambda, \lambda^{(i)}}}(\tau)$,
2. $\chi_{M^{\Lambda, \lambda^{(i)}}}(\tau) = \sum_{\mathcal{S} \in P^k_+} S^P_{(\Lambda, \lambda^{(i)}), (\mathcal{S}, \lambda')} \chi_{M^{\mathcal{S}, \lambda'}}(\tau)$, where

$$S^P_{(\Lambda, \lambda^{(i)}), (\mathcal{S}, \lambda')} = [P/kQ_L]^{-1/2} S_{\Lambda, \mathcal{S}} e^{2\pi i((\lambda + \lambda^{(i)})/(2k))}$$

and $P$ stands for Parafermion.

The main result in this paper is that the transformation formula for the branching functions remains valid for the trace functions $Z_{M^{\Lambda, \lambda}}(w, \tau)$ with $w \in K(\mathfrak{g}, k)$:
Theorem 6.2. Let $\Lambda \in P^k_+$ and $i \in Q/kQ_L$. Then for any $w \in K(\mathfrak{g}, k)$

1. $Z_{M^{\Lambda, \Lambda + \beta_i}}(w, \tau + 1) = e^{2\pi i \langle (\Lambda + 2\pi \Lambda) / (2k+\Lambda), \Delta \rangle / 24} Z_{M^{\Lambda, \Lambda + \beta_i}}(w, \tau)$,

2. $Z_{M^{\Lambda, \Lambda + \beta_i}}(w, \frac{1}{\tau}) = \tau^{wt[w]} \sum_{N' \in P^k_+} S_{(\Lambda, \Lambda + \beta_i), (N, N' + \beta_i)} Z_{M^{N', \Lambda + \beta_i}}(w, \tau)$.

Proof. (1) is straightforward. The proof (2) is divided in several steps.

(a) $\chi_{L^q(k, \Lambda)}(w, h, q)$ converges to a holomorphic function $\chi_{L^q(k, \Lambda)}(w, h, \tau)$ for any $w \in K(\mathfrak{g}, k)$ and $h \in \mathfrak{h}$ where we have identified $x \in \mathfrak{g}$ with $x(-1)1 \in L^q(k, 0)_1$.

We denote the Virasoro vectors of $L^q(k, 0)$, $V_{\sqrt{k}Q_L}$ and $K(\mathfrak{g}, k)$ by $\omega^a$, $\omega^l$ and $\omega^p$ and denote the corresponding components of the vertex operators by $L^a(n)$, $L^l(n)$ and $L^p(n)$ respectively for $n \in \mathbb{Z}$. Also denote the Virasoro central charges of $L^q(k, 0)$ and $K(\mathfrak{g}, k)$ by $c^a$ and $c^p$ respectively. Then $c^a = l + c^p$.

Recall decomposition (33). Then

$$\chi_{L^q(k, \Lambda)}(w, h, q) = \text{tr}_{L^q(k, \Lambda)} o(w) e^{2\pi i h(0) q L^a(0) - c^a/24}$$

$$= \sum_{i \in Q/kQ_L} \text{tr}_{V_{\sqrt{k}Q_L + i/\sqrt{k}(\Lambda + \beta_i) \otimes M^{\Lambda, \Lambda + \beta_i}}} o(w) e^{2\pi i h(0) q L^a(0) - c^a/24}$$

$$= \sum_{i \in Q/kQ_L} \text{tr}_{V_{\sqrt{k}Q_L + i/\sqrt{k}(\Lambda + \beta_i)}} e^{2\pi i h(0) q L^l(0) - l/24} \text{tr}_{M^{\Lambda, \Lambda + \beta_i}} o(w) q L^p(0) - c^p/24$$

$$= \sum_{i \in Q/kQ_L} \chi_{V_{\sqrt{k}Q_L + i/\sqrt{k}(\Lambda + \beta_i)}} (h, q) Z_{M^{\Lambda, \Lambda + \beta_i}}(w, q).$$

Note that $\chi_{V_{\sqrt{k}Q_L + i/\sqrt{k}(\Lambda + \beta_i)}} (h, q)$ converges to a holomorphic function $\chi_{V_{\sqrt{k}Q_L + i/\sqrt{k}(\Lambda + \beta_i)}} (h, \tau)$ [29] and $Z_{M^{\Lambda, \Lambda + \beta_i}}(w, q)$ converges to a holomorphic function $Z_{M^{\Lambda, \Lambda + \beta_i}}(w, \tau)$ [30]. Thus $\chi_{L^q(k, \Lambda)}(w, h, q)$ converges.

For short, we set $\chi_{\Lambda}(w, h, \tau) = \chi_{L^q(k, \Lambda)}(w, h, \tau)$.

(b) By Theorems 33, 12 and Lemma 43 we have

$$\chi_{\Lambda}(w, h, \frac{l}{\tau}) = \tau^{wt[w]} e^{\pi i k(h, h)/\tau} \sum_{N' \in P^k_+} S_{\Lambda, N'} \chi_{N'}(w, h, \tau).$$

(c) Let $L$ be a positive definite even lattice of rank $l$ with bilinear form $(, )$. Recall from [1] and [25] the lattice vertex operator algebra $V_L = M(1) \otimes \mathbb{C}[L]$ and its irreducible modules $V_{L + \lambda_i} = M(1) \otimes \mathbb{C}[L + \lambda_i]$ where $L' = \bigcup_{i \in L'/L} (L + \lambda_i)$. Then $V_L$ is a vertex operator algebra satisfying V1-V3. In this case

$$\chi_{V_{L + \lambda_i}} (h, \tau) = \text{tr}_{V_{L + \lambda_i}} e^{2\pi i h(0) q L^a(0) - l/24} = \frac{\theta_{L + \lambda_i}(h, \tau)}{\eta(\tau)^l}$$

where

$$\theta_{L + \lambda_i}(h, \tau) = \sum_{\lambda \in L + \lambda_i} e^{2\pi i (h, \lambda) q (\lambda, \lambda)/2}.$$
It is well known that \( \{ \theta_{L,\lambda} | L + \lambda \in \mathbb{C} \} \) are linearly independent functions on \( \mathfrak{h} \times \mathbb{H} \) where \( \mathfrak{h} = \mathbb{C} \otimes \mathbb{Z} \), \( L \). Thus, \( \{ \chi_{L,\lambda} | L + \lambda \in \mathbb{C} \} \) are linearly independent functions on \( \mathfrak{h} \times \mathbb{H} \). Using the transformation formula
\[
\theta_{L,\lambda}(\frac{h}{\tau}, \frac{-1}{\tau}) = (-i\tau)^{1/2}|L^\circ/L|^{-1/2}e^{\pi i(h,h)/\tau} \sum_{\lambda' + \lambda \in \mathbb{C}} e^{-2\pi i(\lambda,\lambda')} \theta_{L,\lambda'}(h, \tau)
\]
and
\[
\eta(-1/\tau) = (-i\tau)^{1/2} \eta(\tau)
\]
we see that
\[
\chi_{L+\lambda}(\frac{h}{\tau}, \frac{-1}{\tau}) = |L^\circ/L|^{-1/2}e^{\pi i(h,h)/\tau} \sum_{j \in \mathbb{C}} e^{-2\pi i(\lambda,\lambda_j)} \chi_{L,\lambda_j}(h, \tau).
\]
Set \( S_{L+\lambda,L+\lambda'} = |L^\circ/L|^{-1/2}e^{-2\pi i(\lambda,\lambda')} \) for \( L + \lambda, L + \lambda' \in \mathbb{C} \). Also set
\[
S_L = (S_{L+\lambda,L+\lambda'})_{L+\lambda,L+\lambda' \in \mathbb{C}}
\]
which is the \( S \)-matrix for the lattice vertex operator algebra \( V_L \).

(d) Let \( L = \sqrt{\eta}Q_L \). Then \( \mathbb{C} = \frac{1}{\sqrt{k}} P_+ \). As in [29] we consider column vector
\[
\chi(w, h, \tau) = (\chi_{\lambda})_{\lambda \in P^+_+} = (\chi_{\sqrt{\eta}Q_L})(h, \tau).
\]
Let \( S_A = (S_{\lambda,\lambda'})_{\lambda,\lambda' \in P^+} \) which is the \( S \)-matrix for affine vertex operator algebra \( L_{\sqrt{\eta}}(k,0) \) (see Lemma 4.3). Also consider the matrix
\[
Z(w, \tau) = (Z_{M,\lambda})_{\lambda \in P^+_+ \alpha + L \in \mathbb{C}}
\]
where \( Z_{M,\lambda} = 0 \) if \( \lambda \) does not lie in \( \Lambda + Q \). From the discussion above we see that
\[
\chi(w, h, \tau) = Z(w, \tau)\chi_{\sqrt{\eta}Q_L}(h, \tau).
\]
Performing the transformation of both sides by matrix \( \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \) we see that
\[
\tau^{\text{wt}[w]}e^{\pi ik(h,h)/\tau} S_A \chi(w, h, \tau) = Z(w, \frac{1}{\tau})e^{\pi ik(h,h)/\tau} S_L \chi_{\sqrt{\eta}Q_L}(h, \tau).
\]
Or equivalently,
\[
\tau^{\text{wt}[w]} S_A Z(w, \tau) \chi_{\sqrt{\eta}Q_L}(h, \tau) = Z(w, \frac{1}{\tau}) S_L \chi_{\sqrt{\eta}Q_L}(h, \tau).
\]
The linear independence of functions \( \{ \chi_{L,\lambda} | L + \lambda \in \mathbb{C} \} \) implies that
\[
\tau^{\text{wt}[w]} S_A Z(w, \tau) = Z(w, \frac{1}{\tau}) S_L.
\]
It is well known from [29] that \( S_L \) is symmetric, unitary and \( S_L^{-1} = S_L \). In fact, these properties hold for the \( S \)-matrix associated to any strong rational vertex operator algebra \([13]\). Finally we deduce

\[
Z(w, -1) = \tau^{\text{wt}[w]} S_{\Lambda} Z(w, \tau) S_{\Lambda}^{-1}.
\]

(c) Comparing the \((\Lambda, \lambda)\)-entries of both sides gives

\[
Z_{M^N, \lambda}(w, -1) = \tau^{\text{wt}[w]} \sum_{\lambda' \in P_k, \lambda' \in P/kQ_L} S_{\Lambda, \lambda'} S_{\lambda', \lambda''} Z_{M^N, \lambda''}(w, \tau)
\]

\[
= \tau^{\text{wt}[w]} |P/kQ_L|^{-1/2} \sum_{\lambda' \in P_k, \lambda' \in P/kQ_L} S_{\Lambda, \lambda'} \epsilon^{2\pi i \lambda_j} Z_{M^N, \lambda''}(w, \tau).
\]

Now we take \( \lambda = \Lambda + \beta_i \) for \( i \in Q/kQ_L \). Note that \( M^{N', \lambda'} \) is nonzero if and only if \( N' + kQ_L = \Lambda' + \beta_j + kQ_L \) for some \( j \in Q/kQ_L \). As a result, we see that

\[
Z_{M^\Lambda, \Lambda + \beta_i}(w, -1) = \tau^{\text{wt}[w]} \sum_{\lambda' \in P_k, \lambda' \in Q/kQ_L} S_{(\Lambda, \lambda + \beta_i), (N', \lambda' + \beta_j)} Z_{M^{N', \lambda'}, \lambda''}(w, \tau)
\]

and the proof is complete. \(\square\)

7. Connection with orbifold theory

Set \( H = \frac{1}{k} P \). For \( \alpha \in H \) we define \( g_\alpha = e^{2\pi i \alpha(0)} \) where we have identify \( h \) with \( h^* \) via the bilinear form \( (\cdot, \cdot) \). Then \( g_\alpha \) acts on \( \bar{L}_\theta(k, \Lambda) \) for any \( \Lambda \in P_k^+ \) such that

\[
g_\alpha Y(u, z) g_\alpha^{-1} = Y(g_\alpha u, z)
\]

for \( u \in L_\theta(k, 0) \). In particular, \( g_\alpha \) is an automorphism of vertex operator algebra \( L_\theta(k, 0) \). Moreover, \( g_\alpha = 1 \) on \( L_\theta(k, 0) \) if and only if \( \alpha \in Q^\circ \). That is, \( G = H/Q^\circ \) is an automorphism group of \( L_\theta(k, 0) \). For each \( \beta \in Q \) we define an irreducible character \( \mu_\beta \) of \( G \) such that \( \mu_\beta(g_\alpha) = g_\alpha(\beta) \). Following [15] and [8] we use \( L_\theta(k, 0)^{\mu_\beta} \) to denote the subspace of \( L_\theta(k, 0) \) which is a sum of irreducible \( G \)-submodule with character \( \mu_\beta \). Recall that \( Q = \bigcup_{i \in Q/kQ_L} (kQ_L + \beta_i) \). By Lemma [22] \( \{ \mu_{\beta_i}, i \in Q/kQ_L \} \) gives a complete list of inequivalent irreducible characters of \( G \). The following result is immediate from [8].

**Lemma 7.1.** The \( L_\theta(k, 0) \) is a completely reducible \( V^{\sqrt{k}Q_L} \otimes K(\theta, k) \)-module

\[
L_\theta(k, 0) = \bigoplus_{i \in Q/kQ_L} L_\theta(k, 0)^{\mu_\beta_i},
\]

and \( L_\theta(k, 0)^{\mu_\beta_i} = V^{\sqrt{k}Q_L + \beta_i} \otimes M^{0, \beta_i} \) is an irreducible module for \( V^{\sqrt{k}Q_L} \otimes K(\theta, k) \). Moreover, if \( i \neq j \) then \( L_\theta(k, 0)^{\mu_\beta_i} \) and \( L_\theta(k, 0)^{\mu_\beta_j} \) are inequivalent.
If $\Lambda \in P_+^k$ is not zero, $L_\bar{g}(k, \Lambda)$ is still a module for $H$ but not a module for $G$ unless $\Lambda \in Q$. However, $\alpha \mapsto \tilde{g}_\alpha = g_\alpha e^{-2\pi i (\alpha, \Lambda)}$ gives a $G$-module structure on $L_\bar{g}(k, \Lambda)$. It is clear that

$$\tilde{g}_\alpha Y(u, z)\tilde{g}_\alpha^{-1} = Y(g_\alpha u, z)$$

(5.1)
on $L_\bar{g}(k, \Lambda)$. A generalization of Lemma 7.1 is the following:

**Lemma 7.2.** The $L_\bar{g}(k, \Lambda)$ is a completely reducible $V_{\sqrt{k}Q_L} \otimes K(\mathfrak{g}, k)$-module

$$L_\bar{g}(k, \Lambda) = \bigoplus_{i \in Q/kQ_L} L_\bar{g}(k, \Lambda)^{\mu_i},$$

and $L_\bar{g}(k, \Lambda)^{\mu_i} = V_{\sqrt{k}Q_L + \frac{1}{k}(\Lambda + \beta_i)} \otimes M^{\Lambda, \Lambda + \beta_i}$ is an irreducible module for $V_{\sqrt{k}Q_L} \otimes K(\mathfrak{g}, k)$. Moreover, if $i \neq j$ then $L_\bar{g}(k, \Lambda)^{\mu_i}$ and $L_\bar{g}(k, \Lambda)^{\mu_j}$ are inequivalent.

We can strengthen Lemma 7.2

**Proposition 7.3.** For $\Lambda \in P_+^k$ and $i \in Q/kQ_L$, $L_\bar{g}(k, \Lambda)^{\mu_i}$ are inequivalent irreducible $V_{\sqrt{k}Q_L} \otimes K(\mathfrak{g}, k)$-modules.

*Proof.* From equation (5.1) we know that $L_\bar{g}(k, \Lambda) \circ g_\alpha$ and $L_\bar{g}(k, \Lambda)$ are isomorphic $L_\bar{g}(k, 0)$-modules where $L_\bar{g}(k, \Lambda) \circ g_\alpha = L_\bar{g}(k, \Lambda)$ as vector spaces and $Y_{L_\bar{g}(k, \Lambda)\circ g_\alpha} (v, z) = Y_{L_\bar{g}(k, 0)} (g_\alpha v, z)$ for $v \in L_\bar{g}(k, 0)$. According to a general result in orbifold theory [23, 18], $L_\bar{g}(k, \Lambda)^{\mu_i}$ are inequivalent irreducible $V_{\sqrt{k}Q_L} \otimes K(\mathfrak{g}, k)$-modules.

We can now express the trace functions $Z_{M^{\Lambda, \Lambda + \beta_i}} (w, \tau)$ in terms of $\chi_\Lambda (w, \alpha, \tau)$ and the characters of irreducible modules for lattice vertex operator algebra $V_L$ with $L = \sqrt{k}Q_L$.

For $w \in K(\mathfrak{g}, k)$ we have

$$Z_{V_{\sqrt{k}Q_L + \frac{1}{k}(\Lambda + \beta_i)} \otimes M^{\Lambda, \Lambda + \beta_i}} (w, \tau) = \frac{1}{|Q/kQ_L|} \sum_{\alpha \in G} \text{tr}_{L_\bar{g}(k, \Lambda)} O(w) \tilde{g}_\alpha q^{L(0)-c/24} e^{-2\pi i (\alpha, \beta_i)}$$

$$= \frac{1}{|Q/kQ_L|} \sum_{\alpha \in G} \text{tr}_{L_\bar{g}(k, \Lambda)} O(w) e^{2\pi i (0)} q^{L(0)-c/24} e^{-2\pi i (\alpha, \beta_i + \Lambda)}$$

$$= \frac{1}{|Q/kQ_L|} \sum_{\alpha \in G} e^{-2\pi i (\alpha, \beta_i + \Lambda)} \chi_\Lambda (w, \alpha, \tau).$$

This implies the following:

**Proposition 7.4.** For $\Lambda \in P_+^k$, $i \in Q/kQ_L$ and $w \in K(\mathfrak{g}, k)$ we have

$$Z_{M^{\Lambda, \Lambda + \beta_i}} (w, \tau) = \frac{1}{|Q/kQ_L|} \eta(\tau)^l \theta_{\sqrt{k}Q_L + \frac{1}{k}(\Lambda + \beta_i)} (\tau) \sum_{\alpha \in G} e^{-2\pi i (\alpha, \beta_i + \Lambda)} \chi_\Lambda (w, \alpha, \tau).$$
