

Maps of manifolds of the same dimension with prescribed Thom-Boardman singularities

Andrey Ryabichev*

Abstract

In this paper we extend Y. Eliashberg's h -principle to arbitrary generic smooth maps of smooth manifolds. Namely, we prove a necessary and sufficient condition for a continuous map of smooth manifolds of the same dimension to be homotopic to a generic map with a prescribed Thom-Boardman singularity Σ^I at each point. In dimension 3 we rephrase these conditions in terms of the Stiefel-Whitney classes and the cohomology classes of the given loci of folds, cusps and swallowtail points.

1 Introduction

All manifolds and maps between them are assumed to be infinitely smooth unless we explicitly specify otherwise. All manifolds are assumed to be without boundary. We fix two n -manifolds M and N , $n > 1$.

1.1 Thom-Boardman maps and generic maps

We begin with the Thom-Boardman classification of singularities. Let $f : M \rightarrow N$ be a smooth map. For a nonnegative integer $i_1 \leq n$ denote the set of points $x \in M$ such that $\dim(\ker df(x)) = i_1$ by $\Sigma^{i_1}(f)$. For “almost every” map f the set $\Sigma^{i_1}(f) \subset M$ is a (locally closed) smooth submanifold. Then for a nonnegative integer $i_2 \leq i_1$ let $\Sigma^{i_1, i_2}(f)$ be the set of points $x \in \Sigma^{i_1}(f)$ such that $\dim(\ker df|_{\Sigma^{i_1}(f)}(x)) = i_2$. Similarly, for every sequence $I = i_1, i_2, \dots, i_r$ of integers such that $n \geq i_1 \geq i_2 \geq \dots \geq i_r \geq 0$ we have a subset $\Sigma^I(f) \subset M$.

Also, the set $\Sigma^I(f)$ can be defined as the preimage of a certain submanifold $\Sigma^I(M, N) \subset J^r(M, N)$ of the r -jet space. If the jet extension $j^r(f)$ is transversal to $\Sigma^I(M, N)$, then both definitions coincide (the details can be found in [4], see also [3, §2]). For dimension reasons, we can take $r = n + 1$. In the sequel as I we will take sequences i_1, i_2, \dots, i_r such that $n \geq i_1 \geq i_2 \geq \dots \geq i_r \geq 0$ and $i_1 > 0$.

The Thom-Boardman submanifolds $\Sigma^I(M, N) \subset J^r(M, N)$ for different I do not intersect. Let $\Sigma(M, N)$ be the set of *critical r -jets* of maps $M \rightarrow N$, i.e. jets which correspond to the germs of maps at critical points. It is well known that the Thom-Boardman decomposition $\Sigma(M, N) = \bigsqcup_I \Sigma^I(M, N)$ is not a stratification [4, p.48]. However, since the intersections of $\Sigma^I(M, N) \subset J^r(M, N)$ with the fibers of the projection $J^r(M, N) \rightarrow M \times N$ are (locally

* IUM; Moscow, Russia // ryabichev@179.ru // Supported in part by Young Russian Mathematics award

closed) algebraic subsets, one can choose a stratification of $\Sigma(M, N)$ which is a subdivision of the Thom-Boardman decomposition. We review the definitions and discuss the existence of such a subdivision in §2.2.

If the jet extension $j^r(f) : M \rightarrow J^r(M, N)$ of a map $f : M \rightarrow N$ is transversal to all $\Sigma^I(M, N)$, then we call f a *Thom-Boardman map*, and if $j^r(f)$ is transversal to all strata of $\Sigma(M, N)$, then we say that f is *generic*. Clearly, every generic map is Thom-Boardman.

By the Thom transversality theorem generic maps $M \rightarrow N$ form a dense open subset in the set of all C^∞ -maps $M \rightarrow N$ equipped with the strong Whitney topology (see e.g. [14, §3.2]). The set of Thom-Boardman maps is always dense in this space, but it is not open for $n > 3$ (see e.g. [26]).

For a generic map f the set of its critical points $\Sigma(f) = j^r(f)^{-1}(\Sigma(M, N))$ is a stratified subset of M . Every stratum $C \subset \Sigma(f)$ belongs to a certain $\Sigma^I(f)$, and for dimension reasons the sequence I has a zero at the end. Therefore the restriction $f|_C$ is an immersion $C \rightarrow N$.

1.2 Prescribed singularities

We will now define the notion of “prescribed singularities”. Recall that if n is sufficiently large, then the Thom-Boardman singularities Σ^I are in general not stable, see e.g. [3, §3.7]. In particular, for a fixed I the germs of a given generic map f at two points $x, x' \in \Sigma^I(f)$ may not be equivalent. Therefore we need to specify the germ of a generic map at each critical point.

Namely, we fix a nonempty closed subset $S \subset M$. Suppose we are given a collection of open subsets $U_i \subset M$ such that $S \subset \bigcup U_i$, and a collection of n -manifolds V_i (here $i = 1, 2, \dots$ runs through a fixed, possibly countably infinite, set of values). Suppose for all i we are given generic maps $\varphi_i : U_i \rightarrow V_i$ such that $S = \bigcup \Sigma(\varphi_i)$.

We call the collection $\{\varphi_i\}$ *locally compatible*, if for every i, j the germs of φ_i and φ_j at every point $x \in U_i \cap U_j$ are *L-equivalent*. This means that there are neighborhoods $U_x \ni x$, $V_x \supset \varphi_i(U_x)$ and $V'_x \supset \varphi_j(U_x)$ and a diffeomorphism $\beta_x : V_x \rightarrow V'_x$ such that $\beta_x \circ \varphi_i|_{U_x} = \varphi_j|_{U_x}$. Note that, if the collection $\{\varphi_i\}$ is locally compatible, then S turns out to be a stratified subset since φ_i are generic (see §2.3, Theorem 3).

We say that a map $f' : M \rightarrow N$ has *prescribed singularities* if $\Sigma(f') = S$ and for every i the germs of f' and φ_i at every point $x \in U_i$ are *L-equivalent*. In this paper we address the following question.

Question. *When does there exist a generic map $M \rightarrow N$ that has prescribed singularities?*

1.3 Twisted tangent bundle

Take a locally compatible collection of maps $\{\varphi_i\}$ as above. Next we will construct a rank n vector bundle $T^{\{\varphi_i\}}M$ over M , called the *twisted tangent bundle*. It plays the main role in our construction.

First we set $U_0 = V_0 = M \setminus S$ and $\varphi_0 = \text{Id} : U_0 \rightarrow V_0$. If we add φ_0 to the collection $\{\varphi_1, \varphi_2, \dots\}$, the collection remains locally compatible. Note that then the domains of the maps cover the whole of M .

Next, for every $i = 0, 1, \dots$ we define a vector bundle $E_i \rightarrow U_i$ as the pullback $\varphi_i^*(TV_i)$. Since the collection $\{\varphi_i\}$ is locally compatible, for every i, j and every point $x \in U_i \cap U_j$ we

have an isomorphism of the fibers $d\beta_x : E_i|_x \rightarrow E_j|_x$, where the map β_x establishes an L -equivalence of germs of φ_i and φ_j at x , see above. The isomorphism $d\beta_x$ does not depend on the choice of β_x (see Proposition 9 in §4.2), so we can canonically define an isomorphism $\Phi_{i,j} : E_i|_{U_i \cap U_j} \rightarrow E_j|_{U_i \cap U_j}$ over the whole of $U_i \cap U_j$.

The vector bundle $T^{\{\varphi_i\}}M$ is obtained by gluing E_i via $\Phi_{i,j}$, $i, j = 0, 1, \dots$. We discuss this definition in detail in §4.2.

We suggest the bundle $T^{\{\varphi_i\}}M$ up to isomorphism can be described in terms of the stratification of S and some additional discrete data defined by the germs φ_i , but this conjecture remains unproven at present.

1.4 The h -principle

In [6] Y. Eliashberg proved a theorem, which is important for global singularity theory. It may be rephrased with our terminology in the following way. We discuss its relative version in §2.4.

Theorem ([6, Th. A]). *Suppose $S \subset M$ is a codimension 1 submanifold and the maps $\{\varphi_i\}$ have only fold singularities $\Sigma^{1,0}$. Then a continuous map $f : M \rightarrow N$ is homotopic to a map f' with folds in S and with no other critical points if and only if the vector bundles $T^{\{\varphi_i\}}M$ and $f^*(TN)$ are isomorphic.*

We generalize this theorem and allow the maps $\{\varphi_i\}$ to have arbitrary generic singularities. These maps need to be locally compatible (as in §1.2) for the construction to make sense. The following is the main result of the paper.

Theorem 1. *A continuous map $f : M \rightarrow N$ is homotopic to a generic map f' with prescribed singularities if and only if the vector bundles $T^{\{\varphi_i\}}M$ and $f^*(TN)$ are isomorphic.*

For our proof is necessary that the maps φ_i should be generic. Namely, we use the fact that S is a stratified subset and for every stratum $C \subset S$ and every i the restriction $\varphi_i|_{C \cap U_i}$ is an immersion. We study the properties of such maps in §3. Also, our proof uses a relative version of Eliashberg's theorem (see §2.4), so it is necessary that the subset of points of S where φ_i have fold singularities should be nonempty.

Another approach to an h -principle

There are important results of Y. Ando on maps with prescribed singularities. In [1] he proved a criterion for a map between manifolds to be homotopic to a map which has Thom-Boardman singularities *not worse* (lexicographically) than a given sequence I . This criterion is stated in terms of jets.

The difference between Theorem 1 and the Y. Ando's theorem is that we start with a more detailed set of data (compatible germs at all points of the critical locus instead of a jet section over the whole of M) and as a result we obtain a map with a prescribed singularity *at each point*, while with Ando's approach one does not control either the singularities that appear or the loci of singularities of each type.

1.5 Application to 3-manifolds

Suppose $n = 3$. Then in order to specify prescribed singularities of a generic map one does not need to specify germ at each point of S . Namely, for a generic map $f : M \rightarrow N$ the set of critical points $\Sigma(f)$ is the union of the fold points $\Sigma^{1,0}(f)$, the cusp points $\Sigma^{1,1,0}(f)$ and the swallowtail points $\Sigma^{1,1,1,0}(f)$. These are called *Morin singularities*. These singularities are stable and singularities of the same type are always equivalent [18], [25].

Recall that for every I the set $\Sigma^I \subset J^r(M, N)$ is a smooth submanifold ([4, §6]). So for a generic map $f : M \rightarrow N$ of closed 3-manifolds the set $\Sigma^1(f) \subset M$ is a smooth closed 2-submanifold, the set $\Sigma^{1,1}(f) \subset \Sigma^1(f)$ is a smooth closed 1-submanifold and the set $\Sigma^{1,1,1}(f) = \Sigma^{1,1,1,0}(f) \subset \Sigma^{1,1}(f)$ is a discrete subset. See the details e.g. in [3, pp. 47-48].

We deduce from Theorem 1 the following necessary and sufficient condition for a given continuous map of 3-manifolds to be homotopic to a generic one that has a prescribed singular locus. In the sequel, for a codimension k submanifold $M' \subset M$ we denote the Poincaré dual class of M' in $H^k(M; \mathbb{Z}_2)$ by $[M']$.

Theorem 2. *Suppose M, N are closed 3-manifolds, $S \subset M$ is a nonempty closed 2-submanifold, $C \subset S$ is a closed 1-submanifold and $P \subset C$ is a discrete subset. A continuous map $f : M \rightarrow N$ is homotopic to a generic map f' such that $\Sigma^1(f') = S$, $\Sigma^{1,1}(f') = C$ and $\Sigma^{1,1,1}(f') = P$ if and only if*

- $[S] = w_1(M) + f^*w_1(N)$,
- $[C] = w_1(M) \cdot [S]$ and
- for every component $C' \subset C$ we have $[C'] \cdot [S] \equiv |P \cap C'| \pmod{2}$.

The last condition is needed in order for a characteristic vector field on $C \setminus P$ (see §5.2, Fig. 3) to exist. Moreover, if this condition holds, there are exactly two such vector fields, and a generic map f' can be constructed for each of them.

Note that if a map f' as in Theorem 2 exists, then the conditions of Theorem 2 agree with the Thom polynomial of the Morin singularities. Namely, denote the degree i component of $f'^*w(N)/w(M)$ by \bar{w}_i . Then it is well known that $[\Sigma^1(f')] = \bar{w}_1$, $[\Sigma^{1,1}(f')] = \bar{w}_1^2 + \bar{w}_2$ and $[\Sigma^{1,1,1}(f')] = \bar{w}_1^3 + \bar{w}_1\bar{w}_2$ (see e.g. [2, p. 191]). All these equalities follow from Theorem 2.

Other low-dimensional consequences

In [20] we proved a necessary and sufficient condition for a map of surfaces to be homotopic to a generic map with prescribed folds and cusps. This result is similar to Theorem 2, but it also uses cohomology with local coefficients. In [20] we also proved a necessary and sufficient condition for a pair of surfaces to have a generic map between them which has prescribed folds and cusps.

In other words, for surfaces we can find a generic map with prescribed singularities *among all maps*, while for 3-manifolds we can solve a similar problem *only for maps from a given homotopy class*. However, we can obtain e.g. the following results on generic maps with prescribed singularities using Theorem 2:

Corollary 1. *Suppose M, N are integral homology 3-spheres. Then every map $M \rightarrow N$ is homotopic to a map with any given nonempty set of folds and with no other critical points.*

Corollary 2. *Suppose M, N are closed orientable 3-manifolds, $S \subset M$ is a nonempty codimension 1 submanifold and $[S] = 0$. Then every map $M \rightarrow N$ is homotopic to a map with folds in S and with no other critical points.*

Presumably there are analogues of Theorem 2 for manifolds of dimension 4 and higher. In order to deduce them one would need to describe the twisted tangent bundle (and its characteristic classes) in terms of strata of the singular locus.

Structure of the paper

In §2.2 we recall the definition of Whitney stratification and then in §2.3 we prove that the critical locus of a generic map admits a natural stratification. In §2.4-2.5 we recall the results from [6] and [7] which will be used in the proof of Theorem 1. In §2.6 we give a few definitions of equivalence of germs which are discussed in detail in Appendix A.

In §3.1-3.5 we prove some technical properties of local behavior of generic maps near the strata which we need to prove that locally L -equivalent generic germs at a stratum of the critical set are globally L -equivalent. In §4.1-4.2 we construct the twisted tangent bundle and then in §4.3 we prove Theorem 1.

In §5.1 we discuss the classification of rank 3 vector bundles over 3-manifolds. Then in §5.2-5.3 we give a combinatorial description of the twisted tangent bundle for $n = 3$ and compute its Stiefel-Whitney classes. Finally, in §5.4 we deduce Theorem 2.

Acknowledgments

I wish to thank Alexey Gorinov for helpful suggestions and conversations. Also I am grateful to Maxim Kazarian, Sergey Melikhov, Sergey Natanzon, Petr Pushkar, Victor Vassiliev and Vladimir Zhgun for useful discussions and advice.

2 Preliminaries

2.1 Notation

Suppose we are given a topological space X and a subset $A \subset X$. When we write “a neighborhood $A \subset U \subset X$ ”, this means that U is an open neighborhood of the subset A in the ambient space X . We use the M. Gromov’s notation $\mathcal{O}p(A)$ for a “sufficiently small neighborhood of A ” (see e. g. [11] or [8]).

When we consider a collection of objects A_i , where i belongs to some set of indices \mathfrak{I} , this is always written as $\{A_i\}$ instead of $\{A_i\}_{i \in \mathfrak{I}}$. In most situations the index i takes values in $\mathbb{Z}_{\geq 0}$ or in $\{0, 1, \dots, k\}$ for some k . We specify the set of values of the index when this is necessary.

Suppose we have a set X and a collection $\{X_i\}$ of its subsets. We say that $\{Y_i\}$ is a *refinement* of $\{X_i\}$, if every Y_i is a subset of certain X_j and every X_i can be presented as a union $Y_{i_1} \cup Y_{i_2} \cup \dots$. When we consider *covers* of a fixed subset $Z \subset X$ (i. e. $Z \subset \bigcup X_i$), then $\{Y_i\}$ is called a *refinement* of $\{X_i\}$, if every Y_i is a subset of certain X_j and $Z \subset \bigcup Y_i$.

Covers always supposed *open* unless we explicitly specify otherwise.

2.2 Transversality and stratifications

First we recall main definitions.

Let X_1, X_2, Y be manifolds of arbitrary dimensions. The maps $f_1 : X_1 \rightarrow Y$ and $f_2 : X_2 \rightarrow Y$ are called *transversal* if for every $x_1 \in X_1$ and $x_2 \in X_2$ such that $f_1(x_1) = f_2(x_2) = y$, we have $\text{Im}(df_1(x_1)) + \text{Im}(df_2(x_2)) = T_y Y$. Similarly, submanifolds of Y are *transversal* if their imbedding maps are transversal.

Note that by the implicit function theorem the intersection of transversal submanifolds is a smooth submanifold. Let $E \rightarrow X$ be a vector bundle over a manifold. A collection of sections $\{f_i : X \rightarrow E\}$ is said to be *in general position*, if every f_i is transversal to the intersection of any collection of $f_j(X)$, $j \neq i$.

A *stratified subset* of a manifold X is a locally finite disjoint union of submanifolds (called *strata*) such that the following three conditions are satisfied. The first condition is called *the frontier condition*, we denote it by (fr). Conditions (a) and (b) are called Whitney regularity conditions, they were introduced in [24].

- (fr) The closure of every stratum is a union of this stratum and certain strata of strictly smaller dimension.
- (a) For every strata C, C' , if a sequence $\{x_i\}$, $x_i \in C$, converges to a point $y \in C'$ and $\lim(T_{x_i} C) = T \subset T_y X$, then we have $T \supset T_y C'$.
- (b) For every strata C, C' , if sequences $\{x_i\}$, $x_i \in C$, and $\{y_i\}$, $y_i \in C'$, both converge to a point $y \in C'$, for lines $\overline{x_i y_i}$ (in some local coordinates near the point y) we have $\lim \overline{x_i y_i} = l$ and $\lim(T_{x_i} C) = T \subset T_y X$, then we have $T \supset l$.

Note that condition (b) implies conditions (a) and (fr), see e. g. [23]. The properties of stratified subsets are discussed also in [10, Part I, §1].

Let X, X' be manifolds and let $Y \subset X$ be a stratified subset. A map $f : X' \rightarrow X$ is called *transversal to Y* if it is transversal to every stratum. By the Thom transversality theorem such maps form a dense open subset in $C^\infty(X', X)$. If f is transversal to Y , then $f^{-1}(Y) \subset X'$ is a stratified subset whose strata are the preimages of the strata of Y (see e. g. [10, Part I, §1.3]). In particular, by the implicit function theorem, these preimages are smooth submanifolds of X' .

2.3 The stratification of the jet space

We need to define generic maps so that the set of the critical points of a generic map has a stratification which is invariant under coordinate transformations. It is sufficient to show that the Thom-Boardman decomposition admits a Diff-invariant refinement which is a stratification. The existence of such a refinement is purely natural, it was mentioned in 1973 by J. N. Mather in [16, p. 247] without a proof. Next we prove this assertion, see Theorem 3 below.

First let us prove the following proposition which generalizes the well known result on stratifications of semialgebraic sets [10, Part I, Th. 1.7]. Recall, a subset $Y \subset \mathbb{R}^m$ is called *semialgebraic* if Y is the union of sets given by a finite system of polynomial (in)equations, i. e. of sets of the form

$$\{x \in \mathbb{R}^m \mid f_1(x) = 0, \dots, f_k(x) = 0, g_1(x) > 0, \dots, g_l(x) > 0\},$$

where $f_i, g_i : \mathbb{R}^m \rightarrow \mathbb{R}$ are polynomial functions. Note that the intersection, the union and the difference of semialgebraic sets are always semialgebraic sets. The closure of every semialgebraic set is also a semialgebraic set (see e. g. [5]).

Proposition 1. *Suppose $X_1, \dots, X_k \subset \mathbb{R}^m$ is a collection of semialgebraic sets, $X = \bigcup X_i$ is closed. Suppose a group G acts on \mathbb{R}^m by polynomial diffeomorphisms preserving every X_i . Then X admits a stratification such that every X_i is a union of strata and the action of G preserves every stratum.*

Proof. We will construct a stratification of X by induction on $d = \max(\dim X_i)$. If $d = 0$, then X is a discrete subset of \mathbb{R}^m . Then we may take X_i just to be our strata.

Suppose $d \geq 1$. We may assume that the sets X_i do not intersect each other. Otherwise we replace the collection $\{X_i\}$ by the refinement which sets are of the form

$$\left(\bigcap_{i \in A} X_i \right) \setminus \left(\bigcup_{i \notin A} X_i \right) \quad \text{for all } A \subset \{1, \dots, k\}.$$

Suppose $\dim X_1 = \dots = \dim X_s = d$ and $\dim X_{s+1} < d, \dots, \dim X_k < d$. Let $Y_i = X_i \setminus \text{Sing}(X)$ and $Z_i = \overline{X_i} \setminus Y_i$ for $i = 1, \dots, s$. Here $\text{Sing}(X)$ denotes the set of singular points of X and smooth points of X with the dimension of the tangent space $< d$. Clearly, $\overline{Y_i}$ do not cross Y_j for any $i, j \leq s, i \neq j$. We set Y_1, \dots, Y_s to be d -dimensional strata of our stratification.

Take the collection $\Omega = \{Z_1, \dots, Z_s, X_{s+1}, \dots, X_k\}$. If needed we can use the operation of refinement mentioned above, so further we may assume that the elements of Ω are also disjoint (if some of them coincide, we take them only once). Note that for every $V \in \Omega$ we have $\dim V < d$.

Finally, take any Y_i , and any $V \in \Omega$. Note that either $\overline{Y_i} \cap V = \emptyset$, or $\overline{Y_i} \cap V = V$. Suppose the latter case takes place. The set of points $y \in V$ at which the Whitney's regularity condition (b) does not hold is a semialgebraic set which have *positive codimension* in V , see [15] and [19]. Denote it by W . If $W \neq \emptyset$, we remove V from Ω and add W and $V \setminus W$ to Ω . Then we repeat this procedure to Y_i and W , etc.

After a finite number of steps we eventually obtain a refinement of Ω such that for any Y_i and any $V \in \Omega$ the Whitney's regularity condition (b) holds. Note that if we again replace Ω by any refinement, this property will not be violated. So we can apply the induction hypothesis to Ω to obtain a stratification of X .

Recall that the action of G preserves every X_i . This action is polynomial, so it preserves also $\text{Sing}(X)$ and all operations of subsets such as intersection, union etc., as well as the property that the Whitney's regularity condition (b) holds or not. Therefore the resulting sets of all the described refinements are also preserved by the action of G . \square

Theorem 3. *For any pair of manifolds U, V the set $\Sigma(U, V) \subset J^r(U, V)$ admits a stratification which is a refinement of the Thom-Boardman decomposition and which is invariant under the right action of $\text{Diff}(U)$ and the left action of $\text{Diff}(V)$.*

Such a stratification can be chosen functorially with respect to open imbeddings. More precisely, for open subsets $U' \subset U$ and $V' \subset V$ the stratification of $\Sigma(U', V')$ is equal to the intersection of $J^r(U', V') \subset J^r(U, V)$ with the stratification of $\Sigma(U, V)$.

Proof. Take $x \in U$ and $y \in V$. By choosing local coordinates we can identify the space of r -jets $J_{x,y}^r(U, V)$ of maps that take x to y with \mathbb{R}^m for some m .

For every sequence I of length r the intersection $\Sigma^I(U, V) \cap J_{x,y}^r(U, V) \subset \mathbb{R}^m$ is a variety ([4, §2]; see also [3, §2.5]). Let $X = \Sigma(U, V) \cap J_{x,y}^r(U, V)$ and $X^I = \Sigma^I(U, V) \cap J_{x,y}^r(U, V)$.

The groups $\text{Diff}_x(U)$ and $\text{Diff}_y(V)$ of diffeomorphisms of U , respectively V , which preserve x , respectively y , act on $J_{x,y}^r(U, V)$ by polynomial diffeomorphisms. These actions preserve all X^I . Then we can apply Proposition 1 to $\mathbb{R}^m = J_{x,y}^r(U, V)$, the collection of semialgebraic sets $\{X^I\}$ and the action of the group $G = \text{Diff}_y(V) \times \text{Diff}_x(U)$. We obtain a G -invariant stratification of $\Sigma(U, V) \cap J_{x,y}^r(U, V)$. Every stratum of the stratification lies in some Thom-Boardman submanifold.

Then using the action of $\text{Diff}(V) \times \text{Diff}(U)$ we can transfer this stratification from $J_{x,y}^r(U, V)$ to $J_{x',y'}^r(U, V)$ for all $(x', y') \in U \times V$. As the original stratification is G -invariant, the result is well defined. We define the strata of $\Sigma(U, V)$ as the images of the strata of X under such identifications for all (x', y') .

We have naturally constructed the stratifications on the fibers of the bundle $J^r(U, V) \rightarrow U \times V$. The space $J^r(U', V')$ can be viewed as the restriction of this bundle to $U' \times V' \subset U \times V$, so the functoriality follows. \square

Recall from §1.1 that a map $\varphi : U \rightarrow V$ is called *generic* if and only if $j^r(\varphi)$ is transversal to every stratum of $\Sigma(U, V)$.

2.4 The h -principle for maps with fold singularities

In the proof of Theorem 1 we will use the following theorem from [6, Th. 2.2]. Let us briefly recall the notation.

If $p : E \rightarrow X$ and $p' : E' \rightarrow Y$ are vector bundles, $f : X \rightarrow Y$ is a continuous map and $F : E \rightarrow E'$ is a fiberwise map such that $p' \circ F = f \circ p$, then we say that F *covers* f .

Suppose $C \subset M$ is a codimension 1 closed submanifold without boundary. A C -immersion $M \rightarrow N$ is a map with fold singularities $\Sigma^{1,0}$ along C and no other critical points. A fiberwise map of tangent bundles $F : TM \rightarrow TN$ is called a C -monomorphism if the restrictions $F|_{T(M \setminus C)}$ and $F|_{TC}$ are fiberwise injective and there exist an involution $h : \mathcal{O}p(C) \rightarrow \mathcal{O}p(C)$ with the set of fixed points equal C and such that over $\mathcal{O}p(C)$ we have $F \circ dh = F$.

Let $D \subset M$ be a closed n -submanifold with boundary such that every component of $M \setminus D$ intersects C and let $f_0 : D \rightarrow N$ be a smooth map. Denote the space of maps $f : M \rightarrow N$ such that $f|_D \equiv f_0$ and $f|_{M \setminus D}$ is a C -immersion by $\text{Imm}_{C,D}(M, N)$. Let $\text{Mon}_{C,D}(TM, TN)$ be the space of fiberwise maps $F : TM \rightarrow TN$ such that $F|_{TD} \equiv df_0$ and $F|_{T(M \setminus D)}$ is a C -monomorphism.

Theorem 4 (Eliashberg). *The map $\pi_0(\text{Imm}_{C,D}(M, N)) \rightarrow \pi_0(\text{Mon}_{C,D}(TM, TN))$ induced by taking the differential is surjective.* \square

In other words, every $F \in \text{Mon}_{C,D}(TM, TN)$ can be deformed to the differential of a C -immersion in the class of C -monomorphisms fixed over D . In particular, if $\text{Mon}_{C,D}(TM, TN)$ is nonempty, then $\text{Imm}_{C,D}(M, N)$ is nonempty.

2.5 The h -principle for immersions

We will also use the following theorem, known as the relative Gromov's h -principle for immersions of open manifolds. This result generalizes Smale's and Hirsch's theorems on immersions from [12], [13] and [21]. (Here we state only the partial case of this theorem that we will use.)

Let U, V be n -manifolds with U noncompact. Suppose we are given a continuous map $f : U \rightarrow V$ and a fiberwise isomorphism $F : TU \rightarrow TV$ covering f . Suppose there is a compact n -submanifold with boundary $D \subset U$ such that the restriction $f|_D$ is smooth and $F|_D = df|_D$, and such that for some polyhedron $K \subset U$ of positive codimension U can be compressed into an arbitrarily small neighborhood of $K \cup D$ by an isotopy fixed on D .

Theorem 5 (Gromov). *There exists an immersion $f' : U \rightarrow V$ such that F is homotopic to df' in the class of fiberwise isomorphisms fixed over D .* \square

This theorem can be deduced by using the holonomic approximation theorem, see [7, Th. 1.2.1]. See also [8, §3] or [11, §1.1.3] for more details.

2.6 Local and global equivalences of germs

Here we recall the definitions of local and global (L -)equivalences of germs.

Let $S \subset M$ be a locally closed subset of a manifold. Suppose we are given maps $\varphi_1 : U_1 \rightarrow V_1$ and $\varphi_2 : U_2 \rightarrow V_2$ from neighborhoods $U_1, U_2 \supset S$ to some n -manifolds V_1, V_2 .

Definition 1. The S -germs of φ_1 and φ_2 are called *globally equivalent* if there are a neighborhood $U_3 \supset S$, an n -manifold V_3 , a map $\varphi_3 : U_3 \rightarrow V_3$, immersions $\alpha_1 : U_3 \rightarrow U_1$ and $\alpha_2 : U_3 \rightarrow U_2$ restricting to the identity on S , and immersions $\beta_1 : V_3 \rightarrow V_1$ and $\beta_2 : V_3 \rightarrow V_2$ such that the diagram

$$\begin{array}{ccccc} U_1 & \xleftarrow{\alpha_1} & U_3 & \xrightarrow{\alpha_2} & U_2 \\ \varphi_1 \downarrow & & \varphi_3 \downarrow & & \varphi_2 \downarrow \\ V_1 & \xleftarrow{\beta_1} & V_3 & \xrightarrow{\beta_2} & V_2 \end{array}$$

commutes.

The S -germs of φ_1 and φ_2 are called *globally L -equivalent* if they are globally equivalent, and in addition to that U_3 can be taken to be a subset of $U_1 \cap U_2$ and the maps α_1, α_2 can be taken to be the inclusions.

Definition 2. The S -germs of φ_1 and φ_2 are called *locally equivalent* if for any point $x \in S$ the germs of φ_1 and φ_2 at x are globally equivalent.

The S -germs of φ_1 and φ_2 are called *locally L -equivalent* if for every point $x \in S$ the germs of φ_1 and φ_2 at x are globally L -equivalent.

We discuss these definitions in details in Appendix A. In particular, we will prove that they are actually equivalence relations and that locally (L -)equivalent germs may not be globally (L -)equivalent.

3 Local behavior of generic maps

In this section we study some properties of generic maps which we need to prove Theorem 1. It turns out that the properties hold for a wider class of maps.

3.1 Stratified immersions

Let X be a topological space. We say that a subset $A \subset X$ has *dense interior*, if $\overline{\text{int}(A)} \supset A$.

Proposition 2. *Let V and V' be n -manifolds. Suppose a subset $R \subset V$ has dense interior. Let $\alpha, \beta : V \rightarrow V'$ be maps such that $\alpha|_R \equiv \beta|_R$. Then $d\alpha|_R \equiv d\beta|_R$.*

Proof. Note that $d\alpha|_x = d\beta|_x$ for every $x \in \text{int}(R)$. Then the statement of the proposition directly follows from the continuity of the derivatives. \square

Definition 3. Let U, V be n -manifolds. A map $\varphi : U \rightarrow V$ is called a *stratified immersion*, if there is a stratification of U such that the restriction of φ to any stratum is an immersion.

The union of strata of dimension $< n$ is called *the skeleton* of the stratified immersion. Note that the skeleton can be viewed as a subcomplex of positive codimension in U (one can use e.g. the results of [9] to show that).

Remark 1. Any generic map of n -manifolds is a stratified immersion. Indeed, we can define a dimension n stratum of the source manifold as the set of regular points, and then define a stratification of the set of critical points using Theorem 3.

Proposition 3. *Let U, V and V' be n -manifolds. Suppose $\varphi : U \rightarrow V$ is a stratified immersion and $\alpha, \beta : V \rightarrow V'$ are maps such that $\alpha \circ \varphi = \beta \circ \varphi$. Then $d\alpha|_x = d\beta|_x$ for every $x \in \varphi(U)$.*

Proof. Denote the complement of the skeleton of φ by U° . Recall that $\varphi|_{U^\circ}$ is an immersion, so all points of U° are regular for φ . Therefore all points of $\varphi(U^\circ)$ are interior points of $\varphi(U)$.

Also note that U° is dense in U , so, by continuity, $\varphi(U^\circ)$ is dense in $\varphi(U)$. We have shown that $\varphi(U)$ has dense interior. It remains to apply Proposition 2. \square

3.2 Normal form of a stratified immersion

Below we present some important properties of germs of stratified immersions at the strata. Some of these properties in case of stable maps are well known (see e.g. [3, §9.5]). However, generic maps we consider may not be stable.

Proposition 4. *Suppose U, V are n -manifolds, $C \subset U$ is a locally closed k -submanifold and $f : U \rightarrow V$ is a map such that $f|_C$ is an immersion. Then there is a tubular neighborhood $U_C \supset C$ such that $f|_{U_C}$ is equal to the composition*

$$U_C \xrightarrow{g} V_C \xrightarrow{h} V,$$

where V_C is the total space of some rank $n - k$ vector bundle over C , the neighborhood U_C is viewed as the normal bundle to C , a map g is fiberwise and h is an immersion. More precisely, g can be written as $(s, t) \mapsto (s, g_\nu(s, t))$, where the first coordinate is a coordinate in C and the second coordinate is a local coordinate normal to C in U_C , respectively in V_C .

Proof. For V_C we take the pullback of the normal bundle of $f(C)$. Let h map it to some tubular neighborhood of $f(C)$. Then f restricted to some sufficiently small tubular neighborhood U_C can be lifted to V_C . So we have a map $g : U_C \rightarrow V_C$ and it remains to choose a vector bundle structure on U_C such that g is a fiberwise map.

Since $g|_C$ is a diffeomorphism onto the image, for every $x \in C$ the image $dg(T_x U_C)$ is transversal to fibers of V_C . By continuity of the differential, the same holds for x close to C . In other words, we can replace the neighborhood U_C by a smaller one so that for any point $x \in U_C$ the image $dg(T_x U_C)$ is transversal to the fiber of V_C .

Then by the implicit function theorem the preimage of any fiber of V_C is a smooth submanifold of U_C transversal to C . If needed, replace U_C by a smaller neighborhood one more time to make these preimages diffeomorphic to \mathbb{R}^{n-k} and form a vector bundle over C . \square

Definition 4. In the notation of Proposition 4, we call the map $g : U_C \rightarrow V_C$ a *normal form of f at C* . If a map is its own normal form at C , we call such a map *C -normal*.

Note that the C -germ of a normal form at C is globally equivalent to the C -germ of the original map.

Note that a normal form is not unique. However, in view of the following Proposition 5 a normal form is unique up to global L -equivalence.

Lemma 1. *A stratified immersion has a normal form at every stratum.*

Proof. This directly follows from Definition 3 and Proposition 4. \square

In particular, by Remark 1 a generic map f of n -manifolds has normal form at every stratum of $\Sigma(f)$. Moreover, if we take the fibers $U_s \subset U_C$ and $V_s \subset V_C$ over a point $s \in C$ (using the notation of Proposition 4), then the map $g_\nu|_{U_s} : U_s \rightarrow V_s$ is generic. This fact, which we will not use, can be proved using some “normal modification” of Theorem 3.

3.3 The universal property for a normal form

The following proposition is some kind of universal property for a normal form.

Proposition 5. *Let U, V_1, V_2 be n -manifolds, let $C \subset U$ be a submanifold and let $f_1 : U \rightarrow V_1$ and $f_2 : U \rightarrow V_2$ be maps whose C -germs are globally L -equivalent. Suppose f_1 is C -normal. Then there are neighborhoods $C \subset U' \subset U$ and $f(U') \subset V'_1 \subset V_1$ and an immersion $\beta : V'_1 \rightarrow V_2$ such that $\beta \circ f_1|_{U'} = f_2|_{U'}$.*

First let us prove the following assertion.

Proposition 6. *Let U, V be n -manifolds, let $\varphi : U \rightarrow V$ be an immersion and let $C \subset U$ be a locally closed submanifold of positive codimension such that $\varphi|_C : C \rightarrow V$ is an imbedding as a submanifold. Then there is a neighborhood $C \subset U' \subset U$ such that the restriction $\varphi|_{U'}$ is a diffeomorphism onto the image.*

Proof. Choose a tubular neighborhood $\varphi(C) \subset V' \subset V$ and fix the structure of a normal bundle on V' . The next reasoning is similar to the proof of Proposition 4. Namely, choose a tubular neighborhood $C \subset U' \subset U$ with a vector bundle structure so that φ maps U' to V' fiberwise.

If U' is sufficiently close to C , then the restriction of φ to each fiber is injective. Therefore $\varphi|_{U'}$ is itself injective.

Note that one can give another proof of this proposition, similar to the proof of Lemma 6 from §A.1. \square

Proof of Proposition 5. We will use only that $f_1|_C : C \rightarrow V_1$ is an imbedding as a submanifold, the fiberwise structures on U and V_1 are not necessary.

By definition, if C -germs of f_1 and f_2 are globally L -equivalent, there exist a neighborhood $C \subset U'' \subset U$, an n -manifold V_3 , a map $f_3 : U'' \rightarrow V_3$ and immersions $\beta_1 : V_3 \rightarrow V_1$ and $\beta_2 : V_3 \rightarrow V_2$ such that $\beta_1 \circ f_3 = f_1|_{U''}$ and $\beta_2 \circ f_3 = f_2|_{U''}$.

It is easy to see that $f_3(C) \subset V_3$ is a submanifold and the immersion $\beta_1|_{f_3(C)}$ is a diffeomorphism onto the image. Therefore for some neighborhood $f_3(C) \subset V'_3 \subset V_3$ the restriction $\beta_1|_{V'_3}$ is a diffeomorphism onto the image. Then it remains to set $U' = f_3^{-1}(V'_3)$, $V'_1 = \beta_1(V'_3)$ and $\beta = \beta_2 \circ (\beta_1|_{V'_3})^{-1}$. \square

3.4 Cylindric covers

Let C be a manifold and $p : U \rightarrow C$ and $q : V \rightarrow C$ be vector bundles. Let $\varphi : U \rightarrow V$ be a fiberwise map such that $p = q \circ \varphi$. Take any subset $Z \subset C$.

Definition 5. Suppose we are given a cover $Z \subset \bigcup U_i \subset U$. Denote the union $\bigcup U_i$ by B . The cover is called *cylindric*, if $U_i = B \cap p^{-1}(p(U_i))$ for every i .

Given cylindric covers $Z \subset \bigcup U_i \subset U$ and $\varphi(Z) \subset \bigcup V_i \subset V$, the map φ is called *vertical* (with respect to the covers), if $U_i = B \cap \varphi^{-1}(V_i)$ for every i .

Remark 2. Note that if φ is vertical, then $\varphi(U_i) \subset V_i$ for every i . Clearly, for any i, j we have $f(U_i) \cap f(U_j) = f(U_i \cap U_j)$. Moreover,

$$\varphi(U_i) \cap V_j = \varphi(U_i \cap U_j)$$

for any i, j . This is the key property of cylindric covers and vertical maps.

Proposition 7. Let C be a manifold and $p : U \rightarrow C$ and $q : V \rightarrow C$ be vector bundles. Let $\varphi : U \rightarrow V$ be a fiberwise map such that $p = q \circ \varphi$. We consider C as the zero section of U . Take a closed subset $Z \subset C$.

Suppose we are given locally finite covers $Z \subset \bigcup U_i$ and $\varphi(Z) \subset \bigcup V_i$ such that $\varphi(U_i) \subset V_i$ for all i . Then the covers admit cylindric refinements $\bigcup U'_i$ and $\bigcup V'_i$ such that the map φ is vertical. Moreover, the refinements can be chosen so that $U'_i \subset U_i$ and $V'_i \subset V_i$ for all i .

Proof. Choose norms on the fibers of U and V . We denote these norms similarly by $\|\cdot\|$. Given a fiber F and a point $x \in F$, we denote the open ε -ball about x in F by $B_\varepsilon(x)$.

Choose a cover $Z \subset \bigcup W_i \subset C$ such that $\overline{W_i} \subset U_i$ for all i . Recall that $\varphi(C) \subset V$ is the zero section and $\varphi|_C$ is a homeomorphism. Therefore $\varphi(\overline{W_i}) = \varphi(\overline{W_i}) \subset V_i$ for all i .

To define V'_i , for each i we take a function $\xi_i : \varphi(C) \rightarrow \mathbb{R}_{\geq 0}$ such that $B_{\xi_i(x)}(x) \subset V_i$ for all $x \in \varphi(C)$ and $\xi_i(x) \neq 0$ for all $x \in V_i \cap \varphi(C)$. Then for each i take any function $\eta_i : \varphi(C) \rightarrow \mathbb{R}_{> 0}$ such that $\eta_i \equiv \xi_i$ on $\varphi(\overline{W_i})$ and $\eta_i \equiv 5$ on $\varphi(C) \setminus V_i$.

Define a function $\eta : \varphi(C) \rightarrow \mathbb{R}_{>0}$ as $\eta(x) = \min \eta_i(x)$. Note that, since the cover $\bigcup V_i$ is locally finite, η is well defined and continuous. Then the set $B = \{y \in V \mid \|y\| < \eta(\varphi(q(y)))\}$ is an open neighborhood of $\varphi(C)$.

Finally, we take $V'_i = q^{-1}(W_i) \cap B$ for each i . By the construction, $V'_i \subset V_i$ and $Z \subset \bigcup V'_i$.

To define U'_i we replace U_i by $U_i \cap \varphi^{-1}(B)$ and apply to the obtained cover the procedure similar to the described above. \square

3.5 Building a global L -equivalence

The following assertion will be very important in our proof of Theorem 1.

Theorem 6. *Suppose we are given n -manifolds U, V, V' and stratified immersions $\varphi : U \rightarrow V$ and $\varphi' : U \rightarrow V'$. Suppose for a locally closed submanifold $C \subset U$ the restrictions $\varphi|_C$ and $\varphi'|_C$ are immersions and φ is C -normal. Suppose the C -germs of φ and φ' are locally L -equivalent. Then there is an immersion $\beta : \mathcal{O}_p(\varphi(C)) \rightarrow V'$ such that $\beta \circ \varphi|_{\mathcal{O}_p(C)} = \varphi'|_{\mathcal{O}_p(C)}$.*

Proof. Let $C = \bigcup_{i,k} \Delta_i^k$ be a sufficiently small triangulation. Here Δ_i^k denotes a k -simplex without boundary, $k = 0, 1, \dots, m$, where $m = \dim(C)$. Since the C -germs of φ and φ' are locally L -equivalent, we may assume that for every Δ_i^k there are neighborhoods $\Delta_i^k \subset U_i^k \subset U$ and $\varphi(U_i^k) \subset V_i^k \subset V$ and an immersion $\beta_i^k : V_i^k \rightarrow V'$ such that $\beta_i^k \circ \varphi|_{U_i^k} = \varphi'|_{U_i^k}$. The neighborhoods can be taken so that the cover $\varphi(C) \subset \bigcup V_i^k$ is locally finite and $V_i^k \cap V_j^k = \emptyset$ for $i \neq j$ and all k .

We will prove the lemma by induction. On the k -th step we will obtain an immersion $\beta^k : \mathcal{O}_p(\varphi(\text{sk}^k(C))) \rightarrow V'$ such that $\beta^k \circ \varphi|_{\mathcal{O}_p(\text{sk}^k(C))} = \varphi'|_{\mathcal{O}_p(\text{sk}^k(C))}$. Let us describe the k -th step, $k = 0, 1, \dots, m$.

By the induction hypothesis, there are neighborhoods $\text{sk}^{k-1}(C) \subset U^{k-1} \subset U$ and $\varphi(U^{k-1}) \subset V^{k-1} \subset V$ and an immersion $\beta^{k-1} : V^{k-1} \rightarrow V'$ such that $\beta^{k-1} \circ \varphi|_{U^{k-1}} = \varphi'|_{U^{k-1}}$. (If $k = 0$, we set U^{k-1} and V^{k-1} to be empty.)

We may assume that the covers $\text{sk}^k(C) \subset (U^{k-1} \cup \bigcup U_i^k) \subset U$ and $\varphi(\text{sk}^k(C)) \subset (V^{k-1} \cup \bigcup V_i^k) \subset V$ are cylindric and the map φ is vertical. Otherwise we replace the sets U^{k-1} , V^{k-1} , U_i^k and V_i^k by smaller ones applying Proposition 7. Recall that

$$\beta_i^k \circ \varphi|_{U^{k-1} \cap U_i^k} = \varphi'|_{U^{k-1} \cap U_i^k} = \beta^{k-1} \circ \varphi|_{U^{k-1} \cap U_i^k}.$$

Therefore, by Remark 2, for every j the maps β^{k-1} and β_j^k coincides on the intersection $V^{k-1} \cap V_j^k \cap \varphi(U^{k-1} \cup \bigcup U_i^k)$.

Take a neighborhood $\varphi(\text{sk}^{k-1}(C)) \subset W \subset V$ such that $\overline{W} \subset V^{k-1}$. For every V_i^k we define a function $t : V_i^k \rightarrow [0; 1]$ such that $t = 0$ on $V_i^k \setminus V^{k-1}$ and $t = 1$ on $V_i^k \cap \overline{W}$. Then we define a map $\tilde{\beta}_i^k : V_i^k \rightarrow V'$ as

$$\tilde{\beta}_i^k(x) = t \cdot \beta^{k-1}(x) + (1 - t) \cdot \beta_i^k(x).$$

Here we use an Euclidean structure which comes from arbitrary local coordinates in V near $\varphi(\Delta_i^k)$. Since the triangulation of C is sufficiently small, we may assume that such coordinates exist. Note that the map $\tilde{\beta}_i^k$ depends on the choice of this coordinates, but we can take any of them.

By the construction, $\tilde{\beta}_i^k \equiv \beta_i^k$ on $\varphi(U_i^k)$. So Proposition 3 implies that $d\tilde{\beta}_i^k|_{\varphi(\Delta_i^k)}$ has rank n . Then, by continuity of the differential, $\tilde{\beta}_i^k|_{\mathcal{O}p(\varphi(\Delta_i^k))}$ is an immersion. This immersion coincides with β^{k-1} on W . Together the maps β^{k-1} and $\tilde{\beta}_i^k$ define a desired immersion $\mathcal{O}p(\varphi(\text{sk}^k(C))) \rightarrow V'$, so the proof of k -th step is complete. \square

4 Global approach to generic germs

In this section we will recall the main definitions and then prove Theorem 1.

4.1 Locally compatible maps

First let us recall the following definition.

Definition 6. Suppose we are given a collection of maps $\{\varphi_i : U_i \rightarrow V_i\}$, where $U_i \subset M$ are open subsets and V_i are n -manifolds. We say that $\{\varphi_i\}$ is a *collection of locally compatible maps*, if for every i, j the germs of φ_i and φ_j at $U_i \cap U_j$ are locally L -equivalent.

Two collections of locally compatible maps $\{\varphi_i\}$ and $\{\varphi'_i\}$ are called *locally L -equivalent*, if their union $\{\varphi_i\} \cup \{\varphi'_i\}$ is a collection of locally compatible maps. A map $f : M \rightarrow N$ is *locally L -equivalent* to the collection of locally compatible maps $\{\varphi_i\}$, if the collection $\{\varphi_i\}$ and the collection consisting of a single map $\{f\}$ are locally L -equivalent.

One may think of a collection of locally compatible maps as a global map on $\bigcup U_i$ with variable target.

Proposition 8. *Let $S \subset M$ be a closed subset and let $\{\varphi_i : U_i \rightarrow V_i\}$ be a collection of locally compatible generic maps such that $\bigcup \Sigma(\varphi_i) = S$. Then there is a stratification of S such that for every stratum $C \subset S$ and for every i the restriction $\varphi_i|_{C \cap U_i}$ is an immersion.*

Proof. Using Theorem 3 we choose a stratification of $\Sigma(\varphi_i) = S \cap U_i$ for every i . The obtained stratifications are agreed on the intersections $U_i \cap U_j$ by the naturalness and the Diff-invariance.

Recall that every stratum $C \subset S$ lies in some $\Sigma^I(\varphi_i)$, where I is a sequence of length $n+1$. Since $j^{n+1}(\varphi_i)$ is transversal to $\Sigma^I(U_i, V_i)$, by dimension reason the sequence I has zero at the end. This means that the restriction φ_i to $\Sigma^I(\varphi_i)$ (and, therefore, to $C \cap U_i$) is an immersion.

Note that the obtained stratification of S is a canonical refinement of the Thom-Boardman decomposition, since our operations in the proof of Proposition 1 did not depend on the choice of local coordinates etc. \square

Lemma 2. *For S and $\{\varphi_i\}$ as above, there is a triangulation of S such that every its open simplex Δ is a smooth submanifold in M and for every i the restriction $\varphi_i|_{\Delta \cap U_i}$ is an immersion.*

Proof. First make a stratification of S using Proposition 8, and then apply the result of [9]. Note that, unlike the stratification of S , our triangulation is not at all canonical. \square

Definition 7. Suppose we are given two collections of locally compatible maps $\{\varphi'_i : U'_i \rightarrow V'_i\}$ and $\{\varphi_i : U_i \rightarrow V_i\}$. Then $\{\varphi'_i\}$ is called a *refinement* of $\{\varphi_i\}$, if they are locally L -equivalent and every U'_i lies in some U_j .

4.2 Twisted tangent bundle

Here we recall the definition from §1.3 and prove that it is correct. Let us begin with the following important construction.

Proposition 9. *Let $\{\varphi_i : U_i \rightarrow V_i\}$ be a collection of locally compatible generic maps. Denote the vector bundles $\varphi_i^*(TV_i)$ by E_i . Then there are fiberwise isomorphisms $\Phi_{i,j} : E_i|_{U_i \cap U_j} \rightarrow E_j|_{U_i \cap U_j}$ such that $\Phi_{i,i} = \text{Id}_{E_i}$ and $\Phi_{k,i} \circ \Phi_{j,k} \circ \Phi_{i,j}|_{U_i \cap U_j \cap U_k} = \text{Id}_{E_i|_{U_i \cap U_j \cap U_k}}$ for every i, j, k .*

In fact, the constructed below fiberwise isomorphisms $\Phi_{i,j}$ are natural in the following sense: each $\Phi_{i,j}$ is defined by the maps φ_i and φ_j and does not depend on φ_k , $k \neq i, j$.

Proof. For every point $x \in U_i \cap U_j$ choose a neighborhood $x \in U_x \subset U_i \cap U_j$ and neighborhoods $\varphi_i(U_x) \subset V_{i,x} \subset V_i$ and $\varphi_j(U_x) \subset V_{j,x} \subset V_j$ with a diffeomorphism $\beta_x : V_{i,x} \rightarrow V_{j,x}$ such that $\beta_x \circ \varphi_i|_{U_x} = \varphi_j|_{U_x}$. We set $\Phi_{i,j}$ to be equal $d\beta_x$ on the fiber of E_i at x . By Proposition 3 this does not depend on the choice of the diffeomorphism β_x .

By the same reasoning Proposition 3 implies that $\Phi_{i,j}$ is well defined over the whole of $U_i \cap U_j$. Note that $\Phi_{i,j}$ is continuous and smooth over a neighborhood of any point $x \in U_i \cap U_j$, so it is continuous and smooth over the whole of $U_i \cap U_j$. The equality $\Phi_{k,i} \circ \Phi_{j,k} \circ \Phi_{i,j}|_{U_i \cap U_j \cap U_k} = \text{Id}_{E_i|_{U_i \cap U_j \cap U_k}}$ follows directly from Proposition 3 as well. \square

Suppose we are given a closed subset $S \subset M$ and a collection of locally compatible generic maps $\{\varphi_i : U_i \rightarrow V_i\}$, $i = 1, 2, \dots$ such that $\bigcup \Sigma(\varphi_i) \subset S$.

Definition 8. The *twisted tangent bundle* $T^{\{\varphi_i\}}M$ is the following rank n vector bundle over M . Let $U_0 = V_0 = M \setminus S$ and set $\varphi_0 : U_0 \rightarrow V_0$ to be equal $\text{Id}_{M \setminus S}$. Note that $\{\varphi_i\}$ together with φ_0 is a collection of locally compatible generic maps. Applying Proposition 9 for it, we obtain the vector bundles E_i over U_i and the fiberwise isomorphisms $\Phi_{i,j}$ over $U_i \cap U_j$, $i = 0, 1, \dots$. Then the total space of $T^{\{\varphi_i\}}M$ is obtained by gluing together $\{E_i\}$ using $\{\Phi_{i,j}\}$.

Lemma 3. *We are given two collections of locally compatible generic maps $\{\varphi_i : U_i \rightarrow V_i\}$ and $\{\varphi'_i : U'_i \rightarrow V'_i\}$ such that $\bigcup \Sigma(\varphi_i) \subset S$ and $\bigcup \Sigma(\varphi'_i) \subset S$. Suppose $\{\varphi_i\}$ and $\{\varphi'_i\}$ are locally L -equivalent. Then the twisted tangent bundles $T^{\{\varphi_i\}}M$ and $T^{\{\varphi'_i\}}M$ are isomorphic.*

Proof. By definition, the union $\{\varphi_i\} \cup \{\varphi'_i\}$ is locally compatible. To prove the proposition we just compose the tautological “forgetful” isomorphisms $T^{\{\varphi_i\} \cup \{\varphi'_i\}}M \simeq T^{\{\varphi_i\}}M$ and $T^{\{\varphi_i\} \cup \{\varphi'_i\}}M \simeq T^{\{\varphi'_i\}}M$. \square

4.3 Proof of Theorem 1

Recall that we are given n -manifolds M, N , $n > 1$, a continuous map $f : M \rightarrow N$ and a nonempty closed subset $S \subset M$. Also we are given a collection of locally compatible generic maps $\{\varphi_i : U_i \rightarrow V_i\}$ such that $\bigcup \Sigma(\varphi_i) = S$. We have to prove that f is homotopic to a generic map f' such that f' and $\{\varphi_i\}$ are locally L -equivalent and $\Sigma(f') = S$ if and only if the vector bundles $T^{\{\varphi_i\}}M$ and $f^*(TN)$ are isomorphic.

Proof. Suppose f is homotopic to a generic map f' which is locally L -equivalent to $\{\varphi_i\}$ and which has no critical points outside S . Then by Lemma 3 we have $T^{\{\varphi_i\}}M \simeq f'^*(TN) \simeq f^*(TN)$.

It remains to prove the “if” part of the theorem.

Suppose the bundles $T^{\{\varphi_i\}}M$ and $f^*(TN)$ are isomorphic. By Lemma 2 the subset $S \subset M$ is triangulable. Let $S = \bigcup_{i,k} \Delta_i^k$ be a sufficiently small triangulation. Here Δ_i^k denotes a k -simplex without boundary, $k = 0, 1, \dots, n-1$, and i takes value in some (finite or countable) set of indices. Every $\Delta_i^k \subset M$ is a smooth submanifold.

Since the triangulation is sufficiently small, we may assume that there is a cover of S by tubular neighborhoods of the simplices, which is a refinement of $\{U_i\}$. Therefore we can replace the collection of locally compatible maps $\{\varphi_i\}$ by a refinement $\{\varphi_i^k : U_i^k \rightarrow V_i^k\}$, where every $U_i^k \supset \Delta_i^k$ is a tubular neighborhood. By Lemma 1 we may assume that every map φ_i^k is Δ_i^k -normal. We take U_i^k so close to Δ_i^k that $U_i^k \cap U_j^l \neq \emptyset$ if and only if $\Delta_i^k \subset \partial \Delta_j^l$ or $\Delta_j^l \subset \partial \Delta_i^k$ for any pair of different simplices.

Denote the vector bundle $T^{\{\varphi_i^k\}}M$ by E . Note that $E \simeq T^{\{\varphi_i\}}M$ by Lemma 3. Let $F : E \rightarrow TN$ be a fiberwise isomorphism covering f , which exists by the hypothesis of the “if” part of the theorem. Let $\Phi_i^k : E|_{U_i^k} \rightarrow TV_i^k$ be the tautological fiberwise isomorphism covering φ_i^k , defined as in §4.2.

Next we will deform f and F in n steps, from 0 to $n-1$. After the l -th step we will get a collections of immersions $\beta_i^k : V_i^k \rightarrow N$ for all $k \leq l$ and all i . The immersions β_i^k must be compatible with deformed f and F . Namely,

$$f|_{\mathcal{O}p(\Delta_i^k)} = \beta_i^k \circ \varphi_i^k|_{\mathcal{O}p(\Delta_i^k)} \quad \text{and} \quad F|_{\mathcal{O}p(\Delta_i^k)} = d\beta_i^k \circ \Phi_i^k|_{\mathcal{O}p(\Delta_i^k)} \quad (*)$$

Step 0. For every i we fix any immersion $\beta_i^0 : V_i^0 \rightarrow N$ such that $(\beta_i^0 \circ \varphi_i^0)|_{\Delta_i^0} = f|_{\Delta_i^0}$ and $d\beta_i^0 \circ \Phi_i^0|_{\Delta_i^0} = F|_{\Delta_i^0}$. Take a closed tubular neighborhood $\Delta_i^0 \subset \hat{U}_i^0 \subset U_i^0$. Since \hat{U}_i^0 deformation retracts onto Δ_i^0 , we can homotope $f|_{\hat{U}_i^0}$ to $\beta_i^0 \circ \varphi_i^0|_{\hat{U}_i^0}$. Then we extend the homotopy to the whole of M . Outside \hat{U}_i^0 we allow f to be not smooth.

During the homotopy of f we make a covering deformation of F in the class of fiberwise isomorphisms to obtain $F|_{\hat{U}_i^0} = d\beta_i^0 \circ \Phi_i^0|_{\hat{U}_i^0}$. We can do this since \hat{U}_i^0 deformation retracts onto Δ_i^0 . Make such deformations for all i independently. (To abbreviate notation, we always redenote the obtained maps by f and F , respectively.)

Step k . Take any k -simplex Δ_i^k . Denote $\Delta_i^k \cap \mathcal{O}p(\text{sk}^{k-1}(S))$ by C . As a result of the previous steps we have that the C -germs of f and φ_i^k are locally L -equivalent. Then by Theorem 6 there is an immersion $\beta : \mathcal{O}p(\varphi_i^k(C)) \rightarrow N$ such that $\beta \circ \varphi_i^k|_{\mathcal{O}p(C)} = f|_{\mathcal{O}p(C)}$.

Take a tubular neighborhood $\varphi_i^k(\Delta_i^k \cap \mathcal{O}p(\text{sk}^{k-1}(S))) \subset V' \subset V_i^k$ such that β is defined on $\overline{V'}$. Denote $\varphi_i^k(\Delta_i^k) \cup \overline{V'}$ by K . Then we can define a map $\beta' : K \rightarrow N$ as $f \circ (\varphi_i^k)^{-1}$ on $\varphi_i^k(\Delta_i^k)$ and as β on $\overline{V'}$. Note that β' is continuous. Since V_i^k deformation retracts onto K , the map β' can be extended from K to the whole of V_i^k . Then applying the M. Gromov’s h -principle (Theorem 5) to β' and $F \circ (\Phi_i^k)^{-1}$ we homotope β' to an immersion $\beta_i^k : V_i^k \rightarrow N$ relatively $\overline{V'}$.

Choose sufficiently small tubular neighborhoods $\Delta_i^k \subset U \subset M$ and $\text{sk}^{k-1}(S) \subset U' \subset M$. Denote $\overline{U} \setminus \partial \Delta_i^k$ by \hat{U} . We may assume that φ_i^k is defined on \hat{U} and that $\varphi_i^k(\hat{U} \cap \overline{U'}) \subset \overline{V'}$, see Fig. 1. Let $H = \Delta_i^k \cup (\hat{U} \cap \overline{U'})$. Also we may assume that \hat{U} deformation retracts onto H .

Then we can homotope $f|_{\hat{U}}$ to $\beta_i^k \circ \varphi_i^k|_{\hat{U}}$ relatively $\hat{U} \cap \overline{U'}$. Extend this homotopy to the whole of M relatively $\overline{U'}$. At the same time we deform F in the class of fiberwise isomorphisms fixed on $\overline{U'}$ so that as a result $F|_{\hat{U}} = d\beta_i^k \circ \Phi_i^k|_{\hat{U}}$.

Figure 1: Choosing neighborhoods $U \supset \Delta_i^k$ and $U' \supset \text{sk}^{k-1}(S)$.

We can apply the described deformations of f and F to all the k -simplices independently as they have disjoint neighborhoods.

The final step. At the beginning of this step the map f is smooth on $\mathcal{O}p(S)$ and for all $k = 0, \dots, n-1$ and all i there are immersions $\beta_i^k : V_i^k \rightarrow N$ such that the equalities $(*)$ hold.

Define a fiberwise map $F' : TM \rightarrow TN$ covering f as

$$F'(x) = \begin{cases} F(x) & \text{if } x \in M \setminus S, \\ df(x) & \text{if } x \in \mathcal{O}p(\Delta_i^k) \text{ for any } i, j. \end{cases}$$

Here we identify $TM|_{M \setminus S}$ with $E|_{M \setminus S}$ as in Definition 8. The map F' is well defined and continuous in view of $(*)$ and Proposition 9.

Take sufficiently small closed neighborhood $\text{sk}^{n-2}(S) \subset D \subset M$. We may assume that $M \setminus D$ is path-connected and $\text{sk}^{n-2}(S) \setminus D \neq \emptyset$. Note that $F'|_{M \setminus D}$ is an S -monomorphism. Applying the Eliashberg's h -principle (Theorem 4) to f and F' relative D , we deform f to a smooth map such that $\Sigma(f) = S$ and which is L -equivalent to $\{\varphi_i\}$ as a collection of locally compatible maps. \square

5 Generic maps of 3-manifolds

5.1 Classifications of rank 3 vector bundles

As we saw in Theorem 1, the problem of homotopy of a given map to a map with prescribed singularities is reduced to verifying of an isomorphism of certain vector bundles. In dimension 3 the last problem is equivalent to checking the equality of Stiefel-Whitney characteristic classes.

Lemma 4. *Let $E_1 \rightarrow X$ and $E_2 \rightarrow X$ be rank 3 vector bundles over a CW-complex X of dimension 3. Then $E_1 \simeq E_2$ if and only if $w_1(E_1) = w_1(E_2)$ and $w_2(E_1) = w_2(E_2)$.*

Proof. Obviously, the characteristic classes of isomorphic vector bundles are equal. So it remains only to prove the “if” part.

Suppose that $w_1(E_1) = w_1(E_2)$ and $w_2(E_1) = w_2(E_2)$. Take the line bundle $L \rightarrow X$ such that $w_1(L) = w_1(E_1)$. Then for $E'_1 = E_1 \otimes L$ and $E'_2 = E_2 \otimes L$ we have $w_1(E'_1) = w_1(E'_2) = 0$ and $w_2(E'_1) = w_2(E'_2)$. Let us deduce that $E'_1 \simeq E'_2$, then the statement of the lemma will follow from the isomorphisms $E'_1 \otimes L \simeq E_1$ and $E'_2 \otimes L \simeq E_2$.

Denote the oriented grassmannian $(3, \infty)$ by Gr and let $E \rightarrow Gr$ be the universal bundle. We have to check that the maps $\varepsilon_1 : X \rightarrow Gr$ and $\varepsilon_2 : X \rightarrow Gr$ corresponding to E'_1 , respectively E'_2 , are homotopic if $\varepsilon_1^* w_2(E) = \varepsilon_2^* w_2(E)$.

Since Gr is 1-connected, we may assume that $\varepsilon_1|_{\text{sk}^1(X)} \equiv \varepsilon_2|_{\text{sk}^1(X)}$. By the obstruction theory, the homotopy between ε_1 and ε_2 can be extended from $\text{sk}^1(X)$ to $\text{sk}^2(X)$ if and only if $o_1 = o_2$, where $o_1, o_2 \in H^2(X; \pi_2(Gr))$ are the first obstructions for ε_1 , respectively ε_2 , to be null-homotopic (for details see e. g. [22, §8.4]).

Note that by the Hurewicz theorem and the long exact sequence we have $H_2(Gr; \mathbb{Z}) = \pi_2(Gr) = \pi_1(SO(3)) = \mathbb{Z}_2$. So by the universal coefficient theorem $H^2(Gr; \pi_2(Gr)) = \mathbb{Z}_2$, denote its generator by a . By the construction of o_1 and o_2 we have $o_1 = \varepsilon_1^*(a)$ and $o_2 = \varepsilon_2^*(a)$ (see [22, §8.4, Th. 2]).

On the other hand, there are oriented rank 3 vector bundles with $w_2 \neq 0$ (e. g. the sum of two copies of the nonorientable line bundle over \mathbb{RP}^2 with the trivial line bundle), so we have $w_2(E) \neq 0$, therefore $a = w_2(E)$. Thus $o_1 = \varepsilon_1^* w_2(E) = w_2(E'_1)$ and $o_2 = \varepsilon_2^* w_2(E) = w_2(E'_2)$. So by the equality $w_2(E'_1) = w_2(E'_2)$ the maps $\varepsilon|_{\text{sk}^2(X)}$ and $\varepsilon'|_{\text{sk}^2(X)}$ are homotopic.

Finally, there is no obstruction to extension of the homotopy between ε_1 and ε_2 from $\text{sk}^2(X)$ to $\text{sk}^3(X)$ since $\pi_3(Gr) = \pi_2(SO(3)) = 0$. \square

5.2 Generic germs in dimension 3

Let M, N be closed 3-manifolds. Suppose we are given a generic map $f : M \rightarrow N$. Then $\Sigma^1(f) \subset M$ is a closed 2-submanifold, $\Sigma^{1,1}(f) \subset \Sigma^1$ is a closed 1-submanifold and $\Sigma^{1,1,1}(f) \subset \Sigma^{1,1}$ is a discrete subset.

Recall that the points of $\Sigma^{1,0}(f) = \Sigma^1(f) \setminus \Sigma^{1,1}(f)$ are called *folds*, the germ of f at each of these points is locally equivalent to the germ of the map $\mathbb{R}^3 \rightarrow \mathbb{R}^3$, $(x, y, z) \mapsto (x^2, y, z)$ at the origin. The points of $\Sigma^{1,1,0}(f) = \Sigma^{1,1}(f) \setminus \Sigma^{1,1,1}(f)$ are called *cusps*, for them in some local coordinates f can be written as $(x, y, z) \mapsto (x^3 + xy, y, z)$. And the points of $\Sigma^{1,1,1}(f) = \Sigma^{1,1,1}(f)$ are called *swallowtails*, the singularities of f at these points are of the form $(x, y, z) \mapsto (x^4 + x^2y + xz, y, z)$.

For every generic $f : M \rightarrow N$ the set $\Sigma(f)$ consists only of the three described strata (possibly, empty). The germs of f at different points of the same stratum are locally equivalent. Also these singularities are stable. This means that for every map $f' : U \rightarrow V$, which is sufficiently close to f in C^∞ -topology, its strata $\Sigma^{1,0}(f')$, $\Sigma^{1,1,0}(f')$ and $\Sigma^{1,1,1,0}(f')$ are close to $\Sigma^{1,0}(f)$, $\Sigma^{1,1,0}(f)$ and $\Sigma^{1,1,1,0}(f)$, respectively, and the germs of f' and f at corresponding strata are equivalent.

Figure 2: A characteristic vector field near a point of P .

Suppose we are given a closed 2-submanifold $S \subset M$, a closed 1-submanifold $C \subset S$ and a discrete subset $P \subset C$.

Definition 9. Given the triple S, C, P , a *characteristic field* is a unit vector field in M defined on $C \setminus P$ and normal to S . This vector field must “change the direction” when we go through any point of P , see Fig. 2.

Suppose for a neighborhood $U \supset C$ and a 3-manifold V we have a generic map $\varphi : U \rightarrow V$ such that $\Sigma^1(\varphi) = S \cap U$, $\Sigma^{1,1}(\varphi) = C$ and $\Sigma^{1,1,1}(\varphi) = P$. The *characteristic field* of φ is the unit vector field normal to S whose image is directed “outside” the cusp, see Fig 3. We denote it by $\nu(\varphi)$.

Figure 3: The characteristic field $\nu(\varphi)$ and its image under $d\varphi$.

Note that near a swallowtail point $\nu(\varphi)$ has different directions on the two components of $C \setminus P$, see Fig 4. So the characteristic field of a generic map is actually a characteristic field.

Figure 4: The characteristic field of a generic map near a swallowtail point and its image.

Proposition 10. *Given a characteristic field ν_0 and a tubular neighborhood $U \supset C$ one can construct a generic map $\varphi : U \rightarrow V$ to some 3-manifold V such that $\Sigma^1(\varphi) = S \cap U$, $\Sigma^{1,1}(\varphi) = C$, $\Sigma^{1,1,1}(\varphi) = P$ and $\nu(\varphi) = \nu_0$.*

Proof. Take tubular neighborhoods $U_0 \supset P$ and $U_1 \supset C \setminus P$. There are n -manifolds V_0, V_1 and generic maps $\varphi_i : U_i \rightarrow V_i$, $i = 0, 1$, which have the prescribed singularities and characteristic vectors at all points.

Note that the germs of φ_0 and φ_1 at $(C \setminus P) \cap U_0$ are globally equivalent. Composing φ_1 with a suitable diffeomorphism of U_1 , we can make the germs of φ_0 and φ_1 at $(C \setminus P) \cap U_0$ globally L -equivalent.

Note that the germ of φ_1 is $(C \setminus P) \cap U_0$ -normal. We set V to be the result of gluing V_0 with V_1 via the map β from Proposition 5 and let $U = U_0 \cup U_1$. If needed, we replace U_0 , U_1 , V_0 and V_1 by smaller ones, so we may assume that V is Hausdorff. The maps φ_0 and φ_1 are compatible on $U_0 \cap U_1$, so together they define a desired map $\varphi : U \rightarrow V$. \square

Proposition 11. *There is a characteristic field for the triple S, C, P if and only if for every component $C' \subset C$ we have $[C'] \cdot [S] \equiv |P \cap C'| \pmod{2}$.*

Proof. Suppose there is a characteristic field ν . Passing a component $C' \subset C$ along ν we set it to the general position with S . Then $C' \cap S = P \cap C'$.

To prove the “if” part we slightly perturb every component C' to obtain a new curve $C'' \subset M$ which is transversal to S and so that $C'' \cap S = P \cap C'$. Then the arcs of C'' in $M \setminus S$ show the direction of a characteristic field. \square

Note that if the property $[C'] \cdot [S] \equiv |P \cap C'| \pmod{2}$ holds for all components $C' \subset C$, then the triple S, C, P admits exactly two (opposite) characteristic fields.

Also note that for generic maps of surfaces the notion of characteristic vector is defined similarly, see [6, §4.3] or [20, §1].

5.3 Characteristic classes of the twisted tangent bundle

If $n = 2$ or 3 , then the twisted tangent bundle is well defined by a characteristic vector field. More precisely, if two collections of locally compatible maps with the same singular loci have the same characteristic vector fields, then the corresponding twisted tangent bundles are isomorphic. Next we will show how to compute their characteristic classes.

For generic maps of surfaces, the isomorphism class of the twisted tangent bundle depends on the choice of characteristic vectors of the cusp points, since the Euler class of the obtained bundle depends on this choice [20, §3].

However, in dimension 3 the isomorphism class of the twisted tangent bundle depends only on the choice of S and C , in view of Lemma 4, Proposition 10 and the following two assertions.

Proposition 12. *Let $E, E' \rightarrow X$ be rank m vector bundles over an n -manifold X . Suppose for a tubular neighborhood U of a k -submanifold $Y \subset X$ the restrictions $E|_{X \setminus U}$ and $E'|_{X \setminus U}$ are isomorphic. Then $w_i(E) = w_i(E')$ for all $i < n - k$.*

Proof. Note that \bar{U} deformation retracts onto Y . Using Poincaré duality, for $i < n - k$ we have

$$H^i(\bar{U}, \partial\bar{U}) \simeq H_{n-i}(\bar{U}) \simeq H_{n-i}(Y) = 0.$$

And by excision we have $H^i(\bar{U}, \partial\bar{U}) \simeq H^i(X, X \setminus U)$.

Since $H^i(X, X \setminus U) = 0$ for every $i < n - k$, the homomorphism $H^i(X) \rightarrow H^i(X \setminus U)$ induced by the inclusion $(X \setminus U) \subset X$ has zero kernel. To complete the proof we apply the functoriality of w_i to the last inclusion. \square

Now let M be a connected 3-manifold (for possibly disconnected M the proof of the following lemma is similar). Suppose we are given a closed 2-submanifold $S \subset M$ and a closed 1-submanifold $C \subset S$. Take tubular neighborhoods $C \subset U_1 \subset M$ and $(S \setminus C) \subset U_2 \subset M$.

Then suppose there are generic maps $\varphi_i : U_i \rightarrow V_i$ to some 3-manifolds V_i , $i = 1, 2$, such that $\{\varphi_1, \varphi_2\}$ is a collection of locally compatible maps and such that $\Sigma^1(\varphi_2) = \Sigma^{1,0}(\varphi_2) = S \setminus C$ and $\Sigma^{1,1}(\varphi_1) = C$. Denote the twisted tangent bundle $T^{\{\varphi_1, \varphi_2\}}M$ by E .

Lemma 5. *We have $w_1(E) = w_1(M) + [S]$ and $w_2(E) = w_2(M) + [S]^2 + w_1(M) \cdot [S] + [C]$.*

Note that, in particular, the characteristic classes do not depend on $\Sigma^{1,1,1}(\varphi_1)$ and $\nu(\varphi_1)$.

Proof. We define a vector bundle E' over M obtained by regluing TM along S using the orthogonal involution of $TM|_S$ which is identity on TS . Note that the restrictions $E|_{M \setminus U_1}$ and $E'|_{M \setminus U_1}$ are isomorphic, so by Proposition 12 we have $w_1(E') = w_1(E)$. Next we will compute $w_1(E')$ and $w_2(E')$, and then we will prove that $w_2(E) - w_2(E') = [C]$.

We cut M along S and denote the obtained manifold with boundary by M' . Take the unit vector field on $\partial M'$ which is normal to $\partial M'$ and directed into M' . It can be extended to a nonzero vector field v on the complement in M' of a finite collection of interior points $x_1, x_2, \dots \in \text{int}(M')$. Denote $M' \setminus \{x_1, x_2, \dots\}$ by M° .

Take the line subbundle of $TM'|_{M^\circ \setminus \{x_1, x_2, \dots\}}$ spanned by v . We denote its projections to $TM|_{M^\circ}$ and to $E'|_{M^\circ}$ by L , respectively L' . Note that, since v is orthogonal to $\partial M'$, the subbundles L and L' are well defined over S .

We can see that $TM|_{M^\circ} \simeq L \oplus E_2$ and $E'|_{M^\circ} \simeq L' \oplus E_2$ for some rank 2 vector bundle $E_2 \rightarrow M^\circ$. Then

$$w_i(L \oplus E_2) = \iota^* w_i(M) \quad \text{and} \quad w_i(L' \oplus E_2) = \iota^* w_i(E') \quad \text{for } i = 1, 2, \quad (**)$$

where $\iota : M^\circ \rightarrow M$ is the imbedding.

Now we can compute $w_1(E') - w_1(M)$ and $w_2(E') - w_2(M)$. By the construction, the line bundle L' is trivial, and $w_1(L) = \iota^*[S]$. Therefore by (**) we have

$$\iota^* w_1(E') - \iota^* w_1(M) = w_1(L') - w_1(L) = \iota^*[S].$$

Also by (**) we have $\iota^* w_1(M) = w_1(L) + w_1(E_2)$, therefore

$$\iota^* w_2(E') - \iota^* w_2(M) = (w_1(L') - w_1(L)) \cdot w_1(E_2) = \iota^*[S] \cdot w_1(E_2) = \iota^*[S]^2 + \iota^*[S] \cdot \iota^* w_1(M).$$

Thus we have shown that $w_2(E') - w_2(M) = [S]^2 + [S] \cdot w_1(M)$.

Figure 5: Two sections of $E'|_{\partial U_1}$ and their extensions to U_1 .

Now let us show that $w_2(E) - w_2(E') = [C]$. Take two sections u'_1, u'_2 of E' over ∂U_1 as in Fig. 5, left (here we identify E' with TM outside S). Figure 5, right shows that u'_1, u'_2 can be extended to the whole of U_1 as a pair of linearly independent sections.

Recall that $E|_{M \setminus U_1} \simeq E'|_{M \setminus U_1}$. Let u_1, u_2 be the sections of E over ∂U_1 corresponding to $u'_1|_{\partial U_1}$ and $u'_2|_{\partial U_1}$ under this isomorphism. It is sufficient to show that general position extensions of u_1, u_2 to the whole of U_1 has set of linearly dependence $Z \subset U_1$ homologous to C .

Figure 6: Two sections of $E|_{\partial U_1}$ and their images in TV_1 .

Take a fiber F of the tubular neighborhood U_1 over any point of $C \setminus P$. Apply the natural fiberwise isomorphism $\Phi_1 : E|_{U_1} \rightarrow TV_1$ covering φ_1 to the sections u_1, u_2 .

Take the obtained vector fields $\Phi_1(u_1), \Phi_1(u_2)$ on $\partial\varphi_1(F)$ (Fig. 6, right) and extend them as general position vector fields v_1, v_2 on the whole of $\varphi_1(F)$, which are linearly dependent at one point p (Fig. 7).

Since Φ_1 is a fiberwise isomorphism, we have the well-defined map Φ_1^{-1} , assigning to a section of TV_1 the corresponding section of $E|_{U_1}$. Take the extensions u_1, u_2 to F equal $\Phi_1^{-1}(v_1), \Phi_1^{-1}(v_2)$. Note that these extensions are in general position and they are linearly dependent at odd number of points (since p has 3 preimages). Therefore $|Z \cap F| \equiv 1 \pmod{2}$, so $[Z] = [C]$. \square

Figure 7: Vector fields v_1, v_2 which extends $\Phi_1(u_1), \Phi_1(u_2)$ to $\varphi_1(F)$.

5.4 Proof of Theorem 2

Here we apply the results of this section to deduce Theorem 2 from Theorem 1.

Recall that we have closed 3-manifolds M, N , a closed 2-submanifold $S \subset M$, a closed 1-submanifold $C \subset S$, a discrete subset $P \subset C$ and a continuous map $f : M \rightarrow N$.

We have to prove that the map f is homotopic to a generic map f' such that $\Sigma^1(f') = S$, $\Sigma^{1,1}(f') = C$ and $\Sigma^{1,1,1}(f') = P$ if and only if

- (1) $[S] = w_1(M) + f^*w_1(N)$,
- (2) $[C] = w_1(M) \cdot [S]$ and
- (3) for every component $C' \subset C$ we have $[C'] \cdot [S] \equiv |P \cap C'| \pmod{2}$.

Proof. Suppose there is a generic map $f' : M \rightarrow N$ with prescribed singularities and f is homotopic to f' . Denote the twisted tangent bundle $T^{\{f'\}}M$ by E .

Let us prove conditions (1) and (2). Lemma 5 implies that $w_1(E) = w_1(M) + [S]$ and $w_2(E) = w_2(M) + [S]^2 + w_1(M) \cdot [S] + [C]$. On the other hand, $E \simeq f^*(TN)$. So

$$f^*w_1(N) = w_1(M) + [S] \quad \text{and} \quad f^*w_2(N) = w_2(M) + [S]^2 + w_1(M) \cdot [S] + [C].$$

By the Wu formula (see e. g. [17, p. 131]), $w_1(M)^2 = w_2(M)$ and $w_1(N)^2 = w_2(N)$. Therefore,

$$\begin{aligned} [C] &= f^*w_2(N) + w_2(M) + [S]^2 + w_1(M) \cdot [S] = \\ &= (f^*w_1(N))^2 + (w_1(M))^2 + [S]^2 + w_1(M) \cdot [S] = \\ &= (w_1(N) + w_1(M) + [S])^2 + w_1(M) \cdot [S] = w_1(M) \cdot [S]. \end{aligned}$$

Finally, condition (3) follows from Definition 9 and Proposition 11.

Suppose conditions (1-3) hold. We take the collection of locally compatible maps $\{\varphi_1, \varphi_2\}$ as in the hypothesis of Lemma 5. The existence of such a collection of locally compatible maps follows from condition (3) and Propositions 10 and 11.

Then by Lemmas 4 and 5 and conditions (1-2) the vector bundles $T^{\{\varphi_1, \varphi_2\}}M$ and $f^*(TN)$ are isomorphic. It remains to apply Theorem 1. \square

A Appendix. Equivalences of germs

A.1 Stratumwise equivalence

In §2.6 we introduced several notions of equivalence for germs of maps $M \rightarrow N$ at a locally closed subset $S \subset M$. In this article we always considered germs of stratified immersions at their skeleta, so in our examples S is a stratified subset of positive codimension in M and the map we consider is a stratified immersion with respect to this stratification.

This leads us to another notion of equivalence for germs.

Definition 10. Assume that S is a stratified submanifold. The S -germs of φ_1 and φ_2 are called *stratumwise equivalent* if for every stratum $C \subset S$ the C -germs of φ_1 and φ_2 are globally equivalent.

The S -germs of φ_1 and φ_2 are called *stratumwise L -equivalent* if for every stratum $C \subset S$ the C -germs of φ_1 and φ_2 are globally L -equivalent.

Proposition 13. *The relations introduced in Definitions 1, 2 and 10 are actually equivalence relations.*

In order to prove Proposition 13 we need the following lemma.

Lemma 6. *Suppose S is a locally closed subset of an n -manifold U . Let $\varphi : U \rightarrow U$ be a map such that $\varphi|_S = \text{Id}_S$ and the differential $d\varphi$ is an isomorphism at each point of S . Then there is a neighborhood $S \subset U' \subset U$ such that $\varphi|_{U'}$ is a diffeomorphism onto the image.*

Proof. First we suppose that S is compact. Note that $d\varphi$ is an isomorphism over $\mathcal{O}_p(S)$. Suppose there does not exist a neighborhood U' as in the lemma. Then for every $k = 1, 2, \dots$ there are two points $x_k \neq y_k$ which are $< \frac{1}{k}$ away from S and such that $\varphi(x_k) = \varphi(y_k)$. By choosing subsequences we may assume that $\{x_k\}$ and $\{y_k\}$ are convergent. Their limits lie in S . If the limits coincide, then, since $d\varphi$ is an isomorphism at this point, we have a contradiction with the inverse function theorem. If the limits do not coincide, then we have a contradiction with injectivity of φ on S .

Now we suppose that S is closed but possibly noncompact. Then take a proper map $\xi : U \rightarrow \mathbb{R}_{\geq 0}$. For any $k \in \mathbb{Z}_{\geq 0}$ the set $\xi^{-1}([k-1; k+2]) \cap S$ is compact. So there is a neighborhood $(\xi^{-1}([k-1; k+2]) \cap S) \subset U_k \subset U$ such that $\varphi|_{U_k}$ is a diffeomorphism onto the image. We set

$$W_k = U_{k-1} \cap U_k \cap U_{k+1} \cap \varphi^{-1}(\xi^{-1}((k - \frac{1}{2}; k + \frac{3}{2})))$$

and then let $U' = \bigcup W_k$. Clearly, $U' \subset U$ is open. Also $U' \supset S$ since $W_k \supset \xi^{-1}([k; k+1]) \cap S$. The differential $d\varphi$ is an isomorphism on U' . Let us show that $\varphi|_{U'}$ is injective.

Take any $x \in W_k$. Then $\xi(\varphi(x)) \in (k - \frac{1}{2}; k + \frac{3}{2})$. Therefore if $\varphi(y) = \varphi(x)$, then either $y \in W_{k-1}$, or $y \in W_k$, or $y \in W_{k+1}$. In each of these cases we see that $x, y \in U_k$, but $\varphi|_{U_k}$ is injective, so $y = x$.

Finally, suppose that $S \subset U$ is an arbitrary locally closed subset. Then the set $\tilde{U} = U \setminus (\overline{S} \setminus S)$ is open in U . It remains to apply the same reasoning as above to the closed subset $S \subset \tilde{U}$. \square

Proof of Proposition 13. Reflexivity and symmetry are evident. Next we will show transitivity for the global equivalence. The proof for the other five relations is similar.

Suppose we are given maps $\varphi_1 : U_1 \rightarrow V_1$, $\varphi_2 : U_2 \rightarrow V_2$ and $\varphi_3 : U_3 \rightarrow V_3$ where $U_1, U_2, U_3 \supset S$ are neighborhoods in U and V_1, V_2, V_3 are n -manifolds. Suppose that the S -germ of φ_1 is globally equivalent to the S -germ of φ_2 and the latter is globally equivalent to the S -germ of φ_3 . In more detail, we have the following commutative diagram:

$$\begin{array}{ccccc}
 & & U_{1,2} & & U_{2,3} \\
 & \swarrow \alpha_1 & \downarrow & \swarrow \alpha'_2 & \searrow \alpha'_3 \\
 U_1 & & & & U_2 & & & U_3 \\
 \downarrow \varphi_1 & & \downarrow \varphi_{1,2} & & \downarrow \varphi_2 & & \downarrow \varphi_{2,3} & & \downarrow \varphi_3 \\
 & & V_{1,2} & & & & V_{2,3} & & \\
 & \swarrow \beta_1 & \downarrow & \swarrow \beta'_2 & \searrow \beta'_3 & & & & \\
 V_1 & & & & V_2 & & & & V_3
 \end{array}$$

Here $U_{1,2}, U_{2,3} \supset S$ are neighborhoods and $V_{1,2}, V_{2,3}$ are n -manifolds. The maps $\alpha_1, \alpha_2, \alpha'_2, \alpha'_3$ are immersions which are the identity on S . By Lemma 6 they can be assumed to be diffeomorphisms onto the image if $U_{1,2}$ and $U_{2,3}$ are sufficiently close to S . The maps $\beta_1, \beta_2, \beta'_2, \beta'_3$ are arbitrary immersions.

Take the fiber product $U_{1,2,3} = U_{1,2} \times_{U_2} U_{2,3}$. The differentials of α_2 and α'_2 are isomorphisms, so $U_{1,2,3}$ is a manifold and the maps $\alpha_{1,2} : U_{1,2,3} \rightarrow U_{1,2}$ and $\alpha_{2,3} : U_{1,2,3} \rightarrow U_{2,3}$ are immersions. Since α_2 and α'_2 are injective, the same is true for $\alpha_{1,2}$ and $\alpha_{2,3}$. Therefore we can assume $U_{1,2,3}$ imbedded into M . Then $\alpha_{1,2}$ and $\alpha_{2,3}$ are the identity on S .

Similarly, we take the fiber product $V_{1,2,3} = V_{1,2} \times_{V_2} V_{2,3}$ (it is a manifold since the differentials of β_2 and β'_2 are isomorphisms) and define immersions $\beta_{1,2} : V_{1,2,3} \rightarrow V_{1,2}$ and $\beta_{2,3} : V_{1,2,3} \rightarrow V_{2,3}$. We obtain the following commutative diagram:

By the pullback property of $V_{1,2,3}$ there exists a unique map $\varphi_{1,2,3}$ as in the diagram. Together with the compositions $\alpha_1 \circ \alpha_{1,2}$, $\alpha'_3 \circ \alpha_{2,3}$, $\beta_1 \circ \beta_{1,2}$ and $\beta'_3 \circ \beta_{2,3}$ it establishes a global equivalence of the S -germs of φ_1 and φ_3 . \square

A.2 Relations between the notions of equivalence

Note that the equivalences have trivial reductions: globally L -equivalent germs are always globally equivalent, stratumwise equivalent germs are always locally equivalent etc.

To show that the converse implications do not hold in several cases we will use the following assertion.

Proposition 14. *Let X, Y, Z be topological spaces. Let $g : X \rightarrow Y$ and $h : Y \rightarrow Z$ be continuous maps and suppose h is local homeomorphism. Take a path-connected subset $W \subset X^2$ such that for every $(x, y) \in W$ we have $h(g(x)) = h(g(y))$. Then if $g(x_0) = g(y_0)$ for some $(x_0, y_0) \in W$, then $g(x) = g(y)$ for every $(x, y) \in W$.*

Proof. Suppose there is $(x_1, y_1) \in W$ such that $g(x_1) \neq g(y_1)$. Since W is path-connected, there is a pair of paths $\gamma_1, \gamma_2 : [0; 1] \rightarrow X$ such that $(\gamma_1(t), \gamma_2(t))$ is a path in W from (x_0, y_0) to (x_1, y_1) .

Mark all $s \in [0; 1]$ such that $g(\gamma_1(t)) = g(\gamma_2(t))$ for every $t \in [0; s]$. Let s_0 be the supremum of such s . By continuity, $g(\gamma_1(s_0)) = g(\gamma_2(s_0))$.

On the one hand, $h(g(\gamma_1(t))) = h(g(\gamma_2(t)))$ for all $t \in [0; 1]$ by the definition of W . On the other hand, one can choose $t > s_0$ arbitrarily close to s_0 such that $g(\gamma_1(t)) \neq g(\gamma_2(t))$. This contradicts the fact that the restriction of h to some neighborhood of $g(\gamma_1(s_0))$ is injective. \square

Figure 8: Fold points with the same image near the swallowtail singularity.

Remark 3. For germs of stratified immersions at their skeleta, stratumwise L -equivalent germs (and hence stratumwise equivalent germs) need not be globally equivalent (and moreover, need not be globally L -equivalent).

For example, take a standard map $\varphi : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ with a swallowtail singularity $\Sigma^{1,1,1,0}$. Then the germ of φ at $S = \Sigma(\varphi)$ considered up to global equivalence has an invariant: the curve of double points of S , see Fig. 8.

Let us construct a map $\varphi' : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ which is stratumwise L -equivalent to φ . Take a pair of points $x, y \in S$ with the same image as in Fig. 8. Take a small ball $\varphi(x) \in V \subset \mathbb{R}^3$ and a diffeomorphism $\psi : V \rightarrow V$ which is identity on $\mathcal{O}p(\partial V)$, but not identity at $\varphi(x)$. Let $x \in U_x \subset \mathbb{R}^3$ be a neighborhood including exactly one of the components of $\varphi^{-1}(V)$. Then we set $\varphi' = \varphi$ outside $U_x \cap \varphi^{-1}(V)$ and $\varphi' = \psi \circ \varphi$ on $U_x \cap \varphi^{-1}(V)$.

Proposition 14 implies that the S -germs of φ and φ' are not globally equivalent since $\varphi(x) = \varphi(y)$ and $\varphi'(x) \neq \varphi'(y)$. On the other hand, they are stratumwise L -equivalent (indeed, their $\Sigma^{1,0}$ -germs are globally L -equivalent to normal maps, which have no double points at the critical locus).

Remark 4. Globally equivalent germs (and, so, stratumwise equivalent and locally equivalent) may not even be locally L -equivalent (and, moreover, may be not stratumwise L -equivalent and not globally L -equivalent), because the L -equivalence “remembers” pairs of regular points near S with the same image. For example, the germs of maps $\mathbb{R}^2 \rightarrow \mathbb{R}^2$, defined as $(x, y) \mapsto (x^2, y)$ and $(x, y) \mapsto (x^2, x + y)$, at their critical locus $x = 0$ are globally equivalent but even not locally L -equivalent.

Remark 5. In general, locally equivalent germs may not be stratumwise equivalent. For example, suppose $U = V_1 = S^1 \times [-1; 1]$ and V_2 is the Möbius band. We set the maps $\varphi_1 : U \rightarrow V_1$ and $\varphi_2 : U \rightarrow V_2$ to be the compositions of the projection to the middle line $U \rightarrow S^1$ with the imbeddings of S^1 as the middle line into V_1 and V_2 , respectively. Let $S = S^1 \times 0$ have only one

stratum. Note that $\varphi_1|_S$ and $\varphi_2|_S$ are immersions. Then the S -germs of φ_1 and φ_2 are locally L -equivalent but not stratumwise equivalent.

Proposition 15. *Let U , V and V' be n -manifolds and let $\varphi : U \rightarrow V$ and $\varphi' : U \rightarrow V'$ be maps. Suppose that φ is a stratified immersion with the skeleton S and that the S -germs of φ and φ' are locally L -equivalent. Then these germs are stratumwise L -equivalent.*

Proof. Take a stratum $C \subset S$. We need to prove that C -germs of φ and φ' are globally L -equivalent. We will use a few results of §3. By Lemma 1 the C -germ of φ has a normal form φ'' . Then by Theorem 6 the C -germs of φ'' and φ' are globally L -equivalent. It remains to use the transitivity of globally L -equivalence of C -germs (Proposition 13) or the universal property of a normal form (Proposition 5). \square

We have shown that there are the following implications between the equivalences (implications which may violate in general but always hold for germs of stratified immersions at their skeleta are denoted by thin arrows):

In this diagram every arrow that goes left or down correspond to trivial reductions. A missing up or right arrow means that there is no implication, see remarks above.

Question. *Does the stratumwise equivalence of germs of stratified immersions at their skeleta follow from the local equivalence?*

We do not know the answer to this question, so we used only the L -versions of the local and stratumwise equivalences.
