ON THE INITIAL COEFFICIENTS FOR CERTAIN CLASS OF FUNCTIONS ANALYTIC IN THE UNIT DISC

MILUTIN OBRADOVIĆ AND NIKOLA TUNESKI

ABSTRACT. Let function $f$ be analytic in the unit disk $D$ and be normalized so that $f(z) = z + a_2z^2 + a_3z^3 + \cdots$. In this paper we give sharp bounds of the modulus of its second, third and fourth coefficient, if $f$ satisfies

$$\left| \arg \left( \frac{z}{f(z)} \right)^{1+\alpha} f'(z) \right| < \frac{\gamma \pi}{2} \quad (z \in D),$$

for $0 < \alpha < 1$ and $0 < \gamma \leq 1$.

1. INTRODUCTION AND PRELIMINARIES

Let $A$ denote the family of all analytic functions in the unit disk $D := \{ z \in \mathbb{C} : |z| < 1 \}$ and satisfying the normalization $f(0) = 0 = f'(0) - 1$.

A function $f \in A$ is said to be strongly starlike of order $\beta$, $0 < \beta \leq 1$ if and only if

$$\left| \arg \frac{zf'(z)}{f(z)} \right| < \frac{\beta \pi}{2} \quad (z \in D).$$

We denote this class by $S^*_\beta$. If $\beta = 1$, then $S^*_1 \equiv S^*$ is the well-known class of starlike functions.

In [1] the author introduced the class $U(\alpha, \lambda)$ ($0 < \alpha$ and $\lambda < 1$) consisting of functions $f \in A$ for which we have

$$\left| \left( \frac{z}{f(z)} \right)^{1+\alpha} f'(z) - 1 \right| < \lambda \quad (z \in D).$$

In the same paper it is shown that $U(\alpha, \lambda) \subset S^*$ if

$$0 < \lambda \leq \frac{1 - \alpha}{\sqrt{(1-\alpha)^2 + \alpha^2}}.$$ 

The most valuable up to date results about this class can be found in Chapter 12 from [4].

Key words and phrases. analytic, univalent, coefficient bound, sharp results.
In the paper [2] the author considered univalence of the class of functions \( f \in A \) satisfying the condition

\[
\left| \arg \left( \frac{z}{f(z)} \right)^{1+\alpha} f'(z) \right| < \frac{\gamma \pi}{2} \quad (z \in \mathbb{D})
\]

for \( 0 < \alpha < 1 \) and \( 0 < \gamma \leq 1 \), and proved the following theorem.

**Theorem A.** Let \( f \in A \), \( 0 < \alpha < 2/\pi \) and let

\[
\left| \arg \left( \frac{z}{f(z)} \right)^{1+\alpha} f'(z) \right| < \frac{\gamma_*(\alpha)}{2} \quad (z \in \mathbb{D}),
\]

where

\[
\gamma_*(\alpha) = \frac{2}{\pi} \arctan \left( \sqrt{\frac{2}{\pi \alpha} - 1} \right) - \alpha \sqrt{\frac{2}{\pi \alpha} - 1}.
\]

Then \( f \in S_\beta \), where

\[
\beta = \frac{2}{\pi} \arctan \sqrt{\frac{2}{\pi \alpha} - 1}.
\]

### 2. Main Result

In this paper we will give the sharp estimates for initial coefficients of functions \( f \in A \) which satisfied the condition (1). Namely, we have

**Theorem 1.** Let \( f(z) = z + a_2 z^2 + a_3 z^3 + \cdots \) belongs to the class \( A \) and satisfy the condition (1) for \( 0 < \alpha < 1 \) and \( 0 < \gamma \leq 1 \). Then we have the next sharp estimations:

(a) \( |a_2| \leq \frac{2\gamma}{1-\alpha} \);

(b) \( |a_3| \leq \begin{cases} \frac{2\gamma}{2-\alpha}, & 0 < \gamma \leq \frac{(1-\alpha)^2}{3-\alpha} \\ \frac{2(3-\alpha)^2}{(1-\alpha)^2(2-\alpha)^2}, & \frac{(1-\alpha)^2}{3-\alpha} \leq \gamma \leq 1 \end{cases} \);

(c) \( |a_4| \leq \begin{cases} \frac{3\gamma^2}{3-\alpha}, & 0 < \gamma \leq \gamma_\nu \\ \frac{2(\alpha^2-6\alpha+17)^2}{(1-\alpha)^3(2-\alpha)^2}, & \gamma_\nu \leq \gamma \leq 1 \end{cases} \);

where

\[
\gamma_\nu = \sqrt{\frac{(1-\alpha)^3(2-\alpha)}{\alpha^2-6\alpha+17}}.
\]

**Proof.** We can write the condition (1) in the form

\[
\left( \frac{f(z)}{z} \right)^{-(1+\alpha)} f'(z) = \left( \frac{1+\omega(z)}{1-\omega(z)} \right) \gamma = (1 + 2\omega(z) + 2\omega^2(z) + \cdots) \gamma,
\]

where \( \omega(z) \) is a function of \( z \).
where $\omega$ is analytic in $\mathbb{D}$ with $\omega(0) = 0$ and $|\omega(z)| < 1$, $z \in \mathbb{D}$. If we denote by $L$ and $R$ left and right hand side of equality (2), then we have

\[
L = \left[ 1 - (1 + \alpha)(a_2 z + \cdots) + \frac{-(1 + \alpha)}{2}(a_2 z + \cdots)^2 \\
+ \frac{-(1 + \alpha)^3}{3}(a_2 z + \cdots)^3 + \cdots \right] \cdot (1 + 2a_2 z + 3a_3 z^2 + 4a_4 z^3 + \cdots)
\]

and if we put $\omega(z) = c_1 z + c_2 z^2 + \cdots$

\[
R = 1 + \gamma \left[ 2(c_1 z + c_2 z^2 + \cdots) + 2(c_1 z + c_2 z^2 + \cdots)^2 + \cdots \right] \\
+ \frac{\gamma}{2} \left[ 2(c_1 z + c_2 z^2 + \cdots) + 2(c_1 z + c_2 z^2 + \cdots)^2 + \cdots \right]^2 \\
+ \frac{\gamma}{3} \left[ 2(c_1 z + c_2 z^2 + \cdots) + 2(c_1 z + c_2 z^2 + \cdots)^2 + \cdots \right]^3 + \cdots.
\]

If we compare the coefficients on $z, z^2, z^3$ in $L$ and $R$, then, after some calculations, we obtain

\[
a_2 = \frac{2\gamma}{1 - \alpha} c_1, \\
a_3 = \frac{2\gamma}{2 - \alpha} c_2 + \frac{2(3 - \alpha)\gamma^2}{(1 - \alpha)^2(2 - \alpha)} c_1^2, \\
a_4 = \frac{2\gamma}{3 - \alpha} \left( c_3 + \mu c_1 c_2 + \nu c_1^3 \right),
\]

where

\[
(4) \quad \mu = \mu(\alpha, \gamma) = \frac{2(5 - \alpha)\gamma}{(1 - \alpha)(2 - \alpha)} \quad \text{and} \quad \nu = \nu(\alpha, \gamma) = \frac{1}{3} + \frac{2}{3} \frac{(\alpha^2 - 6\alpha + 17)\gamma^2}{(1 - \alpha)^3(2 - \alpha)}.
\]

Since $|c_1| \leq 1$, then by using (3) we easily obtain the result (a) from this theorem. Also, by using $|c_1| \leq 1$ and $|c_2| \leq 1 - |c_1|^2$, from (3) we have

\[
|a_3| \leq \frac{2\gamma}{2 - \alpha} |c_2| + \frac{2(3 - \alpha)\gamma^2}{(1 - \alpha)^2(2 - \alpha)} |c_1|^2 \\
\leq \frac{2\gamma}{2 - \alpha} (1 - |c_1|^2) + \frac{2(3 - \alpha)\gamma^2}{(1 - \alpha)^2(2 - \alpha)} |c_1|^2 \\
= \frac{2\gamma}{2 - \alpha} + \frac{2\gamma}{2 - \alpha} \left[ \frac{(3 - \alpha)\gamma}{(1 - \alpha)^2} - 1 \right] |c_1|^2
\]

and the result depends of the sign of the factor in the last bracket.

The main tool of our proof for the coefficient $a_4$ will be the results of Lemma 2 in the paper [3]. Namely, in that paper the authors considered the sharp estimate of the functional

\[
\Psi(\omega) = |c_3 + \mu c_1 c_2 + \nu c_1^3|
\]

within the class of all holomorphic functions of the form

\[
\omega(z) = c_1 z + c_2 z^2 + \cdots
\]
and satisfying the condition $|\omega(z)| < 1$, $z \in \mathbb{D}$. In the same paper in Lemma 2, for $\omega$ of previous type and for any real numbers $\mu$ and $\nu$ they give the sharp estimates $\Psi(\omega) \leq \Phi(\mu, \nu)$, where $\Phi(\mu, \nu)$ is given in general form in Lemma 2, and here we will use

$$
\Phi(\mu, \nu) = \begin{cases}
1, & (\mu, \nu) \in D_1 \cup D_2 \cup \{(2, 1)\} \\
|\nu|, & (\mu, \nu) \in \bigcup_{k=3}^{7} D_k
\end{cases},
$$

where

$$
D_1 = \{(\mu, \nu) : |\mu| \leq \frac{1}{2}, -1 \leq \nu \leq 1\},
$$

$$
D_2 = \{(\mu, \nu) : \frac{1}{2} \leq |\mu| \leq 2, \left(\frac{1}{2}(|\mu| + 1)^3 - (|\mu| + 1) \leq \nu \leq 1\right)\},
$$

$$
D_3 = \{(\mu, \nu) : |\mu| \leq \frac{2}{3}, \nu \leq -1\},
$$

$$
D_4 = \{(\mu, \nu) : |\mu| \geq \frac{2}{3}, \nu \leq -\frac{2}{3}(|\mu| + 1)\},
$$

$$
D_5 = \{(\mu, \nu) : |\mu| \leq 2, \nu \geq 1\},
$$

$$
D_6 = \{(\mu, \nu) : 2 \leq |\mu| \leq 4, \nu \geq \frac{1}{24}(\mu^2 + 8)\},
$$

$$
D_7 = \{(\mu, \nu) : |\mu| \geq 4, \nu \geq \frac{2}{3}(|\mu| - 1)\}.
$$

In that sense, we need the values $\alpha$ and $\gamma$ such that $0 < \mu \leq \frac{1}{2}, \mu \leq 2, \mu \leq 4, \nu \leq 1$. So, by using (4), we easily get the next equivalence

$$
0 < \mu \leq \frac{1}{2} \iff \gamma \leq \frac{(1 - \alpha)(2 - \alpha)}{4(5 - \alpha)} := \gamma_{1/2};
$$

$$
\mu \leq 2 \iff \gamma \leq \frac{(1 - \alpha)(2 - \alpha)}{5 - \alpha} := \gamma_2;
$$

$$
\mu \leq 4 \iff \gamma \leq \frac{2(1 - \alpha)(2 - \alpha)}{5 - \alpha} := \gamma_4;
$$

$$
\nu \leq 1 \iff \gamma \leq \sqrt{\frac{(1 - \alpha)^4(2 - \alpha)}{\alpha^2 - 6\alpha + 17}} := \gamma_\nu.
$$

It is easily to obtain that all values $\gamma_{1/2}, \gamma_2, \gamma_4, \gamma_\nu$ are decreasing functions of $\alpha$, $0 < \alpha < 1$ and that

$$
0 < \gamma_{1/2} < \frac{1}{10}, \quad 0 < \gamma_2 < \frac{2}{5}, \quad 0 < \gamma_4 < \frac{4}{5}, \quad 0 < \gamma_\nu < \sqrt{\frac{2}{17}} = 0.342997 \ldots.
$$

Also, it is clear that

$$
0 < \gamma_{1/2} < \gamma_2 < \gamma_4
$$

and it is easily to obtain that

$$
\gamma_{1/2} \leq \gamma_\nu \quad \text{for} \quad \alpha \in (0, \alpha_\nu],
$$

where $\alpha_\nu = 0.951226 \ldots$ is the root of the equation $5\alpha^3 - 56\alpha^2 + 177\alpha - 122 = 0$ (of course $\gamma_\nu \leq \gamma_{1/2}$ for $\alpha \in [\alpha_\nu, 1]$).
Further, the next relation is valid:

$$0 < \gamma_\nu < \gamma_2 < \gamma_4.$$  

**Case 1.** ($0 < \gamma \leq \gamma_\nu$). First, it means that $\nu \leq 1$. If $0 < \gamma \leq \gamma_{1/2}$, then $0 < \mu \leq \frac{1}{2}$ and $0 < \nu \leq 1$, which by Lemma 2 [3] gives $\Phi(\mu, \nu) = 1$. If $\gamma_{1/2} \leq \gamma \leq \gamma_\nu$, $\alpha \in (0, \alpha_\nu)$, then $\frac{1}{2} \leq \mu < 2$, $0 < \nu \leq 1$ and if we prove that

$$\frac{4}{27}(\mu + 1)^3 - (\mu + 1) \leq \nu,$$

then also by Lemma 2 [3] we have $\Phi(\mu, \nu) = 1$. In that sense, let denote

$$L_1 =: \frac{4}{27}(\mu + 1)^3 - (\mu + 1) \quad \text{and} \quad R_1 = \nu.$$

Since $L_1$ is an increasing function of $\mu$ for $\mu \geq \frac{1}{2}$ and since $\gamma \leq \gamma_\nu$, then

$$\mu \leq \frac{2(3 - \alpha)\gamma_\nu}{(1 - \alpha)(5 - \alpha)} = 2\sqrt{\frac{(1 - \alpha)(5 - \alpha)^2}{(2 - \alpha)(\alpha^2 - 6\alpha + 17)}} < 2\sqrt{\frac{2534}{34} = \frac{10}{3}}$$

(because the function under the square root is decreasing) and so

$$L_1 < \frac{4}{27}\left(\frac{10}{\sqrt{34} + 1}\right)^3 - \left(\frac{10}{\sqrt{34} + 1}\right) = 0.249838\ldots,$$

while

$$R_1 = \nu = \frac{1}{3} + \frac{2(\alpha^2 - 6\alpha + 17)\gamma_\nu^2}{3(1 - \alpha)^3(2 - \alpha)} > \frac{1}{3} = 0.33\ldots.$$  

This implies the desired inequality.

**Case 2.** ($\gamma_\nu \leq \gamma \leq 1$) In this case we have that $\nu \geq 1$. If $\gamma_\nu \leq \gamma \leq \gamma_2$, $\alpha \in (0, 1)$, then $0 < \mu \leq 2$, $\nu \geq 1$, which by Lemma 2 [3] implies $\Phi(\mu, \nu) = \nu$. If $\gamma_2 \leq \gamma \leq \gamma_4$, $\alpha \in (0, 1)$, then $2 \leq \mu \leq 4$. Also, after some calculations, the inequality $\nu \geq \frac{1}{12}(\mu^2 + 8)$ is equivalent to

$$\frac{43 - 23\alpha + 5\alpha^2 - \alpha^3}{(1 - \alpha)^3(2 - \alpha)^2} \gamma^2 \geq 1.$$  

Since $\gamma_2 \leq \gamma$, then the previous inequality is satisfied if

$$\frac{43 - 23\alpha + 5\alpha^2 - \alpha^3}{(1 - \alpha)^3(2 - \alpha)^2} \gamma_2^2 \geq 1.$$  

But, the last inequality is equivalent to the inequality $\alpha^2 - 2\alpha - 3 \leq 0$, which is really true for $\alpha \in (0, 1)$. By Lemma 2 [3] we also have $\Phi(\mu, \nu) = \nu$. Finally, if $\gamma \geq \gamma_4$, then $\mu \geq 4$ and if $\nu \geq \frac{4}{3}(\mu - 1)$ we have (by using the same lemma) $\Phi(\mu, \nu) = \nu$. Really, the inequality $\nu \geq \frac{2}{3}(\mu - 1)$ is equivalent with

$$2(\alpha^2 - 6\alpha + 17)\gamma^2 - 4(1 - \alpha)^2(5 - \alpha)\gamma + 3(1 - \alpha)^3(2 - \alpha) \geq 0.$$
Since the discriminant of previous trinomial is
\[ D = 8(1 - \alpha)^3(\alpha^3 - 2\alpha^2 + 17\alpha - 52) < 0 \]
for \( \alpha \in (0, 1) \), then the previous inequality is valid. By using (3) we have that
\[ |a_4| \leq \frac{2}{3-\alpha} \] (Case 1), or \( |a_4| \leq \frac{2}{3-\alpha} \nu \) (Case 2), and from there the statement of the theorem.

All results of Theorem 1 are the best possible as the functions \( f_i, i = 1, 2, 3, \) defined with
\[ \left( \frac{z}{f_i(z)} \right)^{1+\alpha} f_i'(z) = \left( \frac{1 + z^i}{1 - z^i} \right)^\gamma, \]
where \( 0 < \alpha < 1, 0 < \gamma \leq 1 \). We have that
\[ c_i = 1 \quad \text{and} \quad c_j = 0 \text{ when } j \neq i. \]

\[ \square \]

**Remark 1.** By using Theorem A we can conclude that it is sufficient to be \( \gamma \leq \gamma_\ast(\alpha) \) and \( 0 < \alpha < 2/\pi \) for starlikeness of functions \( f \in A \) which satisfied the condition (1).

Also, these conditions imply that the modulus of the coefficients \( a_2, a_3, a_4 \) is bounded with some constants. Namely, from the estimates given in Theorem 1 we have, for example,
\[ |a_2| \leq \frac{2\gamma}{1-\alpha} \leq \frac{2\gamma_\ast(\alpha)}{1-\alpha}, \quad |a_3| \leq \frac{2(3-\alpha)\gamma_\ast(\alpha)}{(1-\alpha)^2(2-\alpha)}, \]

etc.

We note that \( \gamma_\ast(\alpha) < 1 - \alpha \) for \( 0 < \alpha < 2/\pi \). Namely, if we put
\[ \phi(\alpha) =: \gamma_\ast(\alpha) - (1 - \alpha), \]
then \( \phi'(\alpha) = 1 - \sqrt{\frac{2}{\pi\alpha}} - 1 \). It is easily to see that \( \phi \) attains its minimum \( \phi(1/\pi) = -1/2 \) and since \( \phi(0+) = 0, \phi(2/\pi) = 2/\pi - 1 < 0 \), we have the desired inequality.

When \( \alpha \to 0 \), then \( \gamma_\ast(0+) = 1 \), and from Theorem 7 we have the next estimates for \( 0 < \gamma \leq 1 \):
\[ |a_2| \leq 2\gamma \leq 2, \quad |a_3| \leq \begin{cases} \gamma, \quad 0 < \gamma \leq 1/3 \\ 3\gamma^2, \quad 1/3 \leq \gamma \leq 1 \end{cases} \]
and
\[ |a_4| \leq \begin{cases} 2\gamma/3, \quad 0 < \gamma \leq 2/17 \\ 2\gamma(1 + 17\gamma^2)/9 \leq 4, \quad \sqrt{2/17} \leq \gamma \leq 1 \end{cases} \]

This is the case when we have strongly starlike functions of order \( \gamma \).
For $\gamma = 1$ in Theorem 1, i.e. if $\text{Re} \left( \left( \frac{z}{f(z)} \right)^{1+\alpha} f'(z) \right) > 0$, $z \in \mathbb{D}$, we have

$$|a_2| \leq \frac{2}{1-\alpha}, \quad |a_3| \leq \frac{2(3-\alpha)}{(1-\alpha)^2(2-\alpha)}$$

and

$$|a_4| \leq \frac{2}{3-\alpha} \left[ \frac{1}{3} + \frac{2}{3} \frac{(\alpha^2 - 6\alpha + 17)}{(1-\alpha)^2(2-\alpha)} \right].$$
