THE COMPLEX WKB METHOD FOR DIFFERENCE EQUATIONS AND AIRY FUNCTIONS

ALEXANDER FEDOTOV AND FRÉDÉRIC KLOPP

Abstract. We consider the difference Schrödinger equation

\[ \psi(z + h) + \psi(z - h) + v(z)\psi(z) = 0 \]

where \( z \) is a complex variable, \( h \) is a parameter, and \( v \) is an analytic function. As \( h \to 0 \) analytic solutions to this equation have a standard quasiclassical behavior near the points where \( v(z) \neq \pm 2 \). We study analytic solutions near the points \( z_0 \) satisfying

\[ v(z_0) = \pm 2 \] \( v'(z_0) \neq 0 \). For the finite difference equation, these points are the natural analogues of the simple turning points defined for the differential equation

\[ -\psi''(z) + v(z)\psi(z) = 0 \]

We derive uniform asymptotic expansions for analytic solutions to the difference equation.

1. Introduction

We study analytic solutions to the difference Schrödinger equation

\[ \psi(z + h) + \psi(z - h) + v(z)\psi(z) = 0 \quad (1.1) \]

where \( z \) is a complex variable, \( h \) is a positive parameter and \( v \) is an analytic function. We describe their asymptotics as \( h \to 0 \).

Note that the parameter \( h \) is a standard quasiclassical parameter. Indeed, formally,

\[ \psi(z + h) = \sum_{l=0}^{\infty} \frac{h^l}{l!} \frac{d^l}{dz^l} \psi(z) = e^{h\frac{d}{dz}} \psi(z), \]

and \( h \) can be regarded as a small parameter in front of the derivative.

One encounters difference equations in the complex plane in many fields of mathematics and physics. For example, they arise when studying an electron in a crystal submitted to a constant magnetic field (e.g., [17]), wave scattering by wedges (e.g., [1]) and one-dimensional quasi-periodic differential Schrödinger equations with two frequencies (e.g., [10]). The quasiclassical case corresponds respectively to the cases of a small magnetic field, of a thin wedge and the case where one frequency is small with respect to another.

The quasiclassical theory of difference equations in the complex plane can also be useful to study orthogonal polynomials, see section 2.6.

The quasiclassical asymptotics of analytic solutions to ordinary differential equations in the complex plane are described by the well-known complex WKB method (see, e.g., [21, 7]). The complex WKB method for difference equations was developed in [3, 13, 15].

The present paper is devoted to uniform asymptotic formulas describing analytic solutions to (1.1) in \( h \)-independent complex neighborhoods of simple turning points (see sections 2.1.1 and 2.2.3). We note that the results of this paper were partially announced in [12].

Key words and phrases. Difference Schrödinger equation, complex WKB method, Airy functions.

The work was supported by CNRS, France, and the Russian Foundation for Basic Research under the grant No 17-51-150008.
2. Main objects and results

In the present section, we first recall some basic definitions and statements of the complex WKB method for difference equations. Next, we introduce a few objects needed to formulate our results that we then state.

We assume that $v$ is analytic on a disk $U \subset \mathbb{C}$.

Below, a neighborhood is a $\delta$-neighborhood, in particular, a neighborhood of a point is an open disk with the center at this point.

2.1. A very short introduction to the complex WKB method.

2.1.1. The complex momentum. The main analytic object of the complex WKB method is the complex momentum $p$. For (1.1) it is defined by the formula

$$2 \cos p + v(z) = 0$$

(2.1)

It is a multivalued analytic function on $U$. At its branching points $\cos p(z) \in \{\pm 1\}$, thus, $v(z) \in \{\pm 2\}$.

In analogy with the glossary of the complex WKB method for differential equations, the points where $v(z) \in \{\pm 2\}$ are called turning points.

A set $D \subset U$ is regular if $v(z) \neq \pm 2$ in $D$.

2.1.2. The main theorem of the complex WKB method. As in the case of differential equations, the main geometric notion of the complex WKB method is the canonical domain. The reader can find definitions and details in [13, 15]; here we only recall that canonical domains are regular, simply connected domains independent of $h$, and that one has the following two theorems.

**Theorem 2.1.** Any regular point belongs to a canonical domain.

The proof of this statement repeats the proof of Lemma 5.2 from [11].

**Theorem 2.2.** Let $K \subset U$ be a canonical domain, let $z_0 \in K$, and let $p$ be a branch of the complex momentum analytic in $K$. There exist solutions $\psi_{\pm}$ to (1.1) analytic in $K$ and such that as $h \to 0$

$$\psi_{\pm}(z) = \frac{1}{\sqrt{\sin(p(z))}} e^{\pm \frac{i}{h} \int_{z_0}^{z} p(z') \, dz' + o(1)}$$

(2.2)

This asymptotic representation is locally uniform in $K$.

In [13] this theorem was proved for bounded canonical domains, and in [15] it was proved in the case where $v$ is a trigonometric polynomial.

Note that, by definition, at a turning point of $p$, one has $\sin p(z) = 0$. Thus, representation (2.2) can not be valid in a neighborhood of a turning point.

**Remark 2.1.** For the differential equation $-h^2 \psi''(z) + v(z) \psi(z) = 0$, formula (2.2) has to be replaced with $\psi_{\pm}(z) = \frac{1}{\sqrt{p(z)}} e^{\pm \frac{i}{h} \int_{z_0}^{z} p(z') \, dz' + o(1)}$, where the complex momentum is defined by the relation $p^2 + v(z) = 0$, i.e., as for (1.1), by the symbol of the equation.

2.2. The complex momentum and the conformal mapping $\zeta$. The properties of the complex momentum described below easily follow from its definition.

2.2.1. Analytic branches of the complex momentum. Let $p_0$ be a branch of the complex momentum analytic in a regular simply connected domain $D$. Then, an analytic function $\tilde{p} : D \to \mathbb{C}$ is a branch of the complex momentum if and only if there exists $s \in \{\pm 1\}$ and $n \in \mathbb{Z}$ s.t.

$$\tilde{p}(z) = sp_0(z) + 2\pi n, \quad \forall z \in D.$$  

(2.3)
2.2.2. The values of \( p \) at turning points. We note that \( z_0 \in U \) is a turning point if and only if \( p(z_0) = 0 \bmod \pi \). A simple transformation of the equation shows that it suffices to consider the case where \( p(z_0) = 0 \bmod 2\pi \). Indeed, for \( \psi \), a solution to (1.1), we set \( \phi(z) = e^{i\pi z/h}\psi(z) \). Then, \( \phi \) satisfies equation

\[
\phi(z + h) + \phi(z - h) - \psi(z)\phi(z) = 0. \tag{2.4}
\]

The complex momenta for equations (1.1) and (2.4) differ by \( \pi \bmod 2\pi \), and \( z_0 \) is a turning point for (1.1) if and only if it is a turning point for (2.4).

2.2.3. The complex momentum near a turning point. Let \( z_0 \) be a turning point. If \( v'(z_0) \neq 0 \), we call the turning point \( z_0 \) simple. In this case, the complex momentum is analytic in \( \tau = \sqrt{z - z_0} \) in a neighborhood of 0, and as \( \tau \to 0 \) any of its analytic branches admits a representation of the form

\[
p(z) = p(z_0) + k_1\tau + O(\tau^2), \quad \tau = \sqrt{z - z_0}, \quad k_1 \neq 0. \tag{2.5}
\]

2.2.4. Our assumptions. From now on, we assume that

- in the disk \( U \), there exists a single turning point, namely its center \( z_0 \), and it is simple;
- \( p(z_0) = 0 \bmod 2\pi \).

2.2.5. The function \( \zeta \). We cut \( U \) from \( z_0 \) to a point of its boundary along a simple curve and denote the thus obtained domain by \( U' \). In \( U' \), we fix an analytic branch \( p \) of the complex momentum.

We have \( p(z_0) = 2\pi n, \quad n \in \mathbb{Z} \). Clearly, \( p(z) - 2\pi n \) also is a branch of the complex momentum analytic in \( U' \). So, we can and do assume that \( p(z_0) = 0 \).

Let us fix in \( U' \) an analytic branch \( \zeta \) of the function

\[
z \mapsto \left( \frac{3}{2i} \int_{z_0}^z p(z) \, dz \right)^{\frac{3}{2}}. \tag{2.6}
\]

This branch is actually analytic in \( U \). One has \( \zeta(z_0) = 0 \), and \( \zeta'(z_0) \neq 0 \).

Remark 2.2. There are three different analytic branches of function (2.6): they equal \( e^{4\pi j /3} \zeta, \quad j \in \mathbb{Z}_3 = \mathbb{Z}/3\mathbb{Z} \). The set of these branches is independent of the curve along which we cut \( U \) to get \( U' \) and on the precise choice of the branch \( p \).

Possibly reducing \( U \) somewhat, we can and do assume that

- \( \zeta \) is a bi-analytic bijection of \( U \) onto its image.

2.3. Basic facts on Airy functions. The equation

\[
w''(\zeta) = \zeta w(\zeta), \quad \zeta \in \mathbb{C}, \tag{2.7}
\]

is the Airy equation. Its solutions are Airy functions.

Let \((\gamma_j)_{j \in \mathbb{Z}_3}\) be the curves shown in Fig. 1 borrowed from [22]; \( \gamma_0 \) is asymptotic to the half-lines \( e^{\pm 2\pi i /3} \mathbb{R}_+ \), \( \mathbb{R}_+ = [0, +\infty) \subset \mathbb{R} \); for \( j \in \mathbb{Z}_3 \), rotating \( \gamma_0 \) around 0 by \( 2j\pi/3 \), one obtains \( \gamma_j \). The functions defined by the formulas

\[
w_j(\zeta) = \int_{\gamma_j} e^{-(\zeta^2/4 - \zeta s)} \, ds, \quad j \in \mathbb{Z}_3, \quad \zeta \in \mathbb{C}, \tag{2.8}
\]

are three linearly independent Airy functions related to the standard Airy function \( Ai \) by the formulas (see, e.g., [22])

\[
w_j(\zeta) = 2\pi i \omega^j Ai(\omega^j \zeta), \quad \omega = e^{2\pi i /3}, \quad \zeta \in \mathbb{C}. \tag{2.9}
\]

Assume that \( |\arg z| < 2\pi/3 \). As \( |z| \to \infty \) one has
\[ \text{Ai}(z) = \frac{\exp\left(-\frac{2}{3}z^{3/2} + o(1)\right)}{2\sqrt{\pi} \cdot z^{1/4}}, \quad \text{Ai}(-z) = \frac{\cos\left(\frac{2}{3}z^{3/2} + \frac{\pi}{4} + o(1)\right)}{\sqrt{\pi} \cdot z^{1/4}(1 + o(1))} \] (2.10)

where we use the analytic branches of \( z \to z^{3/2} \) and \( z \to z^{1/4} \) that are positive for \( z > 0 \) (see \([18]\), pp. 116, 118 and 392).

2.4. **Notations.** The letter \( C \) denotes various positive constants independent of \( z \) and \( h \).

For two functions \( f \) and \( g \) defined on a domain \( D \subset \mathbb{C} \), we write that \( g(z) = O(f(z)) \) in \( D \) if \( |g(z)| \leq C|f(z)| \) for all \( z \in D \).

2.5. **Solutions in a complex neighborhood of a branch point.**

2.5.1. **Asymptotic solutions.** First, let us describe asymptotic solutions to (1.1). Therefore, we introduce several objects. For a function \( f \) defined on \( U \), we set

\[ [H(f)](z) := f(z + h) + f(z - h) + v(z)f(z), \quad \{z - h, z, z + h\} \subset U. \] (2.11)

We let

\[ g(z) := \frac{\text{sh} \left( \sqrt{\zeta(z)} \zeta'(z) \right)}{\sqrt{\zeta(z)}}, \quad z \in U, \] (2.12)

where the determination of the square roots in the denominator and the numerator are the same (the definition of \( g \) is independent of its choice). The function \( g \) is analytic in \( U \). Possibly reducing \( U \) somewhat, we can and do assume that

- \( g \) does not vanish in \( U \).

We further define

\[ A_0(z) := \frac{1}{\sqrt{g(z)}}. \] (2.13)

The function \( A_0 \) is analytic in \( U \).

One has

**Theorem 2.3.** There exist functions \((A_l)_{l \in \mathbb{N} \cup \{0\}}\) and \((B_l)_{l \in \mathbb{N}}\), \( (A_0 \) being defined by (2.13)), all analytic on \( U \) and such that, for any \( L \in \mathbb{N} \cup \{0\} \) the following holds. Let \( w \) be one of the Airy functions \( w_j, \quad j \in \mathbb{Z}_3 \). If we define

\[ w_h(z) = w \left( \zeta(z)/h^{\frac{2}{3}} \right), \quad w'_h(z) = w' \left( \zeta(z)/h^{\frac{2}{3}} \right), \] (2.14)

and

\[ W(z) = h^{\frac{2}{3}} w_h(z) \sum_{l=0}^L h^l A_l(z) + h^{\frac{2}{3}} w'_h(z) \sum_{l=1}^L h^l B_l(z), \] (2.15)
then one has

\[ H(W) = O \left( h^{L+2+\frac{3}{2}w_h} \right) + O \left( h^{L+2+\frac{3}{2}w_h'} \right). \]  

(2.16)

We call the formal expression

\[ h^{\frac{3}{4}w_h(z)} \sum_{l=0}^{\infty} h^l A_l(z) + h^{\frac{3}{2}w_h'(z)} \sum_{l=1}^{\infty} h^l B_l(z) \]  

(2.17)

an asymptotic solution to (1.1).

Theorem 2.3 is proved in section 4, where we describe, inter alia, a way to compute the coefficients \((A_l)\) and \((B_l)\).

**Remark 2.3.** For the differential equation

\[ -\psi''(z) + v(z)\psi(z) = 0, \]  

in a neighborhood of a simple turning point (a point where \(v(z) = 0\) and \(v'(z) \neq 0\)), there are asymptotic solutions of the form (2.17) (with different coefficients \((A_l)\) and \((B_l)\) and function \(\zeta\)). To justify the Ansatz (2.17) for the difference equation, one has to derive asymptotic formulas of the form

\[ w(h^{-\frac{3}{2}}\zeta(z+h)) = h^{\frac{3}{4}} f(z) w(h^{-\frac{3}{2}}\zeta(z)) + h^{\frac{3}{2}} g(z) w'(h^{-\frac{3}{2}}\zeta(z)) + \ldots, \]  

(2.18)

where \(f(z) = c h (\sqrt{\zeta(z)}\zeta'(z))\) and the dots denote smaller order terms. If one tries to prove this formula using Taylor expansions for the left hand side, one has to handle an infinite number of infinite subsequences of terms of the same order. So, an effective resummation of these sequences is required. To derive formulas analogous to (2.18), instead of resummation of Taylor series, we use tools from complex analysis.

2.5.2. Solutions with standard asymptotic behavior. Our main result is

**Theorem 2.4.** Pick \(L \in \mathbb{N}\). Let \(W\) be one of the functions constructed in Theorem 2.3 for the order \(L\). There exists an \(h\)-independent neighborhood \(\hat{U} \subset U\) of \(z_0\) such that, for sufficiently small \(h\), there exists \(\psi\), a solution to equation (1.1) that is analytic in \(\hat{U}\) and admits there the asymptotic representation

\[ \psi(z) = W(z) + O(w_h h^{L+1+\frac{5}{2}}) + O(w'_h h^{L+1+\frac{5}{2}}) \]  

(2.19)

where \(w_h\) and \(w'_h\) are defined in (2.14).

Theorem 2.4 is proved in sections 6 and 7.

Let us briefly explain the idea of the proof of Theorem 2.4. First, in section 6, using the approximate solutions constructed in Theorem 2.3, we construct a parametrix \(R\), i.e., an operator such that, for suitable functions \(f\), one has \(HRf = f + Df\), where \(H\) is defined in (2.11) and \(D\) is a small operator. The operator \(D\) is a singular integral operator. We estimate its norm using natural geometric objects of the complex WKB method. This allows us to prove Theorem 2.4 on some special subdomains of \(U\). In section 7, we study the thus constructed solutions on larger domains and complete the proof of Theorem 2.4.

To complete this short description, let us underline that, as equation (1.1) is non local in \(z\), the ideas of analysis of (1.1) are different from those used to study the analogous differential equation.

2.6. Related results. The WKB asymptotics of solutions of difference equations on \(\mathbb{Z}\) with “slowly varying” coefficients have been studied since the end of sixties. In [20] and [19], the authors essentially studied equations of the form

\[ Y_{k+1} = M(hk)Y_k, \quad k \in \mathbb{Z}, \]  

(2.20)
with a small positive $h$ and an $(n \times n)$-matrix valued function $M$ defined on $\mathbb{R}$. We note that if

$$Y(x + h) = M(x)Y(x), \quad x \in \mathbb{R},$$

then, the sequence $(Y_k)_{k \in \mathbb{Z}} = (Y(kh))_{k \in \mathbb{Z}}$ satisfies (2.20). We note also that equation (1.1) restricted to $\mathbb{R}$ is equivalent to (2.21) with $M(x) = \begin{pmatrix} -v(x) & 1 \\ 1 & 0 \end{pmatrix}$, and that a turning point for equation (1.1) is a point $x$ where the eigenvalues of the matrix $M(x)$ coincide.

The short note [20] is essentially devoted to the case where all the eigenvalues of the matrix $M$ in (2.20) are distinct. In [19] the author constructed asymptotic solutions to (2.20) in a small (depending on $h$) neighborhood of a point where two eigenvalues of $M(x)$ become equal.

In [5] the authors considered difference equations of the form

$$\sum_{j=0}^{J} a_{j}(hk, h) y_{k+j} = 0, \quad k \in \mathbb{Z}.$$  

We note that this class includes the difference Schrödinger equations

$$y_{k+1} + y_{k-1} + v(hk)y_{k} = 0, \quad k \in \mathbb{Z}.$$  

The authors described the asymptotics of solutions to this equations for $hk$ being in a small (as $h \to 0$) neighborhood of a point where $v(x) \in \{ \pm 1 \}$.

We mention also three (series of) papers motivated by problems originating in the theory of orthogonal polynomials.

First, there is a series of papers by J.S. Geronimo and co-authors, see, e.g. [16] and references therein, devoted to uniform asymptotic formulas for solutions to the equation $a_{k+1}\psi_{k+1} + b_{k}\psi_{k} + a_{k}\psi_{k-1} = \lambda \psi_{k}, \quad k \in \mathbb{Z}$, where $\lambda$ is the spectral parameter, and the coefficients $a_{k}$ are positive and $b_{k}$ are real.

Also we mention papers by R.Wong and coauthors, see e.g., [23], who also studied solutions to three terms recurrence relations with real coefficients for large values of the integer variable.

Finally, we mention paper [6] where the authors studied WKB asymptotics of solutions to a difference equation using the Maslov canonical operator.

There are more papers devoted to the subject. The reader can find more references in the papers that we mentioned above.

To the best of our knowledge, the present paper is the first where one rigorously obtains uniform asymptotics of analytic solutions to a difference equation on $\mathbb{C}$ in an $h$-independent neighborhood of a turning point.

3. The space of solutions to equation (1.1)

The observations that we discuss now are well-known in the theory of difference equations and are easily proved.

Let $c \in \mathbb{R}$ and $I = \{z \in U : \text{Im } z = c\}$. We assume that the length of the segment $I$ is sufficiently large (with respect to $h$) and discuss the set $S$ of solutions to equation (1.1) on $I$.

Let $\{f, g\} \subset S$. The expression

$$(f(z), g(z)) = f(z + h)g(z) - f(z)g(z + h), \quad z, z + h \in I,$$  

is called the Wronskian of $f$ and $g$. It is $h$-periodic in $z$.

If the Wronskian of two solutions does not vanish, they form a basis in $S$, i.e., $\psi \in S$ if and only if

$$\psi(z) = a(z)f(z) + b(z)g(z), \quad z, z + h \in I,$$  

where $a$ and $b$ are $h$-periodic complex coefficients. One has
\begin{equation}
 a(z) = \frac{(\psi(z), g(z))}{(f(z), g(z))}, \quad b(z) = \frac{(f(z), \psi(z))}{(f(z), g(z))}.
\end{equation}

4. Asymptotic solutions: the proof of Theorem 2.3

4.1. The proof of Theorem 2.3 up to two propositions. First, we formulate two statements needed to construct asymptotic solutions to (1.1). Below we use the notations introduced in (2.14).

**Proposition 4.1.** Let $A$ be analytic in $U$. Let $N \in \mathbb{N}$. If $\{z-h, z, z+h\} \subset U$,
\begin{equation}
 H \left( A h^\frac{1}{3} w_h \right) = h^\frac{1}{3} w_h \sum_{l=2}^{N} h^l a_l + O \left( h^{N+1+\frac{1}{3}} w_h \right)
 + h^\frac{2}{3} w_h' \sum_{l=1}^{N} h^l b_l + O \left( h^{N+1+\frac{2}{3}} w_h' \right)
\end{equation}
as $h \to 0$. All the coefficients $(a_l)_{l \geq 2}$ and $(b_l)_{l \geq 1}$ are analytic in $U$, independent of the choice of $w$ in (2.14), and
\begin{equation}
 b_1 = b_1[A] = Ag \frac{d}{dz} \log(A^2 g).
\end{equation}

**Proposition 4.2.** Let $B$ be analytic in $U$, and let $N \in \mathbb{N}$. If $\{z-h, z, z+h\} \subset U$,
\begin{equation}
 H \left( B h^\frac{2}{3} w_h' \right) = h^\frac{2}{3} w_h' \sum_{l=1}^{N} h^l c_l + O \left( h^{N+1+\frac{2}{3}} w_h \right)
 + h^\frac{4}{3} w_h'' \sum_{l=1}^{N} h^l d_l + O \left( h^{N+1+\frac{4}{3}} w_h'' \right)
\end{equation}
as $h \to 0$. All the coefficients $(c_l)_{l \geq 1}$ and $(d_l)_{l \geq 2}$ are analytic in $U$, independent of the choice of $w$ in (2.14), and
\begin{equation}
 c_1 = c_1[B] = \zeta B g \frac{d}{dz} \log(\zeta B^2 g). \tag{4.4}
\end{equation}

Before proving Propositions 4.1 and 4.2, we use them to prove Theorem 2.3. The proof is done by induction on the order $L$. For $L=0$, one has $W = A_0 h^\frac{1}{3} w_h$. In view of (2.13) and (4.2), the coefficient $b_1$ corresponding to $A = A_0$ is equal to 0. So, the statement of Theorem 2.3 for $L = 0$ immediately follows from (4.1) with $N = 1$.

Now, we assume that Theorem 2.3 is proved up to the order $L = L_0 - 1$, $L_0 \in \mathbb{N}$. Let us prove it for $L = L_0$. We set
\begin{equation}
 W(z) = h^\frac{1}{3} w_h(z) \sum_{l=0}^{L_0} h^l A_l(z) + h^\frac{2}{3} w_h'(z) \sum_{l=1}^{L_0} h^l B_l(z), \tag{4.5}
\end{equation}
where $(A_l)_{l < L_0}$ and $(B_l)_{l < L_0}$ are chosen as in the case $L = L_0 - 1$, $A_{L_0}$ and $B_{L_0}$ still having to be chosen. By the induction hypothesis
\begin{equation}
 H \left( h^\frac{1}{3} w_h \sum_{l=0}^{L_0-1} h^l A_l + h^\frac{2}{3} w_h' \sum_{l=1}^{L_0-1} h^l B_l \right)
 = O \left( h^{L_0+1+\frac{1}{3}} w_h \right) + O \left( h^{L_0+1+\frac{2}{3}} w_h' \right). \tag{4.6}
\end{equation}
In view of Propositions 4.2 and 4.1 this implies that
\[
H \left( h^{\frac{3}{8}} w_h \sum_{l=0}^{L_0-1} h^l A_l + h^{\frac{3}{8}} w_h' \sum_{l=1}^{L_0-1} h^l B_l \right) = ah^{L_0+1+\frac{3}{8}} w_h + bh^{L_0+1+\frac{3}{8}} w_h' + O(h^{L_0+2+\frac{3}{8}} w_h) + O(h^{L_0+2+\frac{3}{8}} w_h'),
\]
where \( a \) and \( b \) are analytic functions in \( U \). On the other hand, using (4.1) and (4.3) with \( N = 1 \), we get
\[
\begin{align*}
H(A_{L_0} h^{L_0+\frac{3}{8}} w_h) &= h^{L_0+1+\frac{3}{8}} w_h' b_1[A_{L_0}] + O(h^{L_0+2+\frac{3}{8}} w_h), \quad H(B_{L_0} h^{L_0+\frac{3}{8}} w_h') = h^{L_0+1+\frac{3}{8}} w_h c_1[B_{L_0}] + O(h^{L_0+2+\frac{3}{8}} w_h),
\end{align*}
\]
Therefore,
\[
HW = h^{L_0+1} \left( h^{\frac{3}{8}} w_h (a + c_1[B_{L_0}]) + h^{\frac{3}{8}} w_h' (b + b_1[A_{L_0}]) \right) + O(h^{L_0+2+\frac{3}{8}} w_h).
\]
So, to prove Theorem 2.3, it suffices to choose \( A_{L_0} \) and \( B_{L_0} \) so that
\[
a + c_1[B_{L_0}] = 0, \quad \text{and} \quad b + b_1[A_{L_0}] = 0.
\]
In view of (4.2) and (4.4), these relations are equivalent to the equations
\[
\zeta B_{L_0} g \frac{d}{dz} \log (\zeta B_{L_0}^2 g) = -a, \quad \text{and} \quad A_{L_0} g \frac{d}{dz} \log (A_{L_0}^2 g) = -b. \tag{4.7}
\]
One constructs solutions to these equations by the formulas
\[
A_{L_0}(z) = -\frac{1}{2 \sqrt{g(z)}} \int_{z_0}^z b dz \sqrt{g}, \quad \text{and} \quad B_{L_0}(z) = -\frac{1}{2 \sqrt{\zeta(z)g(z)}} \int_{z_0}^z a dz \sqrt{\zeta g}. \tag{4.8}
\]
As
\[
\bullet \ g \text{ and } \zeta \text{ are analytic in } U,
\bullet \ g \text{ does not vanish in } U,
\bullet \ \zeta \text{ vanishes in } U \text{ only at } z_0 \text{ where it has a simple zero},
\]
the coefficients \( A_{L_0} \) and \( B_{L_0} \) are analytic in \( U \). This completes the proof of Theorem 2.3. \( \square \)

**Remark 4.1.** The function \( B_{L_0} \) constructed by (4.8) is the only solution to the first equation in (4.7) that is analytic in \( U \). The function \( A_{L_0} \) constructed by (4.8) is unique up to a solution to the homogeneous equation \( A_{L_0} g \frac{d}{dz} \log (A_{L_0}^2 g) = 0 \) that is proportional to \( A_0 \) given by (2.13).

### 4.2. The proof of Proposition 4.1.
Consider \((w_j)_{j \in \mathbb{Z}}\), the three solutions to the Airy equation (2.7) defined by (2.8). Let \( w \) be \( w_j \) for some \( j \in \mathbb{Z} \) and let \( \gamma \) be the corresponding integration path \( \gamma_j \) in (2.8).

Note that
\[
h^{\frac{3}{8}} w (h^{-\frac{3}{8}} \zeta) = \int_\gamma e^{-\frac{3}{8} \left( \frac{z^2}{h} - t \zeta \right)} dt, \quad h^{\frac{3}{8}} w' (h^{-\frac{3}{8}} \zeta) = \int_\gamma e^{-\frac{3}{8} \left( \frac{z^2}{h} - t \zeta \right)} t dt. \tag{4.9}
\]
Below, we use the notations from (2.14). Let \( K \subset U \) be a closed disk centered at \( z_0 \) and independent of \( h \). Below, we assume that \( z \in K \) and \( h \) is sufficiently small. The proof of the asymptotics of \( H(A h^{\frac{3}{8}} w) \) in \( K \) as \( h \to 0 \) is broken into several steps.
1. In view of (4.9), we get

\[ H\left(Ah^{\frac{1}{3}}w\right) = \int e^{-\frac{1}{2}\left(\frac{q^2}{3} - t\xi(z)\right)} F_0(t, z, h) \, dt, \] (4.10)

\[ F_0(t, z, h) = A(z + h)e^{\frac{1}{2}t\xi(z + h) - t\xi(z)} + A(z - h)e^{\frac{1}{2}t\xi(z - h) - t\xi(z)} + v(z)A(z). \] (4.11)

Note that \((t, z, h) \mapsto F_0(t, z, h)\) is analytic in \(\mathbb{C} \times K \times V\), where \(V\) is a sufficiently small neighborhood of zero.

2. To get the asymptotics of the integral in (4.10), we apply the well-known method described in detail in section 4 of chapter VII of [22]. First, we represent \(F_0(t, z, h)\) in the form

\[ F_0(t, z, h) = a_0(z, h) + b_0(z, h)t + (t^2 - \xi(z))f_0(t, z, h) \] (4.12)

with

\[ a_0(z, h) = \frac{1}{2} \left( F_0(\sqrt{\xi}(z), z, h) + F_0(-\sqrt{\xi}(z), z, h) \right), \] (4.13)

\[ b_0(z, h) = \frac{1}{2\sqrt{\xi}(z)} \left( F_0(\sqrt{\xi}(z), z, h) - F_0(-\sqrt{\xi}(z), z, h) \right), \] (4.14)

where, in (4.13) and (4.14), we use one and the same branch of \(\sqrt{\xi}(z)\). Both \(a_0\) and \(b_0\) are analytic in \((z, h) \in K \times V\) (we remove the removable singularities at \(z = 0\)). With \(a_0\) and \(b_0\) so chosen, it is easily seen that the function \(f_0\) is analytic in \((t, z, h) \in \mathbb{C} \times K \times V\).

3. Substituting (4.12) into (4.10) and integrating by parts, we get

\[ H\left(Ah^{\frac{1}{3}}w_h\right) = a_0h^{\frac{1}{2}}w_h + b_0h^{\frac{3}{2}}w_h' + \int e^{-\frac{1}{2}\left(\frac{q^2}{3} - t\xi(z)\right)}(t^2 - \xi(z))f_0 \, dt \]

\[ = a_0h^{\frac{1}{2}}w_h + b_0h^{\frac{3}{2}}w_h' + h\int e^{-\frac{1}{2}\left(\frac{q^2}{3} - t\xi(z)\right)}F_1(t, z, h) \, dt. \] (4.15)

where \(F_1(t, z, h) = \frac{\partial f_1}{\partial t}(t, z, h)\).

4. Now, we transform the last integral in (4.15), the one containing \(F_1\), in the same way as we transformed the integral with \(F_0\) from (4.10).

For a fixed positive integer \(N\), we repeat this procedure inductively \(N + 2\) times. Reasoning as above, one proves that

\[ H\left(Ah^{\frac{1}{3}}w_h\right) = h^{\frac{1}{3}}w_h \sum_{l=0}^{N+1} h^l a_l(z, h) + h^{\frac{3}{2}}w_h' \sum_{l=0}^{N+1} h^l b_l(z, h) + h^{N+2}I_{N+2}, \] (4.16)

where, for \(l \in \mathbb{N} \cup \{0\}\), we have defined

\[ I_l = \int e^{-\frac{1}{2}\left(\frac{q^2}{3} - t\xi(z)\right)}F_1(t, z, h) \, dt. \] (4.17)

As when \(l = 0\), the coefficients \(a_l\) and \(b_l\) are expressed in terms of \(F_l\) by

\[ a_l(z, h) = \frac{1}{2} \left( F_l(\sqrt{\xi}(z), z, h) + F_l(-\sqrt{\xi}(z), z, h) \right), \]

\[ b_l(z, h) = \frac{1}{2\sqrt{\xi}(z)} \left( F_l(\sqrt{\xi}(z), z, h) - F_l(-\sqrt{\xi}(z), z, h) \right), \]

and the function \(f_l\) is defined by the relation

\[ F_l(t, z, h) = a_l(z, h) + b_l(z, h)t + (t^2 - \xi(z))f_l(t, z, h) \] (4.18)

Finally, for \(l \geq 1\), one has \(F_l(t, z, h) = \frac{\partial f_{l-1}}{\partial t}(t, z, h)\).

For \(l \in \mathbb{N} \cup \{0\}\), the coefficients \(a_l\) and \(b_l\) are analytic in \((z, h) \in K \times V\).

5. To estimate the integrals \(I_l\), one has to estimate the functions \(F_l\). Below, the
constants $C$ are independent on $z$, $h$ and $t$. The symbol $O(\cdot)$ is subsequently used for estimates uniform in $z$, $t$ and $h$.

Let us assume that that $(t, z, h) \in \mathbb{C} \times K \times V$ and show that there exists a constant $C_0 > 0$ such that, for any $l \in \mathbb{N}$, one has

$$F_l(t, z, h) = O \left( e^{C_0 |t|} \right),$$

(4.19)

where the implicit constant in (4.19) depends only on the index $l$.

This estimate is obvious for $F_0$. Let us assume that it is proved for some $l = l_0$ and prove it for $l = l_0 + 1$.

Clearly, $\zeta(z)$ is bounded on $K$. In view of the definitions of $(a_l)_{l \geq 0}$, $(b_l)_{l \geq 0}$ and the induction hypothesis, we have $a_{l_0}(z, h) = O(1)$ and $b_{l_0}(z, h) = O(1)$. These observations, the definition of $f_l$ (4.18) and the induction hypothesis imply that there exists $R > 0$ independent of $h$ such that, for all $|t| \geq R$, $f_{l_0}(t, z, h) = O(e^{C_0 |t|})$.

By the maximum principle, this implies that $f_h$ satisfies this estimate for all $t \in \mathbb{C}$. Now the Cauchy estimates for the derivatives of the analytic functions imply (4.19) for $l = l_0 + 1$.

6. Let us prove that

$$I_l = O \left( h^{\frac{3}{4}} w_h \right) + O \left( h^{\frac{1}{2}} w'_h \right).$$

(4.20)

Therefore, one essentially has to repeat the reasoning made in Section 4, Chapter VII of [22]. So, we omit some details.

If $Z = h^{-\frac{3}{4}} \zeta(z)$ is bounded by a constant, setting $T = h^{-\frac{1}{4}} t$, we change variable in (4.17). In view of step 5, we get

$$I_l = h^{\frac{3}{4}} \int_{\gamma} e^{-\left( \frac{T^2}{2} - T \zeta(z) \right)} O(e^{C_0 h^{\frac{3}{4}} |T|}) \, dT = O(h^{\frac{3}{4}}),$$

and this leads to (4.20) as $w$ and $w'$ have no common zero.

If $Z = h^{-\frac{3}{4}} \zeta(z)$ is large, we estimate the integral $I_l$ using the method of steepest descent. In view of the fifth step, we have

$$I_l = \int_{\gamma} e^{-\frac{1}{h} \left( \xi^2 - t \zeta(z) \right)} O(e^{C_0 |t|}) \, dt.$$

We deform the integration path to a path of steepest descent for $e^{-\frac{1}{h} \left( \xi^2 - t \zeta(z) \right)}$ exactly as when computing the asymptotics of the Airy function $w$, i.e., the asymptotics of the integral $\int_{\gamma} e^{-\frac{1}{h} \left( \xi^2 - t \zeta(z) \right)} \, dt$. The saddle points $\pm \sqrt{\zeta(z)}$ are uniformly bounded when $z \in K$. We pick $r > 0$ sufficiently large for the saddle points to be inside the disk of radius $r$ centered at 0. We compute the asymptotics of the integral over $\gamma \cap \{|t| \leq r\}$ directly by means of the method of steepest descents and, comparing the answer with the asymptotics of the Airy function $w(Z)$ as $Z \to \infty$, we find that this integral is bounded by $O(h^{\frac{3}{4}} w_h) + O(h^{\frac{1}{2}} w'_h)$. The integral over the remaining part of $\gamma$ quickly tends to 0 as $h \to 0$: actually, it is exponentially small with respect to $O(h^{\frac{3}{4}} w_h) + O(h^{\frac{1}{2}} w'_h)$. This yields (4.20).

7. Formula (4.16) and estimate (4.20) lead to the representation

$$H \left( Ah^{\frac{3}{4}} w_h \right)(z) = h^{\frac{3}{4}} w_h(z) \sum_{l=0}^{N} h^l a_l(z, h) + h^{\frac{3}{4}} w'_h(z) \sum_{l=0}^{N} h^l b_l(z, h)$$

$$+ O \left( h^{N+1+\frac{3}{4}} w_h(z) \right) + O \left( h^{N+1+\frac{1}{2}} w'_h(z) \right),$$

(4.21)
The coefficients \((a_l)_{l \in \mathbb{N}_0}\) and \((b_l)_{l \in \mathbb{N}_0}\) being analytic in \(h\), we can approximate them by Taylor polynomials. This yields

\[
H \left( A h^{4} w_{h} \right) (z) = h^{4} w_{h}(z) \sum_{l=0}^{N} h^{l} a_{l}(z) + h^{2} w_{h}(z) \sum_{l=0}^{N} h^{l} b_{l}(z) + O \left( h^{N+1} \frac{4}{1} w_{h}(z) \right) + O \left( h^{N+1} \frac{2}{1} w_{h}(z) \right),
\]

where \((a_{l}(z))_{l \in \mathbb{N}_0}\) and \((b_{l}(z))_{l \in \mathbb{N}_0}\) are new coefficients independent of \(h\). In particular, one has

\[
a_{0}(z) = a_{0}(0), \quad b_{0}(z) = b_{0}(0), \quad a_{1}(z) = a_{1}(0) + \frac{\partial a_{0}}{\partial h}(z, 0), \quad b_{1}(z) = b_{1}(0) + \frac{\partial b_{0}}{\partial h}(z, 0).
\]

Now, to complete the proof of Proposition 4.1, it suffices to compute \(a_{0}, b_{0}, a_{1}, b_{1}\).

8. We note that the definition of \(\zeta\) (see section 2.2.5) implies that it satisfies one of the two equations

\[
\sqrt{\zeta(z)} \zeta'(z) = \pm ip(z), \quad z \in U.
\]

9. Let us check that

\[
a_{0}(z, 0) = \frac{\partial a_{0}}{\partial h}(z, 0) = 0.
\]

Substituting (4.11) into (4.13), we get

\[
a_{0}(z, h) = A(z + h) ch \left( \sqrt{\zeta(z)} \frac{\zeta(z + h) - \zeta(z)}{h} \right) + A(z - h) ch \left( \sqrt{\zeta(z)} \frac{\zeta(z - h) - \zeta(z)}{h} \right) + v(z) A(z).
\]

Thus,

\[
a_{0}(z, 0) = A(z) \left( 2 ch \left( \sqrt{\zeta(z)} \zeta'(z) \right) + v(z) \right).
\]

Recall that the complex momentum \(p\) is defined in (2.1). In view of (4.24) we get

\[
2 ch \left( \sqrt{\zeta(z)} \zeta'(z) \right) + v(z) = 0.
\]

So, \(a_{0}(z, 0) = 0\). As \(a_{0}(z, h)\) is even in \(h\), we also see that \(\frac{\partial a_{0}}{\partial h}(z, 0) = 0\).

10. Let us check that

\[
b_{0}(z, 0) = 0, \quad \frac{\partial b_{0}}{\partial h}(z, 0) = 2 A'(z) \frac{sh \left( \sqrt{\zeta(z)} \zeta'(z) \right)}{\sqrt{\zeta(z)}} + A(z) ch \left( \sqrt{\zeta(z)} \zeta'(z) \right) \zeta''(z).
\]

Substituting (4.11) into (4.14), we get

\[
b_{0}(z, h) = A(z + h) \frac{sh \left( \sqrt{\zeta(z)} \frac{\zeta(z + h) - \zeta(z)}{h} \right)}{\sqrt{\zeta(z)}} + A(z - h) \frac{sh \left( \sqrt{\zeta(z)} \frac{\zeta(z - h) - \zeta(z)}{h} \right)}{\sqrt{\zeta(z)}}.
\]

Clearly, \(b_{0}(z, h)\) is odd in \(h\), and so \(b_{0}(z, 0) = 0\). Computing \(\frac{\partial b_{0}}{\partial h}(z, 0)\), we complete the proof of (4.27).

11. To compute \(a_{1}(z, 0)\) and \(b_{1}(z, 0)\), we first study \(f_{0}\). Pick \(r > 0\) so that \(|\zeta(z)| \leq r^{2}/2\) for all \(z \in K\). Let \(|t| = r, z \in K\) and \(h \in V\). Formulas (4.11) and (4.26) imply that

\[
F_{0}(t, z, h) = F_{0}(t, z) + O(h), \quad F_{0}(t, z) = 2 A(z) \left( ch \left( t \zeta'(z) \right) - ch \left( \sqrt{\zeta(z)} \zeta'(z) \right) \right).
\]
This result, the formulas $a_0(z,0) = b_0(z,0) = 0$ (see steps 9–10) and (4.12) imply that for $|t| = r$ one has

$$f_0(t, z) = \frac{F_0(t, z)}{t^2 - \zeta(z)} + O(h).$$

By the maximum principle for analytic functions, this representation remains true for all $|t| \leq r$.

12. The result of the previous step and the Cauchy estimates for the derivatives of the analytic functions imply that, for $|t| \leq r/2$, $z \in K$ and $h \in V$, one has

$$F_1(t, z, h) = F_1(t, z) + O(h), \quad \text{where} \quad F_1(t, z) = \frac{\partial}{\partial t} \left( \frac{F_0(t, z)}{t^2 - \zeta(z)} \right). \quad (4.28)$$

Therefore

$$a_1(z, 0) = \frac{F_1(\sqrt{\zeta(z)} z) + F_1(-\sqrt{\zeta(z)} z)}{2}, \quad b_1(z, 0) = \frac{F_1(\sqrt{\zeta(z)} z) - F_1(-\sqrt{\zeta(z)} z)}{2\sqrt{\zeta(z)}}.$$

As $t \mapsto F_1(t, z)$ is odd, one has

$$a_1(z, 0) = 0, \quad b_1(z, 0) = \frac{1}{t} \left. \frac{\partial}{\partial t} \left( \frac{F_0(t, z)}{t^2 - \zeta(z)} \right) \right|_{t = \sqrt{\zeta}}.$$

Elementary calculations yield

$$b_1(z, 0) = \frac{A\zeta'}{2\zeta} \left( \zeta'(z) ch \left( \sqrt{\zeta} \zeta' \right) - \frac{sh \left( \sqrt{\zeta} \zeta' \right)}{\sqrt{\zeta}} \right), \quad \zeta = \zeta(z).$$

The results of the steps 9, 10 and 12 imply that

$$a_0(z) = b_0(z) = a_1(z) = 0, \quad b_1(z) = A(z) g(z) \frac{d\log(A^2 g)}{dz}(z),$$

where $g$ is the defined in (2.12). Substituting these formulae into (4.22), we obtain (4.1) and (4.2). This completes the proof of Proposition 4.1.

4.3. Proof of Proposition 4.2. The proof of Proposition 4.2 being parallel to that of Proposition 4.1, we concentrate only on the differences and omit details.

We assume that $B$ is analytic in $U$. We pick $w, \gamma$ and $K$ as in the proof of Proposition 4.1. We use the notations from (2.14). We assume that $z \in K$ and that $h$ is sufficiently small. The derivation of the asymptotics of $H(Bh^{\frac{\gamma}{2}}w')$ is split into several steps.

1. We get

$$H \left( Bh^{\frac{\gamma}{2}}w' \right) = \int \frac{e^{-\frac{t}{2^2} - \frac{\gamma}{2}t\zeta(z)}}{\zeta(z)} G_0(t, z, h) \, dt, \quad (4.29)$$

$$G_0(t, z, h) = t \left( B(z + h) e^{\frac{c(z+h)-c(z)}{h}t} + B(z - h) e^{\frac{c(z-h)-c(z)}{-h}t} + v(z) B(z) \right). \quad (4.30)$$

2. Fix an $N \in \mathbb{N}$. Reasoning as in steps 1-6 of the proof of Proposition 4.1, instead of (4.21), for $z \in K$ and for sufficiently small $h$, we prove that

$$H \left( Bh^{\frac{\gamma}{2}}w' \right) = h^{\frac{\gamma}{2}}w_h \sum_{l=0}^N h^i d_l(z, h) + h^{\frac{\gamma}{2}}w_h' \sum_{l=0}^N h^i d_l(z, h)$$

$$+ O \left( h^{N+1+\frac{\gamma}{2}}w_h \right) + O \left( h^{N+1+\frac{\gamma}{2}}w_h' \right),$$

where $c(z)$ is sufficiently small. The derivation of the asymptotics of

$$H(Bh^{\frac{\gamma}{2}}w')$$

is split into several steps.
where, for $l \in \mathbb{N} \cup \{0\}$, one computes
\[
   c_l(z,h) = \frac{1}{2} \left( G_l(\sqrt{\zeta(z)},z,h) + G_l(-\sqrt{\zeta(z)},z,h) \right), \quad (4.31)
\]
\[
   d_l(z,h) = \frac{1}{2\sqrt{\zeta(z)}} \left( G_l(\sqrt{\zeta(z)},z,h) - G_l(-\sqrt{\zeta(z)},z,h) \right), \quad (4.32)
\]
\[
   g_l(t,z,h) = \frac{G_l(t,z,h) - c_l - dt}{t^2 - \zeta(z)}, \quad G_{l+1} = \frac{\partial g_l}{\partial t}. \quad (4.33)
\]

In (4.31) and (4.32), we use one and the same branch of $\sqrt{\zeta(z)}$. Approximating the $(c_l)_{l \in \mathbb{N} \cup \{0\}}$ and $(d_l)_{l \in \mathbb{N} \cup \{0\}}$ as functions of $h$ by Taylor polynomials, we get
\[
   H \left( B h^{\frac{3}{2}} w'_{h} \right) = h^{\frac{3}{2}} w_{h} \sum_{l=0}^{N} h^{l} c_{l}(z) + h^{\frac{3}{2}} w'_{h} \sum_{l=0}^{N} h^{l} d_{l}(z) 
\]
\[
   + O \left( h^{N+1+\frac{3}{2}} w_{h} \right) + O \left( h^{N+1+\frac{3}{2}} w'_{h} \right). \quad (4.34)
\]

One has
\[
   c_{0}(z) = c(z,0), \quad d_{0}(z) = d(z,0),
\]
\[
   c_{1}(z) = c_{1}(z,0) + \frac{\partial c_{0}}{\partial h}(z,0), \quad d_{1}(z) = d_{1}(z,0) + \frac{\partial d_{0}}{\partial h}(z,0). \quad (4.35)
\]

3. Substituting (4.30) into formula (4.32) with $l = 0$, we obtain the formulas
\[
   d_{0}(z,0) = \frac{\partial d_{0}}{\partial h}(z,0) = 0 \quad (4.36)
\]
in the same way as we obtained (4.25).

4. Let us check that
\[
   c_{0}(z,0) = 0, \quad \frac{\partial c_{0}}{\partial h}(z,0) = \sqrt{\zeta}(2B'(z)sh(\sqrt{\zeta'}z') + B(z)ch(\sqrt{\zeta'}z')\sqrt{\zeta''}z'), \quad (4.37)
\]
where $\zeta = \zeta(z)$. Substituting (4.30) into formula (4.31) with $l = 0$, we get
\[
   c_{0}(z,h) = B(z+h)\sqrt{\zeta(z)}sh\left(\sqrt{\zeta(z)}\frac{\zeta(z+h) - \zeta(z)}{h}\right)
\]
\[
   + B(z-h)\sqrt{\zeta(z)}sh\left(\sqrt{\zeta(z)}\frac{\zeta(z-h) - \zeta(z)}{h}\right).
\]
The coefficient $c_{0}(z,h)$ is odd in $h$, and so $c_{0}(z,0) = 0$. Computing $\frac{\partial c_{0}}{\partial h}(z,0)$, we complete the proof of (4.37).

5. As $G_{1}$ is computed in the same way as $F_{1}$ in steps 11–12 of the proof of Proposition 4.1, we omit the details and write down the result:
\[
   G_{1}(t,z,h) = G_{1}(t,z) + O(h), \quad G_{1}(t,z) = 2B \frac{\partial}{\partial t} \left( t \left( ch \left( \frac{t\zeta'}{2} \right) - ch \left( \sqrt{\zeta'}z' \right) \right) \right) \quad (4.38)
\]
where $\zeta = \zeta(z)$. This representation is locally uniform in $t$ and uniform in $z \in K$.

6. Having described $G_{1}$, we easily get the formulas
\[
   d_{1}(z,0) = 0, \quad c_{1}(z,0) = \frac{B\zeta'}{2} \left( \zeta'ch \left( \sqrt{\zeta'}z' \right) + sh \left( \sqrt{\zeta'}z' \right) \right), \quad \zeta = \zeta(z).
\]
We again omit elementary details and only note that the first formula follows from the evenness of the function $t \mapsto G_{1}(t,z)$.

7. Substituting the results of steps 3, 4 and 6 into (4.35), we get
\[
   c_{0}(z) = d_{0}(z) = d_{1}(z) = 0, \quad c_{1}(z) = \zeta(z)B(z)g(z) \frac{d \log(\zeta B^2g)}{dz}(z),
\]
where $g$ is the function from (2.12). Substituting these formulae into (4.34), we prove the statement of Proposition 4.2. \hfill \Box

5. Properties of asymptotic solutions

We now study basic properties of the asymptotic solutions. More precisely, we pick an integer $L$ and study the functions $(W_j)_{j \in \mathbb{Z}_3}$, i.e., the functions $W$ from Theorem 2.3 corresponding to the chosen $L$ and to the Airy functions $w = w_j$, $j \in \mathbb{Z}_3$.

5.1. Functional relations. We recall that the function $(W_j)_{j \in \mathbb{Z}_3}$ are defined in a domain $U$ satisfying the assumptions from sections 2.2 and 2.5.1.

Lemma 5.1. One has

$$W_0(z) + W_1(z) + W_2(z) = 0, \quad \forall z \in U.$$  \hspace{1cm} (5.1)

Proof. Formula (2.8) and the definitions of the integration paths $(\gamma_j)_{j \in \mathbb{Z}_3}$ (see Fig. 1) imply that

$$w_0(\zeta) + w_1(\zeta) + w_2(\zeta) = 0, \quad \zeta \in \mathbb{C}. \hspace{1cm} (5.2)$$

As the function $\zeta$ and all the coefficients $(A_l)_{l \in \mathbb{N}_0}$ and $(B_l)_{l \in \mathbb{N}_0}$ in representations (2.14)–(2.15) are independent of the choice of $w$, the solution of the Airy equation in this representation, the relation (5.2) implies (5.1). \hfill \Box

Relation (5.1) implies that

$$(W_0(z), W_1(z)) = (W_1(z), W_2(z)) = (W_2(z), W_0(z)), \quad \forall \{z, z+h\} \subset U. \hspace{1cm} (5.3)$$

where $(f(z), g(z)) = f(z + h)g(z) - g(z + h)f(z)$ is the difference Wronskian of $f$ and $g$.

5.2. Estimates of $W_j$. To prove the existence of analytic solutions that admit asymptotic expansions of the form (2.17), we need rough estimates of $(W_j)_{j \in \mathbb{Z}_3}$ in $U$. Therefore, we first introduce some tools.

5.2.1. Geometry. We recall that the function $\zeta$ defined in (2.6) is analytic in $U$ and bijectively maps $U$ onto $V = \zeta(U)$, $\zeta(z_0) = 0$. We put

$$\sigma_j = \zeta^{-1}(V \cap a_j), \quad a_j = e^{-2\pi ij/3} \mathbb{R}_-, \quad j \in \mathbb{Z}_3, \hspace{1cm} (5.4)$$

where $\mathbb{R}_- = (-\infty, 0]$. The curves $(\sigma_j)_{j \in \mathbb{Z}_3}$ are analytic. They all begin at $z_0$. Any two of them do not intersect except at $z_0$. The angles between these curves at $z_0$ are equal to $2\pi/3$.

The curves $(\sigma_j)_{j \in \mathbb{Z}_3}$ cut the domain $U$ (a neighborhood of $z_0$) into three simply connected subdomains that we call sectors. We denote them by $S_0$, $S_1$ and $S_2$ so that the sector $S_0$ is bounded by $\sigma_1$ and $\sigma_2$, $S_1$ is bounded by $\sigma_2$ and $\sigma_0$, and $S_2$ is bounded by $\sigma_0$ and $\sigma_1$, see Fig. 2. Let

$$U_j = U \setminus \sigma_j, \quad j \in \mathbb{Z}_3. \hspace{1cm} (5.5)$$

These domains do not contain branch points of the complex momentum $p$: the only branch point of $p$ in $U$ is $z = z_0$. We shall use

Lemma 5.2. For $j \in \mathbb{Z}_3$, there exists a branch $p_j$ of the complex momentum $p$ that is analytic in $U_j$ and such that $p_j(z_0) = 0$ and

1. $\text{Im} \int_{z_0}^{z} p_j(z) \, dz > 0$ inside $S_1$;
2. $\text{Im} \int_{z_0}^{z} p_j(z) \, dz < 0$ inside the two other sectors;
3. $\text{Im} \int_{z_0}^{z} p_j(z) \, dz = 0$ along the curves $\sigma_1$, $\sigma_2$ and $\sigma_0$ (in the case of $\sigma_j$, we mean the boundary values);
Moreover, one has
\[ p_1 = -p_0 \quad \text{in} \quad \sigma_0 \cup S_1 \cup \sigma_2 \cup S_0 \cup \sigma_1, \quad p_2 = -p_0 \quad \text{in} \quad \sigma_0 \cup S_2 \cup \sigma_1 \cup S_0 \cup \sigma_2. \quad (5.6) \]

In the WKB method, the curves \( \sigma_j, \ j \in \mathbb{Z}_3 \), are called Stokes lines.

**Proof.** Let us check the first three points of Lemma 5.2 for \( j = 0 \). We recall that \( \zeta \) is an analytic branch of the function (2.6). We can assume that in (2.6) \( p \) is a branch of the complex momentum analytic in \( U_0 \) and such that \( p(z_0) = 0 \).

Formulas (5.4) and the definition of \( \zeta \) imply that \( \text{Im} \int_{z_0}^{z} p(z) \, dz = 0 \) on any of the Stokes lines. We note that
\[ \zeta(S_j) = \{ v \in V : v \neq 0, \ \text{arg} \, v \in [-2\pi j/3, (-\pi/3, \pi/3)] \}, \quad j \in \mathbb{Z}_3. \quad (5.7) \]

This and the definition of \( \zeta \) imply that \( \text{Im} \int_{z_0}^{z} p(z) \, dz \neq 0 \) in each of the sectors. In view of the analysis made in section 2.2.1, in \( U_0 \), we can choose an analytic branch \( p_0 \) of the complex momentum so that \( \text{Im} \int_{z_0}^{z} p_0(z) \, dz > 0 \) in \( S_0 \). For \( p_0 \), the statements 1. and 3. of Lemma 5.2 are obviously valid.

To prove point 2., it suffices to check that \( \text{Im} \int_{z_0}^{z} p_0(z) \, dz < 0 \) in the sectors \( S_1 \) and \( S_2 \). Therefore, we note that as \( z \neq z_0, z \sim z_0, \) crosses \( \sigma_2 \) moving from \( S_0 \) to \( S_1 \) the argument of \( \zeta(z) \) decreases (\( \zeta \) vanishes only at \( z = z_0 \)) as does the argument of \( \int_{z_0}^{z} p_0(z) \, dz \). Therefore, point 2. of Lemma 5.2 follows from points 1. and 3.

To complete the proof of Lemma 5.2, we choose \( p_1 \) in the following way. First, we restrict \( p_0 \) to \( S_1 \); then, in \( S_1 \) we choose \( p_1 = -p_0 \) and continue \( p_1 \) analytically from \( S_1 \) to \( U_1 \). For the thus chosen \( p_1 \), we have
\[ \text{Im} \int_{z_0}^{z} p_1(z) \, dz = -\text{Im} \int_{z_0}^{z} p_0(z) \, dz > 0, \quad z \in S_1. \]

This proves point 1 for \( p_1 \). Point 2 and point 3 for \( p_1 \) are proved as for \( p_0 \) and \( p \).

To choose \( p_2 \), first, we restrict \( p_0 \) to \( S_2 \); then, in \( S_2 \) we choose \( p_2 = -p_0 \) and \( p_2 \) analytically from \( S_2 \) to \( U_2 \). To complete the proof of Lemma 5.2 for \( p_2 \), we reason as for \( p_1 \). We omit further details. \( \square \)

5.2.2. Estimates. For \( j \in \mathbb{Z}_3 \) and \( z \in U_j \), we set
\[ \rho_j(z) = e^{\mp \int_{z_0}^{z} p_j(z') \, dz'}. \quad (5.8) \]

We note that \( \rho_j \) is continuous up to the cut along \( \sigma_j \), and the boundary values of its absolute value \( |\rho_j| \) on both the sides of the cut equal one. So, below, we consider \( |\rho_j| \) as a continuous function in \( U \).

Let us recall that \( H \) is defined by (2.11). We set
\[ \delta_j(z) = |H(W_j)|(z), \quad z \in U, \quad j \in \mathbb{Z}_3. \quad (5.9) \]
Proof of Lemma 5.5.\] has\]

Proposition 5.1 immediately follows from formulas (2.14)–(2.16) with \( w = w_j \) and\]

Lemma 5.3. Pick \( j \in \mathbb{Z}_3 \). One has\]
\[
|w_j(h^{-\frac{2}{3}}\zeta(z))| \leq C|\rho_j(z)|, \quad |w'_j(h^{-\frac{2}{3}}\zeta(z))| \leq Ch^{-\frac{1}{3}}|\rho_j(z)|, \quad z \in U. \tag{5.12}
\]

Proof. We prove (5.12) only for \( j = 0 \). The other cases are treated similarly. We recall that \( w_0 = Ai \), that \( \zeta \) bijectively maps \( U \) onto its image and that \( |\zeta(z)| = 0 \) (see (2.6)). Clearly,\]
\[
w_0(h^{-\frac{2}{3}}\zeta(z)) = O(1) \quad \text{and} \quad w'_0(h^{-\frac{2}{3}}\zeta(z)) = O(1) \quad \text{if} \quad |\zeta(z)| \leq h^{\frac{2}{3}}. \tag{5.13}
\]

Now we turn to the case where \( |\zeta(z)| \geq h^{\frac{2}{3}} \). It suffices to prove (5.12) in \( U_0 \). The asymptotic formulas (2.10) imply that, for \( Z \in \{Z \in \mathbb{C} \setminus \mathbb{R}_- : |Z| \geq 1\} \), one has\]
\[
|w_0(Z)| \leq C|Z|^{-\frac{1}{4}} \left| e^{-\frac{3}{4}Z^{\frac{2}{3}}} \right| \quad \text{and} \quad |w'_0(Z)| \leq C|Z|^\frac{1}{4} \left| e^{-\frac{3}{4}Z^{\frac{2}{3}}} \right|, \tag{5.14}
\]

where the \( Z \mapsto Z^{\frac{2}{3}} \) is analytic in \( \mathbb{C} \setminus \mathbb{R}_- \) and positive when \( Z > 0 \). Estimate (5.14) and the definition of \( U_0 \), see (5.5), imply that, for \( z \in U_0 \) such that \( |\zeta(z)| \geq h^{\frac{2}{3}} \), one has\]
\[
|w_0(h^{-\frac{2}{3}}\zeta(z))| \leq C \left| e^{-\frac{3}{4h^{\frac{2}{3}}}\zeta(z)^{\frac{2}{3}}} \right| \quad \text{and} \quad |w'_0(h^{-\frac{2}{3}}\zeta(z))| \leq Ch^{-\frac{1}{3}} \left| e^{-\frac{3}{4h^{\frac{2}{3}}}\zeta(z)^{\frac{2}{3}}} \right|, \tag{5.15}
\]

where \( z \mapsto \zeta(z)^{\frac{2}{3}} \) is analytic in \( U_0 \) and positive along \( \alpha_0 = \zeta^{-1}((0, \infty)) \). In view of the analysis made in section 2.2.1,\]
\[
\zeta(z)^{\frac{2}{3}} = \pm \frac{3i}{2} \int_{z_0}^z p_0(z') \, dz', \quad z \in U_0.
\]

As \( \alpha_0 = \zeta^{-1}((0, \infty)) \subset S_0 \), along \( \alpha_0 \) one has \( \text{Im} \int_{z_0}^z p_0(z') \, dz' > 0 \). Therefore, in \( U_0 \)\]
\[
\zeta(z)^{\frac{2}{3}} = -\frac{3i}{2} \int_{z_0}^z p_0(z') \, dz', \quad \text{and} \quad \left| e^{-\frac{3}{4h^{\frac{2}{3}}}\zeta(z)^{\frac{2}{3}}} \right| = |p_0(z)|. \tag{5.16}
\]

This and (5.15) imply (5.12) for \( |\zeta(z)| \geq h^{-2/3} \). This and (5.13) imply the statement of the lemma. \( \square \)

5.3. Wronskians. Below \( \mathcal{C} \subset U \) is a closed disk independent of \( h \) with the center at \( z_0 \). We now prove\]

Lemma 5.4. For \( \{z, z + h\} \subset \mathcal{C} \), as \( h \to 0 \) one has\]
\[
(W_0(z), W_1(z)) = h(w_0'(z)w_1(z) - w_0(z)w_1'(z)) + O(h^{\frac{5}{3}}).
\]

Before proving Lemma 5.4, we check\]

Lemma 5.5. Pick \( j \in \mathbb{Z}_3 \). Let \( w = w_j \). For \( \{z, z + h\} \subset \mathcal{C} \), as \( h \to 0 \) one has\]
\[
w_h |_{z+h} = h^{1/3}ch(\sqrt{\zeta}(z)\zeta'(z))w_h + g(z)h^{2/3}w'_h + O(h^{4/3}w_h) + O(h^{5/3}w'_h),\]

where we use the notations from (2.14) and \( g \) is defined in (2.12).\]

Proof of Lemma 5.5. We proceed as in the proof of Proposition 4.1. Thus, we omit some details and concentrate on the new computations. Let \( \gamma = \gamma_j \) be the integration path in (2.8). Also, below we assume that \( z \in \mathcal{C} \) and
that \( h \) is sufficiently small. The proof is broken into several steps.

1. We compute
\[
\frac{h^\frac{2}{3}w_h}{z+h} = \int_{\gamma} e^{-\frac{1}{h} \left( \frac{z}{3} - t \zeta(t) \right)} E(t, z, h) \, dt, \quad E(t, z, h) = e^{\frac{1}{3} \left( \zeta(z+h) - \zeta(z) \right)}. \tag{5.16}
\]

2. We represent \( E(t, z, h) \) in the form
\[
E(t, z, h) = \alpha(z, h) + \beta(z, h) t + (t^2 - \zeta(z)) \phi(t, z, h) \tag{5.17}
\]
with
\[
\alpha(z, h) = \frac{E(\sqrt{\zeta(z)}, z, h) + E(-\sqrt{\zeta(z)}, z, h)}{2} = \frac{ch \left( \sqrt{\zeta(z+h) - \zeta(z)} \right)}{2},
\]
\[
\beta(z, h) = \frac{E(\sqrt{\zeta(z)}, z, h) - E(-\sqrt{\zeta(z)}, z, h)}{2 \sqrt{\zeta(z)}} = \frac{1}{\sqrt{\zeta}} sh \left( \frac{\sqrt{\zeta(z+h) - \zeta(z)}}{h} \right).
\]

3. Clearly,
\[
\alpha(z, h) = ch \left( \sqrt{\zeta(z)} \right) + O(h), \quad \beta(z, h) = g(z) + O(h). \tag{5.18}
\]

4. Substituting (5.17) into (5.16) and integrating by parts, we get
\[
\frac{h^\frac{2}{3}w_h}{z+h} = \alpha(h \hat{w} w_h) + \beta h \hat{w} h \phi_h + h \int_{\gamma} e^{-\frac{1}{h} \left( \frac{z}{3} - t \zeta(z) \right)} E_1(t, z, h) \, dt,
\]
\[
E_1(t, z, h) = \frac{\partial \phi}{\partial t}(t, z, h). \tag{5.19}
\]
Reasoning as when proving Proposition 4.1, we check that the last term in the right hand side of (5.19) is \( O(h \hat{w} w) + O(h \hat{w} w') \). Lemma 5.5 follows from this estimate, asymptotics (5.18) and representation (5.19).

Now, we turn to the proof of Lemma 5.4.

**Proof of Lemma 5.4.** Below we assume that \( \{ z, z+h \} \subset C \) and that \( h \) is sufficiently small. Using (2.15) and Lemma 5.5, we compute
\[
(W_0(z), W_1(z)) = A_0^2(z) \times \left( h^\frac{2}{3} ch \left( \sqrt{\zeta(z)} \right) w_0 + gh \hat{w} w_0' + O(h \hat{w} w_0) + O(h \hat{w} w_0') \right)
\]
\[
\cdot \left( h^\frac{2}{3} w_1 + O(h \hat{w} w_1) + O(h \hat{w} w_1') \right)
\]
\[
- (h^\frac{2}{3} ch \left( \sqrt{\zeta(z)} \right) w_1 + gh \hat{w} w_1' + O(h \hat{w} w_1) + O(h \hat{w} w_1'))
\]
\[
\cdot \left( h^\frac{2}{3} w_0 + O(h \hat{w} w_0) + O(h \hat{w} w_0') \right) \right).
\]
Here, \( w_j = w_j(h \hat{w} \zeta(z)), j \in \mathbb{Z}_3, \zeta = \zeta(z), \) and \( g = g(z) \).

Now, we assume that \( z \in \sigma_0 \cup S_1 \cup \sigma_2 \cup S_0 \cup \sigma_1 \). Then, by (5.12) and (5.6)
\[
|w_0 w_1| \leq C, \quad |w_0 w_1'| \leq Ch^{-\frac{2}{3}}, \quad |w_0 w_1''| \leq Ch^{-\frac{4}{3}}, \quad |w_0 w_1''| \leq Ch^{-\frac{4}{3}}, \tag{5.20}
\]
and we get
\[
(W_0(z), W_1(z)) = h g(z) A_0^2(z)(w_0' w_1 - w_0 w_1') + O(h \hat{w}).
\]
In view of (2.13), Lemma 5.4 is proved for \( z \in \sigma_0 \cup S_1 \cup \sigma_2 \cup S_0 \cup \sigma_1 \).

When \( z \in \sigma_0 \cup S_2 \cup \sigma_1 \cup S_0 \cup \sigma_2 \), we similarly get
\[
(W_0(z), W_2(z)) = h g(z) A_0^2(z)(w_0' w_2 - w_0 w_2') + O(h \hat{w}). \tag{5.21}
\]
In view of (5.3), \( (W_0, W_2) = -(W_0, W_1) \) and relation (5.2) imply that \( w_0' w_2 - w_0 w_2' \equiv -(w_0' w_1 - w_0 w_1') \). Therefore, Lemma 5.4 for \( z \in \sigma_2 \) follows from (5.21).

This completes the proof of Lemma 5.4.
6. Solutions to (1.1) on precanonical domains

Fix $L \in \mathbb{N}$. Here we construct solutions $(\psi_j)_{j \in \mathbb{Z}_3}$ to equation (1.1) that, up to $O(h^L)$, coincide with $(W_j)_{j \in \mathbb{Z}_3}$, the functions from Theorem 2.3. The result of this section is preliminary: we only construct the $(\psi_j)_{j \in \mathbb{Z}_3}$ on some subdomains of $U$.  

6.1. The result of this section.

6.1.1. Notations and some definitions. First, to formulate the results of this section, we introduce some notations and recall some definitions related to the complex WKB method for difference equations, see, for example, [13].

For $z \in \mathbb{C}$, we let $x = \text{Re } z$ and $y = \text{Im } z$. A curve $\gamma \subset \mathbb{C}$ is called vertical, if $z$ is a piecewise continuously differentiable function of $y$ along $\gamma$.

Let $\gamma \subset U$ be a regular vertical curve parameterized by $z = z(y)$. Pick a branch $p$ of the complex momentum continuous on $\gamma$. The curve $\gamma$ is precanonical with respect to $p$, if the function $y \mapsto \text{Im } \int_{z_0}^{z(y)} p(z) \, dz$ is non decreasing and the function $y \mapsto \text{Im } \int_{z_0}^{z(y)} (p(z) - \pi) \, dz$ is non increasing.

Let $d > 0$. We pick $M \subset C$ and define the horizontal $d$-neighborhood of $M$ to be the set $M^d := M + [-d,d]$ and $M^{-d} := (M^d - d) \cap M \cap (M^d + d)$.

We recall that, for $j \in \mathbb{Z}_3$, the sector $S_j$ and the Stokes line $\sigma_j$ are shown in Fig. 2. For $j \in \mathbb{Z}_3$, we denote by $S_j \cup S_{j+1}$ the closure of the domain $S_j \cup S_{j+1}$ without the boundary of $U$. For example, one has

$$S_{1,2} = \sigma_1 \cup S_2 \cup \sigma_0 \cup S_1 \cup \sigma_2.$$  

We also note that relations (5.6) imply that

$$|\rho_j(z)\rho_{j+1}(z)| = 1, \quad z \in S_{j,j+1}, \quad j \in \mathbb{Z}_3. \tag{6.1}$$

Let $r_1 < r_2$. We set $S(r_1, r_2) = \{z \in \mathbb{C} : r_1 < \text{Im } z < r_2\}$.

6.1.2. The main result of the section. One has

**Theorem 6.1.** Pick $j \in \mathbb{Z}_3$, $L \in \mathbb{N}$, $c \in (1,2)$ and $r > 0$. Let $K \subset S_{j,j+1}$ be a regular simply connected domain bounded by two curves having common endpoints $z_1$ and $z_2$ and both precanonical with respect to either the branch $p_j$ or $p_{j+1}$.

For sufficiently small $h$, there exist two solutions $\psi_j$ and $\psi_{j+1}$ to (1.1) that are analytic in $K^{ch}$ and that, in $K^{ch} \cap S(\text{Im } z_1 + rh, \text{Im } z_2 - rh)$ admit the asymptotic representations

$$\psi_l(z) = W_l(z) + O(|\rho_l| h^{L+1+j}), \quad l \in \{j, j+1\}, \tag{6.2}$$

where $W_l$ is the function described in Theorem 2.3 and corresponding to $w_l$ and the order $L$.

Let us discuss the solutions $\psi_j$ and $\psi_{j+1}$ described in Theorem 6.1.

**Corollary 6.1.** In the case of Theorem 6.1, the solutions $\psi_j$ and $\psi_{j+1}$ can be analytically continued to $U \cap S(\text{Im } z_1, \text{Im } z_2)$. Pick $r > 0$. As $h \to 0$, one has

$$(\psi_j(z), \psi_{j+1}(z)) = (W_j(z), W_{j+1}(z)) + O(h^{L+1+j}) \tag{6.3}$$

in $K^{ch} \cap S(\text{Im } z_1 + rh, \text{Im } z_2 - rh)$.

**Proof.** The solutions being analytic in $K^{ch}$ with $c > 1$, they can be analytically continued to $U \cap S(\text{Im } z_1, \text{Im } z_2)$ just be means of equation (1.1).

We pick $l \in \mathbb{Z}_3$ and note that, for all $z$ in a compact set $C \subset U$, for sufficiently small $h$, one has $|\rho_l(z + h)/\rho_l(z)| \leq C$. For $z \in K^{ch} \cap S(\text{Im } z_1 + rh, \text{Im } z_2 - rh)$, representation (6.3) follows from this observation and from (5.10), (6.2) and (6.1).  

\[\square\]
The remainder of this section is devoted to the proof of Theorem 6.1.
For the sake of definiteness, when proving Theorem 6.1, we assume that \( j = 0 \)
and that the two curves from Theorem 6.1 are precanonical with respect to the
branch \( p_0 \). The other cases are treated similarly.
Below, \( K \) is as in the theorem (for \( j = 0 \)), it is bounded by the precanonical
curves \( \gamma_1 \) and \( \gamma_2 \), and their common endpoints satisfy \( \text{Im} \, z_1 < \text{Im} \, z_2 \).
Finally, \( h \) is supposed to be sufficiently small.

6.2. Ideas of the proof. In the present section, we describe the construction of
the solution \( \psi_0 \). The solution \( \psi_1 \) is constructed similarly.
Let us assume that \( \psi_0 \) is a solution to (1.1) analytic in \( K^{ch} \) that we expect to be
close to \( W_0 \). Let us recall that \( \delta_0 = HW_0 \). Clearly, \( \Delta_0 := W_0 - \psi_0 \) satisfies the
equation
\[
H(\Delta_0)(z) = \delta_0(z), \quad \{z - h, z, z + h\} \subset K^{ch}. \tag{6.4}
\]
For \( z \in K^{ch} \), let \( \gamma(z) \) denote a vertical curve in \( K^{ch} \) that contains \( z \) and connects
\( z_1 \) and \( z_2 \). We construct a solution to the equation for \( \Delta_0 \) in the form
\[
\Delta_0 = R_0 g_0 \quad \text{where} \quad R_0 g_0(z) := \int_{\gamma(z)} r_0(z, \zeta) g_0(\zeta) \, d\zeta, \tag{6.5}
\]
\[
r_0(z, \zeta) = \frac{1}{2i\hbar} \frac{W_0(z)W_1(\zeta) - W_0(\zeta)W_1(z)}{(W_0(\zeta), W_1(\zeta))} \theta_0 \left( \frac{\zeta - z}{h} \right), \quad \theta_0(t) = \cot(\pi t) - i. \tag{6.6}
\]
Here, \( (W_0(\zeta), W_1(\zeta)) \) is the difference Wronskian of \( W_0 \) and \( W_1 \). The choice of
Ansatz (6.5) is explained by

**Lemma 6.1.** Let \( 0 < \beta < 1 \). Let \( f \) be a function defined and analytic in \( U \cap S(\text{Im} \, z_1, \text{Im} \, z_2) \) and such that the expression
\[
f_\beta(z) = (z - z_1)^\beta(z - z_2)^\beta f(z) \tag{6.7}
\]
is bounded. If \( \{z - h, z, z + h\} \subset U \cap S(\text{Im} \, z_1, \text{Im} \, z_2) \), one has
\[
HR_0 f(z) = f(z) + D_0 f(z), \quad D_0 f(z) = \int_{\gamma(z)} d_0(z, \zeta) f(\zeta) \, d\zeta \tag{6.8}
\]
where
\[
d_0(z, \zeta) = \frac{1}{2i\hbar} \frac{\delta_0(z)W_1(\zeta) - W_0(\zeta)\delta_1(z)}{(W_0(\zeta), W_1(\zeta))} \theta_0 \left( \frac{\zeta - z - 0}{h} \right), \tag{6.9}
\]
and \( \delta_j := HW_j \) are the “error” terms estimated in (5.11). The function \( D_0 f \) is
analytic in \( U \cap S(\text{Im} \, z_1, \text{Im} \, z_2) \).

**Proof.** The analyticity of \( f \) and the boundedness of \( f_\beta \) imply that \( D_0 f \) is well
defined and analytic in \( U \cap S(\text{Im} \, z_1, \text{Im} \, z_2) \). The relation \( HR_0 f = f + D_0 f \) follows from the residue theorem. We omit further details. \( \square \)

We note that an operator similar to \( R_0 \) was introduced in [14], but, was not
studied for small \( h \).
In view of Lemma 6.1 and the formulas \( \Delta_0 = R_0 g_0 \) and \( H(\Delta_0) = \delta_0 \), we can expect that in \( K^{ch} \)
\[
g_0 + D_0 g_0 = \delta_0. \tag{6.10}
\]
Roughly, to prove Theorem 6.1, we consider (6.10) as an equation on a vertical
curve \( \gamma \). It appears that if \( \gamma \) is precanonical, the operator \( D_0 \) is small. This enables
us to construct a solution \( \psi_0 \) to equation (6.10) on \( \gamma_1 \). Next, we check that it is
analytic in \( K^{ch} \), satisfies (1.1) and admits the asymptotic representation (6.2). The
solution \( \psi_1 \) is constructed similarly.
6.3. **The integral operator** $D_0$. The aim of this section is to estimate the operator norm of $D_0$ in a suitable functional space.

Let $\gamma$ be either $\gamma_1$ or $\gamma_2$. We pick $0 < \alpha < 1$ and define the strip

$$\Pi_{\gamma,\alpha} = \gamma \setminus \{z_1, z_2\} + [-\alpha h, \alpha h].$$

We recall that $z \rightarrow |\rho_0(z)|$ defined in $U_0$ is a continuous function in $U$. We fix $0 < \beta < 1$ and let $H_{\gamma,\alpha,\beta}$ be the linear space of functions analytic in $\Pi_{\gamma,\alpha}$ and having finite norm

$$\|f\| = \sup_{z \in \Pi_{\gamma,\alpha}} \frac{|f_\beta(z)|}{|\rho_0(z)|},$$

$f_\beta$ being defined in (6.7). Obviously, endowed with this norm, $H_{\gamma,\alpha,\beta}$ is a Banach space.

For $f \in H_{\gamma,\alpha,\beta}$, we define $D_0 f$ by the formula in (6.8), where $\gamma(z)$ is a vertical curve that connects the points $z_1$ and $z_2$ in $\Pi_{\gamma,\alpha}$ and passes through $z$. The function $D_0 f$ is then analytic in $\Pi_{\gamma,\alpha}$. One has

**Proposition 6.1.** For sufficiently small $h$

$$\|D_0\|_{H_{\gamma,\alpha,\beta} \rightarrow H_{\gamma,\alpha,\beta}} \leq C h^{L+\frac{3}{2}}.$$  

The remainder of this subsection is devoted to the proof of Proposition 6.1. Therefore we pick $f \in H_{\gamma,\alpha,\beta}$ and estimate $R_f(z)$. Up to the end of this subsection, we assume that $\{z, \zeta\} \subset \Pi_{\gamma,\alpha}$ and that $h$ is sufficiently small.

6.3.1. **Auxiliary lemma.** When estimating $R_f(z)$, we use

**Lemma 6.2.** For $q > 0$, there exists $C > 0$ such that

$$\sup_{\min k \leq \zeta - z - kh \geq qh} \left| \frac{\rho_0(z)}{\rho_0(z)} d_0(z, \zeta) \right| \leq C h^{L+\frac{3}{2}}.$$  

**Proof.** We proceed in several steps.

1. **Proposition 5.1** and **Lemma 5.4** imply that

$$\left| \frac{\rho_0(\zeta)}{\rho_0(z)} d_0(z, \zeta) \right| \leq C h^{L+\frac{3}{2}} \left( |\rho_1(\zeta)\rho_0(\zeta)| + |\rho_1(z)\rho_0(\zeta)| + \left| \frac{\rho_1(z)}{\rho_0(z)} \rho_0(\zeta) \right| \theta_0 \left( \frac{\zeta - z - 0}{h} \right) \right).$$

2. Recall that in $S_{0,1}$ one has $\rho_0(z)\rho_1(z) = 1$ (see (6.1)). As $\gamma_1, \gamma_2 \subset S_{0,1}$, one has $|\rho_0(z)||\rho_1(z)| \leq C$ for $z \not\in \Pi_{\gamma,\alpha}$. Therefore,

$$\left| \frac{\rho_0(\zeta)}{\rho_0(z)} d_0(z, \zeta) \right| \leq C h^{L+\frac{3}{2}} \left( 1 + e(z, \zeta) \right) \left| \theta_0 \left( \frac{\zeta - z - 0}{h} \right) \right|,$$

3. For $z \in \Pi_{\gamma,\alpha}$, we define $z_\perp \in \gamma$ so that $\text{Im} z_\perp = \text{Im} z$. We have

$$|e(z, \zeta)| \leq C \left| \exp \frac{2i}{h} \int_{z_\perp}^{\zeta} \rho_0(z') dz' \right|.$$

4. On the complex plane outside a fixed neighborhood of the points $Z$, we have the estimate

$$|\theta_0(z)| = |\cot(\pi z) - i| \leq C \begin{cases} 1, & \text{Im} z \geq 0; \\ e^{2\pi \text{Im} z}, & \text{Im} z \leq 0. \end{cases}$$
Therefore, for \( \zeta \) outside the \((qh)\)-neighborhood of \( z + h\mathbb{Z} \), we get
\[
\left| \theta_0 \left( \frac{\zeta - z - 0}{h} \right) \right| \leq C \quad \text{and} \quad 
\left| e(z, \zeta) \theta_0 \left( \frac{\zeta - z - 0}{h} \right) \right| \leq C \begin{cases} 
\frac{-\frac{1}{2} \text{Im} \int_{z}^{\zeta} p \, dz}{h} e^{\frac{1}{2} \text{Im} \int_{z}^{\zeta} (p - \pi) \, dz} & \text{if Im} (\zeta - z) \geq 0; \\
\frac{\text{Im} \int_{z}^{\zeta} p \, dz}{h} e^{\frac{1}{2} \text{Im} \int_{z}^{\zeta} (p - \pi) \, dz} & \text{if Im} (\zeta - z) \leq 0.
\end{cases}
\]

5. As \( \gamma \) is a precanonical curve, we finally get
\[
\left| \theta_0 \left( \frac{\zeta - z - 0}{h} \right) \right| \leq C, \quad \text{and} \quad \left| e(z, \zeta) \theta_0 \left( \frac{\zeta - z - 0}{h} \right) \right| \leq C. \quad (6.15)
\]
This and (6.14) imply (6.12). \( \Box \)

6.3.2. Estimates in the strip \( S(\text{Im } z_1 + h/2, \text{Im } z_2 - h/2) \). When \( z \in S(\text{Im } z_1 + h/2, \text{Im } z_2 - h/2) \), we prove
\[
|\rho_0(z)^{-1} D_0 f(z)| \leq C h^{L+\frac{3}{2}} \| f \|. \quad (6.16)
\]
First, we assume that \( z \) is between the curves \( \gamma + ah/2 \) and \( \gamma + ah \). Then, one can deform the integration path \( \gamma(z) \) in (6.8) to \( \gamma \). The distance between the poles of \( d_0 \) and \( \gamma \) is larger than \( Ch \). This, (6.11) and (6.12) imply (6.16).

Next, we assume that \( z \) is either between the curves \( \gamma \) and \( \gamma + ah/2 \) or on one of them. In this case, in (6.8) we can replace the integration path \( \gamma \) by \( \tilde{\gamma} \) where
- \( \tilde{\gamma} \) is a continuous curve that connects \( z_1 \) to \( z_2 \),
- \( \tilde{\gamma} \) coincides with \( \gamma - ah/2 \) in the strip \( \{ \text{Im } z_1 + h/2 \leq \text{Im } z \leq \text{Im } z_2 - h/2 \} \),
- outside this strip, \( \tilde{\gamma} \) consists of two segments of straight lines.

Reasoning as above on this new integral, we again obtain (6.16).

Let us assume now that \( z \) is to the left of \( \gamma \). We note that, by the Residue theorem, the integral in (6.8) decomposes as the sum of
\[
- \frac{\delta_0(z) W_1(z) - W_0(z) \delta_1(z)}{(W_0(z), W_2(z))} f(z) = O(h^{L+1+\frac{3}{2}}) f(z)
\]
and the integral defined by (6.8)-(6.9) with \( \theta((\zeta - (z + 0))/h) \) replaced with \( \theta((\zeta - (z - 0))/h) \).

This new integral for \( z \) to the left of \( \gamma \) is analyzed as above. This completes the proof of (6.16).

6.3.3. Estimates in \( S(\text{Im } z_1, \text{Im } z_1 + h/2) \) and \( S(\text{Im } z_2 - h/2, \text{Im } z_2) \). Both domains are treated similarly. So, we detail only the analysis for the first one. We prove that
\[
|\rho_0(z)^{-1} (D_0 f)_{\beta}(z)| \leq C h^{L+\frac{3}{2}} \| f \|. \quad (6.17)
\]
For \( z \) between \( \gamma + ah/2 \) and \( \gamma + ah \), reasoning as in section 6.3.2, one obtains (6.16) that implies (6.17).

For \( z \) between \( \gamma \) and \( \gamma + ah/2 \), by contour deformation, the integration path in (6.8) is replaced with \( \tilde{\gamma} \) defined in section 6.3.2. We, thus, write \( D_0 f \) as the sum of an integral, say \( A \), over the part of \( \tilde{\gamma} \cap \{ \text{Im } \zeta \leq z_1 + h/2 \} \) and an integral, say \( B \), over the part of \( \tilde{\gamma} \cap \{ \text{Im } z_1 + h/2 \leq \text{Im } \zeta \} \).

Reasoning as in section 6.3.2, we estimate \( B \) and obtain
\[
|\rho_0(z)^{-1} B| \leq C h^{L+\frac{3}{2}} \| f \|. \quad (6.18)
\]
Let us turn to \( A \). We again use (6.13). Now, both \( |z - z_1| \) and \( |\zeta - z_1| \) are bounded by \( Ch \); thus, \( |\rho_0(z)/\rho_0(\zeta)| \leq C \). Furthermore, for such \( z \), only one pole of the
that the last integral is bounded by \( C/\gamma_1 \).

The proof is divided into four parts. Moreover, one has

\[
|\rho_0(z)^{-1}A| \leq C h^{L+1+\frac{2}{3}} \|f\| \int_{\Im z \leq \Im z_1 + h/2} \frac{|d\zeta|}{|\zeta - \zeta_1|^\beta},
\]

where we integrate along \( \tilde{\gamma} \). Changing variable \( t = (\zeta - z_1)/|z - z_1| \), one checks that the last integral is bounded by \( C/|z - z_1|^{\beta} \). Thus,

\[
|\rho_0(z)^{-1}A| \leq C h^{L+1+\frac{2}{3}} \|f\| |z - z_1|^{\beta}.
\]

This and (6.18) yields (6.17).

We omit further details and note only that, to prove (6.17) when \( z \) is to the left of \( \gamma \), we first transform the integral from (6.8) as when doing the estimations in the strip \( S(\Im z_1 + h/2, \Im z_2 - h/2) \) (see the end of the section 6.3.2).

6.3.4. Completing the proof of Proposition 6.1. Proposition 6.1 follows from estimates (6.16) and (6.17).

6.4. Solutions to the integral equation (6.10). Consider the integral equation (6.10) in \( H_{\gamma, \alpha, \beta} \). Proposition 6.1 and the estimate for \( \delta_0 \) from (5.11) imply

**Lemma 6.3.** For sufficiently small \( h \), the equation (6.10) has a unique solution \( g_0 \) in \( H_{\gamma, \alpha, \beta} \). It satisfies

\[
\|g_0(z)\| = O(h^{L+2+\frac{1}{3}}).
\]  

Moreover, one has

**Lemma 6.4.** The solution \( g_0 \), constructed in Lemma 6.3 for the curve \( \gamma = \gamma_1 \), can be analytically continued to the domain \( K^{\alpha h} \). It then satisfies (6.10) and in \( K^{\alpha h} \)

\[
|(z_1 - z)(z_2 - z)|^\beta \frac{|g_0(z)|}{|\rho_0(z)|} \leq C h^{L+2+\frac{1}{3}}.
\]  

**Proof.** The proof is divided into four parts.

1. As \( g_0 \) is analytic in \( \Pi_{\gamma_1, \alpha} \), it suffices to continue it to the right of \( \gamma_1 \). The function \( \zeta \rightarrow \theta_0 \left( \frac{\zeta - z_0}{h} \right) \) has all its poles in \( z + 0 + h\mathbb{Z} \). Hence, for \( z \) between \( \gamma_1 \) and \( \gamma_1 + h \), we can define \( D_0g_0 \) by means of (6.8) with \( \gamma(z) = \gamma_1 \) and \( D_0g_0 \) appears to be analytic between \( \gamma_1 \) and \( \gamma_1 + h \).

As \( g_0 \) is analytic between \( \gamma \) and \( \gamma + ah \), to define \( D_0g_0 \) for \( z \) between \( \gamma_1 + ah \) and \( \gamma_1 + (1 + \alpha)h \), we can deform the path of the integral in (6.8) to a vertical curve connecting \( z_1 \) to \( z_2 \) staying between \( \gamma_1 \) and \( \gamma_1 + ah \). Thus, (6.8) implies that \( D_0g_0 \) is analytic in \( z \) between \( \gamma_1 \) and \( \gamma_1 + ah + h \). In view of equation (6.10), this implies that \( g_0 \) itself is analytic to the left of \( \gamma + (\alpha + 1)h \). Reasoning in this way inductively, one shows that \( g_0 \) and \( D_0g_0 \) are analytic between \( \gamma \) and \( \gamma + (\alpha + 3)h \), between \( \gamma \) and \( \gamma + (\alpha + 2)h \), and so on. As a result, one sees that \( g_0 \) and \( D_0g_0 \) are analytic in \( K^{\alpha h} \) to the right of \( \gamma \) and satisfy (6.10) for all \( z \in K^{\alpha h} \).

2. Clearly, \( g_0 \) is analytic in \( \Pi_{\gamma_2, \alpha} \), the expression \( |(z_1 - z)(z_2 - z)|^\beta |g_0(z)| \) stays bounded in \( \Pi_{\gamma_2, \alpha} \) (as \( \gamma_1 \) and \( \gamma_2 \) have common ends), and \( g_0 \) satisfies equation (6.10) along \( \gamma = \gamma_2 \). By Lemma 6.3, for sufficiently small \( h \), this equation has a unique solution in \( H_{\gamma_2, \alpha, \beta} \) which, thus, coincides with \( g_0 \). Hence, \( g_0 \) satisfies (6.19) with the norm of \( H_{\gamma_2, \alpha, \beta} \).

3. In view of the previous step, \( g_0 \) satisfies (6.20) in \( \Pi_{\gamma_1, \alpha} \cup \Pi_{\gamma_2, \alpha} \). This and the maximum principle for analytic functions imply that \( g_0 \) satisfies (6.20) also in the domain bounded by \( \gamma_1 \) and \( \gamma_2 \), i.e., in \( K \).

The proof of Lemma 6.4 is complete. \( \square \)
6.5. The solution to the difference equation. We define $\Delta_0$ by (6.5) in terms of $g_0$ constructed in section 6.4. One has

**Lemma 6.5.** The function $\Delta_0$ can be analytically continued to $K^{(1+\alpha)h}$ where it satisfies equation (6.4).

Let $0 < c < 1 + \alpha$ and $r > 0$. In $K^{ch} \cap S(\text{Im } z_1 + rh, \text{Im } z_2 - rh)$, one has

$$|\Delta_0(z)| \leq C|\rho_0(z)|^{h^{L+1}}.$$  

(6.21)

**Proof.** By (6.20) the function $g$ is analytic in $K^{ah}$. For a given $z$, the poles of the kernel in (6.5) are contained in $z + h(Z \setminus \{0\})$. Thus, the function $\Delta_0$ is analytic in $(K^{ah})^h = K^{(1+\alpha)h}$.

By means of the Residue theorem, one checks that $H\Delta_0 = H R_0 g_0$ if $z, z + h \in K^{(1+\alpha)h}$. As $g_0$ satisfies (6.10) in $K^{ah}$, we obtain (6.4) if $z, z + h \in K^{(1+\alpha)h}$.

To prove (6.21), we estimate $R_0 g_0$ in the same way as in section 6.3.2 we estimated $D_0 f$. So, we omit further details and only note that

(1) outside $(Ch)$-neighborhood of the set $z + hZ$, instead of (6.12) we obtain

$$\left| \frac{\rho_0(\zeta)}{\rho_0(z)} r_0(z, \zeta) \right| \leq Ch^{-4};$$

(2) on the diagonal $\{ \zeta = z \}$, $r_0$, the kernel of $R_0$, is analytic whereas $d_0$, the kernel of $D_0$, has a pole. This simplifies the estimates of $(R_0 g_0)(z)$ to the left of $\gamma_1$.

Having constructed $\Delta_0$, we construct a solution $\psi_0$ to equation (1.1) setting $\psi_0 = W_0 - \Delta_0$, see (6.4). Pick $c \in (0, 2)$. In view of (6.21), one has

$$\psi_0(z) = W_0(z) + O(|\rho_0(z)|^{h^{L+1}}), \quad z \in K^{ch} \cap S(\text{Im } z_1 + rh, \text{Im } z_2 - rh).$$  

(6.22)

In view of (5.12), estimate (6.22) implies (6.2) with $L$ replaced by $L - 1$. As we could choose a larger $L$, this actually completes the proof of the statement of Theorem 6.1 on the solution $\psi_0$.

6.6. The second solution. Mutatis mutandis, the construction of the solution $\psi_1$ repeats that of $\psi_0$. We omit further details and mention only that, in this case,

- we set $\psi_1 = W_1 - R_1 g_1$ where $R_1$ is an integral operator with the kernel

$$r_1(z, \zeta) = \frac{1}{2\pi i} \frac{W_0(\zeta) W_1(\zeta) - W_0(\zeta) W_1(z)}{(W_0(\zeta), W_1(\zeta))} \theta_1 \left( \frac{\zeta - z}{h} \right), \quad \theta_1(t) = \cot(\pi t) + i;$$

- instead of (6.11), we use the norm $\|f\| = \sup_{z \in \Pi_{\gamma_0}} \frac{|f_\beta(z)|}{|\rho_1(z)|}$

7. Proof of the main Theorem

In this section we finally prove Theorem 2.4. We recall that in $U$ there are three Stokes lines beginning at $z_0$. They are analytic curves, and the angle between any two of them at $z_0$ is equal to $2\pi/3$. So, possibly reducing $U$ somewhat, we can assume that at least two of them form a vertical curve. We prove the theorem in the case where these are $\sigma_1$ and $\sigma_2$, and $\sigma_1$ goes upwards from $z_0$, i.e., the vector tangent to $\sigma_1$ at $z_0$ is directed in the upper half-plane. Mutatis mutandis, the other cases are treated in the same way. Moreover, we assume that the tangent vector to $\sigma_0$ is either directed in the lower half-plane or is parallel to the real line and directed to the left. Then the curves $\sigma_j, j \in \mathbb{Z}_3$, correspond to Fig. 2. The complimentary case is studied similarly.

Below we assume that $h$ is sufficiently small.
7.1. Two geometric lemmas. To prove Theorem 2.4, we shall use the following two lemmas.

**Lemma 7.1.** There exist two curves in $S_{1,2}$ precanonical with respect to $p_2$ and having common endpoints, and $\hat{U}_1 \subset U$, a neighborhood of $z_0$, such that

- the domain $K_1$ bounded by the two curves is simply connected,
- $K_1 \cap \hat{U}_1 = S_{1,2} \cap \hat{U}_1$.

and

**Lemma 7.2.** There are exist two curves in $\sigma_2 \cup S_0 \cup \sigma_1$ precanonical with respect to $p_0$ and having common endpoints, and $\hat{U}_0 \subset U$, a neighborhood of $z_0$, such that

- the domain $K_0$ bounded by the two curves is simply connected,
- $K_0 \cap \hat{U}_0 = (\sigma_2 \cup S_0 \cup \sigma_1) \cap \hat{U}_0$.

We prove these two lemmas in section 8.1.

We define $\hat{U} = \hat{U}_0 \cap \hat{U}_1$.

7.1.1. Solution $\psi_1$. We denote by $\psi_{0,0}$ and $\psi_{1,0}$ the solutions $\psi_0$ and $\psi_1$ constructed by Theorem 6.1 for the domain $K_0$, and consider the solution $\psi_1$ constructed in Theorem 6.1 for the domain $K_1$. In view of Corollary 6.1, in $\hat{U}$ (possibly reduced somewhat), all the three solutions are analytic, the Wronskian of $\psi_{0,0}$ and $\psi_{1,0}$ does not vanish (see also Lemma 5.4), and one has

$$\psi_1 = a\psi_{1,0} + b\psi_{0,0},$$

where $a$ and $b$ are $h$-periodic coefficients (see section 3). We prove

**Lemma 7.3.** One can reduce $\hat{U}$ so that for $z \in \hat{U}$

$$a(z) = 1 + O(h^{L+\frac{3}{4}}), \quad b(z) = O(h^{L+\frac{3}{4}}), \quad h \to 0.$$  

**Proof.** In $\hat{U}$ (possibly reduced somewhat), the coefficients $a$ and $b$ are described by (3.3) with $\psi = \psi_1$, $f = \psi_{1,0}$ and $g = \psi_{0,0}$.

Let $\gamma_{12} = (\sigma_1 \cup \sigma_2) \cap \hat{U}$. By Lemmas 7.1 and 7.2 one has $\gamma_{12} \subset K_0$ and $\gamma_{12} \subset K_1$.

First, we pick $c \in (1,2)$ and assume that $\{z, z + h\} \subset (\gamma_{12})^{ch}$.

In view of Lemma 5.2, one has $|p_1| = |p_2| = 1$ on $\gamma_{12}$. This and the definitions of $|p_1|$ and $|p_2|$, see section 5.2.2, imply that there exists $C > 0$ such that $|p_1(z)|, |p_2(z)| \leq C$ in $(\gamma_{12})^{ch}$.

As $(\gamma_{12})^{ch}$ is a subset of both $K_0^{ch}$ and $K_1^{ch}$, by means of (6.2) and (5.10), we get

$$a = \frac{(\psi_1, \psi_{0,0})}{(\psi_{1,0}, \psi_{0,0})} = \frac{(W_1 + O(h^{L+\frac{3}{4}}), W_0 + O(h^{L+\frac{3}{4}}))}{(W_1 + O(h^{L+\frac{3}{4}}), W_0 + O(h^{L+\frac{3}{4}}))} = \frac{(W_1,W_0) + O(h^{L+\frac{3}{4}})}{(W_1,W_0) + O(h^{L+\frac{3}{4}})},$$

Lemma 5.4, then, yields the asymptotic representation for $a$ from (7.2). Reasoning similarly, we get

$$b = \frac{(\psi_{1,0}, \psi_{1,0})}{(\psi_{1,0}, \psi_{0,0})} = \frac{(W_1,W_1) + O(h^{L+\frac{3}{4}})}{(W_1,W_0) + O(h^{L+\frac{3}{4}})} = O(h^{L+\frac{3}{4}}).$$

This is the estimate for $b$ from (7.2).

Let $c_1$ and $c_2$ correspond to the minimal strip $S(c_1,c_2)$ containing $(\gamma_{12})^{ch}$. We proved estimates (7.2) for $a(z)$ and $b(z)$ in the case where $z, z + h \in (\gamma_{12})^{ch}$. As $c > 1$ and as $a$ and $b$ are $h$-periodic, these estimates remain valid in $S(c_1,c_2)$. This implies Lemma 7.3.  

\[ \square \]
In view of Lemma 7.1, the solution \( \psi_1 \) admits representation (6.2) with \( l = 1 \) in \( S_{1,2} \cap \hat{U} \). Let us prove that it admits this representation in \( S_0 \cap \hat{U} \).

In view of Lemma 7.2, the solutions \( \psi_{0,0} \) and \( \psi_{1,0} \) admit representations (6.2) with \( l = 0 \) and \( l = 1 \) in \( S_0 \cap \hat{U} \). Substituting (7.2) and these representations into (7.1) and using (5.10), we get for \( z \in S_0 \cap \hat{U} \)

\[
\psi_1(z) = (1 + O(h^{L+\frac{7}{2}}))(W_1(z) + O(h^{L+1+\frac{1}{2}} \rho_1(z))) \\
+ O(h^{L+\frac{3}{2}})(W_0(z) + O(h^{L+1+\frac{1}{2}} \rho_0(z))) \\
= W_1(z) + O(h^{L+1} \rho_1(z)) + O(h^{L+1} \rho_0(z)).
\]

In view of Lemma 5.2, in \( S_0 \) one has \( |\rho_0(z)| \leq |\rho_1(z)| \). For \( \psi_1 \) in \( S_0 \cap \hat{U} \), this implies representation (6.2) with \( L \) replaced with \( L - 1 \). As we can increase \( L \), we actually proved (6.2) for \( \psi_1 \) in the whole domain \( \hat{U} \).

Now, we note that

\[
h^{\frac{3}{2}} |\rho_0(z)| \leq C |h^{\frac{3}{2}} w_0(h^{-\frac{3}{2}} \zeta(z))| + C |h^{\frac{3}{2}} w'(h^{-\frac{3}{2}} \zeta(z))|, \quad z \in U. \tag{7.3}
\]

For sufficiently large values of \( h^{-\frac{3}{2}} |\zeta(z)| \), this estimate follows from the definition of \( \rho_0 \) and the asymptotic formulas (2.10). For bounded \( h^{-\frac{3}{2}} |\zeta(z)| \), it follows from the fact that \( w \) and \( w' \) do not have common zeros.

Estimates (6.2) and (7.3) imply (2.19) with \( L \) replaced with \( L - 1 \). As we can increase \( L \), this completes the proof of the statement of Theorem 2.4 on the solution \( \psi_1 \) in the case that we consider.

7.1.2. Solution \( \psi_0 \).

Let \( \psi_{1,1} \) and \( \psi_{2,1} \) be the solutions \( \psi_1 \) and \( \psi_2 \) constructed by Theorem 6.1 for the domain \( K_1 \), and let \( \psi_0 \) be the solution constructed by Theorem 6.1 for the domain \( K_0 \). For \( z \in \hat{U} \) (possibly reduced somewhat) one has

\[
\psi_0 = a \psi_{1,1} + b \psi_{2,1}, \tag{7.4}
\]

where \( a \) and \( b \) are \( h \)-periodic. One proves

**Lemma 7.4.** One can reduce \( \hat{U} \) so that, for \( z \in \hat{U} \), one has

\[
a(z) = -1 + O(h^{L+\frac{7}{2}}), \quad b(z) = -1 + O(h^{L+\frac{7}{2}}), \quad h \to 0. \tag{7.5}
\]

*Proof.* We omit details explained in the course of the proof of Lemma 7.3. We pick \( c \in (1,2) \) and assume that \( z, z + h \in (\gamma_1)_c \). For the coefficient \( a \) from (7.4), we get

\[
a = \frac{(\psi_0, \psi_{2,1})}{(\psi_{1,1}, \psi_{2,1})} = \frac{(W_0, W_2) + O(h^{L+\frac{7}{2}})}{(W_1, W_2) + O(h^{L+\frac{7}{2}})} = \frac{(-W_1 - W_2, W_2) + O(h^{L+\frac{7}{2}})}{(W_1, W_2) + O(h^{L+\frac{7}{2}})},
\]

where, in the last step, we used relation (5.1). Continuing, we get \( a = -1 + O(h^{L+\frac{7}{2}}) \). Similarly one proves that \( b = -1 + O(h^{L+\frac{7}{2}}) \). So, (7.5) is proved for \( z \) we considered. Reasoning as in the completion of the proof of Lemma 7.3, we complete the proof of Lemma 7.4. \( \Box \)

By Theorem 6.1 and Lemma 7.2, the solution \( \psi_0 \) admits representation (6.2) with \( l = 0 \) in \( (\sigma_1 \cup S_0 \cup \sigma_2) \cap \hat{U} \). Estimates (7.5) and (5.10) imply that in \( S_{1,2} \cap \hat{U} \) one has

\[
\psi_0 = -W_1 - W_2 + O(||\rho_1| + |\rho_2||)h^{L+1}) = W_0 + O(||\rho_1| + |\rho_2||)h^{L+1}).
\]

In view of Lemma 5.2 and the definitions of \( |\rho_j| \), in \( S_{1,2} \) one has \( |\rho_1| + |\rho_2| \leq C|\rho_0| \) which yields (6.2) with \( l = 0 \) in \( S_{2} \cap \hat{U} \). Reasoning as in the completion
of section 7.1.1, we complete the proof of Theorem 2.4 for $\psi_0$ in the case that we consider.

7.1.3. Solution $\psi_2$. One proves the main theorem for $\psi_2$ using the same techniques as for $\psi_0$ and $\psi_1$. So, we omit the proof and note only that in $S_0$ one represents $\psi_2$ as a linear combination of $\psi_{1,0}$ and $\psi_{0,0}$, and computes the coefficients in this linear combination as in the case of $\psi_0$.

8. Proof of the geometric lemmas

8.1. Proof of Lemma 7.1. This is done in several steps. Below, all the precanonical lines are precanonical with respect to the branch $p_2$ of the complex momentum. We recall that $p_2$ is defined and analytic in the domain $U_2$ and continuous up to its boundary.

8.1.1. AntiStokes lines. We recall that the Stokes lines $\sigma_j$ are defined by (5.4). The AntiStokes lines, $(\alpha_j)_{j \in \mathbb{Z}_3}$, are defined as

$$\alpha_j := \zeta^{-1}(V \cap e^{-2\pi ij/3}[0, +\infty)),$$

(8.1)

For $j \in \mathbb{Z}_3$, $\sigma_j \cap \alpha_j = \{z_0\}$ and the curve $\sigma_j \cup \alpha_j$ is analytic. The angles between any two of the AntiStokes lines at $z_0$ equal $2\pi/3$.

In the case we study, the Stokes and AntiStokes lines are pictured in Fig. 3; the AntiStokes lines are represented by dotted lines. In particular, $\alpha_2$ goes up from $z_0$, and $\alpha_1$ goes down from $z_0$.

Reducing $U$ if necessary, we assume that the AntiStokes lines $\alpha_1$ and $\alpha_2$ are vertical in $U$. As in Fig. 3, let $z_1$ be the lower end of $\alpha_1$ and $z_2$ the upper end of $\alpha_2$.

One has

Lemma 8.1. Along the AntiStokes lines $\alpha_0$, $\alpha_1$ and $\alpha_2$, one has $\text{Re} \int_{z_0}^z p_2 \, dz = 0$. The vector field $z \mapsto v(z) = \nabla \text{Im} \int_{z_0}^z p_2 \, dz$ vanishes only at $z = z_0$. The AntiStokes lines are tangent to this vector field at $z \neq z_0$. As $z$ moves away from

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure3.png}
\caption{Domain $K_1$}
\end{figure}
Proof. The statement on $\text{Re} \int_{z_0}^z p_2 \, dz$ follows directly from the definitions of the function $\zeta$ and of the AntiStokes lines. We note that $|v(z)| = |p_2(z)|$, and that $p_2(z)$ vanishes only at $z_0$ (the complex momentum vanishes modulo $\pi$ only at turning points and $z_0$ is the only turning point in $U$). Therefore, the vector field $v$ vanishes only at $z = z_0$. The statement on $\text{Re} \int_{z_0}^z p_2 \, dz$ and the Cauchy-Riemann equations imply that the AntiStokes lines are tangent to the vector field $v$ where it does not vanish. This and the first two points of Lemma 5.2 imply the statements of Lemma 8.1 on $\text{Im} \int_{z_0}^z p_2 \, dz$. □

We also use

**Lemma 8.2.** There exists $\tilde{U} \subset U$, a neighborhood of $z_0$, such that the lines $\alpha_1 \cap \tilde{U}$ and $\alpha_2 \cap \tilde{U}$ are precanonical.

Let us parametrize $(\alpha_1 \cup \alpha_2) \cap \tilde{U}$ by $y = \text{Im} \, z$, $z = z(y) = x(y) + iy$. Then, if $y \neq \text{Im} \, z_0$, one has

$$\frac{d}{dy} \text{Im} \int_{z_0}^{z(y)} p_2(z) \, dz > 0, \quad (8.2)$$

$$\frac{d}{dy} \text{Im} \int_{z_0}^{z(y)} (p_2(z) - \pi) \, dz < 0. \quad (8.3)$$

Proof. As $\alpha_1$ and $\alpha_2$ are vertical, inequality (8.2) follows from Lemma 8.1. Furthermore, one has

$$\frac{d}{dy} \text{Im} \int_{z_0}^{z(y)} (p_2 - \pi) \, dz = \text{Im} \, (z'(y)p_2(z)) - \pi.$$

Therefore, as $p_2(z_0) = 0$, reducing $U$ somewhat if necessary, we ensure (8.3). Since $\alpha_1 \cup \alpha_2$ is vertical, (8.2) and (8.3) imply that the curve $\alpha_1 \cup \alpha_2$ is precanonical. □

Below, we assume that $\tilde{U} = U$ (if necessary we reduce $U$ somewhat).

8.1.2. Precanonical line $\gamma_1$. We now construct a precanonical line $\gamma_1 \subset S_{1,2}$. It consists of three segments 1, 2 and 3 shown in Fig. 3. Let us describe them.

The segments 1 and 3. To construct these segments, we use

**Lemma 8.3.** Let $\gamma$ be a compact vertical $C^1$-curve parameterized by $y = \text{Im} \, z$, $z = z(y) = x(y) + iy$. We assume that (8.2)–(8.3) hold along $\gamma$. Then, any compact $C^1$-curve sufficiently close in $C^1$-topology to $\gamma$ is precanonical.

This statement immediately follows from the definition of the precanonical curves.

The segment 1. It is a segment of a compact precanonical $C^1$-curve $c_1 \subset S_{1,2}$ that begins at $z_1$ and above $z_1$ goes to the left of $\alpha_1$. When choosing $c_1$, we pick $\tilde{z}_1$, an internal point of $\alpha_1$, and as $c_1$ we take a $C^1$-curve close enough in $C^1$-topology to $\alpha_1$ between $z_1$ and $\tilde{z}_1$. Lemmas 8.2 and 8.3 guarantee that $c_1$ is a precanonical line.

The segment 3. Similarly, the segment 3 is a segment of a compact precanonical $C^1$-curve $c_3 \subset S_{1,2}$, having the upper end at $z_2$ and going to the left of $\alpha_2$ below the point $z_2$.

The segment 2. We note that $\alpha_1 \cup \alpha_2$ is a level curve of the harmonic function $z \to \text{Re} \int_{z_0}^z p_2(z) \, dz$ in $S_{1,2}$. The segment 2 is a segment of another level curve $c_2$ of this function in $S_{1,2}$. This curve is located to the left of $\alpha_1 \cup \alpha_2$. It does not contain the point $z_0$, the only point in $S_{1,2}$ where $p_2$ vanishes. So, $c_2$ is smooth. We choose $c_2$ sufficiently close to $\alpha_1 \cup \alpha_2$ to ensure that
c_2 is vertical (as \( \alpha_1 \) and \( \alpha_2 \) are);
- one has (8.2) along \( c_2 \) (the vector field \( \nabla \text{Im} \int_{z_0}^z p_2(z) \, dz \) does not vanish along \( c_2 \) and is tangent to \( c_2 \);
- (8.3) holds along \( c_2 \) (as it holds along \( \alpha_1 \cup \alpha_2 \));
- \( c_2 \) intersects both \( c_1 \) and \( c_3 \).

Clearly, \( c_2 \) is precanonical.

The curve \( \gamma_1 \). The segment 1 is the segment of \( c_1 \) between \( z_1 \) and the point of intersection of \( c_1 \) and \( c_2 \), the segment 2 is the segment of \( c_2 \) between the segment 1 and the point of intersection of \( c_2 \) and \( c_3 \), and the segment 3 is the segment of \( c_3 \) connecting the segment 2 with \( z_2 \). Clearly, the curve \( \gamma_1 \) made of segments 1–3 is precanonical.

8.1.3. The sign of \( \text{Im} \, p_2 \) in \( S_2 \). The only place where we use our assumption on the direction of the tangent vector to \( \sigma_0 \) at \( z_0 \) is the proof of

**Lemma 8.4.** Both in \( S_2 \) between the curves \( \alpha_2 \) and \( \sigma_1 \) and on these curves, near \( z_0 \) one has \( \text{Im} \, p_2(z) < 0 \) if \( z \neq z_0 \).

**Proof.** Below we assume that either \( z \) is in \( S_2 \) between the curves \( \alpha_2 \) and \( \sigma_1 \) or on one of these curves. In view of (2.5), we can write

\[
p_2(z) = k_1 \tau (1 + O(\tau)), \quad \int_{z_0}^z p_2(z) \, dz = \frac{2}{3} k_1 \tau^3 (1 + O(\tau)), \quad z \to z_0, \tag{8.4}
\]

where \( k_1 \neq 0 \) and \( \tau \) is the branch of \( \sqrt{z - z_0} \) analytic in \( U_2 \) and positive if \( z > z_0 \). Let \( 0 < \theta_2 < \pi \) be the angle at \( z_0 \) between the line \( \{ z \geq z_0 \} \) and the curve \( \alpha_2 \). Note that the angle between \( \sigma_0 \) and \( \alpha_2 \) equals \( \pi/3 \). Therefore, as the tangent vector to \( \sigma_0 \) at \( z_0 \) is either directed downwards or parallel to the real line and directed to the left, one has \( 2\pi/3 \leq \theta_2 < \pi \).

In view of Lemma 8.1, along \( \alpha_2 \), \( \text{Re} \int_{z_0}^z p_2 \, dz = 0 \) and \( \text{Im} \int_{z_0}^z p_2 \, dz \) is monotonously increasing. This and the second formula in (8.4) imply that

\[
\arg k_1 + \frac{3}{2} \theta_2 = \frac{\pi}{2} \text{mod} \, 2\pi. \tag{8.5}
\]

Let \( z - z_0 = |z - z_0| e^{i\theta} \). Using (8.5) and the first formula in (8.4), we get near \( z_0 \)

\[
\frac{\text{Im} \, p_2(z)}{|p_2(z)|} \approx \sin \left( \arg k_1 + \frac{\theta}{2} + o(1) \right) = \cos \left( \theta_2 - \frac{\theta - \theta_2}{2} + o(1) \right). \tag{8.6}
\]

Now, we note that, for \( z \) we consider, near \( z_0 \) one has \( \theta_2 - \pi/3 + o(1) \leq \theta \leq \theta_2 + o(1) \). Therefore, for \( z \) sufficiently close to \( z_0 \), one has

\[
2\pi \frac{3}{2} + o(1) \leq \theta_2 + o(1) \leq \theta_2 - \frac{\theta - \theta_2}{2} \leq \theta_2 + \frac{\pi}{6} + o(1) < \frac{7\pi}{6}.
\]

This and (8.6) implies the statement of Lemma 8.4. \( \square \)

8.1.4. Precanonical line \( \gamma_2 \). The precanonical line \( \gamma_2 \) is located in \( S_{1,2} \) and consists of six segments 4–9 shown in Fig. 3. Let us describe them.

The segments 4–5-6-7. The segment 4 is a segment of a compact precanonical \( C^1 \)-curve \( c_4 \subset S_{1,2} \). This curve begins at \( z_1 \) and above \( z_1 \) goes to the right of \( \alpha_1 \). It is constructed as the curve \( c_1 \) containing the segment 1.

The segment 5 is a segment of a level curve \( c_5 \) of the function \( z \to \text{Re} \int_{z_0}^z p_2(z) \, dz \) in \( S_{1,2} \). The construction of \( c_5 \) is similar to one of \( c_2 \). The curve \( c_5 \) is located to the right of \( \alpha_1 \). We choose \( c_5 \) sufficiently close to \( \alpha_1 \). Then, \( c_5 \) is a precanonical curve and intersects both \( c_4 \) and the Stokes line \( \sigma_2 \).

The segment 4 is the segment of \( c_4 \) between \( z_1 \) and the point of intersection of \( c_4 \) and \( c_5 \). The segment 5 connects this point with a point of \( \sigma_2 \).

We prove
Lemma 8.5. Let $\gamma$ be a vertical curve, let $a \in \gamma$ and let $p$ be a branch of the complex momentum continuous on $\gamma$. If, on $\gamma$, either $\text{Im} \int_a^z p(z) \, dz = 0$ or $\text{Im} \int_a^z (p(z) - \pi) \, dz = 0$, then $\gamma$ is precanonical with respect to $p$.

Proof. Assume that $\text{Im} \int_a^z p(z) \, dz = 0$ on $\gamma$. Then, $z \mapsto \text{Im} \int_a^z (p(z) - \pi) \, dz = -\pi \text{Im} (z - a)$ is decreasing along $\gamma$ when $\text{Im} z$ increases. Thus, $\gamma$ is precanonical. If $\text{Im} \int_a^z (p(z) - \pi) \, dz = 0$, then $z \mapsto \text{Im} \int_a^z p(z) \, dz = \text{Im} \int_a^z \pi \, dz = \text{Im} (z - a)$ is increasing along $\gamma$ when $\text{Im} z$ increases. Thus, $\gamma$ is precanonical.

The segment 6 is the segment of $c_6 = \sigma_2$ between the upper end of the segment 5 and the point $z_0$. The segment 7 is the segment of $c_7 = \sigma_1$ between $z_0$ and an internal point $a$ of $\sigma_1$. We describe this point later. Lemma 8.8 implies that the segments 6 and 7 are precanonical.

Segment 8. This segment is a segment of $c_8$, the level curve $\gamma(a)$ of the harmonic function $z \mapsto \text{Im} \int_{z_0}^z (p(z) - \pi) \, dz$ that contains $a \in \sigma_1$. To choose the segment 8, we check

Lemma 8.6. If $a \in \sigma_1 \setminus \{z_0\}$ is sufficiently close to $z_0$, then $\gamma(a)$ intersects $\sigma_1$ transversally at $a$, enters at $a$ in $S_2$ going upwards, intersects $\alpha_2$ and, up to intersection and at the intersection point, remains vertical.

Proof of Lemma 8.6. Below, we identify the vectors on $\mathbb{R}^2$ with the complex numbers in the standard way, and the bar denotes complex conjugation. The Stokes line $\sigma_1$ is tangent to the vector field $z \mapsto v_\alpha(z) = p_2(z)$ at $z \neq z_0$ ($p_2(z_0) = 0$). The curve $\gamma(a)$ is tangent to the vector field $z \mapsto v_\pi(z) = p_2(z) - \pi$.

Pick $a \in \sigma_1 \setminus z_0$ near the point $z_0$. In view of Lemma 8.4, $\text{Im} p_2(a) < 0$. Therefore, $\gamma(a)$ is vertical at $a$. Moreover, both the vectors $v_\alpha(a)$ and $v_\pi(a)$ are directed upwards and $v_\pi(a)$ is directed to the left of $v_\alpha(a)$. Therefore, at $a$, the curve $\gamma(a)$ intersects $\sigma_1$ transversally and enters $S_2$ going upwards.

Furthermore, in view of Lemma 8.4, as long as $\gamma(a)$ stays in $S_2$ near $z_0$ between the curves $\alpha_2$ and $\sigma_1$ or on them, it remains vertical.

To complete the proof, it suffices to show that if $a$ is sufficiently close to $z_0$, then $\gamma(a)$ intersects $\alpha_2$ remaining vertical. Therefore, we note that $v_\pi(z_0) = -\pi$. So, at $z_0$ the vector tangent to $\gamma(z_0)$ is parallel to $\mathbb{R}$, and the curve $\gamma(z_0)$ intersects the analytic curve $\alpha_2 \cup \sigma_2$ transversally. Depending continuously on $a$, $\gamma(a)$ intersects this curve also for all $a$ sufficiently close to $z_0$. But, if $\text{Im} a > \text{Im} z_0$ and $a$ is sufficiently close to $z_0$, the curve $\gamma(a)$ goes upward from $a$. Therefore, for $a$ sufficiently close to $z_0$, the curve $\gamma(a)$ intersects $\alpha_2$ still remaining vertical. This completes the proof of Lemma 8.6.

The segments 8 and 9. We choose the point $a$, the end of the segment 7 and the beginning of the segment 8, so that $c_8 = \gamma(a)$ intersects $\alpha_2$ as described in Lemma 8.6. The end of the segment 8 is the point of intersection of $c_8$ and $\alpha_2$. By Lemma 8.5, the segment 8 is precanonical. The segment 9 is the segment of $\alpha_2$ connecting the upper end of the segment 8 to the point $z_2$. It precanonical by Lemma 8.2.

The domain $K_1$ bounded by $\gamma_1$ and $\gamma_2$ is the one described in Lemma 7.1, the proof of which is complete.

8.2. Proof of Lemma 7.2. The proof uses the same techniques as the proof of Lemma 7.1. Therefore, we omit standard details. The construction of the curves $\gamma_1$ and $\gamma_2$ bounding the domain $K_0$ from Lemma 7.2 is illustrated by Fig. 4. Below, all the precanonical lines are precanonical with respect to $p_0$. 
8.2.1. Curve $\gamma_1$. This curve consists of segments 1–3. Let us describe them. We pick $z_1$, an internal point of $\sigma_2$, and $a$, an internal point of $\sigma_1$. The segment 1 is the segment of $\sigma_2$ between $z_1$ and $z_0$, and the segment 2 is the segment of $\sigma_1$ between $z_0$ and $a$.

To describe the segment 3, we consider $\gamma_0(a)$, the curve in $\sigma_2 \cup S_0 \cup \sigma_1$ described by the equation $\text{Im} \int_{z}^{a} (p_0(z) - \pi) \, dz = 0$. We suppose that $a$ is sufficiently close to $z_0$. Then, $\gamma_0(a)$ intersects $\sigma_1$ at $a$ transversally, enters in $S_0$ going upwards and is vertical in a neighborhood of $z_0$ (To prove this, one uses the observation that near $z_0$ on $\sigma_1$ one has $\text{Im} p_0(z) > 0$. The proof of this observation is similar to one of Lemma 8.4.) The segment 3 is a segment of $\gamma_0(a)$ connecting in this neighborhood $a$ to a point $z_2 \in S_2$. We choose $z_2$ later. Lemma 8.5 imply that the segments 1–3 are precanonical.

The points $z_1$ and $z_2$ are the ends of $\gamma_1$.

8.2.2. Curve $\gamma_2$. This curve consists of two segments, segments 4 and 5. The segment 4 is a segment of $c_4$, a level curve of the function $z \rightarrow \text{Re} \int_{z}^{z_1} p_0(z) \, dz$ in $S_0 \cup \sigma_2$ that contains the point $z_1$. The curve $c_4$ is orthogonal to $\sigma_2$ at $z_1$.

Let us note that, under our assumptions on $\sigma_0$ and $\sigma_2$ (see the very beginning of section 7), the angle at $z_0$ between $\sigma_2$ and the horizontal line $\{z \geq z_0\}$ belongs to $(0, \pi/3)$. Possibly reducing $U$ somewhat, we assume that, at any point $\zeta \in \sigma_2$, the angle between $\sigma_2$ and the line $\{z \geq \zeta\}$ belongs to $(0, \pi/2)$. Then, $c_4$ is vertical at least in a neighborhood of the point $z_1$ and goes upward from $z_1$ into $S_0$.

The segment 5 is a segment of a level curve $c_5$ of the function $z \rightarrow \text{Im} \int_{z}^{z_0} p_0(z) \, dz$ in $S_0$. It is located to the right of $\sigma_2 \cup \sigma_1$ (which is also a level curve of this function). We choose the curve $c_5$ sufficiently close to $\sigma_2 \cup \sigma_1$. Then it is vertical, intersects $\gamma_0(a)$ and $c_4$, and the segments of these curves between $\sigma_2 \cup \sigma_1$ and the intersection points are vertical.

The point $z_2$ is the point of intersection of $\gamma_0(a)$ and $c_5$. The segment 4 is the segment of $c_4$ between $\sigma_2 \cup \sigma_1$ and $c_5$, and the segment 5 is the segment of $c_5$ connecting $c_4$ to $z_2$.

The segment 5 is precanonical in view of Lemma 8.5. Arguing as when proving...
Lemma 8.2 and reducing somewhat $U$ if necessary, we check that the segment 4 is precanonical. The domain $K_0$ bounded by the curves $\gamma_1$ and $\gamma_2$, is the one described in Lemma 7.2. Its proof is complete.
