Lyapunov matrix equation

\[ A^H X + XA + C = O_r \] with \( A \) a Jordan matrix

Abstract

A Lyapunov matrix equation can be converted, by using the Jordan decomposition theorem for matrices, into an equivalent Lyapunov matrix equation where the matrix is a Jordan matrix. The Lyapunov matrix equation with Jordan matrix can be reduced to a system of Sylvester-Lyapunov type matrix equations. We completely solve the Sylvester-Lyapunov type matrix equations corresponding to the Jordan block matrices of the initial matrix.

MSC: 15A21, 15A24, 15B57
Keywords: Lyapunov matrix equation, Jordan matrix, Hermitian matrix.

1 Introduction

A Lyapunov matrix equation (or the continuous Lyapunov matrix equation) has the form

\[ A^H X + XA + C = O_r, \]  \hspace{1cm} (1.1)

with \( A \in \mathcal{M}_r(\mathbb{C}) \), \( C \in \mathcal{M}_r(\mathbb{C}) \) and the unknown \( X \in \mathcal{M}_r(\mathbb{C}) \).

The homogeneous Lyapunov matrix equation is:

\[ A^H X + XA = O_r. \]  \hspace{1cm} (1.2)

The Lyapunov matrix equation appeared, see [10] and [6], in the study of the dynamics of a linear differential equation, \( \dot{x} = Ax \), where \( A \in \mathcal{M}_r(\mathbb{C}) \). Dynamical aspects, like stability, are studied using a square function \( V(x) = \frac{1}{2}x^H X x \), with \( X \in \mathcal{M}_r(\mathbb{C}) \) a Hermitian matrix. The function \( V \) is a conserved quantity of the linear system if and only if \( X \) is a Hermitian solution of the homogeneous Lyapunov matrix equation (1.2). The global asymptotic stability of the equilibrium point \( 0 \) is assured by the existence of a Hermitian positive definite solution of the Lyapunov matrix equation (1.1), with \( C \) a Hermitian positive definite matrix.

Lyapunov matrix equations appear also in the study of optimization of a cost function defined on a matrix manifold, see [1].

The Lyapunov matrix equation is a particular case of the Sylvester matrix equation

\[ AX + XB + C = O_r, \]  \hspace{1cm} (1.3)

with \( A \in \mathcal{M}_r(\mathbb{C}) \), \( B \in \mathcal{M}_s(\mathbb{C}) \), \( C \in \mathcal{M}_{r \times s}(\mathbb{C}) \) and the unknown \( X \in \mathcal{M}_{r \times s}(\mathbb{C}) \).

In literature we find some representations of the solutions of Sylvester matrix equation, see [9], but they are difficult to use when \( r \) and \( s \) are large numbers. We also find studies of generalized Sylvester matrix equation, see [4], or studies of other matrix equations which are derived from the Lyapunov matrix equation, see [2] and [13]. Due to the importance of the Lyapunov matrix equations, researchers have made a great effort in studying its numerical solutions, see [7], [12].
The set of solutions of a homogeneous Lyapunov matrix equation defines some types of matrices $A$:

- if the identity matrix is a solution of (1.2), then the matrix $A$ is a skew-Hermitian matrix;
- if the matrix $\begin{pmatrix} O_r & I_r \\ -I_r & O_r \end{pmatrix}$ is a solution of (1.2), then the matrix $A$ is a Hamiltonian matrix;
- if (1.2) has an invertible solution, then $A^H$ and $-A$ are similar matrices.

A Lyapunov matrix equation can be converted, by using the Jordan decomposition theorem for matrices, into an equivalent Lyapunov matrix equation with a Jordan matrix replacing the matrix $A$.

In Section 2 we present some general results concerning the set of solutions of Lyapunov matrix equation, the set of Hermitian solutions and the set of real symmetric solutions. Also, we present the equivalent transformation of (1.1) by using a similar transformation of the matrix $A$, which represents, via Jordan canonical form, the main reason to study the Lyapunov matrix equation with Jordan matrix.

The Lyapunov matrix equation with Jordan matrix is reduced to a system with Sylvester-Lyapunov matrix equations with Jordan block matrices. In Section 3 we completely solve a more general equation as Lyapunov matrix equation with Jordan block matrix, called Sylvester-Lyapunov matrix equation with Jordan block matrices. For the homogeneous case we present the set of solutions, the set of Hermitian solutions, and the set of real symmetric solutions. In the non-homogeneous case with a Jordan block matrix which is not nilpotent we have a unique solution which is written by using the Pascal matrix and the extended generalized Pascal matrix introduced in [14]. For the case of square matrices we study the solution when the matrix $C$ is positive semidefinite or positive definite. When both Jordan block matrices are nilpotent we present the compatibility conditions and, if they are satisfied, the set of solutions, the set of Hermitian solutions, and the set of real symmetric solutions.

In Section 4 we present and study the equivalent system formed with Sylvester-Lyapunov matrix equations which is attached to a Lyapunov matrix equation with a Jordan matrix. For the homogeneous case we present the dimension of the complex vectorial space of solutions and the dimension of the real vectorial spaces of Hermitian solutions and real symmetric solutions. As an example we present these sets for the case of a diagonal matrix. In the homogeneous case we study the conditions for which we have a Hermitian positive definite solution and the conditions for which we have an invertible solution. We present two examples, in the homogeneous case and in the non-homogeneous case, to better understand the used method.

Section 5 is dedicated to the general Lyapunov matrix equation. In the homogeneous case, if we know the set of the eigenvalues of the matrix $A$, by using the Jordan decomposition theorem for matrices and our results from the previous sections, we compute the dimension of the complex vectorial space of solutions, the dimension of the real vectorial space of the Hermitian solutions, and the dimension of the real vectorial space of the real symmetric solutions. In this case we study the existence of the invertible solutions and the positive definite solutions. To compute the solutions in the general case we need to know the set of eigenvalues of $A$ and the matrix $P_A$ which appears in the Jordan decomposition theorem for matrices. We illustrate with an example of solving the Lyapunov matrix equation in the general case by the method presented in this paper.

In the Appendix we recall some notions and results of the matrix theory which appear in our paper.

# 2 Lyapunov matrix equation. Generalities

We denote by $\mathcal{L}_{A,C}$ the set of the solutions of (1.1). It is easy to observe the following result.

**Proposition 2.1.** (i) $O_r \in \mathcal{L}_{A,O_r}$ and $\mathcal{L}_{A,O_r}$ is a complex vectorial subspace of $\mathcal{M}_r(\mathbb{C})$.

(ii) If $Y_C$ is a particular solution of (1.1), then we have $\mathcal{L}_{A,C} = Y_C + \mathcal{L}_{A,O_r}$.

In some important situations the matrix $C$ is supposed to be a Hermitian matrix or real symmetric matrix. We note by $\mathcal{L}_{A,C}^H$ (respectively $\mathcal{L}_{A,C}^{sym}$) the set of Hermitian (respectively real symmetric) solutions of the matrix equation (1.1).
Proposition 2.2. (i) If $\mathcal{L}_{A,C}^H \neq \emptyset$, then $C$ is a Hermitian matrix.
(ii) $O_r \in \mathcal{L}_{A,O_r}^H$ and $\mathcal{L}_{A,O_r}^H \subseteq \mathcal{L}_{A,O_r}$ is a real vectorial space.
(iii) Suppose that $C$ is a Hermitian matrix.

(iii.1) If $X \in \mathcal{L}_{A,C}$, then $X^H \in \mathcal{L}_{A,C}$.
(iii.2) If $X \in \mathcal{L}_{A,C}$, then $X^H = \frac{1}{2} (X + X^H) \in \mathcal{L}_{A,C}^H$.
(iii.3) If $Y_C$ is a particular Hermitian solution of (1.1), then we have $\mathcal{L}_{A,C}^H = Y_C + \mathcal{L}_{A,O_r}^H$.

Proposition 2.3. Suppose that $A, C$ are real matrices.

(i) If $X \in \mathcal{L}_{A,C}$, then $\text{Re}(X) \in \mathcal{L}_{A,C}$.
(ii) If $\mathcal{L}_{A,C}^{\text{sym}} \neq \emptyset$, then $C$ is a real symmetric matrix.
(iii) $O_r \in \mathcal{L}_{A,O_r}^{\text{sym}}$ and $\mathcal{L}_{A,O_r}^{\text{sym}} \subseteq \mathcal{L}_{A,O_r}^H$ is a real vectorial space.
(iv) Suppose that $C$ is a real symmetric matrix.

(iv.1) If $X \in \mathcal{L}_{A,C}$ is a real matrix, then $X^T \in \mathcal{L}_{A,C}$.
(iv.2) If $X \in \mathcal{L}_{A,C}$ is a real matrix, then $X^s = \frac{1}{2} (X + X^T) \in \mathcal{L}_{A,C}^{\text{sym}}$.
(iv.3) If $Z_C$ is a particular real symmetric solution of (1.1), then we have $\mathcal{L}_{A,C}^{\text{sym}} = Z_C + \mathcal{L}_{A,O_r}^{\text{sym}}$.

The existence of an invertible solution of the homogeneous Lyapunov matrix equation (1.2) is equivalent with the fact that matrices $A^H$ and $-A$ are similar.

In some cases we can simplify the Lyapunov matrix equation by using a matrix similar with the matrix $A$.

Proposition 2.4. Let $B \in \mathcal{M}_r(\mathbb{C})$ be a matrix similar with $A$ via the invertible matrix $P \in \mathcal{M}_r(\mathbb{C})$ (i.e. $B = P^{-1}AP$) and $D = P^HCP$. We construct the Lyapunov matrix equation

\[
B^H Z + ZB + D = O_r. \tag{2.1}
\]

The matrix $X$ is a solution of (1.1) if and only if $Z = P^HXP$ is a solution of (2.1).

Proof. We have

\[
A^H X + AX + C = O_r \iff P^{-H}B^H P^H X + XPBP^{-1} + C = O_r \\
\iff B^H P^H X + P^H XPBP^{-1} + P^H C = O_r \iff B^H P^H XP + P^H XBP + P^H CP = O_r \\
\iff B^H Z + ZB + D = O_r.
\]

We have the following properties:

• The equation (1.1) is homogeneous if and only if the equation (2.1) is homogeneous.
• $C$ is a Hermitian matrix if and only if $D = P^HCP$ is a Hermitian matrix.
• If $P$ is a real matrix, then $C$ is a real symmetric matrix if and only if $D$ is a real symmetric matrix.

3 Sylvester-Lyapunov matrix equations with Jordan block matrices

In this section we completely solve the Sylvester-Lyapunov matrix equation with Jordan block matrices, a matrix equation of the form:

\[
J_r(\lambda)^H X + XJ_s(\mu) + C = O_{r,s}, \tag{3.1}
\]

where $J_r(\lambda) \in \mathcal{M}_r(\mathbb{C})$, $J_s(\mu) \in \mathcal{M}_s(\mathbb{C})$ are Jordan block matrices, $C \in \mathcal{M}_{r,s}(\mathbb{C})$ and the unknown matrix $X \in \mathcal{M}_{r,s}(\mathbb{C})$. We denote by $L(\lambda, \mu, C)$ the set of solutions of (3.1). $L^H(\lambda, \mu, C)$ is the set of Hermitian solutions and $L^{\text{sym}}(\lambda, \mu, C)$ is the set of real symmetric solutions.
Proposition 3.1. (i) If $\alpha \in \mathbb{C}^*$ and $C \in \mathcal{M}_{r,s}(\mathbb{C})$, then $\mathcal{L}(\lambda, \mu, \alpha C) = \alpha \mathcal{L}(\lambda, \mu, C)$.

(ii) If $q \in \mathbb{N}^*$, $C_1, \ldots, C_q \in \mathcal{M}_{r,s}(\mathbb{C})$ such that $C = \sum_{i=1}^{q} C_i$, and $\mathcal{L}(\lambda, \mu, C_1) \neq \emptyset, \ldots, \mathcal{L}(\lambda, \mu, C_q) \neq \emptyset$, then $\mathcal{L}(\lambda, \mu, C) = \sum_{i=1}^{q} \mathcal{L}(\lambda, \mu, C_i)$.

(iii) If $\nu = \lambda + \overline{\nu}$, then the matrix equation (3.1) is equivalent with the matrix equation

$$J_r(\nu)^H X + X J_s(0) + C = O_{r,s},$$

i.e. $\mathcal{L}(\lambda, \mu, C) = \mathcal{L}(\nu, 0, C)$.

Proof. To prove (iii) we use the relation (A.1).

The set of matrices $\{e_{\alpha} \otimes f_t^T \in \mathcal{M}_{r,s}(\mathbb{C}) \mid \alpha = 1, r; \beta = 1, s\}$ is a basis of the complex vectorial space $\mathcal{M}_{r,s}(\mathbb{C})$, where $e_1, \ldots, e_r$ is the canonical basis of $\mathbb{C}^r$ and $f_1, \ldots, f_s$ is the canonical basis of $\mathbb{C}^s$.

The above proposition suggests to consider the homogeneous case and the cases when $C$ is an element of the above basis of $\mathcal{M}_{r,s}(\mathbb{C})$.

In what follows we study the equation (3.2). This equation written in components of $X$ is given by

$$\nu x_{ij} + x_{i-1,j} + x_{i,j-1} + c_{ij} = 0, \ \forall i \in \{1, \ldots, r\}, \ \forall j \in \{1, \ldots, s\}, \quad (3.3)$$

where $x_{0j} = x_{i0} = 0$.

### 3.1 The homogeneous case

In this case we have $C = O_{r,s}$ and the equation (3.2) becomes

$$J_r(\nu)^H X + X J_s(0) = O_{r,s}.$$  

(3.4)

Theorem 3.2. (i) If $\nu \neq 0$, then $\mathcal{L}(\nu, 0, O_{r,s}) = \{O_{r,s}\}$.

(ii) $\mathcal{L}(0, 0, O_{r,s})$ is a complex vectorial space with $\dim_{\mathbb{C}} \mathcal{L}(0, 0, O_{r,s}) = \min\{r, s\}$. A solution $X$ of (3.3) has the components:

$$x_{ij} = \begin{cases} 0 & i + j \leq s \text{ if } r \leq s; \ x_{ij} = \begin{cases} 0 & i + j \leq r \text{ if } r > s; \ i + j > r & \text{if } r > s, \end{cases} \end{cases}$$

where $p_1, \ldots, p_{\min\{r,s\}}$ are complex parameters. We can write, see (A.3) and (A.4),

$$X = \sum_{t=1}^{\min\{r,s\}} p_t y_t^{[r,s]} = \begin{cases} \left( \sum_{t=1}^{r} p_t (J_r(0))^{t-1} \right) y^{[r,s]} & \text{if } r \leq s; \\ \left( \sum_{t=1}^{s} p_t (J_s(0))^{t-1} \right) y^{[r,s]} & \text{if } r > s, \end{cases}$$

where the set of matrices $\{y_1^{[r,s]}, \ldots, y_{\min\{r,s\}}^{[r,s]}\}$ is a basis of $\mathcal{L}(0, 0, O_{r,s})$.

Proof. (i) We use the relations (3.3) and mathematical induction.

(ii) First we suppose that $r \leq s$. We choose $i = 1$ in (3.3) and obtain that $x_{11} = \cdots = x_{1,s-1} = 0$. By mathematical induction $x_{i,j} = 0$ for $i + j \leq s$. For an index $i$ we set $x_{is} = p_i$. By induction we obtain that $x_{i+j,s-j} = (-1)^i p_i$ for $j \in \{1, \ldots, r-i\}$. All these matrices are solutions for (3.4). We observe that the set of solutions is a vectorial space with the dimension $r = \min\{r, s\}$.

For the case $r > s$ we can consider the equivalent problem

$$J_s(0)^H X^H + X^H J_r(0) = O_{s,r}$$

and using the above results we find the announced results.

Corollary 3.3. For \( \nu = 0 \) and \( r = s \) a solution of the equation (3.4) has the form

\[
X = \begin{pmatrix}
0 & 0 & \ldots & 0 & 0 & p_1 \\
0 & 0 & \ldots & 0 & -p_1 & p_2 \\
0 & 0 & \ldots & p_1 & -p_2 & p_3 \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
(-1)^{r-1}p_1 & (-1)^{r-2}p_2 & \ldots & p_{r-2} & -p_{r-1} & p_r
\end{pmatrix},
\]

(3.6)

where \( p_1, \ldots, p_r \) are complex parameters. The matrix \( X \) is invertible if and only if \( p_1 \neq 0 \).

Proof. We observe that \( \det(X) = p_1^r \) and we obtain the announced result. \( \square \)

Corollary 3.4. The matrix \( X \in \mathcal{L}^H(0,0,O_r) \) has the form

\[
X = \sum_{i=1}^{r} u_i t^i y_{t}^{[r,r]} \quad \text{if} \quad r \in 2\mathbb{N} \quad \text{and} \quad X = \sum_{i=1}^{r} u_i t^{i-1} y_{t}^{[r,r]} \quad \text{if} \quad r \in 2\mathbb{N} + 1,
\]

where \( u_1, \ldots, u_r \) are real parameters. \( \mathcal{L}^H(0,0,O_r) \) is a real vectorial space with \( \dim \mathcal{L}^H(0,0,O_r) = r \). The Hermitian solution \( X \) is invertible if and only if \( u_1 \neq 0 \).

The set \( \mathcal{L}^H(0,0,O_r) \) contains a positive definite matrix if and only if \( r = 1 \).

Proof. We present the proof for the last affirmation. For \( r = 1 \) it easy to see that we have a positive definite matrix in \( \mathcal{L}^H(0,0,O_r) \). If \( r > 1 \), then an element \( X \) of \( \mathcal{L}^H(0,0,O_r) \) has the component \( x_{11} = 0 \). We have \( e_1^H X e_1 = x_{11} = 0 \), which implies that \( X \) is not positive definite. \( \square \)

Corollary 3.5. The set \( \mathcal{L}_{sym}^H(0,0,O_r) \) of the real symmetric solutions of the equation (3.3) is a real vectorial space with \( \dim \mathcal{L}_{sym}^H(0,0,O_r) = \lceil \frac{r+1}{2} \rceil \). A real symmetric solution has the form

\[
X = \sum_{i=1}^{r} u_i t^i y_{2t}^{[r,r]} \quad \text{if} \quad r \in 2\mathbb{N} \quad \text{and} \quad X = \sum_{i=1}^{r} u_i t^{i-1} y_{2t}^{[r,r]} \quad \text{if} \quad r \in 2\mathbb{N} + 1,
\]

where \( u_1, u_2, \ldots, u_r \) are real parameters. \( X \) is invertible if and only if \( r \in 2\mathbb{N} + 1 \) and \( u_1 \neq 0 \).

Corollary 3.6. Let be \( \lambda, \mu \in \mathbb{C} \) and \( r \in \mathbb{N}^* \).

(i) The matrices \( J^H(\lambda) \) and \( J_r(\mu) \) are similar if and only if \( \lambda + \overline{\mu} = 0 \).

(ii) If \( \lambda + \overline{\mu} = 0 \), then \( J^H(\lambda) \) and \( J_r(\mu) \) are similar via a Hermitian matrix.

(iii) If \( \lambda + \overline{\mu} = 0 \), then \( J^H(\lambda) \) and \( J_r(\mu) \) are similar via a real symmetric matrix if and only if \( r \in 2\mathbb{N} + 1 \).

Corollary 3.7. \( J_{2r}(\lambda) \) is a Hamiltonian matrix if and only if \( r = 1 \) and \( \lambda \) is a purely imaginary number.

Proof. Suppose that \( J_{2r}(\lambda) \) is a Hamiltonian matrix. We consider the homogeneous matrix equation \( J_{2r}^H(\lambda) X + X J_{2r}(\lambda) = O_{2r} \). This equation is equivalent with the following homogeneous Lyapunov matrix equation \( J_{2r}^H(\lambda + \overline{\lambda}) X + X J_{2r}(0) = O_{2r} \). A solution is given by the matrix \( \begin{pmatrix} O_r & I_r \\ -I_r & O_r \end{pmatrix} \). We obtain that \( \lambda + \overline{\lambda} = 0 \). By using the form of the solutions we deduce that \( r = 1 \).

We observe that \( J_{2}(ai), a \in \mathbb{R} \), is a Hamiltonian matrix. \( \square \)

\footnote{We use the floor function \([\cdot]\).}
\section*{3.2 The non-homogeneous case with $\nu \neq 0$}

\textbf{Theorem 3.8.} If $\nu \neq 0$ and $C \in M_{r \times s}(\mathbb{C})$, then the matrix equation (3.2) has a unique solution.

(a) If $C = e_i \otimes f^T_j$, with $(i, j) \in \{1, \ldots, r\} \times \{1, \ldots, s\}$, then the solution is $X_{ij}^{[r, s]} [-\frac{1}{\nu}]$ (see Section A.11).

(b) For a general $C$ the solution is $X = \sum_{i=1}^{r} \sum_{j=1}^{s} c_{ij} X_{ij}^{[r, s]} [-\frac{1}{\nu}]$. We can write

$$X = \sum_{i=1}^{r} \sum_{j=1}^{s} c_{ij} (J^T_r(0))^{-1} X_{ij}^{[r, s]} [-\frac{1}{\nu}] (J_s(0))^{j-1}. \tag{3.7}$$

\textbf{Proof.} The unicity is proved by mathematical induction.

(a) First, we consider the matrix equation (3.2) with $\nu \neq 0$ and $C = -\nu e_1 \otimes f_1^T$. The solution $\hat{X}$ has the component $\hat{x}_{11} = 1$ and the following recursion is verified:

$$\hat{x}_{ij} = -\frac{1}{\nu} (\hat{x}_{i-1,j} + \hat{x}_{i,j-1}), \quad \forall i \in \{1, \ldots, r\}, \forall j \in \{1, \ldots, s\}, (i, j) \neq (1, 1). \tag{3.8}$$

where $\hat{x}_{0j} = \hat{x}_{i0} = 0$.

By using the properties of the matrix $\Psi^{[r, s]}[-\frac{1}{\nu}]$, see Section A, we obtain that $\hat{X} = \Psi^{[r, s]}[-\frac{1}{\nu}]$.

The Proposition 3.1 (i) implies the announced result.

Second, we consider $i = 1$ and $j > 1$ and we write $X = (Y Z)$ with $Y \in M_{r, j-1}(\mathbb{C})$ and $Z \in M_{s, j+1}(\mathbb{C})$. We observe that we can write $J_s(0) = J_{s-1}(0) + J_{s-j+1}(0)$. The equation (3.2) has the form

$$J^H_r(\nu) Y + Y J_{j-1}(0) + (O_{r,j-1} e_1 \otimes \hat{f}_1^T) = (O_{r,j-1} O_{s, j+1}),$$

where $\hat{f}_1 \in \mathbb{R}^{s-j+1}$. It is equivalent with the matrix system

$$\begin{cases} J^H_r(\nu) Y + Y J_{j-1}(0) = O_{r,j-1} \\ J^H_r(\nu) Z + Z J_{s-j+1}(0) + e_1 \otimes \hat{f}_1^T = O_{r,s-j+1}. \end{cases}$$

By using Theorem 3.2 and first step of the induction, we obtain $Y = O_{r,j-1}, \quad Z = -\frac{1}{\nu} \Psi^{[r, s-j+1]}[-\frac{1}{\nu}]$, which implies our result.

Analogously we obtain the announced results for the remaining cases.

(b) We observe that $C = \sum_{i=1}^{r} \sum_{j=1}^{s} c_{ij} e_i \otimes f^T_j$ and we apply Proposition 3.1 and the above results. For the formula (3.7) we use A.11. \hfill \Box

In some important cases we have that $C$ a Hermitian positive semidefinite matrix. There exists $L \in M_{r \times s}(\mathbb{C})$ such that $C = L L^H \in M_{r}(\mathbb{C})$, see Theorem 7.2.7 from [3]. The components verify $c_{ij} = \sum_{q=1}^{r} l_{iq} l_{jq}$. The solution presented in the above theorem has the form

$$X = \sum_{q=1}^{s} L_q X^{[r, s]} [-\frac{1}{\nu}] L_q^H, \tag{3.9}$$

where

$$L_q = \sum_{i=1}^{r} l_{i,q} (J^T_r(0))^{-1} = \begin{pmatrix} l_{1,q} & 0 & 0 & \cdots & 0 \\ l_{2,q} & l_{1,q} & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ l_{r,q} & l_{r-1,q} & l_{r-2,q} & \cdots & l_{1,q} \end{pmatrix}.$$
Proof. We can write $C = LL^H \in \mathbb{M}_r(\mathbb{C})$ with $L \in \mathbb{M}_r(\mathbb{C})$. The solution is a Hermitian matrix.

(i) In this case $-\frac{1}{\nu} < 0$ and the matrix $X^{[r,r]}[-\frac{1}{\nu}]$ is negative definite, see Section A. By using Observation 7.1.8 from \[8\] we have that for $q \in \{1, \ldots, r\}$ the matrix $L_qX^{[r,r]}[-\frac{1}{\nu}]L_q^H$ is negative semidefinite. Using now Observation 7.1.3 from \[8\] we deduce that the solution is negative semidefinite.

The case $\nu < 0$ is treated analogously.

(ii) We observe that $c_{11} = \sum_{i=1}^r |l_{1q}|^2$. If $c_{11} \neq 0$, then it exists $q^* \in \{1, \ldots, r\}$ such that $l_{q^*} \neq 0$. We have $\text{rank}(L_{q^*}) = r$ and we use Observation 7.1.8 from \[8\] to deduce that the matrix $L_qX^{[r,r]}[-\frac{1}{\nu}]L_q^H$ is positive definite. By using (i) and Observation 7.1.3 from \[8\] we deduce that the solution is positive definite. The case $\nu < 0$ is treated analogously. 

\[\square\]

Corollary 3.10. Suppose that $\nu \in \mathbb{R}^*$ and $C$ is a Hermitian positive definite matrix. If $\nu > 0$ (respectively $\nu < 0$), then the solution of (3.2) is a negative (respectively positive) definite matrix.

3.3 The non-homogeneous case with $\nu = 0$

The components of a solution verify

$$\sum_{j=1}^{i-1} (-1)^j c_{i-j,j} = 0, \ \forall i \in \{2, \ldots, \min\{r, s\} + 1\}. \tag{3.11}$$

If $X \in \mathcal{L}(0, 0, C)$, then $\mathcal{L}(0, 0, C) = \tilde{X} + \mathcal{L}(0, 0, O_{r,s})$.

If the above conditions are satisfied, then the components of a particular solution are:

$$\tilde{x}_{ij} = \begin{cases} \sum_{k=1}^{\min\{i,s-j\}} (-1)^k c_{i-k+1, j+k} & \text{if } j < s \\ 0 & \text{if } j = s \end{cases}$$

$$\tilde{x}_{ij} = \begin{cases} 0 & \text{if } i = r \\ \sum_{k=1}^{\min\{j,r-i\}} (-1)^k c_{i+k, j-k+1} & \text{if } i < r \end{cases}$$

Proof. First we suppose that the matrix equation (3.2) has solutions. We write the equation (3.10) for $i = j = 1$ and we obtain $c_{11} = 0$. For $i \geq 3$ we have

$$x_{i-1,1} + c_{i-1,1} = 0, \ x_{i-3,2} + x_{i-2,1} + c_{i-2,2} = 0, \ldots, x_{2,i-3} + x_{1,i-2} + c_{2,i-2} = 0, \ x_{1,i-2} + c_{1,i-1} = 0$$

and we obtain the last equalities.

By calculus it is verified that the matrix $\tilde{X}$ from the statement of the Theorem is a particular solution of (3.11).

By using the Theorem 3.2, the dimension of $\mathcal{L}_{r,s}(0, 0, O_{r,s})$ is $\min\{r, s\}$, which proves that the equalities from hypothesis are sufficient conditions for the existence of solutions for (3.2). 

\[\square\]

Theorem 3.12. Suppose that $C$ is a Hermitian matrix, $r = s \geq 2$ and $\nu = 0$. The matrix equation (3.2) has a Hermitian solution if and only if we have the equalities:

$$\sum_{j=1}^\alpha (-1)^j \text{Im}(c_{j,2\alpha+1-j}) = 0, \ \forall \alpha \in \{1, \ldots, \left\lceil \frac{r}{2} \right\rceil \}.$$
\[ c_{11} = 0, \quad (-1)^{\alpha} c_{\alpha \alpha} + 2 \sum_{j=1}^{\alpha-1} (-1)^{j} \text{Re}(c_{j,2\alpha-j}) = 0, \forall \alpha \in \left\{ 2, \ldots, \left\lceil \frac{r+1}{2} \right\rceil \right\}. \]

If the above conditions are satisfied, then a particular Hermitian solution of \((3.2)\) is \(\hat{X}^h = \frac{1}{2}(\hat{X} + \hat{X}^T)\), where \(\hat{X}\) is the particular solution presented in Theorem 3.11.

**Proof.** By using Proposition 2.2 we have that \(c_{\alpha \alpha} = 0\) and for \(\alpha \in \left\{ 2, \ldots, \left\lceil \frac{r+1}{2} \right\rceil \right\}\), we use Proposition 2.2, Corollary 3.4, and Theorem 3.12. For a general real symmetric solution we use Theorem 3.2, Corollary 3.5, and Theorem 3.13.

To write a general solution we use Theorem 3.2 and Theorem 3.11. For a general Hermitian solution we use Proposition 2.3, Corollary 3.5, and Theorem 3.12. For a general real symmetric solution we use Proposition 2.3, Corollary 3.5, and Theorem 3.13.

**Example 3.1.** The case \(r = s = 3\). The necessary and sufficient conditions for compatibility are: \(c_{11} = 0, \ c_{21} - c_{12} = 0, \ c_{31} - c_{22} + c_{13} = 0\). The particular and general solutions are

\[
\hat{X} = \begin{pmatrix} -c_{12} & -c_{13} & 0 \\
-c_{13} & c_{13} - c_{22} & 0 \\
c_{22} + c_{23} & -c_{33} & 0 \end{pmatrix}, \quad X = \begin{pmatrix} -c_{12} & -c_{13} & p_1 \\
c_{13} - c_{22} & -c_{23} - p_1 & p_2 \\
-c_{32} + c_{33} & -c_{33} & -p_2 \end{pmatrix}, \quad p_1, p_2, p_3 \in \mathbb{C}.
\]

If \(C\) is a Hermitian matrix, then the necessary and sufficient conditions for compatibility are \(c_{11} = 0, \ \text{Im}(c_{12}) = 0, \ \text{and} \ 2\text{Re}(c_{13}) - c_{22} = 0\). The Hermitian particular and general solutions are

\[
\hat{X}^h = \begin{pmatrix} -c_{12} & -c_{13} & -\text{Im}(c_{23}) \\
-c_{13} & -\text{Re}(c_{23}) & -\text{Re}(c_{23}) \\
\text{Im}(c_{23}) & \text{Im}(c_{23}) + u_1 & -u_2i \end{pmatrix}, \quad X = \begin{pmatrix} -c_{12} & -c_{13} & -\text{Im}(c_{23}) + u_1 \\
-c_{13} & -\text{Re}(c_{23}) - u_1 & -u_2i \\
\text{Im}(c_{23}) + u_1 & \text{Im}(c_{23}) + u_1 & u_3 \end{pmatrix},
\]

\[
\hat{X} = \begin{pmatrix} -c_{12} & -c_{13} & 0 \\
-c_{13} & c_{13} - c_{22} & 0 \\
c_{22} + c_{23} & -c_{33} & 0 \end{pmatrix}, \quad X = \begin{pmatrix} -c_{12} & -c_{13} & p_1 \\
c_{13} - c_{22} & -c_{23} - p_1 & p_2 \\
-c_{32} + c_{33} & -c_{33} & -p_2 \end{pmatrix}, \quad p_1, p_2, p_3 \in \mathbb{C}.
\]

If \(C\) is a Hermitian matrix, then the necessary and sufficient conditions for compatibility are \(c_{11} = 0, \ \text{Im}(c_{12}) = 0, \ \text{and} \ 2\text{Re}(c_{13}) - c_{22} = 0\). The Hermitian particular and general solutions are

\[
\hat{X}^h = \begin{pmatrix} -c_{12} & -c_{13} & -\text{Im}(c_{23}) \\
-c_{13} & -\text{Re}(c_{23}) & -\text{Re}(c_{23}) \\
\text{Im}(c_{23}) & \text{Im}(c_{23}) + u_1 & -u_2i \end{pmatrix}, \quad X = \begin{pmatrix} -c_{12} & -c_{13} & -\text{Im}(c_{23}) + u_1 \\
-c_{13} & -\text{Re}(c_{23}) - u_1 & -u_2i \\
\text{Im}(c_{23}) + u_1 & \text{Im}(c_{23}) + u_1 & u_3 \end{pmatrix},
\]

\[
\hat{X} = \begin{pmatrix} -c_{12} & -c_{13} & 0 \\
-c_{13} & c_{13} - c_{22} & 0 \\
c_{22} + c_{23} & -c_{33} & 0 \end{pmatrix}, \quad X = \begin{pmatrix} -c_{12} & -c_{13} & p_1 \\
c_{13} - c_{22} & -c_{23} - p_1 & p_2 \\
-c_{32} + c_{33} & -c_{33} & -p_2 \end{pmatrix}, \quad p_1, p_2, p_3 \in \mathbb{C}.
\]
4 Lyapunov matrix equation with Jordan matrix

We suppose that the matrix \( A \in \mathcal{M}_r(\mathbb{C}) \) is a Jordan matrix; i.e.

\[
A = J_{r_1}(\lambda_1) \oplus J_{r_2}(\lambda_2) \oplus \cdots \oplus J_{r_k}(\lambda_k),
\]

with \( k \in \mathbb{N}^* \), \( \lambda_1, \ldots, \lambda_k \in \mathbb{C} \), for all \( \alpha \in \{1, \ldots, k\} \) the matrix \( J_{r_\alpha}(\lambda_\alpha) \in \mathcal{M}_{r_\alpha}(\mathbb{C}) \) is a Jordan block matrix, and \( \sum_{\alpha=1}^k r_\alpha = r \).

Remark 4.1. If \( k = r \) we have \( r_1 = r_2 = \cdots = r_n = 1 \) and \( A \) is a diagonal matrix.

To describe the Lyapunov matrix equation for this case we denote \( X = (X_{\alpha\beta})_{\alpha,\beta \in \{1,\ldots,k\}} \) and \( C = (C_{\alpha\beta})_{\alpha,\beta \in \{1,\ldots,k\}} \) with \( X_{\alpha\beta}, C_{\alpha\beta} \in \mathcal{M}_{r_\alpha r_\beta}(\mathbb{C}) \) for all \( \alpha, \beta \in \{1,\ldots,k\} \).

The Lyapunov matrix equation (4.1) is reduced to the system

\[
J_{r_\alpha}(\lambda_\alpha)X_{\alpha\beta} + X_{\alpha\beta}J_{r_\beta}(\lambda_\beta) + C_{\alpha\beta} = O_{r_\alpha r_\beta}, \quad \forall \alpha, \beta \in \{1,\ldots,k\}.
\]

We have \( k^2 \) Sylvester-Lyapunov matrix equations with Jordan block matrices. We make the notation:

\[
\mathcal{K}_A = \{(\alpha, \beta) \in \{1, \ldots, k\}^2 \mid \lambda_\alpha + \overline{\lambda_\beta} = 0\}.
\]

Remark 4.2. We have \((\alpha, \alpha) \in \mathcal{K}_A\) if and only if \( \alpha = a \) with \( a \in \mathbb{R} \). If \((\alpha, \beta) \in \mathcal{K}_A\), then \((\beta, \alpha) \in \mathcal{K}_A\).

4.1 The homogeneous case

In this section we suppose that \( C = O_r \). The system (4.2) becomes

\[
J_{r_\alpha}(\lambda_\alpha)X_{\alpha\beta} + X_{\alpha\beta}J_{r_\beta}(\lambda_\beta) = O_{r_\alpha r_\beta}, \quad \forall \alpha, \beta \in \{1,\ldots,k\}.
\]

It is easy to obtain the following result.

Proposition 4.1. Let \( (\alpha, \beta) \in \{1,\ldots,k\}^2 \). Then \( X \in \mathcal{L}(\lambda_\alpha, \lambda_\beta, O_{r_\alpha r_\beta}) \) if and only if \( X^H \in \mathcal{L}(\lambda_\lambda, \lambda_\alpha, O_{r_\beta r_\alpha}) \).

For solving the system (4.3) we solve \( k^2 \) homogeneous matrix equations with Jordan block matrices; more precisely the equations \((\alpha, \beta)\) with \( \alpha \leq \beta \).

By using the results of Section 3 we have the following theorems.

Theorem 4.2. Let \( A \) be a Jordan matrix of the form (4.1).

(i) If \( \mathcal{K}_A = \emptyset \), then \( \mathcal{L}_{A,O_r} = \{O_r\} \).

(ii) If \( \mathcal{K}_A \neq \emptyset \), then \( \dim_{\mathbb{C}} \mathcal{L}_{A,O_r} = \sum_{(\alpha, \beta) \in \mathcal{K}_A} \min\{r_\alpha, r_\beta\} \).

Theorem 4.3 (Hermitian solutions). Let \( A \) be of the form (4.1).

(i) If \( \mathcal{K}_A = \emptyset \), then \( \mathcal{L}^H_{A,O_r} = \{O_r\} \).

(ii) If \( \mathcal{K}_A \neq \emptyset \), then \( \dim_{\mathbb{C}} \mathcal{L}^H_{A,O_r} = \sum_{(\alpha, \beta) \in \mathcal{K}_A} \min\{r_\alpha, r_\beta\} \).

Theorem 4.4. Let \( A \) be a Jordan matrix. The homogeneous Lyapunov matrix equation (4.2) has a Hermitian positive definite solution if and only if \( A \) is a diagonal matrix with purely imaginary numbers on the diagonal (all the eigenvalues of \( A \) are purely imaginary and semisimple).
Proof. Suppose that $A$ has the form \( \begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix} \) and all the eigenvalues of $A$ are purely imaginary and semisimple, then $k = r$ and $r_1 = \cdots = r_k = 1$. $L$ is a Hermitian positive definite solution of \((1.2)\).

Suppose that the homogeneous Lyapunov matrix equation \((1.2)\) has a Hermitian positive definite solution $X$. Let $i \in \{1, \ldots, k\}$, then $X_{ii}$ is a Hermitian positive definite matrix which is the solution of the homogeneous Lyapunov matrix equation $J_i^H(\lambda_i)X_{ii} + X_{ii}J_r(\lambda_i) = O_r$. This matrix equation is equivalent with $J_i^H(\lambda_i + \overline{\lambda_i})X_{ii} + X_{ii}J_r(0) = O_r$. By using Theorem 4.2 and Corollary 4.4 we obtain that $r_i = 1$ and $\lambda_i + \overline{\lambda_i} = 0$, which implies the announced result.

\[\Box\]

**Theorem 4.5 (Real symmetric solutions).** Let $A$ be a real matrix of the form \( \begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix} \).

(i) If $\mathcal{K}_A = \emptyset$, then $\mathcal{L}_{A,O_r}^{sym} = \{O_r\}$.

(ii) If $\mathcal{K}_A \neq \emptyset$, then $\dim \mathcal{L}_{A,O_r}^{sym} = \sum_{(\alpha,\alpha) \in \mathcal{K}_A} \left[ \frac{1}{2} \right] + \sum_{\alpha < \beta \in \mathcal{K}_A} \min\{r_{\alpha}, r_{\beta}\}$.

**Example 4.1.** If $A$ is a diagonal matrix and $\mathcal{K}_A \neq \emptyset$, then

\[\mathcal{L}_{A,O_r} = \left\{ \sum_{(\alpha,\alpha) \in \mathcal{K}_A} z_{\alpha\beta} e_\alpha \otimes e_\beta^T | z_{\alpha\beta} \in \mathbb{C} \right\} \to \mathbb{C} \]

\[\mathcal{L}_{A,O_r}^H = \left\{ \sum_{(\alpha,\alpha) \in \mathcal{K}_A} u_{\alpha\alpha} e_\alpha \otimes e_\alpha^T + \sum_{(\alpha,\beta) \in \mathcal{K}_A \alpha < \beta} \left((u_{\alpha\beta} + iv_{\alpha\beta})e_\alpha \otimes e_\beta^T + (u_{\alpha\beta} - iv_{\alpha\beta})e_\beta \otimes e_\alpha^T \right) | u_{\alpha\beta}, v_{\alpha\beta} \in \mathbb{R} \right\} \]

\[\mathcal{L}_{A,O_r}^{sym} = \left\{ \sum_{(\alpha,\alpha) \in \mathcal{K}_A} u_{\alpha\alpha} e_\alpha \otimes e_\alpha + \sum_{(\alpha,\beta) \in \mathcal{K}_A \alpha \leq \beta} u_{\alpha\beta} (e_\alpha \otimes e_\beta + e_\beta \otimes e_\alpha) | u_{\alpha\beta} \in \mathbb{R} \right\} \]

**Example 4.2.** We consider the homogeneous Lyapunov matrix equation \((1.2)\) with Jordan matrix $A = J_1(0) \oplus J_2(0) \oplus J_3(2)$. In this case we have $n = 4$, $k = 3$, $\lambda_1 = \lambda_2 = 0$, $\lambda_3 = 2$, $r_1 = 1$, $r_2 = 2$, $r_3 = 1$, and $\mathcal{K}_A = \{(1,1), (1,2), (2,1), (2,2)\}$. We make the notation $X = (X_{ij})_{i,j \in \{1, \ldots, 4\}}$, where $X_{11}, X_{13}, X_{31}, X_{33} \in M_{1,1}(\mathbb{C})$, $X_{12}, X_{23} \in M_{1,2}(\mathbb{C})$, $X_{21}, X_{22} \in M_{2,1}(\mathbb{C})$, and $X_{22} \in M_{2,2}(\mathbb{C})$.

The system \((4.1)\) becomes

\[
\begin{align*}
J_1(0)^HX_{11} + X_{11}J_1(0) &= O_{1,1} \\
J_1(0)^HX_{12} + X_{12}J_2(0) &= O_{1,2} \\
J_1(0)^HX_{13} + X_{13}J_3(1) &= O_{1,1} \\
J_2(0)^HX_{21} + X_{21}J_1(0) &= O_{2,1} \\
J_2(0)^HX_{22} + X_{22}J_2(0) &= O_{2,2} \\
J_2(0)^HX_{23} + X_{23}J_3(1) &= O_{2,1} \\
J_1(2)^HX_{31} + X_{31}J_1(0) &= O_{1,1} \\
J_1(2)^HX_{32} + X_{32}J_2(0) &= O_{2,1} \\
J_1(2)^HX_{33} + X_{33}J_3(1) &= O_{1,1}
\end{align*}
\]

By using the results of the above section we have: $X_{11} = (x)$, with $x \in \mathbb{C}$, $X_{12} = (0 \ y)$, with $y \in \mathbb{C}$, $X_{13} = O_{1,1}$, $X_{21} = \begin{pmatrix} 0 \\ z \end{pmatrix}$, with $z \in \mathbb{C}$, $X_{22} = \begin{pmatrix} 0 & t \\ -t & u \end{pmatrix}$, with $t, u \in \mathbb{C}$, $X_{23} = O_{2,1}$, $X_{31} = O_{1,1}$, $X_{32} = O_{2,1}$, $X_{33} = O_{1,1}$.

\[\text{\textsuperscript{\textcommast} e_1, \ldots, e_r\text{ is the canonical base.} \]
\(X_{32} = O_{1,2}\), and \(X_{33} = O_{1,1}\). The general solution of the homogeneous Lyapunov matrix equation is

\[
X = \begin{pmatrix}
x & 0 & y & 0 \\
0 & 0 & t & 0 \\
z & -t & u & 0 \\
0 & 0 & 0 & 0 
\end{pmatrix}, \quad x, y, z, t, u \in \mathbb{C}.
\]

We have the following description of a general Hermitian solution:

\[
X = \begin{pmatrix}
x & 0 & y + zi & 0 \\
0 & 0 & ti & 0 \\
y - zi & -ti & u & 0 \\
0 & 0 & 0 & 0 
\end{pmatrix}, \quad x, y, z, t, u \in \mathbb{R}.
\]

A general real symmetric solution has the form:

\[
X = \begin{pmatrix}
x & 0 & y & 0 \\
0 & 0 & 0 & 0 \\
y & 0 & u & 0 \\
0 & 0 & 0 & 0 
\end{pmatrix}, \quad x, y, u \in \mathbb{R}.
\]

In what follows we study the invertible solutions.

**Lemma 4.6.** Let \(r_1, \ldots, r_k \in \mathbb{N}^*, r := \sum_{i=1}^k r_i, A_1 \in \mathcal{M}_{r_1} (\mathbb{C}), \ldots, A_k \in \mathcal{M}_{r_k} (\mathbb{C}), \) and \(A = A_1 \oplus A_2 \oplus \cdots \oplus A_k\). If for all \(i = 1, k\) the invertible matrix \(X_i\) verify \(A_1^H X_i + X_i A_i = O_{r_i}\), then \(X = X_1 \oplus X_2 \oplus \cdots \oplus X_k\) is an invertible solution of the homogeneous Lyapunov matrix equation (1.2).

**Proof.** It is easy to observe that \(X\) is a solution of (1.2). We have the equality \(\det X = \prod_{i=1}^k \det X_i\) which implies the fact that \(X\) is an invertible matrix. \(\square\)

**Lemma 4.7.** Let \(\lambda \in \mathbb{C}\) with \(\text{Re}(\lambda) = 0\), \(r_1, \ldots, r_k \in \mathbb{N}^*, r := \sum_{i=1}^k r_i\), and \(A := J_{r_1}(\lambda) \oplus J_{r_2}(\lambda) \oplus \cdots \oplus J_{r_k}(\lambda)\). The homogeneous Lyapunov matrix equation (1.2) has an invertible solution.

**Proof.** We observe that the matrix \(X = y^{[r_1]} \oplus y^{[r_2]} \oplus \cdots \oplus y^{[r_k]}\) is an invertible solution, where the matrix \(y^{[r_i]}\) is defined in Section A. \(\square\)

**Lemma 4.8.** Let \(\lambda, \mu \in \mathbb{C}\) with \(\lambda \neq \mu\) and \(\lambda + \mu = 0\), \(r_1, \ldots, r_k \in \mathbb{N}^*, r := \sum_{i=1}^k r_i, A(\lambda) := J_{r_1}(\lambda) \oplus J_{r_2}(\lambda) \oplus \cdots \oplus J_{r_k}(\lambda), A(\mu) := J_{r_1}(\mu) \oplus J_{r_2}(\mu) \oplus \cdots \oplus J_{r_k}(\mu),\) and \(A := A(\lambda) \oplus A(\mu)\). The homogeneous Lyapunov matrix equation (1.2) has an invertible solution.

**Proof.** We denote \(X = \begin{pmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{pmatrix}\); it follows that (1.2) is equivalent with the system

\[
\begin{align*}
A^H(\lambda)X_{11} + X_{11}A(\lambda) &= O_r \\
A^H(\mu)X_{12} + X_{12}A(\mu) &= O_r \\
A^H(\mu)X_{21} + X_{21}A(\lambda) &= O_r \\
A^H(\mu)X_{22} + X_{22}A(\mu) &= O_r.
\end{align*}
\]

We observe that the first matrix equation is equivalent with \(A^H(\lambda + \overline{\lambda})X_{11} + X_{11}A(0) = O_r\). Because \(\lambda + \overline{\lambda} \neq 0\) we deduce that \(X_{11} = O_r\). Analogously it can be proved that \(X_{22} = O_r\).

The second matrix equation is equivalent with \(A^H(0)X_{12} + X_{12}A(0) = O_r\). By using Lemma 4.7 we have that a solution is \(\hat{X}_{12} = \hat{X}_{21} = y^{[r_1]} \oplus y^{[r_2]} \oplus \cdots \oplus y^{[r_k]}\). The particular solution \(\hat{X} = \begin{pmatrix} O_r & \hat{X}_{12} \\ \hat{X}_{21} & O_r \end{pmatrix}\) is invertible because \(\det \hat{X} = \pm \det \hat{X}_{12} \cdot \det \hat{X}_{21} \neq 0\). \(\square\)
Theorem 4.9. Suppose that $A$ is a Jordan matrix of the form \((1.1)\). The necessary and sufficient condition for the homogeneous Lyapunov matrix equation \((1.2)\) to have an invertible solution is that for all $\alpha \in \{1, \ldots, k\}$ we have $-\lambda_{\alpha} \in \{\lambda_{1}, \ldots, \lambda_{k}\}$ and $w(A, \lambda_{\alpha}) = w(A, -\lambda_{\alpha})$.

Proof. If the homogeneous Lyapunov matrix equation \((1.2)\) has an invertible solution, then the matrices $A^H$ and $-A$ are similar. We deduce that $\forall \alpha \in \{1, \ldots, k\} \Rightarrow -\lambda_{\alpha} \in \{\lambda_{1}, \ldots, \lambda_{k}\}$ and $\forall \alpha \in \{1, \ldots, k\}$ we have $w(A^H, \lambda_{\alpha}) = w(-A, -\lambda_{\alpha})$ which implies $w(A, \lambda_{\alpha}) = w(A, -\lambda_{\alpha})$.

The reverse problem. We denote $\mu_{1}, \ldots, \mu_{q}$ ($q \leq k$) the distinct elements of the set $\{\lambda_{1}, \ldots, \lambda_{k}\}$ such that: $\mu_{\gamma} + \overline{\mu_{\gamma}} \neq 0$ for $\gamma \in \{1, \ldots, 2p\}$, $\mu_{\gamma} + \overline{\mu_{\gamma}} = 0$ for $\gamma \in \{2p + 1, \ldots, q\}$, $\mu_{2p_{\gamma}} = \overline{\mu_{2p_{\gamma}-1}}$ for $\gamma \in \{1, \ldots, p\}$. We construct the matrix $B := (B(\mu_{1}) \oplus B(\mu_{2}) \oplus \cdots \oplus B(\mu_{q}))$, where $B(\mu_{i})$ contains all the Jordan blocks of $A$ with $\mu_{i}$ on the diagonal; more precisely we have $B(\mu_{i}) = J_{t_{i}}(\mu_{i}) \oplus J_{t_{2i}}(\mu_{i}) \oplus \cdots \oplus J_{t_{w_{i}(A,\lambda)}}(\mu_{i})$. By hypotheses for $i \in \{1, \ldots, p\}$ we have $w_{1}(A, \mu_{2i-1}) = w_{1}(A, \mu_{2i})$, $t_{i}^{2i-1} = t_{i}^{2i}$, ..., $t_{w_{1}(A,\mu_{2i-1})}^{2i-1} = t_{w_{1}(A,\mu_{2i})}^{2i}$.

For $i \in \{1, \ldots, p\}$ we note $B(\mu_{2i-1}, \mu_{2i}) = B(\mu_{2i-1}) \oplus B(\mu_{2i})$ and we can write

$$B = B(\mu_{1}, \mu_{2}) \oplus B(\mu_{2p-1}, \mu_{2p}) \oplus B(\mu_{2p+1}) \oplus \cdots \oplus B(\mu_{q}).$$

By using Lemma 3.1.18 from \cite{8} we deduce that $A$ and $B$ are similar matrices; $B = P^{-1}AP$.

We consider the homogeneous Lyapunov matrix equation

$$B^H Y + Y B = O_r.$$

By using Lemma 4.6, Lemma 4.7 and Lemma 4.8 the above matrix equation has an invertible solution $\hat{Y}$. From Proposition 2.4 we deduce that $\hat{X} = P^{-H} \hat{Y} P^{-1}$ is an invertible solution of homogeneous Lyapunov matrix equation \((1.2)\).

Remark 4.3. In the above results we have a method to construct an invertible solution if the conditions of Theorem 4.9 are satisfied.

Corollary 4.10. (i) If $A$ is a Jordan matrix of the form \((1.1)\) and for all $\alpha \in \{1, \ldots, k\}$ the number $\lambda_{\alpha}$ is purely imaginary, then the homogeneous Lyapunov matrix equation \((1.2)\) has an invertible solution.

(ii) If $A$ is a nilpotent Jordan matrix, then the homogeneous Lyapunov matrix equation \((1.2)\) has an invertible solution.

4.2 The non-homogeneous case

Theorem 4.11. Let $A$ be a Jordan matrix of the form \((1.1)\).

(i) If $\mathcal{K}_A = \emptyset$, then the Lyapunov matrix equation \((1.1)\) has a unique solution.

(ii) If $\mathcal{K}_A \neq \emptyset$, then the matrix equation has solutions if and only if the components of the matrices $C_{\alpha \beta}$, with $(\alpha, \beta) \in \mathcal{K}_A$, verify the conditions $\sum_{j=1}^{r-1} (-1)^{i} e_{i-j,\beta}^{(\alpha,\beta)} = 0$, $\forall i \in \{2, \ldots, \min\{r_{\alpha}, r_{\beta}\} + 1\}$.

Example 4.3. Suppose that $A$ is a diagonal matrix, i.e. $A = \text{diag}(\lambda_{1}, \ldots, \lambda_{r})$.

If $\mathcal{K}_A = \emptyset$, then $\mathcal{L}_{A,C} = \left\{ - \sum_{\alpha, \beta = 1}^{r} \frac{c_{\alpha \beta}}{\lambda_{\alpha} + \lambda_{\beta}} e_{\alpha} \otimes e_{\beta}^{T} \right\}$.

If $\mathcal{K}_A \neq \emptyset$, then the compatibility conditions are $c_{\alpha \beta} = 0$ for all $(\alpha, \beta) \in \mathcal{K}$. We have

$$\mathcal{L}_{A,C} = \left\{ - \sum_{(\alpha, \beta) \notin \mathcal{K}_A} \frac{c_{\alpha \beta}}{\lambda_{\alpha} + \lambda_{\beta}} e_{\alpha} \otimes e_{\beta}^{T} - \sum_{(\alpha, \beta) \in \mathcal{K}_A} z_{\alpha \beta} e_{\alpha} \otimes e_{\beta}^{T} | z_{\alpha \beta} \in \mathbb{C} \right\}.$$
Example 4.4. We consider the matrix equation \((4.1)\) with the Jordan matrix \(A\) as in Example 4.2.

We use the notations presented in Example 4.2 and we denote by \(C = \begin{pmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{pmatrix}\), where

\[
\begin{align*}
C_{11} &= (c_{11}), & C_{12} &= (c_{12} & c_{13}), & C_{13} &= (c_{14}), \\
C_{21} &= (c_{21} & c_{31}), & C_{22} &= (c_{22} & c_{23} & c_{33}), & C_{23} &= (c_{24} & c_{34}), \\
C_{31} &= (c_{41}), & C_{32} &= (c_{42} & c_{43}), & C_{33} &= (c_{44}).
\end{align*}
\]

The system (4.2) becomes

\[
\begin{align*}
J_1(0)X_{11} + X_{11}J_1(0) + C_{11} &= 0, \\
J_1(0)X_{12} + X_{12}J_2(0) + C_{12} &= 0, \\
J_1(0)X_{13} + X_{13}J_3(0) + C_{13} &= 0, \\
J_2(0)X_{21} + X_{21}J_1(0) + C_{21} &= 0, \\
J_2(0)X_{22} + X_{22}J_2(0) + C_{22} &= 0, \\
J_2(0)X_{23} + X_{23}J_3(0) + C_{23} &= 0, \\
J_1(2)X_{31} + X_{31}J_1(0) + C_{31} &= 0, \\
J_1(2)X_{32} + X_{32}J_2(0) + C_{32} &= 0, \\
J_1(2)X_{33} + X_{33}J_3(0) + C_{33} &= 0.
\end{align*}
\]

The compatibility conditions are \(c_{11} = c_{12} = c_{21} = c_{22} = 0, c_{23} - c_{32} = 0\).

If the compatibility conditions are satisfied, then the solution has the form

\[
X = \begin{pmatrix} p & -c_{13} & q & -c_{24} \\ -c_{31} & -c_{23} & v & -c_{34} \\ u & -c_{33} & -c_{34} & w \\ -c_{41} & -c_{42} & -c_{43} & -c_{44} \end{pmatrix}, \quad p, q, v, w \in \mathbb{C}.
\]

If \(C\) is a Hermitian matrix, then a Hermitian solution has the form

\[
X = \begin{pmatrix} p_1 & -c_{13} & q_1 + q_2i & -c_{24} \\ -c_{31} & -c_{23} & -c_{24} - v_2i & -c_{34} \\ q_1 - q_2i & -c_{34} - v_2i & w_1 & c_{44} \\ -c_{44} - v_2i & -c_{44} & c_{44} & -c_{44} \end{pmatrix}, \quad p_1, q_1, q_2, v_2, w_1 \in \mathbb{R}.
\]

If \(C\) is a real symmetric matrix, then a real symmetric solution has the form

\[
X = \begin{pmatrix} p_1 & -c_{13} & q_1 & -c_{24} \\ -c_{31} & -c_{23} & -c_{24} & -c_{34} \\ q_1 & -c_{34} & w_1 & c_{44} \\ -c_{44} & -c_{44} & c_{44} & -c_{44} \end{pmatrix}, \quad p_1, q_1, w_1 \in \mathbb{R}.
\]

5 Lyapunov matrix equation. General case.

For an arbitrary matrix \(A\) we can use the results presented in the previous sections when we can find the eigenvalues of the matrix \(A\). In this case we can construct the Jordan matrix \(J_A\) which is similar to the matrix \(A\) and we find some theoretical results. To find the solutions of the Lyapunov matrix equation in the general case we need to know the invertible matrix \(P_A\) which appears in the condition for similarity of the matrices \(A\) and \(J_A\).

We consider the Lyapunov matrix equation (4.1) and we denote by \(J_A \in \mathcal{M}_r(\mathbb{C})\) a Jordan matrix such that \(A\) and \(J_A\) are similar matrices. The invertible matrix \(P_A \in \mathcal{M}_r(\mathbb{C})\) verifies the equality
\( J_A = P_A^{-1} A P_A \). For a real matrix \( A \) with all the eigenvalues being real numbers we choose \( P_A \) to be a real matrix. We have \( J_A = J_1(\lambda_1) \oplus J_2(\lambda_2) \oplus \cdots \oplus J_k(\lambda_k) \) with \( k \in \mathbb{N}^* \), \( \lambda_1, \ldots, \lambda_k \in \mathbb{C} \), for all \( \alpha \in \{1, \ldots, k\} \) the matrix \( J_{r_{\alpha}}(\lambda_{\alpha}) \in M_{r_{\alpha}}(\mathbb{C}) \) is a Jordan block matrix, and \( \sum_{\alpha=1} r_{\alpha} = r \). We denote by

\[
\mathcal{K}_A = \{ (\alpha, \beta) \in \{1, \ldots, k\} \mid \lambda_{\alpha} + \overline{\lambda}_{\beta} = 0 \}.
\]

We construct the Lyapunov matrix equation with Jordan matrix

\[
J_A^H Z + Z J_A + D = O_r,
\]

where \( D = P_A^H C P_A \). A solution of the Lyapunov matrix equation \((1.1)\) has the form \( X = P_A^{-H} Z P_A^{-1} \), where \( Z \) is a solution of the the Lyapunov matrix equation with Jordan matrix \((5.1)\).

### 5.1 The homogeneous case

In this case we have \( C = O_r \) and consequently we obtain \( D = O_r \). The Lyapunov matrix equation with Jordan matrix \((5.1)\) becomes

\[
J_A^H Z + Z J_A = O_r.
\]

The following proposition is obtained by direct computations.

**Proposition 5.1.** Consider the function \( \mathcal{F}_A : \mathcal{L}_{J_A,O_r} \to \mathcal{L}_{A,O_r} \) given by \( \mathcal{F}_A(Z) = P_A^{-H} Z P_A^{-1} \).

(i) \( \mathcal{F}_A \) is an \( \mathcal{C} \)-isomorphism.

(ii) The restriction \( \mathcal{F}_A \big|_{\mathcal{L}_{J_A,O_r}^{\mathcal{H}}} : \mathcal{L}_{J_A,O_r}^{\mathcal{H}} \to \mathcal{L}_{A,O_r}^{\mathcal{H}} \) is an \( \mathbb{R} \)-isomorphism.

(iii) \( Z \in \mathcal{L}_{J_A,O_r}^{\mathcal{H}} \) is positive definite if and only if \( \mathcal{F}_A(Z) \in \mathcal{L}_{A,O_r}^{\mathcal{H}} \) is positive definite.

(iv) If \( A, J_A, \) and \( P_A \) are real matrices, then the restriction \( \mathcal{F}_A \big|_{\mathcal{L}_{J_A,O_r}^{\mathcal{sym}}} : \mathcal{L}_{J_A,O_r}^{\mathcal{sym}} \to \mathcal{L}_{A,O_r}^{\mathcal{sym}} \) is an \( \mathbb{R} \)-isomorphism.

By using Proposition \( \mathcal{P}_A \text{ and } \mathcal{T}_A \text{ and } \mathcal{R}_A \text{ and } \mathcal{M}_A \) we obtain the following result.

**Theorem 5.2.** The following holds true.

(i) If \( \mathcal{K}_A = \emptyset \), then \( \mathcal{L}_{A,O_r} = \{O_r\} \).

(ii) If \( \mathcal{K}_A \neq \emptyset \), then \( \dim_{\mathbb{C}} \mathcal{L}_{A,O_r} = \sum_{(\alpha, \beta) \in \mathcal{K}_A} \min\{r_{\alpha}, r_{\beta}\} \).

(iii) If \( \mathcal{K}_A \neq \emptyset \), then \( \dim_{\mathbb{R}} \mathcal{L}_{A,O_r}^{\mathcal{H}} = \sum_{(\alpha, \beta) \in \mathcal{K}_A} \min\{r_{\alpha}, r_{\beta}\} \).

(iv) If \( A \) is a real matrix, \( \text{Spec}(A) \subset \mathbb{R} \), and \( \mathcal{K}_A \neq \emptyset \), then \( \dim_{\mathbb{R}} \mathcal{L}_{A,O_r}^{\mathcal{sym}} = \sum_{(\alpha, \alpha) \in \mathcal{K}_A} \left[ \frac{r_{\alpha}^2 + 1}{2} \right] + \sum_{\substack{(\alpha, \beta) \in \mathcal{K}_A \\alpha < \beta}} \min\{r_{\alpha}, r_{\beta}\} \).

**Corollary 5.3.** If \( A \in \mathcal{M}_r(\mathbb{C}) \), then \( \text{rank}(I_r \otimes A^H + \overline{A^H} \otimes I_r) = r^2 - \sum_{(\alpha, \beta) \in \mathcal{K}_A} \min\{r_{\alpha}, r_{\beta}\} \).

**Proof.** By using the rank-nullity theorem we have that

\[
\text{rank}(I_r \otimes A^H + \overline{A^H} \otimes I_r) + \dim_{\mathbb{C}} \{x \in \mathbb{C}^{n^2} | (I_r \otimes A^H + \overline{A^H} \otimes I_r)x = 0\} = r^2.
\]

The homogeneous Lyapunov matrix equation \((1.2)\) is equivalent with the linear system of equations

\[
(I_r \otimes A^H + \overline{A^H} \otimes I_r)\text{vec}(X) = 0.
\]

By using the above theorem we obtain the announced result.
The Jordan matrix is $J$

We write

5.2 The non-homogeneous case

We consider the homogeneous Lyapunov matrix equation

Example 5.2.

Proof. We use Theorem 4.9, Spec$(A) = \text{Spec}(J_A)$ and the fact that for all $\lambda \in \text{Spec}(A)$ we have $w(A, \lambda) = w(A, -\lambda)$. □

Theorem 5.5. The homogeneous Lyapunov matrix equation (1.2) has a Hermitian positive definite solution if and only if $A$ is a diagonalizable matrix with all eigenvalues being purely imaginary (i.e. the eigenvalues are purely imaginary and semisimple).

Proof. If all the eigenvalues of $A$ are purely imaginary and semisimple, then all eigenvalues of $J_A$ are purely imaginary and semisimple and, by using Theorem 4.4, we deduce that the matrix equation (5.2) has a Hermitian positive definite solution $Z$. The Proposition 5.1 implies that $F_A(Z)$ is a Hermitian positive definite solution of (1.2).

If the homogeneous Lyapunov matrix equation (1.2) has a Hermitian positive definite solution $Z$, then $F_A^{-1}(X)$ is a Hermitian positive definite solution of (5.2). Using Theorem 4.4 we have that all eigenvalues of $A$ are purely imaginary and semisimple. □

Example 5.1. If $A$ is a diagonalizable matrix, then $J_A = \text{diag}(\lambda_1, \ldots, \lambda_r)$.

If $X_A = \emptyset$, then $O_r$ is the unique solution of the homogeneous Lyapunov matrix equation (1.2). If $X_A \neq \emptyset$, then $\mathcal{L}_{A,O_r} = \left\{ \sum_{(\alpha, \beta) \in X_A} z_{\alpha \beta} P_A^H e_\alpha \otimes e_\beta^T P_A^{-1} | z_{\alpha \beta} \in \mathbb{C} \right\}$.

Example 5.2. We consider the homogeneous Lyapunov matrix equation with $A = \left( \begin{array}{ccc} 0 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 2 \end{array} \right)$. The Jordan matrix is $J_A = J_1(0) \oplus J_2(0) \oplus J_1(2)$, $X_A = \{(1, 1), (1, 2), (2, 1), (2, 2)\}$ and the matrix $P_A = \left( \begin{array}{ccc} 0 & 0 & 1 \\ 0 & -1 & 0 \\ -1 & 0 & 1 \\ 1 & 0 & -1 \end{array} \right)$. By using the Example 1.2 we obtain the general solution

\[
X = \left( \begin{array}{ccc} x + y + z + u & t & -x - z \\ -t & 0 & 0 \\ -x - y & 0 & x \\ 1 & 0 & 0 \end{array} \right), \quad x, y, z, t, u \in \mathbb{C}.
\]

5.2 The non-homogeneous case

We write $D = (D_{\alpha \beta})_{\alpha, \beta \in \{1, \ldots, k\}}$ with $D_{\alpha \beta} = \left( \frac{d_{ij}^{\alpha \beta}}{\lambda_\alpha + \lambda_\beta} \right) \in \mathcal{M}_{r_\alpha, r_\beta}(\mathbb{C})$ for all $\alpha, \beta = \overline{1, k}$.

Theorem 5.6. (i) If $X_A = \emptyset$, then the Lyapunov matrix equation (1.1) has a unique solution.

(ii) If $X_A \neq \emptyset$, then the matrix equation has solutions if and only if the components of the matrices $D_{\alpha \beta}$, with $(\alpha, \beta) \in X_A$, verify the conditions \[
\sum_{j=1}^{r-1} (-1)^j d_{\alpha \beta}^{i\bar{j}} = 0, \quad \forall i \in \{2, \ldots, \min \{r_\alpha, r_\beta\} + 1\}.
\]

Example 5.3. If $A$ is a diagonalizable matrix, then $J_A = \text{diag}(\lambda_1, \ldots, \lambda_r)$.

If $X_A = \emptyset$, then $\mathcal{L}_{A,C}{\alpha, \beta} = \left\{ \sum_{\alpha, \beta = 1}^{r} \frac{c_{\alpha \beta}}{\lambda_\alpha + \lambda_\beta} P_A^H e_\alpha \otimes e_\beta^T P_A^{-1} \right\}$.

If $X_A \neq \emptyset$, then $\mathcal{L}_{A,C}{\alpha, \beta} = \left\{ \sum_{(\alpha, \beta) \in X_A} \frac{c_{\alpha \beta}}{\lambda_\alpha + \lambda_\beta} P_A^H e_\alpha \otimes e_\beta^T P_A^{-1} - \sum_{(\alpha, \beta) \in X_A} z_{\alpha \beta} P_A^H e_\alpha \otimes e_\beta^T P_A^{-1} | z_{\alpha \beta} \in \mathbb{C} \right\}$.

\[\text{IVw is the Weyr characteristic, see Section A}\]
Example 5.4. We consider a Lyapunov matrix equation (1.1) with the matrix $A$ from the Example 5.2 and an arbitrary matrix $C$. The Jordan matrix $J_A$ and $P_A$ are the ones from the above example. The matrix $D$ is formed with the blocks:

$$
D_{11} = (c_{4,3} - c_{4,3} - c_{4,4} + c_{4,4}) : D_{12} = \left( \begin{array}{cc} c_{3,2} - c_{4,2} & -c_{3,1} + c_{4,1} - c_{3,3} + c_{4,3} + c_{3,4} - c_{4,4} \\ c_{3,2} & -c_{2,3} \\
\end{array} \right),
$$

$$
D_{13} = ( -c_{3,4} + c_{4,4} ) , \ D_{21} = \left( \begin{array}{cc} c_{2,3} - c_{2,4} \\ -c_{1,3} - c_{3,3} + c_{4,3} + c_{1,4} + c_{3,4} - c_{4,4} \\
\end{array} \right),
$$

$$
D_{22} = \left( \begin{array}{cc} c_{2,2} & -c_{2,1} - c_{2,3} + c_{2,4} \\ -c_{1,2} - c_{3,2} + c_{4,2} & c_{1,1} + c_{3,1} - c_{4,1} + c_{1,3} + c_{3,3} - c_{4,3} - c_{1,4} - c_{3,4} + c_{4,4} \\
\end{array} \right),
$$

$$
D_{31} = ( -c_{4,3} + c_{4,4} ), \ D_{32} = ( -c_{4,2} c_{4,1} + c_{4,3} - c_{4,4} ), \ D_{33} = ( c_{4,4} ).
$$

The compatibility conditions become

$$
\begin{cases}
  c_{3,3} - c_{4,3} - c_{4,4} + c_{4,4} = 0 \\
  c_{3,2} - c_{4,2} = 0 \\
  c_{2,3} - c_{2,4} = 0 \\
  c_{2,2} = 0 \\
  -c_{2,1} - c_{2,3} + c_{2,4} + c_{1,2} + c_{3,2} - c_{4,2} = 0.
\end{cases}
$$

By using Theorem 3.2 and Theorem 3.8 we obtain the following particular solution of the Lyapunov matrix equation (1.1):

$$
\hat{X} = \left( \begin{array}{cccc}
0 & c_{1,1} + c_{1,3} - c_{1,4} & -\frac{1}{2}c_{2,3} - \frac{1}{2}c_{1,4} & -\frac{1}{2}c_{2,3} - \frac{1}{2}c_{1,4} \\
-c_{1,3} + c_{1,4} & c_{1,2} & c_{1,3} - c_{1,4} - \frac{1}{2}c_{2,3} & -\frac{1}{2}c_{2,3} \\
-\frac{1}{2}c_{3,2} - \frac{1}{2}c_{4,1} & c_{3,1} - c_{4,1} - \frac{1}{2}c_{3,2} & -\frac{1}{2}c_{3,3} + \frac{1}{2}c_{3,4} + \frac{1}{2}c_{4,3} - \frac{1}{2}c_{3,4} - \frac{1}{2}c_{4,3} - \frac{1}{2}c_{3,4} \\
-\frac{1}{2}c_{3,2} - \frac{1}{2}c_{4,1} & -\frac{1}{2}c_{3,3} & -\frac{1}{2}c_{3,3} + \frac{1}{2}c_{3,4} - \frac{1}{2}c_{4,3} + \frac{1}{2}c_{3,3} - \frac{1}{2}c_{4,3} - \frac{1}{2}c_{3,4}
\end{array} \right).
$$

By using Example 5.2 we can write the general solution.

Appendix A  Matrix notions and results

□ An element $x \in \mathbb{C}^r$ has the form $x = \begin{pmatrix} x_1 \\ \vdots \\ x_r \end{pmatrix}$.

□ $M_{r \times s}(\mathbb{C})$ is the set of matrices with complex elements which have $r$ rows and $s$ columns. We use also the following notations: $M_r(\mathbb{C}) := M_{r \times r}(\mathbb{C})$, $O_{r,s} \in M_{s \times r}(\mathbb{C})$ is the null matrix, $O_r$ is the null matrix in $M_r(\mathbb{C})$, and $I_r \in M_r(\mathbb{C})$ is the identity matrix.

□ For a matrix $M \in M_{r \times s}(\mathbb{C})$ we make the notations: $M^T \in M_{s \times r}(\mathbb{C})$ is the transpose matrix, $M^H \in M_{s \times r}(\mathbb{C})$ is the conjugate transpose matrix.

□ $M \in M_r(\mathbb{C})$ is a Hermitian matrix if $M^H = M$. A real symmetric matrix is a Hermitian matrix.

□ A Hermitian matrix $M \in M_r(\mathbb{C})$ is positive definite if for all $z \in \mathbb{C}^r\setminus \{0\}$ we have $z^HMz > 0$. A Hermitian matrix $M \in M_r(\mathbb{C})$ is positive definite if $-M$ is positive definite.

□ A Hermitian matrix $M \in M_r(\mathbb{C})$ is positive semidefinite if for all $z \in \mathbb{C}^r$ we have $z^HMz \geq 0$. A Hermitian matrix $M \in M_r(\mathbb{C})$ is negative semidefinite if $-M$ is positive semidefinite.

□ The matrix $A \in M_r(\mathbb{C})$ is similar with the matrix $B \in M_r(\mathbb{C})$ if exists the invertible matrix $P \in M_r(\mathbb{C})$ such that $B = P^{-1}AP$. We say that $A$ is similar with $B$ via the matrix $P$. 

16
The matrix $A$ is diagonalizable if it is similar to a diagonal matrix. A matrix that is not diagonalizable is said to be defective.

□ For a matrix $A \in M_r(\mathbb{C})$, we denote by $\text{Spec}(A)$ the set of the eigenvalues of $A$.

The algebraic multiplicity $m(A, \lambda)$ of the eigenvalue $\lambda$ is its multiplicity as a root of the characteristic polynomial. We denote by $r(A, \lambda)$ the index of $\lambda \in \text{Spec}(A)$ and it is the smallest positive integer $k$ such that $\text{rank}(A - \lambda I_r)^k = \text{rank}(A - \lambda I_r)^{k+1}$. It is the size of the largest Jordan block of $A$ with eigenvalue $\lambda$. For $\lambda \in \text{Spec}(A)$ we denote by, see $[8]$, $w_1(A, \lambda) = r - \text{rank}(A - \lambda I_r)$, $w_k(A, \lambda) = \text{rank}(A - \lambda I_r)^{k-1} - \text{rank}(A - \lambda I_r)^k$, for $k > 1$.

The number $w_1(A, \lambda)$ is the number of Jordan blocks of $A$ of all sizes that have eigenvalue $\lambda$ (which is the geometric multiplicity of $\lambda$). The number $w_k(A, \lambda) - w_{k+1}(A, \lambda)$ is the number of blocks with eigenvalues $\lambda$ that have size exactly $k$. The Weyr characteristic of $A$ associated with the eigenvalue $\lambda$ is $w(A, \lambda) = (w_1(A, \lambda), \ldots, w_r(A, \lambda))^T \in \mathbb{N}^r$.

The matrices $A, B \in M_r(\mathbb{C})$ are similar if and only if they have the same distinct eigenvalues, and the same Weyr characteristic associated with each eigenvalue (see Lemma 3.1.18 in $[8]$).

The eigenvalue $\lambda$ is semisimple if its algebraic and geometric multiplicities are equal; $\lambda$ is a semisimple eigenvalue if and only if every Jordan block corresponding to $\lambda$ is 1-by-1.

The matrix $A$ is diagonalizable if and only if all the eigenvalues are semisimple (all the Jordan blocks are 1-by-1).

□ Let $r_1, \ldots, r_k \in \mathbb{N}^*$, $r = \sum_{i=1}^k r_i$, and $M_i \in M_{r_i}(\mathbb{C})$. The direct sum of $M_1, \ldots, M_k$ is

$$ M := M_1 \oplus M_2 \oplus \cdots \oplus M_k = \begin{pmatrix} M_1 & 0_{r_1 r_2} & \cdots & 0_{r_1 r_k} \\ 0_{r_2 r_1} & M_2 & \cdots & 0_{r_2 r_k} \\ \vdots & \vdots & \ddots & \vdots \\ 0_{r_k r_1} & 0_{r_k r_2} & \cdots & M_k \end{pmatrix} \in M_r(\mathbb{C}). $$

□ If $M \in M_{m \times n}(\mathbb{C})$, $M = [m_{ij}]$, and $N \in M_{r \times s}(\mathbb{C})$ then the Kronecker product is

$$ M \otimes N = \begin{pmatrix} m_{11} N & \cdots & m_{1n} N \\ \vdots & \ddots & \vdots \\ m_{m1} N & \cdots & m_{mn} N \end{pmatrix} \in M_{mr \times ns}(\mathbb{C}). $$

If $\{e_1, \ldots, e_m\}$ is the canonical basis of $\mathbb{C}^m$ and $\{f_1, \ldots, f_s\}$ is the canonical basis of $\mathbb{C}^s$, then $\{e_i \otimes f_j^T\}$ is the canonical basis of $M_{m \times s}(\mathbb{C})$.

□ A Jordan block matrix is a matrix $J_r(\lambda) \in M_r(\mathbb{C})$, with $r \in \mathbb{N}^*$ and $\lambda \in \mathbb{C}$, of the form

$$ J_1(\lambda) = (\lambda), \quad J_r(\lambda) = \begin{pmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & \lambda \end{pmatrix}, \text{ if } r > 1. $$

The matrix $J_r(0)$ is called nilpotent Jordan block matrix. We have the following properties:

- $\text{Spec}(J_r(\lambda)) = \{\lambda\}$.
- The matrix $J_r(\lambda)$ is invertible if and only if $\lambda \neq 0$.
- We have the equality:
  $$ J_r(\lambda) = \lambda M_r + J_r(0). \quad (A.1) $$

- $m(J_r(\lambda), \lambda) = r(J_r(\lambda), \lambda) = r$ and $w(J_r(\lambda)) = (1, 1, \ldots, 1)^T \in \mathbb{N}^r$.
- $J_r(0)$ is a nilpotent matrix with the index of nilpotence equal with $r$; we can write $J_r(0) = O_r$.  

17
• The components of \( J_r(0)^j \) are \([J_r(0)^j]_{\alpha \beta} = \begin{cases} 1 & \text{if } \beta = \alpha + j \\ 0 & \text{otherwise} \end{cases} \).
• The matrix \( J_r(0) \) is known as the upper shift matrix of order \( s \). If \( M \in \mathcal{M}_{r \times s}(C) \), then in the matrix \( MJ_r(0) \) the first column has zeros and the \( k \)-th column coincide with the \((k - 1)\)-th column of \( M \). If \( j \in \{1, \ldots, s - 1\} \), then the matrix \( M(J_s(0))^j \) has the columns \( 1, \ldots, j \) with zeros, the \( j + 1 \)-th column coincide with the first column of \( M \) and so on, the last column coincide with the \((s - j)\)-th column of \( M \).
• The matrix \( J_r^T(0) \) is known that the lower shift matrix of order \( r \). If \( M \in \mathcal{M}_{r \times s}(C) \), then in the matrix \( J_r^T(0)M \) appear the elements of \( M \) shifted downward by one position, with zeros appearing in the top row. If \( i \in \{1, \ldots, r - 1\} \), then \((J_r^T(0))^jM \) has the rows \( 1, \ldots, i \) with zeros, the \((i + 1)\)-th row coincide with the first row of \( M \) and so on, the last row coincide with the \((r - i)\)-th row of \( M \).

For \( \lambda \neq 0 \) we have \( J_r(\lambda)^{-1} = \sum_{j=0}^{r-1} (-1)^j \lambda^{j+1} J_r(0)^j \).

\[ \text{A matrix } A \in \mathcal{M}_r(C) \text{ is a Jordan matrix if it has the form} \]
\[ A = J_{r_1}(\lambda_1) \oplus J_{r_2}(\lambda_2) \oplus \cdots \oplus J_{r_k}(\lambda_k) \]

with \( k \in \mathbb{N}^* \), \( \sum_{i=1}^k r_i = n \), \( \lambda_1, \ldots, \lambda_k \in \mathbb{C} \), and for all \( i \in \{1, \ldots, k\} \) the matrix \( J_{r_i}(\lambda_i) \in \mathcal{M}_{r_i}(C) \) is a Jordan block.

If \( \lambda_1 = \lambda_2 = \cdots = \lambda_k = 0 \), then \( A \) is a nilpotent Jordan matrix.

The Jordan matrix \( A \) has the following properties:
• \( \text{Spec}(A) = \{ \lambda_1, \ldots, \lambda_k \} \).
• \( \det A = \prod_{i=1}^k \lambda_i^r \). \( A \) is invertible if and only if \( \lambda_i \neq 0 \) for all \( i \in \{1, \ldots, k\} \).
• If \( A \) is invertible, then \( A^{-1} = J_{r_1}(\lambda_1)^{-1} \oplus J_{r_2}(\lambda_2)^{-1} \oplus \cdots \oplus J_{r_k}(\lambda_k)^{-1} \).
• If \( k = r \), then \( A \) is a diagonal matrix.

**Theorem A.1.** [Jordan canonical form theorem (see [8])] \( \text{Let } A \in \mathcal{M}_r(C) \). There is a nonsingular matrix \( P \in \mathcal{M}_r(C) \), natural numbers \( r_1, \ldots, r_k \) with \( \sum_{i=1}^k r_i = r \), and scalars \( \lambda_1, \ldots, \lambda_k \in \mathbb{C} \) such that \( A = P \cdot J_{r_1}(\lambda_1) \oplus J_{r_2}(\lambda_2) \oplus \cdots \oplus J_{r_k}(\lambda_k) \cdot P^{-1} \). The Jordan matrix \( J_A = J_{r_1}(\lambda_1) \oplus J_{r_2}(\lambda_2) \oplus \cdots \oplus J_{r_k}(\lambda_k) \) is uniquely determined by \( A \) up to a permutation of Jordan block matrices \( J_{r_1}(\lambda_1), \ldots, J_{r_k}(\lambda_k) \).

If \( A \) is a real matrix and has only real eigenvalues, then \( P \) can be chosen to be real.

\[ \text{If } r, s \in \mathbb{N}^* \) and \( t \in \{1, \ldots, \min\{r, s\}\} \) we introduce the matrices \( y_t^{[r, s]} \in \mathcal{M}_{r \times s}(C) \). If \( r \leq s \), then

\[ y_t^{[r, s]} = \sum_{\beta=t+s-r}^s (-1)^s-\beta e_{t+s-\beta} \otimes f_\beta^T, \quad (y_t^{[r, s]})_{ij} = \begin{cases} (-1)^{s-r} & \text{if } i + j = t + s \\ 0 & \text{otherwise} \end{cases}, \]

where \( \{e_\alpha\} \) and \( \{f_\beta\} \) are the canonical bases of \( \mathbb{C}^r \) and \( \mathbb{C}^s \). If \( r > s \), then \( y_t^{[r, s]} = (y_t^{[s, r]})^T \).

We denote \( y^{[r, s]} := y_1^{[r, s]} \) and we notice that

\[ y_1^{[r, s]} = \begin{cases} (J_r^T(0))^{t-1} y_t^{[r, s]} & \text{if } r \leq s \\ y_t^{[r, s]} (J_s(0))^{t-1} & \text{if } r > s \end{cases}. \]

The matrices \( y_1^{[r, s]}, \ldots, y_{\max\{r, s\}}^{[r, s]} \) are linearly independent. The square matrix \( y_t^{[r, s]} \) is an anti-diagonal matrix.

For \( r = 2 \) and \( s = 3 \) we have \( y_1^{[2, 3]} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix} \), \( y_2^{[2, 3]} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \).
For $r = 3$ and $s = 2$ we have $y_{1}^{[3,2]} = \begin{pmatrix} 0 & 0 \\ 0 & -1 \\ 1 & 0 \end{pmatrix}$,  
$y_{2}^{[3,2]} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}$.

□ The Pascal matrix $\Psi^{[r,s]} \in M_{r,s}(\mathbb{C})$ has the components and the form, see [3] and [5] (for $r = s$),

$$
\left( \Psi^{[r,s]} \right)_{ij} = \binom{i + j - 2}{j - 1}, \quad i \in \{1, \ldots, r\}, \, j \in \{1, \ldots, s\}, \quad \Psi^{[r,s]} = \begin{pmatrix}
1 & 1 & 1 & 1 & \cdots \\
1 & 2 & 3 & 4 & \cdots \\
1 & 3 & 6 & 10 & \cdots \\
\vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}.
$$

(A.5)

The components verify the Pascal’s recursion:

$$
\begin{align*}
\left( \Psi^{[r,s]} \right)_{1j} &= \left( \Psi^{[r,s]} \right)_{i,1} = 1, \quad i \in \{1, \ldots, r\}, \, j \in \{1, \ldots, s\}, \\
\left( \Psi^{[r,s]} \right)_{ij} &= \left( \Psi^{[r,s]} \right)_{i-1,j} + \left( \Psi^{[r,s]} \right)_{i,j-1}, \quad i \in \{2, \ldots, r\}, \, j \in \{2, \ldots, s\}.
\end{align*}
$$

(A.6)

In the paper [14] it is considered the extended generalized Pascal matrix $\Psi[x,y]$ with the components

$$
\left( \Psi^{[r,s]}[x,y] \right)_{ij} = x^{i-j} y^{j-2} \binom{i + j - 2}{j - 1}.
$$

(A.7)

The components verify the recursion

$$
\left( \Psi^{[r,s]}[x,y] \right)_{ij} = xy \left( \Psi^{[r,s]}[x,y] \right)_{i-1,j} + \frac{y}{x} \left( \Psi^{[r,s]}[x,y] \right)_{i,j-1}.
$$

(A.8)

It is noticeable that we have $\Psi^{[r,s]} = \Psi^{[r,s]}[1,1]$.

We are interested in the case $x = 1$. We make the notation $\Psi^{[r,s]}[y] = \Psi^{[r,s]}[1,y]$ and we have

$$
\left( \Psi^{[r,s]}[y] \right)_{ij} = y^{i-j-2} \binom{i + j - 2}{j - 1}, \quad \Psi^{[r,s]}[y] = \begin{pmatrix}
1 & y & y^2 & y^3 & \cdots \\
y & 2y^2 & 3y^3 & 4y^4 & \cdots \\
y^2 & 3y^3 & 6y^4 & 10y^5 & \cdots \\
\vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}.
$$

(A.9)

The matrix has the following properties:

(a) $\left( \Psi^{[r,s]}[y] \right)_{11} = 1$.

(b) For $i \in \{1, \ldots, r\}$, $j \in \{1, \ldots, s\}$, and $(i, j) \neq (1, 1)$ it is verified the recursion

$$
\left( \Psi^{[r,s]}[y] \right)_{ij} = y \left( \Psi^{[r,s]}[y] \right)_{i-1,j} + y \left( \Psi^{[r,s]}[y] \right)_{i,j-1},
$$

(A.10)

where $\left( \Psi^{[r,s]}[y] \right)_{0,j} = \left( \Psi^{[r,s]}[y] \right)_{i,0} = 0$.

(c) If $r \in \mathbb{N}^*$, then det $\Psi^{[r,r]}[y] = y^{r(r-1)}$ (see Theorem 8 from [14]).

(d) If $r \in \mathbb{N}^*$ and $y \in \mathbb{R}^*$, then $\Psi^{[r,r]}[y]$ is a positive definite matrix. We can use the Sylvester’s criterion and the above result.

□ We consider $r, s \in \mathbb{N}^*$ and we construct a number of $r \cdot s$ matrices from $M_{r \times s}(\mathbb{C})$ in a point $y \in \mathbb{C}$.

(i) $\chi^{[r,s]}_{11}[y] = y^r \Psi^{[r,s]}[y]$.

(ii) $\chi^{[r,s]}_{1j}[y] = y \left( O_{r-j-1} \Psi^{[r,s-j+1]}[y] \right)$, with $j \in \{2, \ldots, s\}$.

(iii) $\chi^{[r,s]}_{i1}[y] = y \left( O_{r-i+1,s} \Psi^{[r-i+1,s]}[y] \right)$, with $i \in \{2, \ldots, r\}$.

(iv) $\chi^{[r,s]}_{ij}[y] = y \left( O_{r-i+j-1} \Psi^{[r-i+j-1]}[y] \right)$, with $i \in \{2, \ldots, r\}$ and $j \in \{2, \ldots, s\}$.

We denote by $\chi^{[r,s]} := \chi^{[r,s]}_{11}$ and we notice that

$$
\chi^{[r,s]}_{ij} = (J^T_r(0))^{i-1} \chi^{[r,s]}(J_s(0))^{j-1}.
$$

(A.11)
We consider the case when \( r = 2 \) and \( s = 3 \). The constructed matrices are:

\[
X_{11}^{[2,3]}[y] = \begin{pmatrix} y & y^2 & y^3 \\ y^2 & 2y^3 & 3y^4 \end{pmatrix}, \quad X_{12}^{[2,3]}[y] = \begin{pmatrix} 0 & y & y^2 \\ 0 & y^2 & 2y^3 \end{pmatrix}, \quad X_{13}^{[2,3]}[y] = \begin{pmatrix} 0 & 0 & y \\ 0 & 0 & y^2 \end{pmatrix},
\]

\[
X_{21}^{[2,3]}[y] = \begin{pmatrix} 0 & 0 & 0 \\ y & y^2 & y^3 \end{pmatrix}, \quad X_{22}^{[2,3]}[y] = \begin{pmatrix} 0 & 0 & 0 \\ 0 & y & y^2 \end{pmatrix}, \quad X_{23}^{[2,3]}[y] = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & y \end{pmatrix}.
\]

We present some properties of the above matrices.

(a) We have the equalities \( X_{ij}^{[r,s]}[y] = (X_{ji}^{[s,r]}[y])^T \).

(b) If \( y \in \mathbb{R} \) and \( r \in \mathbb{N}^* \), then for \( y > 0 \) the matrix \( X_{ij}^{[r,r]}[y] \) is positive definite and for \( y < 0 \) the matrix \( X_{ij}^{[r,r]}[y] \) is negative definite. We use the fact that \( \Psi_{ij}^{[r,r]}[y] \) is a positive definite matrix.
