CLOSED FUNCTION SETS ON GROUPS OF PRIME ORDER

SEBASTIAN KREINECKER

Sebastian Kreinecker, Institute for Algebra, Johannes Kepler University Linz, Altenbergerstraße 69, 4040 Linz, Austria

Abstract. We give a full description of all sets of functions on the group $(\mathbb{Z}_p, +)$ of prime order which are closed under the composition with the clone generated by $+$ from both sides. Thereby, we also get a description of all iterative algebras on $\mathbb{Z}_p$ which are closed under the composition with the clone generated by $+$ from both sides. As another consequence, there are infinitely many non finitely generated clones above $\text{Clo}(\mathbb{Z}_p \times \mathbb{Z}_p, +)$ for $p > 2$.

1. Motivation and Introduction

Starting from Emil Post’s characterization of all closed sets of functions on a two-element set [21], there are many results describing sets of functions that are closed under certain properties. This led to the study of clones [20], iterative algebras [14], clonoids [3], minor closed sets [19] and other closed sets [15]. Results for clones containing only affine mappings are given in [23], a full characterization for polynomial clones (clones containing the constants) on $\mathbb{Z}_p \times \mathbb{Z}_p$ and on $\mathbb{Z}_{pq}$ for any prime $p$ can be found in [7], a description for polynomial clones on $\mathbb{Z}_{pq}$ for different primes $p, q$ is given in [2] and polynomial clones on $\mathbb{Z}_n$ for $n$ squarefree are described in [17]. Let $\mathbb{N} := \{1, 2, 3, \ldots\}$ and $\mathbb{N}_0 := \mathbb{N} \cup \{0\}$. Let $S$ be a nonempty set. For $n \in \mathbb{N}$, we then denote by $S^{[n]}$ the set of $n$-ary operations on $S$. We will express closure properties by means of the product defined in [8] which we describe for nonempty sets $A, B, C$, for $E \subseteq \bigcup \{A^{B^n} \mid n \in \mathbb{N}\}$, and for $F \subseteq \bigcup \{B^{C^n} \mid n \in \mathbb{N}\}$ by

$$EF := \{f(g_1, \ldots, g_n) \mid n, m \in \mathbb{N}, f \in E^{[n]}, g_1, \ldots, g_n \in F^{[m]}\}.$$
For \( n \in \mathbb{N} \) and for all \( j \in \mathbb{N} \) with \( j \leq n \) we define the \( j \)-th projection of \( A^n \) by 
\[
\pi^n_j(x_1, \ldots, x_n) := x_j \text{ for } x_1, \ldots, x_n \in A.
\]
Then \( J_A := \{ \pi^n_j \mid n, j \in \mathbb{N} \text{ with } j \leq n \} \) is called the clone of projections. An iterative algebra on \( A \) is a set \( I \subseteq \bigcup \{ A^n \mid n \in \mathbb{N} \} \) such that \( I(I \cup J_A) \subseteq I \) (called semiclone in [4]). If also \( J_A \subseteq I \), we call \( I \) a clone on \( A \) (cf. [24]).

The goal of this paper is a characterization for sets of finitary functions of the following concept. Let \( A \) be an algebra with universe \( A \). We call \( C \) a clonoid with source set \( B \) and target algebra \( A \) if \( \text{Clo}(A)(CJ_B) \subseteq C \) (cf. [3]). Now let \( p \) be a prime. We denote the set of linear functions on \( \mathbb{Z}_p \), which we define as the clone generated by the operation +, by \( \mathcal{L}_{\mathbb{Z}_p} \). We call a nonempty set \( C \) of finitary operations on \( \mathbb{Z}_p \) a linearly closed clonoid on \( \mathbb{Z}_p \) if \( \mathcal{L}_{\mathbb{Z}_p} C \subseteq C \) and \( C \mathcal{L}_{\mathbb{Z}_p} \subseteq C \).

The smallest linearly closed clonoid which contains two linearly closed clonoids \( D_1 \) and \( D_2 \) is given by \( D_1 + D_2 := \{ f + g \mid n \in \mathbb{N}, f \in D_1^{[n]}, g \in D_2^{[n]} \} \). The set of all linearly closed clonoids on \( \mathbb{Z}_p \), together with the intersection and the sum forms a lattice. Now we introduce an important definition which will lead to our desired characterization.

**Definition 1.1.** Let \( M \subseteq \mathbb{N}_0 \) and let \( p \) be a prime. We call \( M \) a \( p \)-minor subset if \( n - (p - 1) \in M \) for all \( n \in M \) with \( n > p - 1 \).

In Section 3 we will prove the following main result of this paper which gives a full characterization of linearly closed clonoids on \( \mathbb{Z}_p \):

**Theorem 1.2.** The lattice of \( p \)-minor subsets (under intersection and union) is isomorphic to the lattice of linearly closed clonoids on \( \mathbb{Z}_p \) (under intersection and sum).

We call a linearly closed clonoid \( C \) with \( C(C \cup J_A) \subseteq C \) a linearly closed iterative algebra. In Section 4 we then will get a full description for linearly closed iterative algebras and for clones on \( \mathbb{Z}_p \) which contain +. In Section 5 we will show a different approach to get the same result for clones using a result of Hagemann and Herrmann [13].

Hence we will find for a prime \( p \) how many different linearly closed iterative algebras on \( \mathbb{Z}_p \) there are and also how many clones on \( \mathbb{Z}_p \) contain +:

**Corollary 1.3.** Let \( p \) be a prime number. Then there exist exactly \( |\{ t \in \mathbb{N} \mid t \text{ divides } p - 1 \}| + 3 \) different clones on \( \mathbb{Z}_p \) which contain +.

We mention that Corollary 1.3 is known from [22] and it also follows from [18, Theorem 22]. By an embedding of linearly closed clonoids on \( \mathbb{Z}_p \) into clones on \( \mathbb{Z}_p \times \mathbb{Z}_p \), we will show the following result in Section 6:

**Theorem 1.4.** Let \( p > 2 \) be a prime number. Then there are infinitely many non finitely generated clones on \( \mathbb{Z}_p \times \mathbb{Z}_p \) which contain +.
2. Notations and Preliminaries

In this section we fix some notation.

2.1. Important sets of functions. Let \( p \) be a prime. We have already introduced the set of linear functions on \( \mathbb{Z}_p \). Now we define the set of constant functions on \( \mathbb{Z}_p \) by
\[
K_{\mathbb{Z}_p} := \{ \mathbb{Z}_n \to \mathbb{Z}_p, (x_1, \ldots, x_n) \mapsto a \mid n \in \mathbb{N}, a \in \mathbb{Z}_p \}.
\]
Furthermore, let \( A_{\mathbb{Z}_p} \) be the set of affine functions on \( \mathbb{Z}_p \), that is, the clone generated by \( K_{\mathbb{Z}_p} \) and the operation +.

2.2. Linearly closed clonoids. Let \( p \) be a prime. Let \( F \subseteq \bigcup \{ \mathbb{Z}_n | n \in \mathbb{N} \} \). We define \( \langle F \rangle_{C} \), the linearly closed clonoid on \( \mathbb{Z}_p \) which is generated by \( F \), by
\[
\langle F \rangle_{C} := \bigcap \{ G \mid F \subseteq G, G \text{ is a linearly closed clonoid on } \mathbb{Z}_p \}.
\]
Since on a field every finitary function is induced by a polynomial, it is sufficient to investigate polynomials and their properties.

2.3. Polynomials. Let \( p \) be a prime. We fix an alphabet \( X := \{ x_i \mid i \in \mathbb{N} \} \) and denote the set of polynomials on \( \mathbb{Z}_p \) which are written in \( X \) by \( \mathbb{Z}_p[X] \). Let \( g \in \mathbb{Z}_p[X] \). We define \( \text{Var}(g) \) as the set of all variables which occur in \( g \) and by \( mI(g) \) we denote \( \max(\{0\} \cup \{i \in \mathbb{N} \mid x_i \in \text{Var}(g)\}) \). Let \( 0 \neq g \in \mathbb{Z}_p[X] \). Then \( g \) can be written as
\[
g = \sum_{i=1}^{n} a_i \prod_{j=1}^{m} x_j^{\alpha(i,j)}
\]
with the properties that for all \( i \leq n, a_i \neq 0 \), and for all \( i, i' \leq n \) with \( i \neq i' \), there exists a \( j \leq m \) such that \( \alpha(i, j) \neq \alpha(i', j) \). For the monomial \( h := \prod_{j=1}^{m} x_j^{\beta(i)} \in \mathbb{Z}_p[X] \) we write \( x^{\beta} \) where \( \beta = (\beta(1), \beta(2), \ldots, \beta(m)) \) and for \( g \) we then write \( \sum_{i=1}^{n} a_i x^{\alpha(i)} \). We denote the total degree of a monomial \( h \), which is defined by the sum of the exponents, by \( tD(h) \). We denote the set of all degrees of \( g \) by
\[
\text{DEGS}(g) := \{ \alpha(i) \mid i \leq n \}
\]
and \( \text{DEGS}(0) := \emptyset \). We denote the set of all total degrees of \( g \) by
\[
\text{TD}(g) := \{ \sum_{j=1}^{m} \alpha(i, j) \mid i \leq n \}
\]
and \( \text{TD}(0) := \emptyset \).

Now we introduce a notation for the composition of multivariate polynomials: Let \( m \in \mathbb{N}, f_1, \ldots, f_m \in \mathbb{Z}_p[X] \), and let \( b = (b_1, \ldots, b_m) \in \mathbb{N}^m \) with \( b_1 < b_2 < \ldots < b_m \). Then we define
\[
g \circ_b (f_1, \ldots, f_m) :=
\]
$g(x_1, \ldots, x_{b_1-1}, f_1, x_{b_1+1}, \ldots, x_{b_2-1}, f_2, x_{b_2+1}, \ldots, x_{b_m-1}, f_m, x_{b_m+1}, \ldots)$. 

Furthermore, we define 

$$g \circ_b f_1 := g \circ_b (f_1, \ldots, f_1).$$

**Examples:** $(x_1 + x_2^2) \circ_{(1,2)} (x_1^3, x_1 + x_2) = x_1^3 + x_1^2 + 2x_1 x_2 + x_2^2$, and $(x_1) \circ_{(2)} (x_3) = x_1$.

Let $d \in \mathbb{N}$. We write $1_d$ for $(1, \ldots, 1)$.

Adapting our notations for the the product of two sets of finitary functions we define now the product of $A, B \subseteq Z_p[X]$ (cf. [1]) by 

$$AB := \{ f(g_1, \ldots, g_n) \mid n, m \in \mathbb{N}_0, f \in A^{[n]}, g_1, \ldots, g_n \in B^{[m]} \}.$$

**Remark:** A polynomial can be seen as a polynomial in any arity greater equal than its greatest variable. This means if $f \in Z_p[X]$, then for all $m \geq mI(f)$, $f \in Z_p[X]^{[m]}$.

Now we define 

$$L := \{ \sum_{i=1}^n a_i x_i \mid n \in \mathbb{N}, \forall i \leq n: a_i \in Z_p \}.$$

We call $C \subseteq Z_p[X]$, nonempty, a **polynomial linearly closed clonoid** if $L C \subseteq C$ and $C L \subseteq C$. Let $F \subseteq Z_p[X]$. Then we denote by $(F)_p$ the **polynomial linearly closed clonoid that is generated by $F$**.

Now we show a fact about polynomial linearly closed clonoids and the composition of polynomials.

**Lemma 2.1.** Let $C$ be a polynomial linearly closed clonoid and $g \in Z_p[X]$ then the following hold:

- For all $m \in \mathbb{N}$, for all $(b_1, \ldots, b_m) \in \mathbb{N}^m$, with $b_1 < \ldots < b_m$, for all $f_1 \ldots, f_m \in L$, we have 
  $$g \circ_b (f_1, \ldots, f_m) \in C.$$
- As a special case we get:
  - For all $m \in \mathbb{N}$, for all $b \in \mathbb{N}^m$, we have $g \circ_b 0 \in C$.

**Proof.** Let $\bar{m} = mI(g)$. Let $n := \max(\{mI(f_i) \mid i \leq m\})$. Now we set 

$$(g_1, g_2, g_3, \ldots) := (x_1, \ldots, x_{b_1-1}, f_1, x_{b_1+1}, \ldots, x_{b_m-1}, f_m, x_{b_m+1}, \ldots),$$

where $g_1, g_2, \ldots$ are polynomials of arity $n$. Then 

$$g(g_1, g_2, \ldots, g_m) = g \circ_{(1, \ldots, \bar{m})} (g_1, g_2, \ldots, g_m) = g \circ_b (f_1, \ldots, f_m) \in C,$$
since the left hand side lies in \( C \) by the definition of a polynomial linearly closed clonoid.

The connection of these concepts to linearly closed clonoids on \( \mathbb{Z}_p \) will be given in the next subsection.

Let \( p \) be a prime. Let \( f \in \mathbb{Z}_p[X] \), and let \( N := \langle x_i^p - x_i \mid i \in \mathbb{N} \rangle \) be the ideal in \( \mathbb{Z}_p[X] \) generated by \( x_i^p - x_i \) for \( i \in \mathbb{N} \). Following [10] Chapter 15.3 there is a remainder \( f' \) of \( f \) with respect to \( N \). In this case the remainder is unique. We denote this remainder by \( \text{rem}(f) \) and call \( \text{rem}(f) \) the \( p \)-representative of \( f \). The \( p \)-representative has the property that all exponents of the variables of \( \text{rem}(f) \) are less or equal \( p - 1 \). We denote the set of all polynomials on \( \mathbb{Z}_p \) with this property by \( \mathbb{Z}_p[X] := \{ 0 \} \cup \{ \sum_{i=1}^n a_i \prod_{j=1}^m x_j^{\alpha(i,j)} \mid n, m \in \mathbb{N}, \forall i \leq n: a_i \in \mathbb{Z}_p \setminus \{ 0 \}, \forall i \leq n \forall j \leq m: \alpha(i,j) \leq p - 1, \alpha(i) \neq \alpha(i') \text{ for } i \neq i' \} \). We call \( \mathbb{Z}_p[X] \) the set of reduced polynomials over \( \mathbb{Z}_p \).

2.4. Induced Functions. Let \( p \) be a prime, let \( f \in \mathbb{Z}_p[X] \) and let \( n \in \mathbb{N} \) with \( n \geq \text{ml}(f) \). We denote the function from \( \mathbb{Z}_p^n \) to \( \mathbb{Z}_p \) which is induced by \( f \in \mathbb{Z}_p[X] \) on \( \mathbb{Z}_p \), by \( f^{\mathbb{Z}_p}_n \). Since \( a^p = a \) for all \( a \in \mathbb{Z}_p \), we have \( f^{\mathbb{Z}_p}_n = (\text{rem}(f))^{\mathbb{Z}_p}_n \). Therefore we can always assume that a function of a linearly closed clonoid on \( \mathbb{Z}_p \) is induced by a polynomial from \( \mathbb{Z}_p[X] \).

We mention that \( \max(\{i \mid x_i \in \text{Var}(\text{rem}(f))\}) \) can be smaller than \( \text{ml}(f) \), e.g. \( p = 3 \), \( f = x_1 + x_2 + 2x_2^3 \) then \( \text{rem}(f) = x_1 \). This does not cause any problems: Let \( C \) be a linearly closed clonoid on \( \mathbb{Z}_p \). If \( f^{\mathbb{Z}_p}_n \in C \), then \( \text{rem}(f)^{\mathbb{Z}_p}_n \in C \) for all \( m \geq \max(1, \text{ml}(\text{rem}(f))) \) since \( C \) is a linearly closed clonoid.

Now we are able to give the connection between polynomial linearly closed clonoids and linearly closed clonoids on \( \mathbb{Z}_p \).

Lemma 2.2. Let \( C \subseteq \mathbb{Z}_p[X] \) be a polynomial linearly closed clonoid. Then the set \( \{ \text{rem}(f)^{\mathbb{Z}_p}_n \mid f \in C, n \geq \max(1, \text{ml}(\text{rem}(f))) \} \) is a linearly closed clonoid on \( \mathbb{Z}_p \).

Proof. Immediate.

Proposition 2.3. Let \( C, D \) be linearly closed clonoids on \( \mathbb{Z}_p \) and let \( F, G \subseteq \mathbb{Z}_p[X] \) such that \( C = \langle \{ f^{\mathbb{Z}_p}_n \mid f \in F, n = \max(1, \text{ml}(f)) \} \rangle_C \) and \( D = \langle \{ g^{\mathbb{Z}_p}_n \mid g \in G, n = \max(1, \text{ml}(G)) \} \rangle_C \). If \( \langle F \rangle_p = \langle G \rangle_p \), then \( C = D \).

Proof. Let

\[
C' := \{ \text{rem}(f)^{\mathbb{Z}_p}_n \mid f \in \langle F \rangle_p, n \geq \max(1, \text{ml}(\text{rem}(f))) \}
\]

and

\[
D' := \{ \text{rem}(f)^{\mathbb{Z}_p}_n \mid f \in \langle G \rangle_p, n \geq \max(1, \text{ml}(\text{rem}(f))) \}.
\]
First we show that $C = C'$ and $D = D'$. $C'$ is by Lemma 2.2 a linearly closed clonoid on $\mathbb{Z}_p$ and it contains all generators of $C$ since $F \subseteq \langle F \rangle_p$. Hence $C \subseteq C'$. For the other inclusion, let $f \in C'$. Then there exists $g \in \langle F \rangle_p$ such that $f = \text{rem}(g)_{Z_p^n}$ for some $n \in \mathbb{N}$. We have $\text{rem}(g)_{Z_p^n} \in C$ since $C = \{ \{ f_{Z_p^n} | f \in F, n = \max(1, \text{ml}(f)) \} \}_C$. Hence $f \in C$ and thus $C = C'$. For $D = D'$ the proof is analogous.

Now we get if $\langle F \rangle_p = \langle G \rangle_p$, then $C = C' = D' = D$. \qed

In order to study linearly closed clonoids on $\mathbb{Z}_p$ we will investigate some properties of polynomial linearly closed clonoids and by Lemma 2.2 and Proposition 2.3 we are then able to transfer these results to linearly closed clonoids on $\mathbb{Z}_p$.

3. $p$-MINOR SUBSETS

Let $p$ be a prime, fixed for the rest of the section. In this section we will get the main result of the paper by using $p$-minor subsets. Remember, we call $M \subseteq N_0$ a $p$-minor subset if $n - (p - 1) \in M$ for all $n \in M$ with $n > p - 1$. Here a short example:

**Example 3.1.** Let $p = 3$ and $M$ be a 3-minor subset. If $9 \in M$, then $\{ 7, 5, 3, 1 \} \subseteq M$. If also $4 \in M$, then $\{ 7, 5, 4, 3, 2, 1 \} \subseteq M$, but not necessarily $0 \in M$.

The next definition will connect $p$-minor subsets to linearly closed clonoids on $\mathbb{Z}_p$.

**Definition 3.2.** For every $p$-minor subset $M$ we define

$$
\mathcal{C}(M) := \{ 0_{Z_p^n} | n \in \mathbb{N} \} \\
\cup \{ f_{Z_p^n} | f \in \mathbb{Z}_p[X], n \geq \max(1, \text{ml}(f)), \text{TD}(f) \subseteq M \}
$$

and

$$
\mathcal{P}(M) := \{ 0 \} \cup \{ f | f \in \mathbb{Z}_p[X], \text{TD}(f) \subseteq M \}.
$$

The main goal is to show that $\mathcal{C}$ is a lattice isomorphism from the set of all $p$-minor subsets to the set of all linearly closed clonoids on $\mathbb{Z}_p$. In order to show this, we will work on polynomials and use the connection between $\mathcal{C}$ and $\mathcal{P}$.

**Lemma 3.3.** Let $M$ be a $p$-minor subset. Then

$$
\mathcal{C}(M) = \{ 0_{Z_p^n} | n \in \mathbb{N} \} \cup \{ \text{rem}(f)_{Z_p^n} | f \in \mathcal{P}(M), n \geq \max(1, \text{ml}(\text{rem}(f))) \}.
$$

**Proof.** If $\text{TD}(f) \subseteq M$, then $\text{TD}(\text{rem}(f)) \subseteq M$, since for $n \in M$ we have $n - t(p - 1) \in M$ for all $t \in \mathbb{N}_0$ with $n - t(p - 1) > 0$. Hence $\text{rem}(f) \in \mathcal{P}(M)$ for all $f \in \mathcal{P}(M)$ and thus we get

$$
\{ \text{rem}(f)_{Z_p^n} | f \in \mathcal{P}(M), n \geq \max(1, \text{ml}(\text{rem}(f))) \}.
$$
Now the result follows since
\[ C(M) = \{0^{\mathbb{Z}_p} \mid n \in \mathbb{N}\} \cup \{f^{\mathbb{Z}_p}_{\mathbb{Z}_p[X]} \cap \mathcal{P}(M), n \geq \max(1, m\mathcal{I}(f))\}. \]

The first step is to verify that the function \( C \) is a map into the set of all linearly closed clonoids on \( \mathbb{Z}_p \).

**Proposition 3.4.** Let \( M \) be a \( p \)-minor subset. Then \( \mathcal{P}(M) \) is a polynomial linearly closed clonoid, and \( C(M) \) is a linearly closed clonoid on \( \mathbb{Z}_p \).

**Proof.** If \( M = \emptyset \), then \( \mathcal{P}(M) = \{0\} \), which is a polynomial linearly closed clonoid. Now let \( M \neq \emptyset \). First we show \( L(\mathcal{P}(M)) \subseteq \mathcal{P}(M) \). Let \( n \in \mathbb{N}_0 \) and \( l \in L^n \). If \( TD(l) = \emptyset \), then \( l = 0 \). We know that \( 0 \in \mathcal{P}(M) \). Let \( TD(l) = \{1\} \). Now let \( m \in \mathbb{N}_0 \) and let \( f_1, \ldots, f_n \in \mathcal{P}(M)[m] \). We define \( f := l(f_1, \ldots, f_n) \). Since \( TD(f_i) \subseteq M \) for all \( i \leq n \) and \( TD(l) = \{1\} \), we have \( TD(f) \subseteq M \). Hence, \( f \in \mathcal{P}(M) \). Now we show \( (\mathcal{P}(M))L \subseteq \mathcal{P}(M) \). Let \( n \in \mathbb{N}_0 \) and let \( f \in \mathcal{P}(M)[m] \). Then let \( m \in \mathbb{N}_0 \) and let \( l_1, \ldots, l_n \in L^m \). We define \( g := f(l_1, \ldots, l_n) \). Now we have \( TD(g) \subseteq TD(f) \) and since \( TD(f) \subseteq M \) we have \( g \in \mathcal{P}(M) \). Therefore \( \mathcal{P}(M) \) is a polynomial linearly closed clonoid, and by Lemma 2.2 and Lemma 3.3, \( C(M) \) is a linearly closed clonoid on \( \mathbb{Z}_p \).

**Lemma 3.5.** \( C \) is a lattice homomorphism from the set of all \( p \)-minor subsets to the set of all linearly closed clonoids on \( \mathbb{Z}_p \).

**Proof.** Let \( M_1 \) and \( M_2 \) be two \( p \)-minor subsets. Then \( M_1 \cup M_2 \) and \( M_1 \cap M_2 \) are \( p \)-minor subsets. It holds that \( C(M_1 \cup M_2) = C(M_1) \cup C(M_2) \) and \( C(M_1 \cap M_2) = C(M_1) \cap C(M_2) \).

The next lemma shows that \( C \) is a function which preserves the ordering.

**Lemma 3.6.** Let \( M_1, M_2 \) be two \( p \)-minor subsets. Then \( M_1 \subseteq M_2 \) if and only if \( C(M_1) \subseteq C(M_2) \).

**Proof.** “\( \Rightarrow \)”: If \( M_1 \subseteq M_2 \), then \( C(M_1) \subseteq C(M_2) \), by the definition of \( C \).

“\( \Leftarrow \)”: If \( M_1 = \emptyset \), this is obvious. Let \( m \in M_1 \). If \( m = 0 \), then \( c^{\mathbb{Z}_p} \in C(M_1) \) for all \( c \in \mathbb{Z}_p \) and for all \( n \in \mathbb{N} \). Let \( c \in \mathbb{Z}_p \) and \( n \in \mathbb{N} \). Since \( C(M_1) \subseteq C(M_2) \), we have \( c^{\mathbb{Z}_p} \in C(M_2) \). The \( p \)-representative of a constant \( c \) is \( c \), hence \( m \in M_2 \).

If \( m > 0 \), we let \( n \geq m \). Then \( (x_1 \cdots x_m)^{\mathbb{Z}_p} \in C(M_1) \). Since \( C(M_1) \subseteq C(M_2) \), we have \( (x_1 \cdots x_m)^{\mathbb{Z}_p} \in C(M_2) \). Since \( x_1 \cdots x_m \) is the \( p \)-representative for a polynomial which induces \( (x_1 \cdots x_m)^{\mathbb{Z}_p} \) it follows that \( m \in M_2 \).
We now get as an easy consequence from Lemma 3.6 that \( C \) is an injective function.

**Lemma 3.7.** Let \( M_1, M_2 \) be two \( p \)-minor subsets. If \( C(M_1) = C(M_2) \), then \( M_1 = M_2 \).

**Proof.** Follows from Lemma 3.6. \( \square \)

The next step is to show that \( C \) is surjective. To this end, we will now prove some facts about polynomial linearly closed clonoids.

**Lemma 3.8.** Let \( d \in \mathbb{N} \) and let \( g \in \mathbb{Z}_p[X] \) with \( \max(\text{TD}(g)) \leq d \), and \( 1_d \not\in \text{DEGS}(g) \). Then \( x_1 \cdots x_d \in \langle \{x_1 \cdots x_d + g\} \rangle_p \).

**Proof.** If \( g = 0 \), the result is obvious. Let \( g \neq 0 \) and let \( C := \langle \{x_1 \cdots x_d + g\} \rangle_p \). First, we show that there exists a \( g' \in \mathbb{Z}_p[X] \) with \( \max(\text{TD}(g')) \leq d \), \( 1_d \not\in \text{DEGS}(g') \) and \( \text{Var}(g') \subseteq \{x_1, \ldots, x_d\} \) such that \( x_1 \cdots x_d + g' \in C \). If \( \text{Var}(g) \subseteq \{x_1, \ldots, x_d\} \), we are done. Otherwise let \( B := \text{Var}(g) \setminus \{x_1, \ldots, x_d\} \). Let \( k \in \mathbb{N} \) and let \( b_1, \ldots, b_k \in \mathbb{N} \) such that \( b_1 < \ldots < b_k \) and \( B = \{x_{b_1}, \ldots, x_{b_k}\} \). We set \( g' := g \circ (b_1, \ldots, b_k) 0 \). We have \( \text{Var}(g') \subseteq \{x_1, \ldots, x_d\} \) and thus

\[
x_1 \cdots x_d + g' = (x_1 \cdots x_d + g) \circ (b_1, \ldots, b_k) 0 \in C.
\]

Now let \( g' \in \mathbb{Z}_p[X] \) with \( \max(\text{TD}(g')) \leq d \), \( 1_d \not\in \text{DEGS}(g') \) and \( \text{Var}(g') \subseteq \{x_1, \ldots, x_d\} \) such that \( x_1 \cdots x_d + g' \in C \).

We proceed by induction on the number of monomials of \( g' \) to show that \( x_1 \cdots x_d \in \langle \{x_1 \cdots x_d + g'\} \rangle_p \subseteq C \). If the number of monomials of \( g' \) is zero we are done. For the induction step, we observe that there exists \( l \leq d \) and a monomial \( m \) of \( g' \) such that \( x_l \) does not appear in \( m \). Then we get

\[
(x_1 \cdots x_d + g') - ((x_1 \cdots x_d + g') \circ (l) 0) = x_1 \cdots x_d + g'' \in C,
\]

where \( g'' := g' - g' \circ (l) 0 \) has the properties that \( \max(\text{TD}(g'')) \leq d \), \( 1_d \not\in \text{DEGS}(g'') \), \( \text{Var}(g'') \subseteq \{x_1, \ldots, x_d\} \) and \( g'' \) has fewer monomials than \( g' \) since the monomial \( m \) is cancelled by the calculation \( g' - g' \circ (l) 0 \). Hence our induction hypothesis yields \( x_1 \cdots x_d \in C \). \( \square \)

**Lemma 3.9.** Let \( 0 \neq f \in \mathbb{Z}_p^n[X] \) with \( d := \max(\text{TD}(f)) \). Then the following hold:

1. If \( d = 0 \), then \( 1 \in \langle \{f\} \rangle_p \).
2. If \( d > 0 \), then \( x_1 \cdots x_d \in \langle \{f\} \rangle_p \).

**Proof.** Let \( C := \langle \{f\} \rangle_p \). We write \( f \) in the form \( f = \sum_{i=1}^n a_i \prod_{j=1}^m x_j^{\alpha(i,j)} \) such that \( a_i \neq 0 \) for all \( i \leq n \), and \( \alpha(i) \neq \alpha(i') \) for all \( i, i' \leq n \) with \( i \neq i' \).
If \( d = 0 \), then \( f = a \) for some \( a \in \mathbb{Z}_p \setminus \{0\} \). There exists a \( b \in \mathbb{Z}_p \) such that \( b \cdot a \equiv_p 1 \), hence we have \( 1 \in C \).

If \( d > 0 \), we fix an \( i' \leq n \) with \( \sum_{j=1}^{m} \alpha(i', j) = d \). Now we show for all \( m \in \mathbb{N} \) with \( |\text{Var}(a_i x^{\alpha(i')})| \leq m \leq d \) that there exists a monomial \( h := ax^\beta \) in \( f \) with \( a \in \mathbb{Z}_p \setminus \{0\} \) with \( |\text{Var}(h)| = m \), \( \text{td}(h) = d \) and \( \beta(j) \leq p - 1 \) for all \( j \leq m \) and there exists \( f' \in \mathbb{Z}_p[X] \) with \( \max(\text{td}(f')) \leq d \) and \( \beta \not\in \text{DEGS}(f') \) such that \( h + f' \in C \).

For the induction base \( m = |\text{Var}(\alpha(i'))| \), we see that \( h = a_i x^{\alpha(i')}(x_{i} + x_{m+1}) \). By the induction hypothesis there is a monomial \( Z \) with \( a \in \mathbb{Z}_p \setminus \{0\} \) such that \( Z \not\in \text{DEGS}(f') \) and \( \beta(l) \cdot a \equiv_p 0 \).

For the induction step, let \( m < d \) such that the induction hypothesis holds for \( m \). By the induction hypothesis there is a monomial \( h := ax^\beta \) and \( f' \in \mathbb{Z}_p[X] \) with \( a \in \mathbb{Z}_p \setminus \{0\} \) with \( |\text{Var}(h)| = m \), \( \text{td}(h) = d \) and \( \beta(j) \leq p - 1 \) for all \( j \leq m \), and \( \max(\text{td}(f')) \leq d \) and \( \beta \not\in \text{DEGS}(f') \) such that \( h + f' \in C \). Since \( m < d \), we have \( l \in \mathbb{N} \) such that \( \beta(l) > 1 \). We define \( f'' := f' \circ (l)(x_{i} + x_{m+1}) \). Now we calculate

\[
(h + f') \circ (l)(x_{i} + x_{m+1}) = ax^\beta \circ (l)(x_{i} + x_{m+1}) + f' \circ (l)(x_{i} + x_{m+1})
\]

\[
= a(x_{i} + x_{m+1})^{\beta(l)} \cdot \prod_{j=1, j \neq l}^{m} x_j^{\beta(j)} + f''
\]

\[
= a \left( \sum_{k=0}^{\beta(l)} \binom{\beta(l)}{k} x_{i}^{\beta(l)-k} x_{m+1}^{k} \right) \cdot \prod_{j=1, j \neq l}^{m} x_j^{\beta(j)} + f''
\]

\[
= \beta(l) \cdot a \cdot x^{(\beta(1),,\beta(l-1),\beta(l-1),,\beta(l),,\beta(m),1)}
\]

\[
+ \left( \sum_{k=0}^{\beta(l)} \binom{\beta(l)}{k} x_{i}^{\beta(l)-k} x_{m+1}^{k} \right) \cdot \prod_{j=1, j \neq l}^{m} x_j^{\beta(j)} + f''.
\]

Since \( \beta(l) \leq p - 1 \), we have \( \beta(l) \cdot a \equiv_p 0 \).

Let \( h' := \beta(l) \cdot a \cdot x^{(\beta(1),,\beta(l-1),\beta(l-1),,\beta(l),,\beta(m),1)} \)
and

\[
g := \left( \sum_{k=0}^{\beta(l)} \binom{\beta(l)}{k} x_{i}^{\beta(l)-k} x_{m+1}^{k} \right) \cdot \prod_{j=1, j \neq l}^{m} x_j^{\beta(j)} + f''.
\]

Then \( h' \) also has the properties that \( \text{td}(h) = d \), \( \beta(j) \leq p - 1 \) for all \( j \leq m + 1 \) and \( |\text{Var}(h)| = m + 1 \). The polynomial \( g \) has the properties that \( \max(\text{td}(g)) \leq d \) and \( (\beta(1),,\beta(l-1),\beta(l-1),,\beta(l),,\beta(m),1) \not\in \text{DEGS}(g) \) since \( k \neq 1 \) and
\( f'' = f' \circ (x_1 + x_{m+1}) \) where \( \beta \not\in \text{DEGS}(f') \). Since \( (h + f') \circ (x_1 + x_{m+1}) \in C \), \( h' \) and \( f''' := g \) are the searched polynomials. This concludes the induction step.

Hence there exist \( a \in \mathbb{Z}_p \setminus \{0\} \), \( h := x^\beta \in \mathbb{Z}_p[X] \) with \( |\text{Var}(h)| = d \) and \( \text{tD}(h) = d \), \( f' \in \mathbb{Z}_p[X] \) with \( \max(\text{tD}(f')) \leq d \) and \( \beta \not\in \text{DEGS}(f') \) such that
\[
  a \cdot h + f' \in C.
\]

There exists \( b \in \mathbb{Z}_p \) such that \( b \cdot a \equiv_p 1 \). Thus,
\[
  h + b \cdot f' \in C.
\]

Since \( C \) is closed under composition with linear polynomials, it is also closed under relabeling the variables. After relabeling the variables we get
\[
  x_1 \cdots x_d + f'' \in C,
\]
for some \( f'' \in \mathbb{Z}_p[X] \). Now Lemma 3.8 yields that \( x_1 \cdots x_d \in C \).

With the help of Lemma 3.9, we are now able to show the next crucial lemma by using the connection between linearly closed clonoids on \( \mathbb{Z}_p \) and polynomial linearly closed clonoids.

**Lemma 3.10.** Let \( C \) be a linearly closed clonoid on \( \mathbb{Z}_p \) and let \( P := \{ x_1 \cdots x_i \mid i \in \mathbb{N} \} \cup \{1\} \). Then there exists \( T \subseteq P \) such that \( C = \langle \{ f^\mathbb{Z}_p \mid f \in T, \ n = \max(\text{mI}(f), 1) \} \rangle_C \).

**Proof.** If \( C = \{0^\mathbb{Z}_p \mid i \in \mathbb{N} \} \), let \( T = \{ \} \). Let \( C \neq \{0^\mathbb{Z}_p \mid i \in \mathbb{N} \} \). Let \( G \subseteq \mathbb{Z}_p[X] \) such that
\[
  C = \langle \{ g^\mathbb{Z}_p \mid g \in G, \ n = \max(\text{mI}(g), 1) \} \rangle_C.
\]

We know that every function \( f^\mathbb{Z}_p \) of \( C \) can be induced by the \( p \)-representative \( \text{rem}(f) \) of \( f \). Hence we can assume \( g \in \mathbb{Z}_p[X] \) for all \( g \in G \).

For each \( i > 0 \) let \( f_i := x_1 \cdots x_i \) and \( f_0 := 1 \). Let \( I := \{ i \in \mathbb{N}_0 \mid \exists g \in G: i \in \text{TD}(g) \} \) and let \( T = \{ f_i \mid i \in I \} \). We want to show that
\[
  C = \langle \{ f^\mathbb{Z}_p \mid f \in T, \ n = \max(\text{mI}(f), 1) \} \rangle_C.
\]

By Proposition 2.3, it is sufficient to show that
\[
  \langle G \rangle_p = \langle T \rangle_p.
\]

“\( \subseteq \)”: It is sufficient to show that \( g \in \langle T \rangle_p \) for \( g \in G \). Let \( g \in G \). If \( g = 0 \), we are done since \( 0 \in \langle T \rangle_p \). If \( g \neq 0 \), then let \( g = \sum_{i=1}^n a_i \prod_{j=1}^m x_j^{\alpha(i,j)} \). We define \( d(l) := \sum_{j=1}^m \alpha(l, j) \in \text{TD}(g) \) for all \( l \leq n \). If \( d(l) = 0 \), then \( f_0 \in T \), and therefore
Now let \( l \in (\{T\}_P) \). Then \( f_{d(l)} = \ldots \cdot x_{d(l)} \) and \( f_{d(l)} \in T \). For each \( l \in n \), we define

\[
f'_l := \prod_{j=1}^{m} x^{\alpha(l,j)} = f_{d(l)}(x_1, \ldots, \ldots, x_m, \ldots, x_m)
\]

where for all \( j \leq m \), \( x_j \) appears exactly \( \alpha(l,j) \) times. By the axioms of a polynomial linearly closed clonoid we now have \( f'_l \in (\{T\}_P) \) for all \( l \leq n \), and thus also \( g = \sum_{i=1}^{n} a_i f'_i \in (\{T\}_P) \).

\( \rightarrow \) It is sufficient to show that \( f_i \in (\{G\}_P) \) for \( i \in I \). Let \( i' \in I \). Then there is a \( g \in G \) such that \( i' \in TD(g) \). Let \( g = \sum_{i=1}^{n} a_i \prod_{j=1}^{m} x^\alpha(i,j) \). We proceed by induction on the total degrees of \( g \) to show \( f_d \in (\{g\}_P) \) for \( d \in TD(g) \).

For the induction base let \( d = \max(TD(g)) \). Since \( g \in \mathbb{Z}_p[X] \), Lemma 3.9 yields that \( f_d \in (\{g\}_P) \). For the induction step let \( d < \max(TD(g)) \). Then for all \( d' \in TD(g) \) with \( d' > d \) the induction hypothesis yields that \( f_{d'} \in (\{g\}_P) \).

This means for all \( i \leq n \) with \( \sum_{j=1}^{m} \alpha(i,j) > d \) we have \( \prod_{j=1}^{m} x^\alpha(i,j) \in C \) and thus for all \( i \leq n \) with \( \sum_{j=1}^{m} \alpha(i,j) > d \) we have \( a_i \prod_{j=1}^{m} x^\alpha(i,j) \in (g)_P \). Let \( D := \{ i \leq n \mid \sum_{j=1}^{m} \alpha(i,j) > d \} \).

Now we calculate

\[
g' = g - \left( \sum_{i \in D} a_i \prod_{j=1}^{m} x^\alpha(i,j) \right) \in (\{g\}_P).
\]

Then \( \max(TD(g')) \) is equal to \( d \). Now Lemma 3.9 yields that \( f_{d} \) is an element of \( (\{g\}_P) \), which concludes the induction step. Since \( i' \in TD(g) \), we have \( f_{i'} \in (\{g\}_P) \) and thus \( f_{i'} \in (\{G\}_P) \). This concludes the proof of (3.2) and hence (3.1) holds.

Now we are able to show that \( C \) is surjective.

**Lemma 3.11.** Let \( C \) be a linearly closed clonoid on \( \mathbb{Z}_p \). Then there exists a \( p \)-minor subset \( M \) such that \( C = C(M) \).

**Proof.** If \( C = \{0^{\mathbb{Z}_p} \mid i \in \mathbb{N}\} \), let \( M := \{\} \). Let \( C \neq \{0^{\mathbb{Z}_p} \mid i \in \mathbb{N}\} \). Let \( f_0 := 1 \) and \( f_i := x_1 \cdot \ldots \cdot x_i \) for \( i \in \mathbb{N} \). By Lemma 3.10 there exists \( I \subseteq \mathbb{N}_0 \) such that \( (\{f_i^{\mathbb{Z}_p} \mid i \in I\})_C = C \). Now let \( M \) be the smallest \( p \)-minor subset which contains \( I \). Now we show that

\[
(3.3) \quad C = C(M).
\]

\( \subseteq \) Holds since \( T \subseteq \mathcal{P}(M) \).
We have \( C(M) = \langle \{ f_i^{Z_p} \mid i \in M \} \rangle \), and hence it is sufficient to show for all \( i \in M \) that \( f_i^{Z_p} \) lies in \( C \). Let \( n \in M \). If \( n = 0 \), then \( 0 \in M \) and \( f_0^{Z_p} \in C \). Let \( n > 0 \). By the definition of \( M \) there is a \( t \in N_0 \) such that \( (f_{n+t(p-1)}) \in T \). Now we calculate

\[
f_{n+t(p-1)}^{(n,\ldots,n+t(p-1))} (x_n) = \prod_{i=1}^{n-1} x_i \cdot x_n^{(p-1)+1} \equiv_p \prod_{i=1}^n x_i.
\]

Hence \( f_n^{Z_p} \in C \). This concludes the proof of (3.3).

By Lemma 3.5, Lemma 3.7 and Lemma 3.11 we have proven the following theorem, which proves Theorem 1.2.

**Theorem 3.12.** \( C \) is a lattice isomorphism from the set of all \( p \)-minor subsets of \( N_0 \) to the set of all linearly closed clonoids on \( Z_p \).

In the next section we will see some consequences of Theorem 3.12.

4. Results and consequences

Before we come to linearly closed iterative algebras and to clones which contain + we see that for a prime \( p \neq 2 \) there are infinitely many different non finitely generated \( p \)-linear closed clonoids.

**Proposition 4.1.** There are 2 different non finitely generated linearly closed clonoids on \( Z_2 \). For \( p \) an odd prime, there are countably infinitely many different non finitely generated linearly closed clonoids on \( Z_p \).

**Proof.** Let \( C \) be a linearly closed clonoid on \( Z_p \). \( M \) is finite if and only if \( C(M) \) is finitely generated, since a finite \( M \) gives a bound on the total degrees of the polynomials which induces the generators for \( C(M) \) and if \( M \) is infinite there is no maximum on the total degrees.

If \( p = 2 \), then \( C(N) \) and \( C(N_0) \) are different and not finitely generated. These are the only cases where \( C(M) \) is not finitely generated, since for all 2-minor subsets with \( M \neq N \) and \( M \neq N_0 \), \( M \) is finite.

If \( p > 2 \). Then there are \( m_1, m_2 \leq p - 1 \) with \( 0 < m_1, m_2 \) such that \( m_1 \neq m_2 \). We define \( M(n) := \{ m_1 + t_1(p-1) \mid t_1 \in N_0 \} \cup \{ m_2 + t_2(p-1) \mid t_2 \leq n \} \) for \( n \in N_0 \). Then \( M(n) \) is an infinite \( p \)-minor subset for all \( n \in N_0 \). This means there are infinitely many different \( p \)-minor subsets, and therefore infinitely many non finitely generated linearly closed clonoids on \( Z_p \). Furthermore, we see that there are only countably many linearly closed clonoids on \( Z_p \) since \( M \) is completely
determined by the family $\langle \sup(M \cap [i]_{p-1}) \mid i \in \{1, \ldots, p-1\} \rangle$ in $(\mathbb{N}_0 \cup \{\infty\})^{p-1}$
and whether $0 \in M$. □

Figure 1 shows the lattice of 3-minor subsets without 0. By Theorem 3.12 this lattice is isomorphic to the lattice of linearly closed clonoids on $\mathbb{Z}_3$ which do not contain the functions induced by constants (except the constant 0).

\end{tikzpicture}
\caption{Lattice of those 3-minor subsets that do not contain 0}
\end{figure}

Let $p$ be a prime. Now we use our results of linearly closed clonoids on $\mathbb{Z}_p$ to characterize linearly closed iterative algebras on $\mathbb{Z}_p$. Remember, $C \subseteq \bigcup \{\mathbb{Z}^n_p \mid n \in \mathbb{N}\}$ is a linearly closed iterative algebra if $C$ is a linearly closed clonoid on $\mathbb{Z}_p$ and $C(C \cup J_{\mathbb{Z}_p}) \subseteq C$. Since $J_{\mathbb{Z}_p} \subseteq \mathcal{L}_{\mathbb{Z}_p}$ and by the Associativity Lemma of \cite{8} this is equivalent to $\mathcal{L}_{\mathbb{Z}_p}(C(C \cup \mathcal{L}_{\mathbb{Z}_p})) \subseteq C$. Let $C$ be a linearly closed iterative algebra on $\mathbb{Z}_p$.

Theorem 4.2 now characterizes all linearly closed iterative algebras on $\mathbb{Z}_p$ for any prime $p$.

**Theorem 4.2.** Let $p$ be a prime number and let $M$ be a $p$-minor subset. Then $\mathcal{C}(M)$ is a linearly closed iterative algebra on $\mathbb{Z}_p$ if and only if $M \subseteq \{0, 1\}$, $M = \mathbb{N}_0$ or $M = \{1 + tm \mid t \in \mathbb{N}_0\}$ for some $m \mid p - 1$.

**Proof.** Let $m \in \mathbb{N}$ such that $m \mid p - 1$. Then clearly $M = \{1 + t \cdot m \mid t \in \mathbb{N}_0\}$ is a $p$-minor subset.

“$\Rightarrow$”: Let $M \not\subseteq \{0, 1\}$ and $M \neq \mathbb{N}_0$ be a $p$-minor subset such that $\mathcal{C}(M)$ is a linearly closed iterative algebra on $\mathbb{Z}_p$.

Let $m \in M$ with $m \leq p - 1$, let $n \in M \setminus \{0\}$, and let $t \in \mathbb{N}_0$. We show (4.1) \[ n + t(m - 1) \in M. \]

We know that $(x^n_m)_p \in \mathcal{C}(M)$. Then $(x_1 \cdots x_n)_p \in \mathcal{C}(M)$. Since $\mathcal{C}(M)$ is closed under composition, we also have $((x_1 \cdots x_n) \circ_1 x^n_m)_p = (x^n_1 x_2 \cdots x_n)_p \in \mathcal{C}(M)$. Since $m < p$, $x^n_1 x_2 \cdots x_n$ is a $p$-representative of a polynomial which induces
(x_1^m x_2 \ldots x_n) \mathbb{Z}_p^m and thus we have n+m-1 \in M. Therefore M is infinite and thus n+1 \in M. This concludes the proof of (4.1). Now let n > \gcd(m-1, p-1).

We show

\[ n - \gcd(m-1, p-1) \in M. \tag{4.2} \]

By the definition of a p-minor subset, n - t(p-1) \in M for all t \in \mathbb{N}_0 with t < \left\lfloor \frac{n}{p-1} \right\rfloor. With (4.1) we then get for all t_1 \in \mathbb{N}_0 and for all t_2 \in \mathbb{N}_0 with t_2 < \left\lfloor \frac{n+t_1(m-1)}{p-1} \right\rfloor that n + t_1(m-1) - t_2(p-1) \in M. Therefore we also get that n - \gcd(m-1, p-1) \in M, hence (4.2) holds.

Let m^* be the smallest element in M \ {0, 1}. We assume that m^* - 1 does not divide p - 1. In this case p has to be greater 2 and thus m^* > 3 and 1 \leq \gcd(m^*-1, p-1) < m^*. By (4.2) we have 1 < m^*-\gcd(m^*-1, p-1) \in M. This contradicts the fact that m^* is the smallest element in M \ {0, 1}. Thus we know that m^* - 1 divides p - 1. Now we show that

\[ M = \{1 + t(m^*-1) \mid t \in \mathbb{N}_0\}. \tag{4.3} \]

\[ \text{“}\supseteq\text{”}: \text{ Since } m^*-1 \mid p-1, \text{ there exists a } t_1 \in \mathbb{N} \text{ such that } t_1 \cdot (m^*-1) = p-1. \]

Since m^* \in M, we know m^* + (t_1-1)(m^*-1) = m^* + t_1(m^*-1) - m^* + 1 = p \in M by (4.1). Hence p - (p-1) = 1 \in M. Therefore 1 + t \cdot (m^*-1) \in M for t \in \mathbb{N}_0.

\[ \text{“}\subseteq\text{”}: \text{ Let } m \in M \text{ with } m \notin \{1 + t(m^*-1) \mid t \in \mathbb{N}_0\}. \text{ Then there exists } u \in \mathbb{N} \text{ such that } m^* + (u-1)(m^*-1) < m < m^* + u(m^*-1). \text{ Then } 1 < m - u(m^*-1) < m^*, \text{ and by (4.1) } m - u(m^*-1) \in M \text{ which contradicts that } m^* = \min(M \setminus \{0, 1\}). \text{ This concludes the proof of (4.3).} \]

\[ \text{“}\leftarrow\text{”}: \text{ If } M \subseteq \{0, 1\} \text{ or } M = \mathbb{N}_0, \text{ the result is obvious. Let } M = \{1 + t \cdot m \mid t \in \mathbb{N}_0\}, \text{ where } m \mid p-1. \text{ Let } k, l \in \mathbb{N}_0, \text{ let } f \in \mathcal{P}(M)^{|k|} \text{ and let } g_1, \ldots, g_k \in \mathcal{P}(M)^{|l|}. \text{ It is sufficient to show that for all } i \leq k \text{ there is a } \beta_i = (\beta_i(1), \ldots, \beta_i(l)) \in \text{DEGS}(g_i) \text{ such that } d = \sum_{i=1}^k \alpha(i)(\sum_{j=1}^l \beta_i(j)). \text{ Since } \sum_{i=1}^k \alpha(i) \equiv_m 1 \text{ and } \sum_{j=1}^l \beta_i(j) \equiv_m 1 \text{ for all } i \leq k, \text{ we have } d = \sum_{i=1}^k \alpha(i)(\sum_{j=1}^l \beta_i(j)) \equiv_m 1. \]

Hence \(d \in M.\)

Now we know how many different linearly closed iterative algebras there exist.

**Corollary 4.3.** Let \(p\) be a prime. Then there exist exactly \(|\{t \in \mathbb{N} \mid t \text{ divides } p-1\}| + 5\) different linearly closed iterative algebras on \(\mathbb{Z}_p\).

**Proof.** By Theorem 4.2 we get the following: For each subset of \(\{0, 1\}\), for \(\mathbb{N}_0\) and for each divisor of \(p-1\) we get a linearly closed iterative algebra via \(\mathcal{C}\). All of
them are different, and there do not exist more linearly closed iterative algebras. Thus there are exactly $|\{t \in \mathbb{N} \mid t \text{ divides } p-1\}| + 5$ different linearly closed iterative algebras on $\mathbb{Z}_p$. □

Let $C$ be a linearly closed iterative algebra on $\mathbb{Z}_p$ and let $M$ be a $p$-minor subset such that $C = C(M)$. $C$ is a clone on $\mathbb{Z}_p$ which contains $+$ if $C$ contains the projections. This holds if and only if $1 \in M$.

By Theorem 4.2 all clones on $\mathbb{Z}_2$ which contain $+$ are given by $C(M)$, where

- $M = \{1\}$ (linear functions), or
- $M = \{0, 1\}$ (affine functions), or
- $M = \mathbb{N}$ (0-symmetric functions), or
- $M = \mathbb{N}_0$ (all functions).

These clones can also be easily found in Post’s Lattice [21]. Theorem 4.2 now gives a characterization for any prime $p$ for all clones on $\mathbb{Z}_p$ which contain $+$ and thus we also get Theorem 1.3.

Figure 2 visualizes Theorem 4.2. In Figure 2A the lattice of linearly closed iterative algebras on additive groups of prime order is given and in Figure 2B we see the corresponding isomorphic lattice of $p$-minor subsets. LL and ML are sublattices of the corresponding lattices which are isomorphic to the divisor lattice of $p - 1$. In the case of ML the maximum element is $\mathbb{N}$ and the smallest element is $M_{p-1} := \{1 + t(p-1) \mid t \in \mathbb{N}_0\}$. In the case of LL the maximum element is the set of all 0-symmetric functions on $\mathbb{Z}_p$ denoted by $O_{\mathbb{Z}_p}$, and the smallest element is $\{0^{\mathbb{Z}_p} \mid n \in \mathbb{N}\} \cup \{f^{\mathbb{Z}_p} \mid f \in \mathbb{Z}_p[X], \ n \geq \text{mI}(f), \ \text{TD}(f) \subseteq M_{p-1}\}$. We define the following other sets in 2A: $\Delta_{\mathbb{Z}_p}$ denotes the set of functions induced by $0$, and $\nabla_{\mathbb{Z}_p}$ denotes the set of all functions on $\mathbb{Z}_p$.

In Figure 3 we see the lattice of clones on $\mathbb{Z}_p$ which contain $+$. 

**Figure 2.** Lattice of linearly closed iterative algebras

In Figure 3 we see the lattice of clones on $\mathbb{Z}_p$ which contain $+$. 

![Figure 2](image-url)
In this section we see that we can find the clones on $\mathbb{Z}_p$ with $+$ by another approach using a more abstract result by Hagemann and Herrmann \cite{13}.

Let $A$ be an algebra. Then $\alpha \in \text{Con}(A \times A)$ is a product congruence if there are $\beta, \gamma \in \text{Con}(A)$ such that for all $(v, w), (x, y) \in A \times A$, $(v, w)\alpha(x, y)$ if and only if $v\beta x$ and $w\gamma y$. Otherwise, we call $\alpha$ a skew congruence. We denote the smallest class of algebras which contains $A$, and which is closed under all direct unions, homomorphic images, subalgebras and direct products with finitely many factors by $\text{Loc}(A)$. Such a class is called a locally equational class. An $n$-ary partial operation on $A$ is a map $f: D \rightarrow A$ where $D \subseteq A^n$. We say that $f$ preserves a relation $B \subseteq A^I$ for some index set $I$ if for all $v_1, \ldots, v_n \in B$, $(f(v_1(i), \ldots, v_n(i)) | i \in I) \in B$. We then write $f \triangleright B$.

**Proposition 5.1** (\cite{13} Proposition 3.2). Let $A$ be an algebra. Then the following are equivalent:

1. Loc($A$) is congruence permutable and every subalgebra $B \leq A$ is simple and $B \times B$ has no skew congruences.
2. Every partial operation on $A$ which preserves isomorphisms between subalgebras of $A$ can be locally represented by terms.

Let $p$ be a prime and let $C$ be a clone on $\mathbb{Z}_p$ which contains $+$ and $C \not\subseteq \mathcal{A}_{\mathbb{Z}_p}$. Then we investigate the algebra $A := (\mathbb{Z}_p, (f)_{f \in C})$. Since $+$ is in $C$, the algebra $A$ contains a Mal’cev term $(d(x, y, z) = x - y + z)$, hence $\text{HSP}(A)$ is congruence permutable (\cite{16}) and also congruence modular (\cite{9}). We have $\text{Loc}(A) \leq \text{HSP}(A)$ (cf. \cite{5} Theorem 3.44) and thus $\text{Loc}(A)$ is congruence permutable. If $A$ contains a constant function different from 0, then the only subalgebra of $A$ is $A$ itself, otherwise also $(\{0\}, (f)_{f \in C})$ is a subalgebra of $A$. Both subalgebras are simple. Since $A$ contains a function which is not affine, the algebra is not affine and thus not abelian (\cite{12} Corollary 5.9). By \cite{6} Theorem 7.30 $\text{Con}(A \times A)$ does not...
contain a sublattice isomorphic to $M_3$, hence the algebra $A$ does not contain any skew congruences. $\{(0), (f)_{f \in C}\} \times \{(0), (f)_{f \in C}\}$ obviously does not contain any skew congruences, since the only congruence is $\{((0,0), (0,0))\}$. Now Proposition 5.1 leads to a characterization for the clones on $\mathbb{Z}_p$ with $+$ via automorphisms. Let $\text{Aut}(\mathbb{Z}_p)$ be the automorphism group of $(\mathbb{Z}_p, +)$. We know that the set of automorphisms of $(\mathbb{Z}_p, +)$ is given by the functions $\pi_a : \mathbb{Z}_p \to \mathbb{Z}_p$, $x \mapsto ax$, where $a \in \mathbb{Z}_p \backslash \{0\}$.

We have to distinguish between the cases if $C$ does not preserve $\{(0)\}$ and $C$ preserves $\{(0)\}$.

**Corollary 5.2.** Let $p$ be a prime number and let $C$ be a clone on $\mathbb{Z}_p$ which contains $+$. We assume that $C \not\subseteq A_{\mathbb{Z}_p}$ and $C$ does not preserve $\{(0)\}$. Then $C$ contains all functions on $\mathbb{Z}_p$.

**Proof.** Let $A := (\mathbb{Z}_p, (f)_{f \in C})$. The isomorphisms between the subalgebras of $A$ are the automorphisms of $(\mathbb{Z}_p, +)$. Since $C$ does not preserve $\{(0)\}$, the only automorphism which is preserved by $C$ is the identity mapping $\pi_1$. Let $g$ be a function on $\mathbb{Z}_p$. Then $g$ obviously preserves $\pi_1$. Now Proposition 5.1 yields that $g$ can be represented by terms, which means that $g \in C$. \hfill \Box

**Corollary 5.3.** Let $p$ be a prime number and let $C$ be a clone on $\mathbb{Z}_p$ which contains $+$. We assume that $C \not\subseteq A_{\mathbb{Z}_p}$ and $C$ does not preserve $\{(0)\}$. Let $R := \{\pi \in \text{Aut}(\mathbb{Z}_p) \mid \forall f \in C : f \triangleright \pi\}$ and let $g$ be a function on $\mathbb{Z}_p$. If $g$ preserves $\pi$ for all $\pi \in R$ and $g$ preserves $\{(0)\}$, then $g \in C$.

**Proof.** Let $A := (\mathbb{Z}_p, (f)_{f \in C})$. The isomorphisms between the subalgebras of $A$ are the automorphisms of $(\mathbb{Z}_p, +)$ and $h : \{0\} \to \{0\}$, $h(0) = 0$. Since $g$ preserves $\pi$ for all $\pi \in R$ and $g$ preserves $\{(0)\}$, Proposition 5.1 yields that $g$ can be represented by terms, which means that $g \in C$. \hfill \Box

Now we get a characterization for the clones on $\mathbb{Z}_p$ which contain $+$, preserve $\{(0)\}$ and are not a subset of the affine functions. We denote the set of these clones by $C^+$. Let $R$ be a set of relations on $\mathbb{Z}_p$. We denote the set of all functions on $\mathbb{Z}_p$ that preserve all relations in $R$ by $\text{Pol}(R)$.

**Theorem 5.4.** There is a bijective mapping between $C^+$ and the set of subgroups of $\text{Aut}(\mathbb{Z}_p)$.

**Proof.** We denote the set of subgroups of $\text{Aut}(\mathbb{Z}_p)$ by $S(\text{Aut}(\mathbb{Z}_p))$. Now we define $\phi : S(\text{Aut}(\mathbb{Z}_p)) \to C^+$, $R \mapsto \text{Pol}(R')$, where $R' := R \cup \{\{(0)\}\}$. Here $\text{Pol}(R')$ is the clone determined by the set of binary relations $R$ and the unary relation $\{(0)\}$. We show that $\phi$ is an isomorphism. Let $R$ be a subgroup of $\text{Aut}(\mathbb{Z}_p)$. By [20 Satz 1.2.1] $\text{Pol}(R')$ is a clone on $\mathbb{Z}_p$. 

First, we show surjectivity. Let $C \in \mathbb{C}^\ast$. Let $R := \{ \pi \in \text{Aut}(\mathbb{Z}_p) \mid \forall f \in C: f \triangleright \pi \}$. Now Corollary 5.3 yields that $R \mapsto \text{Pol}(R')$. It is left to show that $(R, \circ)$ is a subgroup of $\text{Aut}(\mathbb{Z}_p)$. To this end, it is sufficient to show that $R$ is closed under $\circ$. Let $a, b \in \mathbb{Z}_p \setminus \{0\}$ such that $\pi_a, \pi_b \in R$. Let $f \in C$. We show $f \triangleright \pi_a \circ \pi_b$. Let $n \in \mathbb{N}$ be the arity of $f$. Since $f \triangleright \pi_a$ and $f \triangleright \pi_b$ we get

$$f(\pi_a(\pi_b(x_1)), \ldots, \pi_a(\pi_b(x_n))) = af(bx_1, \ldots, bx_n) = abf(x_1, \ldots, x_n).$$

Hence $f \triangleright \pi_a \circ \pi_b$. Therefore $\pi_a \circ \pi_b \in R$.

Now we show injectivity of $\phi$. To this end, we show for two different subgroups $(R_1, \circ)$ and $(R_2, \circ)$ of $\text{Aut}(\mathbb{Z}_p)$, with $R_1 \not\subseteq R_2$ that $\text{Pol}(R'_1) \neq \text{Pol}(R'_2)$. Since the automorphism group of $\mathbb{Z}_p$ is cyclic, every subgroup of $\text{Aut}(\mathbb{Z}_p)$ is cyclic. Now let $a, b \in \mathbb{Z}_p \setminus \{0\}$ such that $\pi_a$ generates $(R_2, \circ)$ and $\pi_a$ generates $(R_1, \circ)$. Let $\text{ord}(a)$ denote the size of the subgroup of $\text{Aut}(\mathbb{Z}_p)$ generated by $\pi_a$. Since $R_1 \not\subseteq R_2$ we have $\text{ord}(b) \nmid \text{ord}(a)$. Let $g := x_1 \cdot \cdots \cdot x_{\text{ord}(a)+1}$. Now we have $g(ax_1, \ldots, ax_{\text{ord}(a)+1}) = a^{\text{ord}(a)+1}x_1 \cdot \cdots \cdot x_{\text{ord}(a)+1} = ax_1 \cdot \cdots \cdot x_{\text{ord}(a)+1}$. Thus $g$ preserves $\pi_a$ and $g$ also preserves $\{0\}$. Since $g \triangleright \pi_{ak}$ for all $k \in \mathbb{N}$, and $\pi_a$ generates $R_2$, we have $g \in \text{Pol}(R'_2)$. Now $g(bx_1, \ldots, bx_{\text{ord}(a)+1}) = b^{\text{ord}(a)+1}x_1 \cdot \cdots \cdot x_{\text{ord}(a)+1}$. Since $\text{ord}(b) \nmid \text{ord}(a)$, we have $b^{\text{ord}(a)+1} \neq b$ and hence $g$ does not preserve $\pi_b$ which means that $g \not\in \text{Pol}(R'_1)$. \hfill\Box

The automorphism group of $\mathbb{Z}_p$ is of size $p - 1$. All subgroups of $\text{Aut}(\mathbb{Z}_p)$ are given by all the divisors of $p - 1$. Therefore we get by Theorem 5.3 that $\mathbb{C}^\ast$ is isomorphic to the divisor lattice of $p - 1$. Since the only clones with $+$ which are subsets of $\mathcal{A}_{\mathbb{Z}_p}$ are the linear functions and the affine functions, we get with the help of Corollary 5.2 again the whole lattice of clones on $\mathbb{Z}_p$ with $+$ which we have already found in Figure 3.

6. A result for clones on $\mathbb{Z}_p \times \mathbb{Z}_p$

Let $p > 2$ be a prime number. The goal of this section is to show that we can embed the linearly closed clonoids on $\mathbb{Z}_p$ into clones on $\mathbb{Z}_p \times \mathbb{Z}_p$ and obtain infinitely many non finitely generated clones on $(\mathbb{Z}_p \times \mathbb{Z}_p, \oplus)$, where $\oplus$ is the componentwise addition. Let $n \in \mathbb{N}$. Then we write $\bar{x}^n$ for $(x_1, \ldots, x_n) \in \mathbb{Z}_p^n$.

Definition 6.1. Let $p$ be a prime number and let $C$ be a linearly closed clonoid on $\mathbb{Z}_p$. Then we define

$$\phi(C) := \{(\mathbb{Z}_p^n)^2 \to \mathbb{Z}_p^n, ((x_1, y_1), \ldots, (x_n, y_n)) \mapsto (l_1(\bar{x}^n) + f(\bar{y}^n), l_2(\bar{y}^n)) \mid n \in \mathbb{N}, l_1, l_2 \in \mathcal{L}^{[n]}_{\mathbb{Z}_p}, f \in C^{[n]}\}.$$

Remark: A more general embedding was introduced in a manuscript of Stefano Fioravanti [11].
Proposition 6.2. Let \( p \) be a prime number and let \( C, D \) be linearly closed clonoids on \( \mathbb{Z}_p \). Then \( \phi(C) \) is a clone on \( \mathbb{Z}_p \times \mathbb{Z}_p \) which contains \( \oplus \). Furthermore, \( C \subseteq D \) if and only if \( \phi(C) \subseteq \phi(D) \).

Proof. First we show that \( \phi(C) \subseteq \bigcup\{(\mathbb{Z}_p \times \mathbb{Z}_p)^i | i \in \mathbb{N}\} \) is a clone on \( \mathbb{Z}_p \times \mathbb{Z}_p \). To this end we show that the projections lie in \( \phi(C) \) and \( \phi(C)\phi(C) \subseteq \phi(C) \).

Let \( n \in \mathbb{N} \). We have \( 0^\mathbb{Z}_p^i \in C \), and the projection \( \pi^\mathbb{Z}_p^i \in \mathcal{L}_{\mathbb{Z}_p} \) for all \( j \leq n \). Hence \( \Pi^\mathbb{Z}_p^j : (\mathbb{Z}_p^2)^n \rightarrow \mathbb{Z}_p^2, ((x_1, y_1), \ldots, (x_n, y_n)) \mapsto (x_j, y_j) \) lies in \( \phi(C) \) for all \( j \leq n \).

Now we show \( \phi(C)\phi(C) \subseteq \phi(C) \). To this end, let \( n, m \in \mathbb{N} \), let \( g \in \phi(C)^[m] \) and let \( f_1, \ldots, f_n \in \phi(C)^{[n]} \). Now we show \( g(f_1, \ldots, f_n) \in \phi(C) \). For \( i \leq n \), let \( l_i, l'_i \in \mathcal{L}_{\mathbb{Z}_p} \) and \( h_i \in C \) such that

\[
f_i((x_1, y_1), \ldots, (x_m, y_m)) = (l_i(x^m) + h_i(y^m), l'_i(y^m)).
\]

Now let \( k_1, k_2 \in \mathcal{L}_{\mathbb{Z}_p} \) and \( g' \in C \) such that

\[
g((x_1, y_1), \ldots, (x_n, y_n)) = (k_1(x^n) + g'(y^n), k_2(y^n)).
\]

Now we have

\[
\begin{align*}
&(g(f_1, \ldots, f_n))(x_1, y_1, \ldots, x_m, y_m) \\
&= g\left(f_1((x_1, y_1), \ldots, (x_m, y_m)), \ldots, f_n((x_1, y_1), \ldots, (x_m, y_m))\right) \\
&= g\left((l_1(x^m) + h_1(y^m), l'_1(y^m)), \ldots, (l_n(x^m) + h_n(y^m), l'_n(y^m))\right) \\
&= \left(k_1\left((l_1(x^m) + h_1(y^m)), \ldots, (l_n(x^m) + h_n(y^m))\right) + g'\left(l'_1(y^m), \ldots, l'_n(y^m)\right), \\
&\quad k_2\left(l'_1(y^m), \ldots, l'_n(y^m)\right)\right) \\
&= \left(k_1(l_1(x^m), \ldots, l_n(x^m)) + k_1(h_1(y^m), \ldots, h_n(y^m)) \\
&\quad + g'\left(l'_1(y^m), \ldots, l'_n(y^m)\right), k_2(l'_1(y^m), \ldots, l'_n(y^m))\right).
\end{align*}
\]

Since \( h_1, \ldots, h_n \in C \) and \( g' \in C \) we have by the axioms of a linearly closed clonoid that \( k_1(h_1(y^m), \ldots, h_n(y^m)) + g'(l'_1(y^m), \ldots, l'_n(y^m)) \in C \). We also have \( \mathcal{L}_{\mathbb{Z}_p} \mathcal{L}_{\mathbb{Z}_p} \subseteq \mathcal{L}_{\mathbb{Z}_p} \) and thus we see that \( g(f_1, \ldots, f_n) \) lies in \( \phi(C) \).

Obviously, \( \oplus \) lies in \( \phi(C) \). This concludes the proof that \( \phi(C) \) is a clone on \( \mathbb{Z}_p \times \mathbb{Z}_p \) which contains \( \oplus \).

Now we show \( C \subseteq D \) if and only if \( \phi(C) \subseteq \phi(D) \).

\( \Rightarrow \): Holds by the definition of \( \phi \).
“⇐” Let $n \in \mathbb{N}$ and let $f \in C[n]$. Then $\bar{f} : (\bar{x}, \bar{y}) \in \phi(C)$ since $0 \bar{Z}_p \in \mathcal{L}_p$. Then $\bar{f} \in \phi(D)$ and thus $f \in D$. \hfill \Box

**Theorem 6.3.** Let $p > 2$ be a prime number. Then there are infinitely many non finitely generated clones on $\mathbb{Z}_p \times \mathbb{Z}_p$ which contain $\oplus$.

**Proof.** Let $C$ be a linearly closed clonoid which is not finitely generated. Then let $(C_i)_{i \in \mathbb{N}}$ be an infinite ascending chain of linearly closed clonoids on $\mathbb{Z}_p$ such that $C = \bigcup \{C_i \mid i \in \mathbb{N}\}$. By Proposition 6.2 $\phi$ is an embedding from the lattice of linearly closed clonoids on $\mathbb{Z}_p$ to the lattice of clones on $\mathbb{Z}_p \times \mathbb{Z}_p$, and thus $(\phi(C_i))_{i \in \mathbb{N}}$ is an infinite ascending chain of clones on $\mathbb{Z}_p \times \mathbb{Z}_p$ which contain $\oplus$. Then $\phi(C) = \bigcup \{\phi(C_i) \mid i \in \mathbb{N}\}$ is not finitely generated. By Proposition 4.1 we know that there are infinitely many non finitely generated linearly closed clonoids on $\mathbb{Z}_p$ and thus there are infinitely many non finitely generated clones on $\mathbb{Z}_p \times \mathbb{Z}_p$ which contain $\oplus$. \hfill \Box

**Remark:** The generalization from $\mathbb{Z}_p$ to any abelian group of prime power order is not straightforward, since in the case of an abelian group of prime power order the clone generated by $+$ does not contain all possible endomorphisms. So the proof of Lemma 3.9 does not work for an abelian group of prime power order in general.

**Acknowledgements**

The author thanks Erhard Aichinger, who has inspired this work, and Stefano Fioravanti for many hours of helpful discussions. The author is also grateful to the anonymous referee for a very careful report.
