Matrix-Monotonic Optimization — Part I: Single-Variable Optimization

Chengwen Xing, Member, IEEE, Shuai Wang, Member, IEEE, Sheng Chen, Fellow, IEEE, Shaodan Ma, Member, IEEE, H. Vincent Poor, Fellow, IEEE, and Lajos Hanzo, Fellow, IEEE

Abstract—Matrix-monotonic optimization exploits the monotonic nature of positive semi-definite matrices to derive optimal diagonalizable structures for the matrix variables of matrix-variable optimization problems. Based on the optimal structures derived, the associated optimization problems can be substantially simplified and underlying physical insights can also be revealed. In our work, a comprehensive framework of the applications of matrix-monotonic optimization to multiple-input multiple-output (MIMO) transceiver design is provided for a series of specific performance metrics under various linear constraints. This framework consists of two parts, i.e., Part-I for single-variable optimization and Part-II for multi-variable optimization. In this paper, single-variable matrix-monotonic optimization is investigated under various power constraints and various types of channel state information (CSI) condition. Specifically, three cases are investigated: 1) both the transmitter and receiver have imperfect CSI; 2) perfect CSI is available at the receiver but the transmitter has no CSI; 3) perfect CSI is available at the receiver but the channel estimation error at the transmitter is norm-bounded. In all three cases, the matrix-monotonic optimization framework can be used for deriving the optimal structures of the optimal matrix variables.

I. MOTIVATIONS

Antenna arrays are widely employed for improving the bandwidth- and/or the power-efficiency, resulting in the concept of multiple-input multiple-output (MIMO) system. [1]–[9]. Transceiver optimization is of critical importance for fulfilling the potential of MIMO communication systems [7]–[10]. MIMO transceiver optimization hinges on numerous factors, including their implementation issues, the availability of channel state information (CSI) and their system architectures. More specifically, MIMO transceivers can be classified into linear transceivers [8], [9] and nonlinear transceivers [11]–[13]. According to the different levels of CSI knowledge, MIMO transceiver designs can be classified into designs relying on perfect CSI [4]–[6] and designs having partial CSI [15]–[19]. Finally, according to the system architecture, transceiver optimization can be used for point-to-point systems [10], [20], for multi-user (MU) MIMO systems [21], for distributed MIMO systems [22], [23], and for cooperative MIMO systems [24], [25].

In all the above-mentioned multiple antenna aided systems, the corresponding optimization variables become matrix variables [26]. As a result, optimization relying on matrix variables plays an important role in MIMO systems [27]. Optimization relying on matrix variables is generally very challenging and such problems are much more difficult to solve than their counterparts with vector variables or scalar variables, because matrix variable based optimization usually involves complex matrix operations, such as the calculation of the determinants, inverses, matrix decompositions and so on. Furthermore, because of spatial multiplexing gains, MIMO systems are capable of supporting multiple data streams. This fact makes transceiver optimization problems inherently multi-objective optimization problems. For example, given a limited transmit power, any specific transceiver optimization is a tradeoff between the performance of different data streams. This is the reason why there exists a rich body of work addressing various different MIMO transceiver designs [9], [10].

Any transceiver optimization problem hinges on the fundamental elements of the objective function and the specific optimization tools used for finding the extremities of the objective function. The more components the objective function has, the larger the search space becomes, which often makes a full hard utilization. A third related component is constituted by the constraints. The most widely used objective functions or performance metrics of MIMO transceiver optimization include the classic mean square error (MSE) minimization, signal to interference plus noise ratio (SINR) maximization or mutual information maximization, bit error rate (BER) minimization, etc. [9]. Different performance metrics reflect different design preferences and different tradeoffs among the transmitted data streams [10]. Transceiver optimization problems using different performance metrics imposes different degrees of difficulty to solve. Furthermore, different objective functions also correspond to different implementation strategies resulting in, for example, linear transceivers, nonlinear transceivers using Tomlinson-Harashima precoding (THP) or decision feedback equalizer (DFE) etc. [12]–[14], [26]. Suffice to say that the specific choice of the objective function has a more substantial impact on the overall MIMO design than that of the tools used for optimizing it.

On the other hand, there are many different types of power constraints, such as the sum power constraint [26], per-antenna...
power constraint [28]–[34], shaping constraint [35], [36], joint power constraints [37], cognitive constraint [34], etc. The most widely used power constraint is the sum power constraint requiring the sum of the powers at all the transmit antennas to be lower than a threshold. In communication systems, usually each antenna has its own amplifier [21]. Therefore, the per-antenna power constraint is more practical than the sum power constraint. However, the per-antenna power constraint is more challenging to consider than the sum power constraint [21], [29]–[31], [34]. The existing literature has revealed that if different transmit antennas have the same statistics, the performance gain of considering the more challenging per-antenna power constraint based design over using the simpler sum power constraint design is negligible [32]. Thus, under the scenario of similar statistics for different transmit antennas, the sum power constraint is an effective modeling technique.

It is worth noting however that in some cases, as in distributed antenna systems or heterogeneous networks, different antennas have significantly different statistics, and thus the per-antenna power constraint cannot be replaced by the sum power constraint without a significant performance loss [32], [34]. Moreover, considering other practical constraints, such as signal variances or the peak-to-average-ratio, joint power constraints or other types of constraints have to be taken into account [37].

It can be readily seen from the existing literature [10], [26], [34] that the underlying design principles for various transceiver optimization problems are almost the same. Generally, the main idea is taking advantage of the specific structure of the underlying optimization problem to simplify the transceiver optimization. Optimization theory plays an important role in MIMO transceiver optimization, and in the past decade many elegant results have been derived based on convex optimization theory [23], [27]. Deriving optimal structures is critical in transceiver optimization [1], [6], [9]. Clearly, a general-purpose optimal structure that can cover every MIMO transceiver optimization problems does not exist, and most the research has been focused on finding an optimal diagonalizable structure for MIMO transceiver optimization. This is because based on the optimal diagonalizable structures of the MIMO transceivers, the corresponding optimization problems can be substantially simplified and deeply underlying physical insights can also be revealed [1], [6], [9].

Again, optimization variables of MIMO transceiver designs are generally matrix variables. Matrix-monotonic optimization exploits the monotonic nature of positive semi-definite matrices to derive optimal structures of the matrix variables in the underlying optimization problems [26], [34], [36]. Based on matrix-monotonic optimization, the matrix variables can be substantially simplified into vector variables. The optimal structures delivered by matrix-monotonic optimization, therefore, greatly simplify complicated MIMO transceiver designs and make the underlying physical interpretation more transparent. From a matrix-monotonic optimization perspective, MIMO transceiver optimization problems relying on different objective functions and power constraints can be unified and, therefore, their associated optimal structures can be derived using the same matrix-monotonic optimization tool. Exploiting matrix-monotonic optimization is a powerful mathematical tool conceived for solving challenging matrix-variable transceiver optimization problems.

This paper offers a comprehensive and novel work for matrix-monotonic optimization for a series of specific performance metrics under linear constraints in the context of MIMO transceiver optimization. Matrix monotonic optimization problem with various levels of CSI is investigated in depth. Our main contributions are listed as follows.

- In contrast to [26] with only simple sum power constraint, the framework of matrix-monotonic optimization investigated in this treatise is subjected to diverse power constraints, including the sum power constraint, multiple weighted power constraints, joint power constraints and shaping constraints. In other words, the framework investigated in this paper subsumes the solutions in [26] and several other MIMO transceiver optimization solutions as its special cases.
- In contrast to [9] and [11], where the linear and nonlinear transceiver designs are investigated separately under only the sum power constraint, the framework proposed in this paper unifies the families of linear and nonlinear MIMO transceiver optimization under the sum power constraint, shaping constraint, joint power constraints and multiple weighted power constraints.
- Moreover, robust MIMO transceiver optimization relying on partial CSI under various power constraints is investigated based on the matrix-monotonic optimization framework. Specifically, the following three cases are investigated:
  1) Both the transmitter and receiver have only imperfect CSI.
  2) The receiver has perfect CSI but the transmitter has only channel statistics.
  3) The receiver has perfect CSI but the channel estimate available at the transmitter is subject to a certain uncertainty norm-bounded error.

Although having imperfect CSI makes the MIMO transceiver optimization more complex and challenging, the proposed matrix-monotonic optimization framework is still capable of deriving the underlying optimal structures.

The remainder of this paper is organized as follows. In Section II, we present the fundamentals of the matrix-monotonic optimization framework. Then Section III investigates classic Bayesian robust matrix-monotonic optimization for robust transceiver design when the channel estimation errors are Gaussian distributed. In Section IV, stochastic robust matrix-monotonic optimization is investigated for MIMO transceiver optimization where the receiver has perfect CSI but the transmitter knows only the channel statistics. Section V is devoted to worst case matrix-monotonic optimization, which focuses on transceiver optimization in the face of norm-bounded channel estimation errors.

Notation: The following notational conventions are adopted throughout our discussions. The normal-faced letters denote scalars, while bold-faced lower-case and upper-case letters
denote vectors and matrices, respectively. \( Z^H \), \( \text{Tr}(Z) \) and \( |Z| \) denote the Hermitian transpose, trace and determinant of complex matrix \( Z \), respectively. Statistical expectation is denoted by \( E[\cdot] \), and \( a^+ = \max\{0, a\} \), while \( (\cdot)^T \) denotes the vector/matrix transpose operator. \( Z^2 \) is the Hermitean square root of \( Z \) which is positive semi-definite. The \( i \)th largest eigenvalue of \( Z \) is denoted by \( \lambda_i(Z) \), and the \( i \)th-row and \( j \)th-column element of \( Z \) is denoted by \( [Z]_{i,j} \), while \( d[Z] \) denotes the vector consisting of the diagonal elements of \( Z \) and \( \text{diag}\{\{A_k\}^K_{k=1}\} \) denotes the block diagonal matrix whose diagonal sub-matrices are \( A_1, \ldots, A_K \). The symbol \( d^2[Z] \) denotes the vector consisting of the squared moduli of the diagonal elements of \( Z \). Additionally, the \( i \)th element of a vector \( z \) is denoted by \( [z]_i \). The identity matrix of appropriate dimension is denoted by \( I \), and \( \otimes \) is the Kronecker product. In this paper, \( \Lambda \) always denotes a diagonal matrix, and the expressions \( \Lambda^{-1} \) and \( \Lambda^\top \) represent a rectangular or square diagonal matrix with the diagonal elements in descending order and ascending order, respectively.

II. FUNDAMENTALS OF MATRIX-MONOTONIC OPTIMIZATION

An optimization problem with a real-valued objective function \( f_0(\cdot) \) that depends on a complex matrix variable \( X \) is generally formulated as

\[
\min_{X \in C} \ f_0(X), \quad \text{s.t.} \quad \psi_i(X) \leq 0, 1 \leq i \leq I, \tag{1}
\]

where \( \psi_i(\cdot), 1 \leq i \leq I \), are the constraint functions and \( C \) denotes the complex matrix set. A wide range of optimization problems can be cast in this optimization framework, including the classic MIMO transceiver optimization [10], training designs [26], MIMO radar waveform optimization [26], etc. In order to analyze the properties of this generic optimization problem, we first discuss two of its basic components, namely, the objective function and the constraints, separately.

A. Objective Functions

The objective function reflects the cost or utility of the optimization problem. In this paper, all the optimization problems discussed are formulated with the objective of minimizing a cost function. Let us now discuss the commonly used objective functions, listed in Table I. For transceiver optimization, the mutual information is one of the most important performance metrics. For training optimization, the mutual information is also an important performance metric as it reflects the correlation between the estimated parameters and the true parameters. In these cases, the objective function is given by \textbf{Obj. 1} [38], where \( \Pi \) and \( \Phi \) are constant positive semi-definite matrices which have different physical meanings for different systems. The MSE is another important performance metric for transceiver or training optimization, which reflects how accurately a signal can be recovered rather than how much information can be transmitted. For the optimization problem of sum MSE minimization, the objective function is given in the form of \textbf{Obj. 2} [38].

Generally, the MSE formulation for linear transceiver optimization is determined by the specific signal model considered. For example, in a dual-hop AF MIMO relaying network, the MSE minimization has \textbf{Obj. 3} [39], where \( \alpha \) is a positive scalar and \( A \) is a constant complex matrix. Similarly, the mutual information maximization for a dual-hop AF MIMO relaying network aims at minimizing the objective function \textbf{Obj. 4} [39]. For linear transceiver optimization, to realize different levels of fairness between different transmitted data streams, a general objective function can be formulated as an additively Schur-convex function \textbf{[9]} or additively Schur-concave function \textbf{[9]} of the diagonal elements of the MSE matrix, which are given by \textbf{Obj. 5.1} and \textbf{Obj. 5.2} [10], respectively. The additively Schur-convex function \( f_{\text{Convex}}^{A-\text{Schur}}(\cdot) \) and the additively Schur-concave function \( f_{\text{Concave}}^{A-\text{Schur}}(\cdot) \) represent different levels of fairness among the diagonal elements of the data MSE matrix. In addition, \( f_{\text{Convex}}^{A-\text{Schur}}(\cdot) \) and \( f_{\text{Concave}}^{A-\text{Schur}}(\cdot) \) are both increasing functions with respect to the vector variables.

When nonlinear transceivers are chosen for improving the BER performance at the cost of increased complexity, e.g., THP or DFE, the objective functions of the transceiver optimization can be formulated as a multiplicative Schur-convex function or a multiplicative Schur-concave function of the vector consisting of the squared diagonal elements of the Cholesky-decomposition triangular matrix of the MSE matrix, that is, \textbf{Obj. 6.1} and \textbf{Obj. 6.2} [26], respectively, where

\footnote{This conclusion is achieved is based on the fact that maximizing mutual information is equivalent to minimizing the determinant of the MSE matrix [26].}
In wireless communication designs, even for the same system or the same optimization problem, the mathematical formulae are not unique. More specifically, for the mutual information maximization, we have the alternative objective function \( \text{Obj. 7} \) [26]. Similarly, the sum MSE minimization has the alternative objective function \( \text{Obj. 8} \) [26]. Moreover, the weighted MSE minimization can be considered as a general extension of the sum MSE minimization by introducing a weighting matrix, which has the objective function \( \text{Obj. 9} \).

As discussed in the existing literature, some MIMO system optimization problems may involve Kronecker products due to \( \text{vec}(\cdot) \) operations [26]. The optimization problems relying on Kronecker product usually look very complicated. In this paper, the pair of optimization problems relying on either the matrix determinant or on the the matrix trace are discussed that involve Kronecker products. Based on \( \text{Obj. 1} \), we have the extended Kronecker structured objective function \( \text{Obj. 10} \), which is equivalent to \( \text{Obj. 11} \) [26]. It can readily be seen that with the choice of \( \Sigma_1 = \Sigma_2 \), \( \text{Obj. 10} \) and \( \text{Obj. 11} \) are equivalent to \( \text{Obj. 1} \). In this paper, we also consider a more general case in which \( \Sigma_1 \) and \( \Sigma_2 \) have the same eigenvalue decomposition (EVD) unitary matrix. Under this assumption and based on \( \text{Obj. 2} \), we have the extended Kronecker structured objective function \( \text{Obj. 12} \), which is equivalent to \( \text{Obj. 13} \). Similarly, based on \( \text{Obj. 3} \), we have the objective function \( \text{Obj. 14} \), which is also equivalent to \( \text{Obj. 15} \). In our following discussions involving \( \text{Obj. 10} \) to \( \text{Obj. 15} \), it is always assumed that \( \Sigma_1 \) and \( \Sigma_2 \) have the same EVD unitary matrix.

### B. Constraint Functions

In practical communication system designs, typically the associated optimization problems have constraints, and these constraints have different physical meanings for different communication systems.

The most natural constraints are the power constraints, since practical amplifiers have certain maximum transmit power thresholds. The simplest power constraint, is the sum power constraint which can be expressed as

\[ \text{Constraint 1: } \text{Tr}(XX^H) \leq P. \]  

\[ (2) \]

With the sum power constraint, the optimization problems associated with training sequence designs or transceiver designs are subjected to the constraint of the power sum of all the transmit antennas. In practical systems, each antenna has its own power amplifier and, therefore, the per-antenna power constraints or individual power constraints provide a more reasonable power constraint model, which is expressed as

\[ \text{Constraint 2: } [XX^H]_{n,n} \leq P_n, \quad n = 1, \ldots, N. \]  

\[ (3) \]  

where we have assumed that the number of transmit antennas is \( N \) and the matrix variable \( X \) has \( N \) rows. The per-antenna

\( L \) is a lower triangular matrix. The multiplicatively Schur-convex function \( f_{\text{Convex M-Schur}}^\lambda (\cdot) \) and the multiplicatively Schur-concave function \( f_{\text{Convex M-Schur}}^{\lambda^{-1}} (\cdot) \) reflect the different levels of fairness among the different data streams, i.e., different tradeoffs among the performance of different data streams [26]. In addition, \( f_{\text{Convex M-Schur}}^{\lambda^{-1}} (\cdot) \) and \( f_{\text{Convex M-Schur}}(\cdot) \) are both increasing functions with respect to the vector variables.
power constraint (3) may be more practical but it does not include the sum power constraint (2) as its special case.

In sophisticated communication networks, the constraints are not limited to reflect the maximum power constraints at the transmit antennas for the desired signal but they also reflect many other constraints such as the interference constraints between adjacent links. A more general power constraint is the following one having multiple weighted components [38]

**Constraint 3:** \( \text{Tr}(\Omega_i XX^H) \leq P_i, \quad i = 1, \cdots, I \)

where \( I \) is the number of weighted power constraints. **Constraint 3** is more general than **Constraint 1** and **Constraint 2**. The constraint model (4) includes the sum power constraint (2) and per-antenna power constraint (3) as its special cases. Specifically, by choosing \( I = 1 \) and \( \Omega_1 = I \), this power constraint model becomes the sum power constraint (2). Furthermore, when \( I = N \) and \( \Omega_i \) is the matrix whose \( i \)th diagonal element is one and all the other elements are zeros, this model is exactly the per-antenna power constraint (3).

In order to avoid or control the interference, it is expected to be cast to the null space of the desired signals, hence the signal and interference become orthogonal to each other. In order to achieve this, constraints can be imposed on the covariance matrix of the transmitted signal, which are referred to as spectral mask constraints [35]. A classic example is the shaping constraint, which is formulated as the following matrix inequality [35], [36]

**Constraint 4:** \( XX^H \preceq R_c \).

From matrix inequality theory, this constraint is equivalent to [40, 471]

\[
\text{Tr}(\Omega_i XX^H) \leq \text{Tr}(\Omega_i R_c),
\]

for any positive semi-definite matrix \( \Omega_i \). Based on this fact, we can argue that the shaping constraint represents a special case of the multiple weighted power constraint. A simplified version of **Constraint 4** is the constraints imposed on the eigenvalues of the covariance matrix \( XX^H \) formulated as

**Constraint 5:** \( \lambda_i(XX^H) \leq \tau_i \).

A widely used eigenvalue constraint is the constraint on the maximum eigenvalue, \( \lambda_1(XX^H) \leq \tau_1 \), which is equivalent to [36]

\[
XX^H \preceq \tau_1 I.
\]

This constraint can be used together with the sum power constraint to limit the transmitter’s peak power. This is because most of the existing power constraints are based on statistical averages, while from a practical implementation perspective, the power constraint is an instantaneous constraint instead of being an average one [37]. This kind of combined power constraint is termed as the joint power constraint, which is expressed as [36]

**Constraint 6:** \( \text{Tr}(XX^H) \leq P, XX^H \preceq \tau_1 I \).

In cognitive radio communications, the interference imposed by the secondary user on the primary user must be smaller than a threshold and this constraint can be written in the following form

**Constraint 7:** \( \text{Tr}(H_c XX^H H_c^H) \leq \tau_c, \)

where \( H_c \) is the channel matrix between the secondary user and primary user, while \( \tau_c \) is the interference threshold. This kind of constraint is also a special case of **Constraint 3**.

In summary, all the power constraint models discussed above represent the different physical constraints on the covariance matrix of the transmit signal, which equals \( XX^H \). These constraints shape the positive semidefinite covariance matrix. For the simplest sum power constraint model, the sum of the eigenvalues of the covariance matrix has to be smaller than a threshold. For the multiple weighted power constraint model, the eigenvalues of the covariance matrices are constrained in the polyhedron region constructed by the multiple weighting matrices. In this case, except for the restrictions on the eigenvalues, the constraints also restrict the unitary matrix in the eigenvalue decomposition of the covariance matrix. Moreover, for the joint power constraint model the sum of the eigenvalues and the maximum eigenvalue are simultaneously smaller than the predefined thresholds. The upper-bound on the maximum eigenvalue significantly impacts the power allocations on the eigenchannels. For example, some subchannels that are allocated zero power for the sum power constraint will be assigned non-zero powers for the joint power constraints.

Before turning attention to discuss the optimization problem (1), two fundamental definitions are first introduced.

**Definition 1** A constraint \( \psi(X) \leq 0 \) is a left unitary invariant constraint if we have

\[
\psi(Q_L X) = \psi(X),
\]

where \( Q_L \) is an arbitrary unitary matrix.

**Definition 2** A constraint \( \psi(X) \leq 0 \) is a right unitarily-invariant constraint if we have

\[
\psi(X Q_R) = \psi(X),
\]

where \( Q_R \) is an arbitrary unitary matrix.

It is worth noting that all the constraints discussed above are right unitarily-invariant. Specifically, in **Constraints 1** to **7**, after replacing \( X \) by \( X Q_R \), it can be concluded that these constraints do not change. Therefore, we can focus our attention on the family of right unitarily-invariant constraints only. In particular, we will focus our attention on the shaping constraint, joint power constraints and multiple weighted power constraints.

**C. Matrix-Monotonic Optimization**

Based on the above discussions, with the objective functions in Table I, the generic optimization problem of MIMO systems can be formulated as

**Opt. 1.1:** \( \min \int (X^H \Pi X), \text{s.t. } \psi_i(X) \leq 0, \quad 1 \leq i \leq I. \)
The function $f(\cdot)$ is matrix monotone decreasing function \([27], [41], [42]\). Since the constraints are right unitarily-invariant, we introduce the auxiliary matrix variable $F$ and express the original matrix variable $X$ as
\[
X = FQ_X,
\]
where $Q_X$ is an arbitrary unitary matrix. Based on (14), the optimization problem (13) can be reformulated as
\[
\min_{F, Q_X} f(Q_X^H F^H \Pi F Q_X),
\]
\[\text{s.t. } \psi_i(F Q_X) = \psi_i(F) \leq 0, \ 1 \leq i \leq I,
\]
where the specific objective functions are given in the left column of Table II. Note that the constraints do not depend on $Q_X$. Therefore, the optimal $Q_X$ is independent of the constraints.

1) Optimization of $Q_X$: Generally, there are two basic approaches to optimize $Q_X$. The first one is based on the basic matrix inequality and the other is based on majorization theory.

Basic Matrix Inequalities Typically, the extreme values of basic matrix operations e.g., trace, determinant, etc., are functions of the eigenvalues of the matrices involved. Given the positive semi-definite matrices $C \in \mathbb{C}^{N \times N}$ and $D \in \mathbb{C}^{N \times N}$, we consider the following EVDs
\[
C = U_C \Lambda_C U_C^H \quad \text{with } \Lambda_C \prec \Lambda,
\]
\[
D = U_D \Lambda_D U_D^H \quad \text{with } \Lambda_D \prec \Lambda,
\]
\[
D = U_D \Lambda_D U_D^H \quad \text{with } \Lambda_D \succ \Lambda,
\]
where $\Lambda_D$ and $\Lambda_D$ consist of the eigenvalues of $D$ arranged in descending order and ascending order, while $U_D$ and $\bar{U}_D$ contain the corresponding eigenvectors of $D$, respectively. We then have the four basic matrix inequalities, ranging from (19) to (22), shown at the bottom of this page. Furthermore, in both Matrix Inequality 1 [43, P340, P341] and Matrix Inequality 2 [26, Appendix A], the left equality holds when $U_C = \bar{U}_D$ and the right equality holds when $U_C = U_D$; while in both Matrix Inequality 3 [43, P333, P334] and Matrix Inequality 4, the left equality holds when $U_C = \bar{U}_D$, and the right equality holds when $U_C = U_D$ [26].

Majorization Theory Majorization theory constitutes an important branch of matrix equality theory \([27], [43]\). We have the following two important definitions.

Definition 3 ([43]) For two vectors $x, y \in \mathbb{R}^N$, $x$ is said to be majorized by $y$, denoted as $x \prec y$, when the following inequalities are satisfied: $\bigcap_{i=1}^{k} [x]_i \subseteq \bigcap_{i=1}^{k} [y]_i$, for $1 \leq k \leq N - 1$, and $\bigcap_{i=1}^{N} [x]_i = \bigcap_{i=1}^{N} [y]_i$, where $\bigcap$ denotes a mathematical operator.

In the following, we only consider the addition and product operators of $\bigcap = \bigcup$ and $\bigcap = \bigcap$.

Definition 4 ([43]) A real-valued function $\phi : \mathbb{R}^N \to \mathbb{R}$ is additively or multiplicatively Schur-convex for any $x, y$ in the feasible set, $x \prec y \Rightarrow \phi(x) \leq \phi(y)$. On the other hand, $\phi$ is additively or multiplicatively Schur-concave when $x \prec y \Rightarrow \phi(x) \geq \phi(y)$.

Optimal $Q_X$ Based on the basic matrix inequalities and majorization theory together with the following EVDs (23) to (26) and the singular value decomposition (SVD) (27)
\[
F^H \Pi F = U_{F_{\Pi F}} \Lambda_{F_{\Pi F}} U_{F_{\Pi F}}^H \quad \text{with } \Lambda_{F_{\Pi F}} \prec \Lambda,
\]
\[
\Phi = U_{\Phi} \Lambda_{\Phi} U_{\Phi}^H \quad \text{with } \Lambda_{\Phi} \prec \Lambda,
\]
\[
\Phi = U_{\Phi} \Lambda_{\Phi} U_{\Phi}^H \quad \text{with } \Lambda_{\Phi} \succ \Lambda,
\]
\[
A \Phi^{-1} A^H = U_{A \Phi A} \Lambda_{A \Phi A} U_{A \Phi A}^H \quad \text{with } \Lambda_{A \Phi A} \prec \Lambda,
\]
\[
A = U_{A} \Lambda_{A} U_{A}^H \quad \text{with } \Lambda_{A} \succ \Lambda,
\]
the optimal unitary matrices $Q_X$ corresponding to the various objective functions can be derived and they are listed in the right column of Table II. The detailed proofs are given in Appendix A. In the SVD (27), $A_A$ contains the singular values of $A$, while $U_A$ and $V_A$ are the corresponding left and right unitary matrices, respectively.

In Table II, the unitary $U_{\text{DFT}}$ for Obj. 5.1 is a discrete Fourier transform (DFT) matrix, and $U_{\text{GMD}}$ for Obj. 6.1 is the unitary matrix that makes the diagonal elements of $L$ identical, that is, $U_{\text{GMD}}$ is the right unitary matrix of the geometric mean decomposition (GMD) of $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-0.5}$. It is also worth highlighting that for Obj. 8 and Obj. 9, in general, the closed-form optimal $Q_X$ cannot be derived, and only the approximated optimal solutions can be obtained at high signal-to-noise ratio (SNR) conditions.

2) Optimization of $F$: For Opt. 1.1, given the optimal $Q_X$ in Table II, the objective functions in Table II are monotonically decreasing functions with respect to the eigenvalues of $F^H \Pi F$. Therefore, the optimal solutions of $F$ fall in the Pareto optimal solution set of the following multi-objective optimization problem [26]
\[
\max_{F} \lambda(F^H \Pi F), \text{s.t. } \psi_j(F) \leq 0, \ 1 \leq j \leq I,
\]
where $\lambda(F^H \Pi F) = [\lambda_1(F^H \Pi F) \cdots \lambda_N(F^H \Pi F)]^T$. Clearly, the optimal structure of $F$ depends on both the

Note that the solutions of Obj. 8 and Obj. 9 are derived based on high SNR approximation as the effects of $\alpha I$ and $\Phi$ are neglected.
objective function and on the constraints. As discussed in [26],
deriving the optimal structure of $F$ for Opt. 1.2 corresponds
to deriving the optimal structures of $F$ for Opt. 1.1 for various
objective functions, including Obj. 1 to Obj. 15.

Since $\psi_j(F)$ is right unitarily-invariant, Opt. 1.2 is equiva-
lent to the following matrix-monotonic optimization problem

$$\text{Opt. 1.3: } \max_{F} F^H \Pi F \text{ s.t. } \psi_j(F) \leq 0, \ 1 \leq j \leq I. \hspace{1cm} (29)$$

Generally, matrix-monotonic optimization maximizes a pos-
itive semi-definite matrix under certain power constraints.
The fundamental idea of matrix-monotonic optimization is to
extend the objective functions and solution sets to get in
return more freedoms that can be exploited to simplify the
analysis. The optimal solutions of Opt. 1.1 for the objective
functions Obj. 1 to Obj. 15 are all in the Pareto optimal
solution set of Opt. 1.3. Since matrix-monotonic optimization
derives the common structure of the Pareto optimal solution
set of Opt. 1.3, the common optimal structures derived are ex-
actly the structures of the optimal solutions of Opt. 1.1. By
taking advantage of these optimal structures, Opt. 1.1 can be
substantially simplified.

Interestingly, $F^H \Pi F$ can be interpreted as a matrix version
SNR [26]. Thus, based on Opt. 1.3 it can be concluded that
various MIMO transceiver optimization problems maximize
this matrix version SNR. When there are multiple data streams,
majorizing the matrix version SNR inherently constitute a
multi-objective optimization problem. In addition, each uni-
tary matrix $Q_X$ corresponds to a specific implementation
scheme. The focus of matrix-monotonic optimization is how
to maximize the positive semi-definite matrix $F^H \Pi F$ under
certain constraints. Different objective functions realize dif-
derent tradeoffs among the multiple data streams, and matrix-
monotonic optimization is a powerful tool that unifies the
different constrained optimization problems with various ob-
jective functions. Specifically, based on matrix-monotonic opt-
imization, the common properties of these objective functions
are revealed, which are reflected on the optimal diagonalizable
structures.

These structures can transform complex optimization prob-
lems relying on matrix variables into much simpler ones with
only vector variables. Thus case-by-case investigations for dif-
ferent objective functions are avoided. Since the optimal
structure of $F$ also depends on the specific form of the
constraints, in the following, three right unitary invariant con-
straints are investigated, namely, shaping constraint [36], joint
power constraint [36] and multiple weighted power constraints
[34].

**Shaping Constraint** For the shaping constraint, i.e., Con-
straint 4, Opt. 1.3 becomes the following optimization prob-
lem [36]

$$\text{Opt. 1.4: } \max_{F} F^H \Pi F \text{ s.t. } FF^H \preceq R_s. \hspace{1cm} (30)$$

The following lemma reveals the optimal structure of $F$ for
Opt. 1.4 with the shaping constraint.

**Lemma 1** When $R_s$ is attainable, i.e., the rank of $R_s$ is not
higher than the number of columns and the number of rows
in $F$, the optimal solution $F_{opt}$ of Opt. 1.4 is a square root of
$R_s$, i.e., $F_{opt} F_{opt}^H = R_s$.

**Proof 1** Since the shaping constraint in Opt. 1.4 is right
unitarily-invariant for $F$, the objective is equivalent to maxi-
mizing $\lambda(F^H \Pi F)$, which is in turn equivalent to maximizing
$\lambda(\Pi^{1/2} FF^H \Pi^{1/2})$. As $FF^H \preceq R_s$, it can be concluded
that $\lambda(\Pi^{1/2} FF^H \Pi^{1/2}) \preceq \lambda(\Pi^{1/2} R_s \Pi^{1/2})$, in which the
equality holds when $FF^H = R_s$. When the rank of $R_s$ is
higher than the number of columns and the number of rows in
$F$, the optimal solution $F_{opt}$ is a square root of $R_s$. It is
worth noting that the square roots of $R_s$ are not unique.
There are many square roots of $R_s$, however the different square
roots have the same performance. We can choose an arbitrary square root of $R_s$ without performance loss.

**Joint Power Constraint** Under the joint power constraint,
Constraint 6, Opt. 1.3 can be rewritten as

$$\text{Opt. 1.5: } \max_{F} F^H \Pi F \text{ s.t. } \text{Tr}(FF^H) \leq P, \quad FF^H \preceq \tau I. \hspace{1cm} (31)$$

The optimal solution $F_{opt}$ for Opt. 1.5 is given in Lemma 2.

**Lemma 2** For Opt. 1.5 with the joint power constraint, the
Pareto optimal solutions satisfy the following structure

$$F_{opt} = U_{\Pi} \Lambda_F U_{\Pi}^H_{Arb}, \hspace{1cm} (32)$$

where the unitary matrix $U_{\Pi}$ is specified by the EVD

$$\Pi = U_{\Pi} \Lambda_{\Pi} U_{\Pi}^H \text{ with } \Lambda_{\Pi} \succeq \tau,$$ \hspace{1cm} (33)

every diagonal element of the rectangular diagonal matrix $\Lambda_F$
is smaller than $\sqrt{\tau}$, and $U_{Arb}$ is an arbitrary unitary matrix
having the appropriate dimension.

**Proof 2** The proof is given in Appendix B.

**Remark 1** For the optimization problem only under the sum
power constraint, the optimal structure for $F_{opt}$ is also speci-
ified by (32), where the sum of the diagonal elements of $\Lambda_F$
is no larger than $P$.

**Multiple Weighted Power Constraints** Under the multi-
ple weighted power constraints, Opt. 1.3 becomes

$$\text{Opt. 1.6: } \max_{F} F^H \Pi F \text{ s.t. } \text{Tr}(\Omega_i FF^H) \leq P, \ 1 \leq i \leq I. \hspace{1cm} (34)$$

Note that the weighted power constraints are convex [23] and
the detailed proof is given in Appendix C. The weighted power
constraints include both the sum power constraint and per-
rentenna power constraints as its special cases. The optimal
solution $F_{opt}$ for Opt. 1.6 is given in Lemma 3.

**Lemma 3** The Pareto optimal solutions of Opt. 1.6 satisfy the
following structure

$$F_{opt} = \Omega^{-\frac{1}{2}} U_{\Pi} \Lambda_F U_{\Pi}^H_{Arb}, \hspace{1cm} (35)$$

where $U_{Arb}$ is an arbitrary unitary matrix of appropriate
dimension, $\Omega = \sum_{i=1}^{I} \alpha_i \Omega_i$, the nonnegative scalars $\alpha_i$
are the weighting factors that ensure that the constraints
$\text{Tr}(\Omega_i FF^H) \leq P_i$ hold and they can be computed by classic
Three specific applications are given in two perspectives. Firstly, in [10], linear and nonlinear theory. Our work is different from this existing framework [45, P244].

Important variants of classic water-filling solutons are in fact diverse. Linear and nonlinear optimization problems are unified in the framework based on majorization theory [10]. Our work is different from this existing framework in two perspectives. Firstly, in [10], linear and nonlinear transceiver optimization is considered separately. In our work, they are considered in the same framework. Additionally, in our work, more objective functions are considered. More importantly, the shaping constraint, joint power constraint and multiple weighted power constraints are considered in our work instead of merely the sum power constraint.

For the multiple weighted power constraints, to the best of our knowledge, all the existing works are based on the KKT conditions. There are several limitations for these existing works. Firstly, this method is only applicable to mutual information maximization and MSE minimization. It cannot be used for more general objective functions. The method is not applicable for example to more complex systems, such as multi-hop AF MIMO relaying systems. Moreover, the KKT condition based methods also suffer from a serious weaknesses due to the fact that the KKT conditions are only necessary conditions for the optimal solutions. As discussed in [44], the so-called turning-off effect and ambiguity effect usually perturb the KKT conditions based methods when deriving the optimal solutions. To overcome this problem, a widely used method is to consider the covariance matrix as a new variable in order to exploit its hidden convex nature.

Unfortunately, the cost of adopting this approach is that the rank constraint has to be relaxed first. By contrast, our matrix-monotonic optimization framework does not suffer from these problems and has much wider applications.

III. BAYES ROBUST MATRIX-MONOTONIC OPTIMIZATION

In wireless communication systems, the channel parameters have to be estimated. However, due to the uncertainty introduced both by noise and the time-varying nature of wireless channels, channel estimation errors inevitably exist [17], the true channel matrix $H$ can be expressed by the following Kronecker formula [18], [20]

$$H = \hat{H} + H_W \Psi \hat{\Phi},$$

where $\hat{H}$ is the estimated channel matrix and $H_W \Psi \hat{\Phi}$ is the channel estimation error, in which the elements of $H_W$ obey the independent and identical complex Gaussian distribution $CN(0, 1)$ and the covariance matrix $\Psi$ of the channel estimate is a function of both the training sequence and of the channel estimator [18], [20]. It is worth noting that in this section we focus our attention on the robust transceiver design for the scenario, where both the source and destination have imperfect CSI. Based on (37), for the Bayes robust transceiver optimization, the matrix $\Pi$ in the matrix-monotonic optimization can be expressed as [26]

$$\Pi = \hat{H}(\sigma_n^2 I + \text{Tr}(XX^H\Psi)I)^{-1}\hat{H},$$

where $\sigma_n^2$ is the additive white noise power in the data transmission.

As a result, the generic Bayes robust matrix-variable optimization can be formulated as [26]

$$\text{Opt. 2.1:} \quad \min_{X} f(X^H\hat{H}K_n^{-1}\hat{H}X),$$

s.t. $K_n = \sigma_n^2 I + \text{Tr}(XX^H\Psi)I$, \hspace{1cm} (39)

$$\psi_i(X) \leq 0, \quad 1 \leq i \leq I.$$
unitarily-invariant. Opt. 2.1 is transferred equivalently to the following matrix-monotonic optimization problem:

**Opt. 2.2:** \( \max_F F^H \tilde{H}^H K_n^{-1} \tilde{H} F, \)  
\[ \text{s.t. } K_n = \sigma_n^2 I + \text{Tr}(F F^H \Psi), \]  
\[ \psi_1(F) \leq 0, 1 \leq i \leq I. \]  

(40)

Here the matrix \( F^H \tilde{H}^H K_n^{-1} \tilde{H} F \) can be regarded as an extended SNR matrix in the presence of channel estimation errors, and this kind of matrix-monotonic optimization is named as robust matrix-monotonic optimization in [26]. In the following, we discuss the optimal solutions of this robust matrix-monotonic optimization problem under specific power constraints.

1) **Shaping Constraint:** Consider the shaping constraint of \( \psi_1(F) = FF^H - R_s, \)

(41)

As proved in Appendix E, for the general case of \( \Psi \not\propto I, \) a suboptimal solution for Opt. 2.2 which maximizes a lower bound of the objective of Opt. 2.2 is given by Lemma 1. When \( \Psi = 0, \) the lower bound is tight and the solution given in Lemma 1 is exactly the Pareto optimal solution of Opt. 2.2.

2) **Joint Power Constraint:** Next consider the joint power constraint specified by

\( \psi_1(F) = \text{Tr}(F F^H) - P, \) \( \psi_2(F) = FF^H - \tau I. \)

(42)

For the perfect CSI case associated with \( \Psi = 0, \) the Pareto optimal solutions of Opt. 2.2 are specified by Lemma 2. When \( \Psi \propto I \) and \( \psi_1(F) = 0 \) is active at the optimal solutions \( F_{\text{opt}}, \) the Pareto optimal solutions of Opt. 2.2 also satisfy the structure given in Lemma 2, since in this case \( K_n \) is constant. As proved in Appendix E, for the general case \( \Psi \not\propto I, \) the suboptimal solution that maximizes a lower bound of the objective of Opt. 2.2 satisfies the following structure

\( F = \frac{\sigma_n \tilde{\Psi}^{-\frac{1}{2}} V_H \Lambda_\tilde{F} F U_{\text{Arb}}} {\left(1 - \text{Tr} \left( \tilde{\Psi}^{-\frac{1}{2}} \tilde{\Psi}^{-\frac{1}{2}} V_H \Lambda_\tilde{F} F V_H^H \right) \right)^\frac{1}{2}}, \)

(43)

where \( \tilde{\Psi} = \sigma_n^2 I + P \tilde{\Psi} \) and the unitary matrix \( V_H \) is defined based on the following SVD

\( \tilde{H} (\sigma_n^2 I + P \Psi)^{-\frac{1}{2}} = U_H \Lambda_\tilde{H} V_H^H, \) with, \( \Lambda_\tilde{H} \prec \).

(44)

The diagonal elements of the rectangular diagonal matrix \( \Lambda_\tilde{F} \) are smaller than \( \sqrt{\text{Tr}(\sigma_n^2 + P \lambda_{\text{min}}(\Psi))/\text{Tr}(\sigma_n^2 + P \lambda_{\text{max}}(\Psi))}. \)

3) **Multiple Weighted Power Constraints:** When the multiple weighted power constraints are used, we have

\( \psi_1(F) = \text{Tr}(\Omega_i F F^H) - P_i, 1 \leq i \leq I. \)

(45)

From \( \text{Tr}(\Omega_i F F^H) \leq P_i, \) it is readily seen that the following inequality holds

\( \text{Tr}(\left(\sigma_n^2 \Omega_i + P_i \Psi\right) F F^H) = \text{Tr}(\sigma_n^2 \Omega_i F F^H) + P_i \text{Tr}(\Psi FF^H) \leq \sigma_n^2 P_i + P_i \text{Tr}(\Psi FF^H). \)

(46)

Hence \( \text{Tr}(\Omega_i F F^H) \leq P_i \) is equivalent to

\[ \frac{\text{Tr}(\left(\sigma_n^2 \Omega_i + P_i \Psi\right) F F^H)}{\sigma_n^2 + \text{Tr}(FF^H \Psi)} \leq P_i. \]

(47)

As a result, the Bayes robust matrix-monotonic optimization problem (40) is equivalent to the following problem

**Opt. 2.3:** \( \max_F F^H \tilde{H}^H K_n^{-1} \tilde{H} F, \)  
\[ \text{s.t. } K_n = \sigma_n^2 I + \text{Tr}(F F^H \Psi), \]  
\[ \frac{\text{Tr}(\left(\sigma_n^2 \Omega_i + P_i \Psi\right) F F^H)}{\sigma_n^2 + \text{Tr}(FF^H \Psi)} \leq P_i, 1 \leq i \leq I. \]  

(48)

By defining the auxiliary matrix variable

\( \tilde{F} = [\sigma_n^2 + \text{Tr}(F F^H \Psi)]^{-\frac{1}{2}} F, \)

the optimization problem (48) can be simplified to:

**Opt. 2.4:** \( \max_F \tilde{F}^H \tilde{H}^H \tilde{H} \tilde{F}, \)  
\[ \text{s.t. } \text{Tr}(\left(\sigma_n^2 \Omega_i + P_i \Psi\right) \tilde{F} \tilde{F}^H) \leq P_i, 1 \leq i \leq I. \]

(50)

Similar to the proof of Lemma 3, specifically to (102) in Appendix D, the above optimization problem is equivalent to

**Opt. 2.5:** \( \max_{\tilde{F}} \tilde{F}^H \tilde{H}^H \tilde{H} \tilde{F}, \text{s.t.} \text{Tr}(\Omega \tilde{F} \tilde{F}^H) \leq \sum_{i=1}^{I} P_i, \)

(51)

where

\( \Omega = \sum_{i=1}^{I} \alpha_i (\sigma_n^2 \Omega_i + P_i \Psi). \)

(52)

According to Lemma 3, the Pareto optimal solutions \( \tilde{F}_{\text{opt}} \) of Opt. 2.5 satisfy the following structure

\( \tilde{F}_{\text{opt}} = \Omega^{-\frac{1}{2}} V_\Omega \Lambda_\tilde{F} F U_{\text{Arb}}, \)

(53)

where the unitary matrix \( V_\Omega \) is specified by the SVD of:

\( \tilde{H} = U_\Omega \Lambda_\tilde{H} V_\Omega^H \).

(54)

From (49), we have \( [\sigma_n^2 + \text{Tr}(F F^H \Psi)]^{-\frac{1}{2}} F = F \) and based on this conclusion we have the following equation

\( [\sigma_n^2 + \text{Tr}(F F^H \Psi)] \text{Tr}(\tilde{F} \tilde{F}^H) + \sigma_n^2 = \text{Tr}(\Psi FF^H) + \sigma_n^2. \)

(55)

This yields

\( \sigma_n^2 + \text{Tr}(F F^H \Psi) = \sigma_n^2/(1 - \text{Tr}(\Psi FF^H)). \)

(56)

Thus, given the Pareto optimal \( \tilde{F}_{\text{opt}}, \) the Pareto optimal \( F_{\text{opt}} \) is expressed as

\( F_{\text{opt}} = \sqrt{\sigma_n^2/\left[1 - \text{Tr}(\Omega^{-\frac{1}{2}} \Psi \Omega^{-\frac{1}{2}} V_\Omega \Lambda_\tilde{F} F U_{\text{Arb}} V_\Omega^H \right]} \).

(57)

Given (57) and (53), we arrive at the following lemma.

**Lemma 4** The Pareto optimal solutions \( F_{\text{opt}} \) of Opt. 2.2 under the multiple weighted power constraints satisfy the following structure

\( F_{\text{opt}} = \frac{\sigma_n \Omega^{-\frac{1}{2}} V_\Omega \Lambda_\tilde{F} F U_{\text{Arb}} \left[1 - \text{Tr}(\Omega^{-\frac{1}{2}} \Psi \Omega^{-\frac{1}{2}} V_\Omega \Lambda_\tilde{F} F U_{\text{Arb}} V_\Omega^H \right]^{-1}} \).

(58)

The robust optimal structure under the multiple weighted power constraints given in Lemma 4 is significantly different from the existing conclusions previously designed for the robust solutions under the sum power constraints [26] and for the transceiver designs relying on perfect CSI under the
Opt. 3.3: \[
\min_{Q, X} f \left( Q^H \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right)^H R_n^{-1} \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right)^{H} X \right) p(H_W) dH_W, \text{s.t. } \psi_i(F) \leq 0, 1 \leq i \leq I, \tag{63}
\]

Opt. 3.4: \[
\min_{Q, X} f \left( Q^H \int F^H \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right)^H R_n^{-1} \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right)^{H} X \right) p(H_W) dH_W Q_X, \text{s.t. } \psi_i(F) \leq 0, 1 \leq i \leq I. \tag{64}
\]

Opt. 3.5: \[
\min_{F} \lambda \left( \mathbb{E} \{ F^H (\Psi^+ H_W \Sigma^+ + \hat{H}^{H}) R_n^{-1} (\Sigma^+ H_W \Psi^+ + \hat{H}) F \} \right), \text{s.t. } \psi_i(F) \leq 0, 1 \leq i \leq I. \tag{65}
\]

per-antenna power constraints [34]. In the traditional robust transceiver designs under the sum power constraint, there is no restriction on the unitary matrix in the eigenvalue decomposition of the covariance matrix \(FF^H\). For the multiple weighted power constraints, there is a restriction on the unitary matrix in the eigenvalue decomposition. Then a new rotation matrix \(\hat{H}^{-\frac{1}{2}}\) is needed, based on which the precoder matrix can align the direction with the space constructed by the multiple weighting matrices.

IV. STOCHASTICALLY ROBUST MATRIX-MONOTONIC OPTIMIZATION

When CSI at the receiver (CSIR) is perfect, but only statistical CSI at the transmitter (CSIT) is available, the corresponding stochastically robust matrix-monotonic optimization can be formulated as [15]

Opt. 3.1: \[
\min_{X} \mathbb{E}_H \{ f \left( X^H H^H R_n^{-1} H X \right) \}, \tag{59}
\]

s.t. \( \psi_i(X) \leq 0, 1 \leq i \leq I, \)

where \(R_n\) is the noise covariance matrix. For simplicity, we mainly consider \(R_n = \sigma^2 n I\) as that in Section III. For this kind of optimization problems, the objective function is an average value over the distribution of the channel matrix \(H\) modeled by

\[
H = \hat{H} + \Sigma^+ H_W \Psi^+, \tag{60}
\]

where \(\Sigma\) and \(\Psi\) are the row and column correlation matrices, respectively. For MIMO systems, \(\Sigma\) is the spatial correlation matrix of the receiver antenna array, while \(\Psi\) is the spatial correlation matrix of the transmitter antenna array. Since the constraints are right unitarily-invariant, Opt. 3.1 can be expressed as

Opt. 3.2: \[
\min_{F} \mathbb{E}_H \{ f \left( Q^H \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right)^H X \right) \}, \tag{61}
\]

s.t. \( \psi_i(F) \leq 0, 1 \leq i \leq I. \)

The stochastically robust matrix-monotonic optimization naturally aims at optimizing the distribution of the random matrix \(HF\), based on the channel model (60). Therefore, Opt. 3.2 can be rewritten as Opt. 3.3 of (63) at the top of the next page, where \(p(H_W)\) is the probability density function (PDF) of \(H_W\). As pointed out in [17], the analytical expression of the average value of an arbitrary objective function \(f(\cdot)\) in Opt. 3.3 is impossible to obtain, which thus makes Opt. 3.3 difficult to address. An alternative scheme is to consider the average matrix in the objective function \(f(\cdot)\) and the corresponding optimization problem is Opt. 3.4 given in (64). Taking

\[
\Pi = \mathbb{E} \{ \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right)^H R_n^{-1} \left( \hat{H} + \Sigma^+ H_W \Psi^+ \right) \}, \tag{62}
\]

the optimal solutions of \(Q_X\) are given in Table II. Based on the optimal solutions of \(Q_X\), similar to Opt. 1.2, the optimal solutions \(F\) of Opt. 3.4 fall in the Pareto optimal solution set of Opt. 3.5 in (65). It is obvious that the key to the optimization of Opt. 3.5 is to maximize eigenvalues of \(F^H (\hat{H} + \Sigma^+ H_W \Psi^+ + \hat{H}^H) R_n^{-1} (\Sigma^+ H_W \Psi^+ + \hat{H}) F\) = \(F^H(H^H R_n^{-1} H + \text{Tr}(\Sigma R_n^{-1}) \Psi) F\). Hence, this stochastically robust optimization problem Opt. 3.5 is equivalent to

Opt. 3.6: \[
\max_{F} \lambda (F^H (H^H R_n^{-1} H + \text{Tr}(\Sigma R_n^{-1}) \Psi) F), \tag{66}
\]

s.t. \( \psi_i(F) \leq 0, 1 \leq i \leq I. \)

As discussed previously in Section II-C, the above multi-objective optimization problem is equivalent to the following matrix-monotonic optimization problem

Opt. 3.7: \[
\max_{F} F^H (H^H R_n^{-1} H + \text{Tr}(\Sigma R_n^{-1}) \Psi) F, \tag{67}
\]

s.t. \( \psi_i(F) \leq 0, 1 \leq i \leq I. \)

Again, we discuss the Pareto optimal solutions of this stochastically robust matrix-monotonic optimization problem under three specific power constraints, respectively.

1) Shaping Constraint: Under the shaping constraint of \(\psi(F) = FF^H - R_s\), the optimal solution \(F_{\text{opt}}\) to Opt. 3.7 is specified by Lemma 1. Specifically, when the rank of \(R_n\) is not higher than the number of columns and the number of rows in \(F\), \(F_{\text{opt}}\) is a square root of \(R_s\).

2) Joint Power Constraint: Clearly, under the joint power constraint (42), Opt. 3.7 is identical to Opt. 1.5 with

\[
\Pi = \hat{H}^H R_n^{-1} \hat{H} + \text{Tr}(\Sigma R_n^{-1}) \Psi. \tag{68}
\]

Therefore, the Pareto optimal solutions \(F_{\text{opt}}\) of Opt. 3.7 under the joint power constraint are defined exactly in Lemma 2 by simply replacing \(\Pi\) in (32) and (33) with (68).

3) Multiple Weighted Power Constraints: Obviously, under the multiple weighted power constraints (45), the Pareto optimal solutions \(F_{\text{opt}}\) of Opt. 3.7 are specified by Lemma 3, where \(\Pi\) should be replaced by (68).

V. WORST CASE ROBUST MATRIX-MONOTONIC OPTIMIZATION

In this section, we consider the norm bounded CSI error, i.e., \(\| \Delta H \|_2 \leq \gamma\) with \(\| \cdot \|_2\) denoting matrix Spectral norm,
and adopt the worst case (min-max) criterion as a figure-of-merit for robust designs [19]. Hereafter, spectral norm is adopted since it can act as both lower and upper bounds of the widely adopted Frobenius and Nuclear norms and is generally tractable [19], [47]. For example, we have \( \| \cdot \|_F \leq \sqrt{\text{rank}(\cdot)} \| \cdot \|_2 \), implying that spectral norm constrained error can also provide valuable insights for Frobenius norm constrained case. Moreover, for the same error size, spectral norm generally covers the largest error region.

Let us denote the estimated channel matrix and channel error matrix by \( \hat{H} \) and \( \Delta H \). With norm-bounded CSI error \( \| \Delta H \|_2 \leq \gamma \), substituting \( H = \hat{H} - \Delta H \) and \( R_n = \sigma_n^2 I \) into Opt. 1.3, the robust matrix-monotonic optimization problem under Spectral norm bounded CSI error can be formulated as

\[
\text{Opt. 4.1: } \max_{\Delta H} \sigma_n^{-2} \mathbf{F}^H (\hat{H} - \Delta H)^H (\hat{H} - \Delta H) \mathbf{F},
\]

s.t. \( \psi_i(\mathbf{F}) \leq 0, 1 \leq i \leq I, \| \Delta H \|_2 \leq \gamma \). (69)

The Spectral norm is unitarily-invariant, which means that for the arbitrary \( |E| \| \leq \varepsilon_s \), it yields \( \| UEV \|_2 \leq \varepsilon_s \) given any unitary matrices \( U \) and \( V \). Based on the following matrix inequality [40, P471]

\[
(\sigma_i(B) - \sigma_i(C))^+ \leq \sigma_i(B + C)
\]

we readily conclude that

\[
\sigma_i(\hat{H} - \Delta H) \geq (\sigma_i(\hat{H}) - \sigma_i(\Delta H))^+. \tag{71}
\]

Therefore, we have the following eigenvalue inequality

\[
\lambda \left((\hat{H} - \Delta H)^H (\hat{H} - \Delta H)\right) \geq \lambda \left((\hat{H} - U_{\hat{H}} \Lambda_{\Delta H} V_{\hat{H}})^H (\hat{H} - U_{\hat{H}} \Lambda_{\Delta H} V_{\hat{H}}^H)\right),
\]

where \( U_{\hat{H}} \) and \( V_{\hat{H}} \) are derived from the following SVD

\[
\hat{H} = U_{\hat{H}} \Lambda_{\hat{H}} V_{\hat{H}}^H, \text{ with } \Lambda_{\hat{H}} \succeq \cdot . \tag{73}
\]

The diagonal matrix \( \Lambda_{\Delta H} \) equals

\[
[\Lambda_{\Delta H}]_{i,i} = \min \left( [\Lambda_{\hat{H}}]_{i,i}, \gamma \right), \forall i. \tag{74}
\]

Then there exists a unitary matrix \( Q \) makes the following matrix inequality hold

\[
Q^H (\hat{H} - \Delta H)^H (\hat{H} - \Delta H) Q \geq (\hat{H} - U_{\hat{H}} \Lambda_{\Delta H} V_{\hat{H}}^H)^H (\hat{H} - U_{\hat{H}} \Lambda_{\Delta H} V_{\hat{H}}^H). \tag{75}
\]

Based on (75), when the constraint functions \( \psi_i(\mathbf{F}) \)'s in Opt. 4.1 are left unitarily invariant, the worst-case \( \Delta H \) for Opt. 4.1 is

\[
\Delta H_{\text{worst}} = U_{\hat{H}} \Lambda_{\Delta H} V_{\hat{H}}^H. \tag{76}
\]

That is because when \( \psi_i(\mathbf{F}) \)'s in Opt. 4.1 are left unitarily invariant, such as Constraint 6: the joint power constraint or Constraint 5: the constraints on the eigenvalues of \( \mathbf{F} \mathbf{F}^H \), for any feasible \( \mathbf{F} \) and an arbitrary unitary matrix \( Q, Q \mathbf{F} \) is also feasible. Thus it is always possible to find \( Q \) that makes the matrix inequality in (75) hold. Furthermore, based on the worst-case \( \Delta H_{\text{worst}} \) in (76), Opt. 4.1 is rewritten as

\[
\text{Opt. 4.2: } \max_{\mathbf{F}} \sigma_n^{-2} \mathbf{F}^H (\hat{H} - \Delta H_{\text{worst}})^H (\hat{H} - \Delta H_{\text{worst}}) \mathbf{F},
\]

s.t. \( \psi_i(\mathbf{F}) \leq 0, 1 \leq i \leq I, \| \Delta H \|_2 \leq \gamma \). (77)

We would like to highlight that all the constraints \( \psi_i(\mathbf{F}) \)'s in Opt. 4.1 are right unitarily invariant. The objective function in Opt. 4.2 is an upper bound of the worst case of the objective function of Opt. 4.1 and this bound is tight when \( \psi_i(\mathbf{F}) \)'s are also left unitarily invariant. Specifically, when \( \psi_i(\mathbf{F}) \)'s in Opt. 4.1 are right unitarily invariant, the term \( (\hat{H} - \Delta H_{\text{worst}})^H (\hat{H} - \Delta H_{\text{worst}}) \) is the worst case of \( (\hat{H} - \Delta H)^H (\hat{H} - \Delta H) \) only when \( \Delta H \) is restricted to have the same SVD unitary matrices as \( \hat{H} \).

1) Shaping Constraint: For the shaping constraint (41), the optimal solution \( \mathbf{F}_{\text{opt}} \) of Opt. 4.2 is also specified by Lemma 1. That is, when the rank of \( R_n \) is not larger than the number of columns and the number of rows in \( \mathbf{F} \), \( \mathbf{F}_{\text{opt}} \) of Opt. 4.2 is a square root of \( R_n \).

2) Joint Power Constraint: Under the joint power constraint (42), Opt. 4.2 is identical to Opt. 1.5 with

\[
\Pi = \sigma_n^{-2} (\hat{H} - \Delta H_{\text{worst}})^H (\hat{H} - \Delta H_{\text{worst}}). \tag{78}
\]

As a result, the Pareto optimal solutions \( \mathbf{F}_{\text{opt}} \) of Opt. 4.2 under the joint power constraint are defined exactly in Lemma 2 by simply replacing \( \Pi \) in (32) and (33) with (78).

3) Multiple Weighted Power Constraints: With the multiple weighted power constraints of (45), the Pareto optimal solutions of Opt. 4.2 are specified by Lemma 3, where \( \Pi \) should be replaced by (78).

VI. SIMULATION RESULTS AND DISCUSSIONS

In this section, we take the MSE criterion (Obj. 2 in Table I) of MIMO systems as a central figure-of-merit to demonstrate the proposed robust designs in Section III with statistically imperfect CSIT (ICSIT) and CSIR (ICCSIR), Section IV with statistically imperfect CSIT (ICSIT) and perfect CSIR (PC-CSIR), and Section V with deterministically imperfect CSIT and CSIR. Specifically, in Section III and Section IV, the sum average MSE is studied to illustrate the influence of imperfect CSIT and/or CSIR on average symbol detection performance. While in Section V, the worst-case MSE is adopted to guarantee the symbol detection performance for all channel realizations. Notice that the proposed robust designs in above Sections all have analytical solutions, and can be reduced to simple power allocation problems with water-filling solutions.

Unless otherwise stated, numerical results are presented for the point-to-point MIMO scenario with the transmitter and receiver equipped with \( N_t = 4 \) and \( N_r = 4 \) antennas, respectively. Moreover, the number of data streams is \( L = 2 \). According to (37) adopted in Section III and Section IV, we assume that the imperfect CSI consists of the estimated term \( \hat{H} \) distributed as \( \mathcal{CN}(0,(1 - \sigma^2)I_{N_r} \otimes I_{N_t}) \) and the error term \( H_\Psi \Psi^T \), where \( \Psi \) is defined by the exponential
model, i.e., \( \mathbf{h}_{m,n} = \sigma_n^2 p_t (m-n) \) with \( p_t = 0.5 \) and \( \sigma_n^2 = 0.1 \), to realize the normalized channel \( \mathbb{E}\{ [\mathbf{H}]_{m,n} | [\mathbf{H}]_{m,n} \} = 1 \), \( \forall m, n \). While for the worst-case optimization in Section V, the relative error threshold subject to Spectral norm is set as \( \gamma = s \| \hat{\mathbf{H}} \|_2 \) with \( s \in [0,1] \). In addition, for both Section III and Section IV, since the unknown weighting factors need to be determined via the sub-gradient method, the per-antenna power constraints \( \text{Tr}(\mathbf{\Omega}_i \mathbf{F}^H \mathbf{F}) \leq P_t, \forall i \), where \( \mathbf{\Omega}_i = \text{diag}([0,1,\ldots,N_i],\forall i) \) and \( P_t = P_t, \forall i \), are mainly studied in the simulations as a special case of multiple weighted power constraints. While for Section V, the joint power constraints \( \text{Tr}(\mathbf{F}^H \mathbf{F}) \leq (L-1)P_t \) and \( \mathbf{F}^H \mathbf{F} \preceq P_t \mathbf{I}_N \), are investigated due to the tractability. Particularly, the per-antenna power limitation \( \gamma = \frac{\text{Tr}(\mathbf{\Omega}_i \mathbf{F}^H \mathbf{F}) - 1}{P_t, \forall i} \) can be readily inferred from the shaping power constraint \( \mathbf{F}^H \mathbf{F} \preceq P_t \mathbf{I}_N \). We also define the SNR as \( \frac{P_t}{\sigma_n^2} \), where \( P_t = 1W \) and the noise power \( \sigma_n^2 \) is varied.

For a comprehensive comparison, we also consider three baselines for the MIMO scenario as follows: For Section III and Section IV, the naive design that simply regards \( \hat{\mathbf{H}} \) as a perfect channel estimate of the instantaneous channel \( \mathbf{H} \) is studied, to which the optimal solution is derived by solving the problem \((51)\) with \( \Psi = 0 \), and the sum average MSE is obtained through Monte Carlo experiments. While for Section V, the nonrobust design is studied by firstly considering \( \Delta \mathbf{H} = 0 \) in the problem \((69)\), and then the obtained optimal solution is substituted into the inner minimization of the problem \((69)\) to find the worst-case MSE. Moreover, the ideal case assuming both PCSIR and perfect CSIT (PCSIT) is also considered for all above Sections.

Fig. 1 shows the sum average MSE of all studied designs in Section III and Section IV as the function of the channel error \( \sigma_n^2 \). Clearly, it is observed that when \( \sigma_n^2 \) decreases, sum average MSE performances of all studied designs improve. Also, the performance gap between the native design and robust design in Section III with ICSIT and ICSIR becomes narrower. In particular, as the rise of \( \sigma_n^2 \), the less performance loss of the robust design in Section IV with PCSIR compared to that in Section III with ICSIR can be observed, which further indicates that PCSIR is crucial to realize the acceptable average MSE performance.

Fig. 2 shows the worst-case MSE of the proposed robust design in Section V and the other baselines as the function of SNR. Naturally, the ideal design achieves the best worst-case MSE performance, and the proposed robust design is the next. The nonrobust design has the worst performance since the robustness against channel error is not considered. Similarly to the robust design in Section IV with ICSIT and PCSIR, we also find that the slopes of all studied worst-case designs are nearly identical, and the corresponding worst-case MSE performance is similar especially at high SNR region, because that in this context the high transmit power weakens the influence of deterministic channel error on the achievable MSE. The above conclusions can also be drawn when the increasing number of data streams \( L = 3 \) is considered. In this context, the performance gap among all studied designs is further enlarged.

Fig. 3 shows the worst-case MSE of the proposed robust design in Section V and the other baselines as the function of the relative error threshold \( s \). As expected, the robust design outperforms the non-robust one, and the performance gain becomes more evident with the increase of the number of data streams \( L = 3 \) and error threshold \( s \).

In order to assess the performance of the proposed solutions under general multiple weighted power constraints, without loss of generality we first build an exponential correlation matrix \( \Omega \) with \( \Omega_{ij} = 0.3^{\lfloor i-j \rfloor} \). Based on \( \Omega \), a pair of weight-
Inequality 3 and taking $C$ Obj. 1:

Table II are given. the optimal $C$ Inequality 2 and taking Obj. 2:

$\Omega$ corresponds to the first two eigenchannels and $Q$ has been investigated in depth, which are: 1) both transmitter and $X$ can be derived.

In the following, the detailed proofs for the optimal $Q_X$ in VII. CONCLUSIONS

In this paper, a comprehensive framework for matrix-monotonic optimization has been given under various power constraints, including shaping constraint, joint power constraint and multiple weighted power constraints. Matrix-monotonic optimization of three different CSI scenarios has been investigated in depth, which are: 1) both transmitter and receiver have imperfect CSI; 2) perfect CSI is available at the receiver but the transmitter has only channel statistics; and 3) perfect CSI is available at the receiver, but the channel estimation error at the transmitter is norm-bounded. In all three cases, the matrix-monotonic optimization framework has been used to derive closed-form optimal structures of the optimal matrix variables, which significantly simplifies the associated optimization problems and reveals a range of underlying physical insights.

APPENDIX A

PROOF OF TABLE II

In the following, the detailed proofs for the optimal $Q_X$ in Table II are given.

**Obj. 1:** For **Obj. 1**, based on the righthand side of Matrix Inequality 3 and taking $C = Q_X^H F^H \Pi F Q_X$ and $D = \Phi$, the optimal $Q_X$ can be derived.

**Obj. 2:** For **Obj. 2**, based on the lefthand side of Matrix Inequality 2 and taking $C = Q_X^H F^H \Pi F Q_X$ and $D = \Phi$, the optimal $Q_X$ can be derived.

**Obj. 3:** For **Obj. 3**, based on the lefthand side of Matrix Inequality 1 and taking $C = (Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$ and $D = AA^H$, the optimal $Q_X$ can be derived.

**Obj. 4:** For **Obj. 4**, the following equality holds

$$
\log|A^H (Q_X^H F^H \Pi F Q_X + \alpha I)^{-1} A + \Phi| = \log|A^H (Q_X^H F^H \Pi F Q_X + \alpha I)^{-1} A \Phi^{-1} + I| + c
$$

where $c = \log|\Phi|$ is a constant. Then based on the lefthand side of Matrix Inequality 4 and taking $C = (Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$ and $D = A \Phi^{-1} A^H$, the optimal $Q_X$ can be derived.

**Obj. 5.1:** For **Obj. 5.1** based on the majorization theory the minimum value of an additively Schur-convex function is achieved when all the diagonal elements of $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$ equal with each other. Therefore the optimal $Q_X$ can be derived.

**Obj. 5.2:** For **Obj. 5.2** based on the majorization theory the minimum value of an additively Schur-convex function is achieved when all the diagonal elements of $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$ equal the eigenvalues of $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$. Therefore the optimal $Q_X$ can be derived.

**Obj. 6.1:** For **Obj. 6.1** based on the majorization theory the minimum value of a multiplicatively Schur-convex function is achieved when all the diagonal elements of the lower triangular matrix of the Cholesky-decomposition $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$ have the same squared modulus. Therefore, the optimal $Q_X$ can be derived.

**Obj. 6.2:** For **Obj. 6.2** based on the majorization theory the minimum value of a multiplicatively Schur-convex function is achieved when all the squared diagonal elements of the lower triangular matrix of the Cholesky-decomposition $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$ equal the eigenvalues of $(Q_X^H F^H \Pi F Q_X + \alpha I)^{-1}$. Therefore the optimal $Q_X$ can be derived.

**Obj. 7:** For **Obj. 7** the objective function can be rewritten as

$$
\log|A^H Q_X^H F^H \Pi F Q_X A + \Phi| = \log|A^H Q_X^H F^H \Pi F Q_X A \Phi^{-1} + I| + c
$$

(80)
where $c = \log |\Phi|$. Then based on the righthand side of Matrix Inequality 4 and taking $C = Q_X^H F^H \Pi F_X$ and $D = A \Phi^{-1} A^H$ the optimal $Q_X$ can be derived.

**Obj. 8:** For **Obj. 8** the objective function equals

$$\text{Tr} \left( (A^H Q_X^H F^H \Pi F_X A + \alpha I)^{-1} \right) = \sum_{k=1}^{N} \frac{1}{\lambda_k(A^H Q_X^H F^H \Pi F_X A + \alpha)} + \alpha \tag{81}$$

At high SNR, when $k \leq N$ and $N$ is the rank of $A^H Q_X^H F^H \Pi F_X A$ we have

$$\lambda_k(A^H Q_X^H F^H \Pi F_X A) \gg \alpha \tag{82}$$

Then at high SNR, minimizing **Obj. 8** is equivalent to minimizing the following function

$$\sum_{k=1}^{N} \frac{1}{\lambda_k(A^H Q_X^H F^H \Pi F_X A + \alpha)} \approx \sum_{k=1}^{N} \frac{1}{\lambda_k(A^H Q_X^H F^H \Pi F_X A)} \tag{83}$$

Because $\sum_{k=1}^{N} \frac{1}{\lambda_k}$ is multiplicatively Schur-convex, based on majorization theory the optimal $Q_X$ can be derived.

**Obj. 9:** For **Obj. 9** at high SNR the objective function can be approximated by

$$\text{Tr} \left( (A^H (Q_X^H F^H \Pi F_X + \Phi)^{-1} A) \right) \approx \text{Tr} \left( (A^H (Q_X^H F^H \Pi F_X)^{-1} A) \right) \tag{84}$$

where the approximation comes from the fact that at high SNR $Q_X^H F^H \Pi F_X$ is much larger than $\Phi$ and $Q_X^H F^H \Pi F_X + \Phi \approx Q_X^H F^H \Pi F_X$. Then based on the lefthand side of Matrix Inequality 1 and taking $C = (Q_X^H F^H \Pi F_X)^{-1}$ and $D = AA^H$, the optimal $Q_X$ can be derived.

**Obj. 10:** For **Obj. 10** based on the righthand side of Matrix Inequality 3 and taking $C = Q_X^H F^H \Pi F_X \otimes \Sigma_2$ and $D = \Phi \otimes \Sigma_1$ the optimal $Q_X$ can be derived.

**Obj. 11:** For **Obj. 11** based on the righthand side of Matrix Inequality 3 and taking $C = \Sigma_2 \otimes Q_X^H F^H \Pi F_X$ and $D = \Sigma_1 \otimes \Phi$ the optimal $Q_X$ can be derived.

**Obj. 12:** For **Obj. 12** based on the lefthand side of Matrix Inequality 2 and taking $C = Q_X^H F^H \Pi F_X \otimes \Sigma_2$ and $D = \Phi \otimes \Sigma_1$ the optimal $Q_X$ can be derived.

**Obj. 13:** For **Obj. 13** based on the righthand side of Matrix Inequality 1 and taking $C = (I + Q_X^H F^H \Pi F_X \otimes \Sigma_2)^{-1}$ and $D = AA^H \otimes \Sigma_1$, the optimal $Q_X$ can be derived.

**Obj. 14:** For **Obj. 14** based on the lefthand side of Matrix Inequality 2 and taking $C = (I + \Sigma_2 \otimes Q_X^H F^H \Pi F_X)^{-1}$ and $D = \Sigma_1 \otimes (AA^H)$, the optimal $Q_X$ can be derived.

**APPENDIX B**

**PROOF OF LEMMA 2**

The Pareto optimal solution set of (31) falls in the optimal solution set of the following optimization problem for all the possible $F_{in}$ that are in the region of $\text{Tr}(FF^H) \leq P$ and $FF^H \preceq \tau I$:

$$\max_{F,\alpha} \quad \alpha \tag{85}$$

s.t. $F^H \Pi F = \alpha F_{in}^H \Pi F_{in}$

$$\text{Tr}(FF^H) \leq P, \quad FF^H \preceq \tau I. \tag{86}$$

This conclusion is obvious because for any Pareto optimal solution of (31) $F_{opt}$, for an $\alpha < 1$, $F_{in} = \alpha F_{opt}$ obviously satisfies $\text{Tr}(F_{in}^H F_{in}) \leq P$ and $F_{in} F_{in}^H \preceq \tau I$. In the following, we will prove that the optimal solutions of (85) own the same structure.

Based on the matrix equality properties that when $A$ and $B$ have the same dimensionality $A^H A = B^H B$ is equivalent to $A = U A$ with $U$ being an unitary matrix [40, P406], the first constraint of (85) is equivalent to

$$\Pi^{1/2} F = \sqrt{\alpha} U \Pi^{1/2} F_{in} \tag{87}$$

based on which and defining the pseudo inverse of $\Pi^{1/2}$ as $(\Pi^{1/2})^+$, we have

$$\Pi^{1/2} F = \sqrt{\alpha} (\Pi^{1/2})^+ U \Pi^{1/2} F_{in}. \tag{88}$$

It is obvious that $\alpha$ is solved to be

$$\alpha = \frac{\text{Tr} \left[ (\Pi^{1/2})^+ U \Pi^{1/2} F_{in}^H (\Pi^{1/2})^+ U \Pi^{1/2} F_{in} \right]}{\text{Tr} \left[ (\Pi^{1/2})^+ U \Pi^{1/2} F_{in}^H (\Pi^{1/2})^+ U \Pi^{1/2} F_{in} \right]} \tag{89}$$

Based on **Matrix Inequality 1**, the numerator of the righthand side of the above equation satisfies

$$\text{Tr} \left[ (\Pi^{1/2})^+ U \Pi^{1/2} F_{in}^H (\Pi^{1/2})^+ U \Pi^{1/2} F_{in} \right] \leq \sum_j \lambda_j (FF^H) \tag{90}$$

and meanwhile the denominator satisfies

$$\text{Tr} \left[ (\Pi^{1/2})^+ U \Pi^{1/2} F_{in}^H (\Pi^{1/2})^+ U \Pi^{1/2} F_{in} \right] \leq \sum_j \lambda_j \left( (\Pi^{1/2})^+ F_{in}^H (\Pi^{1/2})^+ \right) \tag{91}$$

Based on (89) and (90), $\alpha$ is maximized when $F$ satisfies the following structure

$$F = U_{\Pi} A_F V_{\Pi}^H \tag{92}$$

where the unitary matrices $U_{\Pi}$ and $V_{\Pi}$ are defined based on the following EVDs

$$\Pi = U_{\Pi} \Lambda_{\Pi} U_{\Pi}^H \quad \text{with} \quad \Lambda_{\Pi} \prec \Lambda, \quad F_{in}^H \Pi F_{in} = V_{in} A_{in} V_{in}^H \quad \text{with} \quad A_{in} \prec \Lambda. \tag{93}$$

It is worth noting that the final two constraints in the optimization problem (85) only constrain the eigenvalues of $FF^H$. In other words, the final two constraints in (85) are both right unitarily invariant and left unitarily invariant. The derivations in (89) and (90) are independent of the singular values of $F$. It means that for any given $A_F$ in (91) the optimal $F$ maximizing $\alpha$ satisfies the structure in (91) without violating...
the final two constraints in (85). Therefore, it is concluded that the optimal solutions of (85) satisfies the structure in (91) and thus the Pareto optimal solutions of (50) satisfies the structure given by (91). Furthermore, substituting (91) into the objective function of (50), it can be seen that for the Pareto optimal solutions, the value of the unitary matrix $V_{in}$ in (91) does not affect the optimality of the Pareto optimal solutions. Finally, the Pareto optimal solutions of (50) satisfies the following structure
\begin{equation}
F_{opt} = U_{\Pi} A_F U_{Ab}^H.
\end{equation}

\section*{Appendix C}
\textbf{Proof of Convexity}

The proof is exactly based the definition of convex function. Taking the complex matrix $F$ as optimization variable, based on the definition of convex function, the function $\text{Tr}(\Omega, FF^H)$ is convex with respect to $F$ if and only if for two complex matrices $F_1$ and $F_2$ and $0 \leq a \leq 1$ the following inequality holds [45]
\begin{equation}
\text{Tr}(\Omega F_1 F_1^H) a + \text{Tr}(\Omega FF^H) (1-a) \geq \text{Tr}(\Omega (a F_1 + (1-a) F_2) (a F_1 + (1-a) F_2)^H).
\end{equation}

This inequality can be proven when $\Omega$ is a positive semidefinite matrix because
\begin{align}
&\text{Tr}(\Omega F_1 F_1^H) a + \text{Tr}(\Omega FF^H) (1-a) \\
&- \text{Tr}(\Omega (a F_1 + (1-a) F_2) (a F_1 + (1-a) F_2)^H) \\
&= a(1-a) \text{Tr}(\Omega (F_1 - F_2)(F_1 - F_2)^H) \geq 0.
\end{align}

Therefore, it can be concluded that when $\Omega$ is a positive semidefinite matrix $\text{Tr}(\Omega FF^H)$ is convex with respect to $F$.

\section*{Appendix D}
\textbf{Proof of Lemma 3}

Any Pareto optimal solution of \textbf{Opt. 1.6}, $F_{\text{Pareto}}$, is also a Pareto optimal solution of the following multi-objective optimization problem
\begin{equation}
\min_{F} \left\{ \text{Tr}(\Omega_i FF^H) \right\}_{i=1}^{I}, \text{ s.t. } FF^H = F_{\text{Pareto}}^H F_{\text{Pareto}}.
\end{equation}

This transformation is built on the proof by contradiction. If $F_{\text{Pareto}}$ is not a Pareto optimal solution of (96), it means that we can find a matrix $F_1$ satisfying
\begin{align}
F_1^H F_1 &= F_{\text{Pareto}}^H F_{\text{Pareto}}, \\
\text{Tr}(\Omega_i F_1 F_1^H) &\leq \text{Tr}(\Omega_i F_{\text{Pareto}} F_{\text{Pareto}}^H) \leq P_i.
\end{align}

Moreover, at least there exists an index $i$ for which the first inequality in the second line will hold. Then it is obvious that we can find a matrix $F_2$ satisfying
\begin{align}
\text{Tr}(\Omega_i F_1 F_1^H) &\leq \text{Tr}(\Omega_i F_2 F_2^H) \leq P_i, \\
F_2^H F_2 &\geq F_1^H F_1 = F_{\text{Pareto}}^H F_{\text{Pareto}}.
\end{align}

As a result, a contradiction is achieved on the assumption that $F_{\text{Pareto}}$ is Pareto optimal.

Since the constraint of (96) is equivalent to $U \Pi^{\frac{1}{2}} F = \Pi^{\frac{1}{2}} F_{\text{Pareto}}$, where $U$ is a suitable unitary matrix [40, P406], the optimization problem (96) is equivalent to
\begin{equation}
\min_{F} \left\{ \text{Tr}(\Omega_i F F^H) \right\}_{i=1}^{I}, \text{ s.t. } U \Pi^{\frac{1}{2}} F = \Pi^{\frac{1}{2}} F_{\text{Pareto}}.
\end{equation}

In (99), the objective functions are quadratic functions and the constraint is a linear function with respect to $F$, which means that the multi-objective optimization problem (99) is convex [45, P135] and the corresponding proof is given in Appendix C. Therefore, for any Pareto optimal solution of (99), there exist the weights $\alpha_i$, $1 \leq i \leq I$, for ensuring that the Pareto optimal solution can be computed via solving the following weighted sum optimization problem [45, P179]
\begin{equation}
\min_{F} \sum_{i=1}^{I} \alpha_i \text{Tr}(\Omega_i FF^H), \text{ s.t. } U \Pi^{\frac{1}{2}} F = \Pi^{\frac{1}{2}} F_{\text{Pareto}}.
\end{equation}

The above conclusion for computing Pareto optimal solution of (99) using weights $\alpha_i$, $1 \leq i \leq I$ in (100) are feasible to any unitary matrix $U$. Meanwhile, it is worth noting that $F_{\text{Pareto}}^H F_{\text{Pareto}}$ is equivalent to $U \Pi^{\frac{1}{2}} F = \Pi^{\frac{1}{2}} F_{\text{Pareto}}$ where $U$ is a suitable unitary matrix [40, P406]. Thus the whole Pareto optimal solution set of (96) can be achieved via solving the following optimization problem by changing the weights $\alpha_i$, $1 \leq i \leq I$,
\begin{equation}
\min_{F} \sum_{i=1}^{I} \alpha_i \text{Tr}(\Omega_i FF^H), \text{ s.t. } FF^H F_{\text{Pareto}} = F_{\text{Pareto}}^H F_{\text{Pareto}}.
\end{equation}

For the optimal solution of (101), $\sum_{i=1}^{I} \alpha_i \text{Tr}(\Omega_i FF^H) = P$. Then $F_{\text{Pareto}}$ is a Pareto optimal solution of the following optimization problem
\begin{equation}
\max_F F^H F^H, \text{ s.t. } \text{Tr} \left( \sum_{i=1}^{I} \alpha_i \Omega_i FF^H \right) \leq P.
\end{equation}

This is concluded based on the proof of contradiction. If $F_{\text{Pareto}}$ is not a Pareto optimal solution of (102), for (102) there will exist $F_1$ which satisfies $F_1^H F_1 \geq F_{\text{Pareto}}^H F_{\text{Pareto}}$ and $\text{Tr} \left( \sum_{i=1}^{I} \alpha_i \Omega_i F_1 F_1^H \right) \leq P$. For positive semidefinite matrices, $A \succeq B$ implies $\lambda(A) \geq \lambda(B)$ [40, P471]. Meanwhile, for two complex matrices $C$ and $D$, $CD$ and $DC$ have the same nonzero eigenvalues. Therefore we have
\begin{equation}
\lambda(\Pi^{\frac{1}{2}} F_1 F_1^H \Pi^{\frac{1}{2}}) \geq \lambda(\Pi^{\frac{1}{2}} F_{\text{Pareto}} F_{\text{Pareto}}^H \Pi^{\frac{1}{2}}),
\end{equation}

based on which it can be concluded that we can find a matrix $F_2$ which satisfies
\begin{align}
F_2^H F_2 &\leq F_1^H, \\
\lambda(\Pi^{\frac{1}{2}} F_2 F_2^H \Pi^{\frac{1}{2}}) &= \lambda(\Pi^{\frac{1}{2}} F_{\text{Pareto}} F_{\text{Pareto}}^H \Pi^{\frac{1}{2}}).
\end{align}

As the weighted power constraint is right unitarily invariant, there will exist a unitary matrix $Q_2$ making the following equality hold
\begin{equation}
Q_2^H F_2^H \Pi F_2 Q_2 = F_{\text{Pareto}}^H F_{\text{Pareto}}.
\end{equation}

Taking $F_2 Q_2 = F_3$ as a new variable, it is concluded that for (101) $F_3^H F_3 = F_{\text{Pareto}}^H F_{\text{Pareto}}$ and $\sum_{i=1}^{I} \alpha_i \text{Tr}(\Omega_i F_3 F_3^H) < \sum_{i=1}^{I} \alpha_i \text{Tr}(\Omega_i F_{\text{Pareto}} F_{\text{Pareto}}^H) \leq P$. This contradicts with previous
conclusion. In other words, $F_{\text{Pareto}}$ is a Pareto optimal solution of (102).

In a nutshell, for any Pareto optimal solution of $\text{Opt. 1.6}$, there exist the weights $\alpha_i$, $1 \leq i \leq I$, for ensuring that this Pareto optimal solution of $\text{Opt. 1.6}$ is also the Pareto optimal solution of (102). Therefore, it can be concluded that any Pareto optimal solution of $\text{Opt. 1.6}$ satisfies the common structures of the Pareto optimal solutions of (102).

Next, we show that the Pareto optimal solutions of (102) own the same diagonalizable structure and thus this structure is also the optimal structure of the Pareto optimal solutions of $\text{Opt. 1.6}$. First define the auxiliary variables

$$\tilde{F} = \left( \sum_{i=1}^{I} \alpha_i \Omega_i \right)^{\frac{1}{2}} F, \quad \Omega = \left( \sum_{i=1}^{I} \alpha_i \Omega_i \right)$$

and the optimization (102) is transferred into:

$$\max_{F} F^H (\Omega^{-\frac{1}{2}})^H \Pi \Omega^{-\frac{1}{2}} \tilde{F}, \quad \text{s.t.} \quad \text{Tr}(\tilde{F} F^H) \leq P. \quad (107)$$

The Pareto optimal solution set of (107) consists of the optimal solutions of the following problem for all the possible $\tilde{F}_n$ in that are in the sphere region of $\text{Tr}(\tilde{F} \tilde{F}^H) \leq P$:

$$\max_{\tilde{F}, \alpha} \alpha, \quad \text{s.t.} \quad \tilde{F}^H (\Omega^{-\frac{1}{2}})^H \Pi \Omega^{-\frac{1}{2}} \tilde{F} = \alpha \tilde{F}_n^H (\Omega^{-\frac{1}{2}})^H \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n, \quad (108)$$

$$\text{Tr}(\tilde{F} F^H) \leq P.$$

The first constraint in (108) is equivalent to

$$\Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F} = \sqrt{\alpha} U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n, \quad (109)$$

Using pseudo inverse, we have

$$\left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F} = \sqrt{\alpha} \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n, \quad (110)$$

based on which we have

$$\left\| \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F} \right\|_F^2 = \text{Tr} \left( \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F} \right) \tilde{F}^H \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F}_n \right)$$

$$= \alpha \text{Tr} \left( \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n \right) \tilde{F}^H \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n$$

$$= \alpha \left\| \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n \right\|_F^2. \quad (111)$$

Therefore, $\alpha$ is solved as

$$\alpha = \frac{\left\| \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n \right\|_F^2}{\left\| \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F} \right\|_F^2}. \quad (112)$$

Based on Matrix Inequality 1, the numerator of (112) satisfies

$$\left\| \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \tilde{F} \right\|_F^2 \leq \sum_j \lambda_j \left( \tilde{F} \tilde{F}^H \right), \quad (113)$$

while its denominator satisfies

$$\left\| \left( \Pi^\frac{1}{2} \Omega^{-\frac{1}{2}} \right)^H U \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n \right\|_F^2 \geq \sum_j \frac{\sigma_j^2 \left( \Pi \Omega^{-\frac{1}{2}} \tilde{F}_n \right)}{\sigma_j^2 \left( \Pi \Omega^{-\frac{1}{2}} \tilde{F} \right)}. \quad (114)$$

where $\sigma_j^2(A)$ denotes the $j$th singular value of $A$. Clearly, $\alpha$ attains the maximum value when the both equalities in (113) and (114) hold. For the optimal $\tilde{F}$ and $U$ together with the fact that for $\text{Opt. 1.6}$, the optimal $F$ is right unitary invariant, the optimal $\tilde{F}$ satisfies the following structure

$$\tilde{F} = U \Lambda \tilde{F} U^H_{\text{Arb}}, \quad (115)$$

where the unitary matrix $U$ is defined based on the following EVD

$$\Pi^{-\frac{1}{2}} \Pi \Pi^{-\frac{1}{2}} = U \Lambda \tilde{F} U^H_{\text{Arb}} \text{ with } \Lambda \Lambda \preceq I.$$

Based on (115) and the definition of $\tilde{F}$ in (106)

$$F = \Omega^{-\frac{1}{2}} U \Lambda \tilde{F} U^H_{\text{Arb}}. \quad (117)$$

**APPENDIX E**

**BAYES ROBUST MATRIX-MONOTONIC OPTIMIZATION**

**A. Shaping Constraint**

With the shaping constraint, $\text{Opt. 2.2}$ becomes

$$\max_{F} F^H H^H K_n^{-1} H F, \quad \text{s.t.} \quad K_n = \sigma_n^2 I + \text{Tr}(FF^H \Psi) I, \quad FF^H \preceq R_n. \quad (118)$$

Note that $\text{Tr}(FF^H \Psi) \leq \text{Tr}(R \Psi)$ and then we have the following matrix inequality

$$F^H H^H K_n^{-1} H F \geq \sigma_n^2 \text{Tr}(R \Psi). \quad (119)$$

Replacing the objective in (118) by its lower bound in (119), the following optimization problem is achieved

$$\max_{F} F^H H^H H F \geq \sigma_n^2 \text{Tr}(R \Psi), \quad \text{s.t.} \quad FF^H \preceq R_n \quad (120)$$

whose Pareto optimal solution is given by Lemma 1. It is obvious that when $\Psi = 0$ or $\Psi \propto I$ and $\text{Tr}(FF^H) = \text{Tr}(R_n)$ is achievable the lower bound is tight.

**B. Joint Power Constraints**

Under the joint power constraints, $\text{Opt. 2.2}$ is written in the following formula

$$\max_{F} F^H H^H K_n^{-1} H F, \quad \text{s.t.} \quad K_n = \sigma_n^2 I + \text{Tr}(FF^H \Psi) I, \quad \text{Tr}(FF^H) \leq P, \quad FF^H \preceq \tau I. \quad (121)$$

The sum power constraint $\text{Tr}(FF^H) \leq P$ is equivalent to the following equality [26]

$$(\sigma_n^2 + \text{Tr}(FF^H \Psi))^2 \text{Tr} \left[ (\sigma_n^2 I + P \Psi) FF^H \right] \leq P. \quad (122)$$

Based on (122), the optimization problem (121) is equivalent to the following one

$$\max_{F} F^H H^H K_n^{-1} H F, \quad \text{s.t.} \quad K_n = \sigma_n^2 I + \text{Tr}(FF^H \Psi) I, \quad \frac{\text{Tr} \left[ (\sigma_n^2 I + P \Psi) FF^H \right]}{\sigma_n^2 + \text{Tr}(FF^H \Psi)} \leq P, \quad FF^H \preceq \tau I. \quad (123)$$

By defining the following matrix variable

$$\tilde{F} = \left[ \sigma_n^2 + \text{Tr}(FF^H \Psi) \right]^{-\frac{1}{2}} \left( \sigma_n^2 I + P \Psi \right)^{-\frac{1}{2}} F, \quad (124)$$
the optimization problem (123) can be transferred into the following equivalent one

\[
\max_{\mathbf{F}} \mathbf{F}^H \tilde{\mathbf{H}}^H \tilde{\mathbf{F}},
\]

s.t. \( \text{Tr}(\mathbf{F}^H \tilde{\mathbf{H}}^H) \leq P, \quad \tilde{\mathbf{F}} \tilde{\mathbf{F}}^H \leq \tau \frac{\sigma_n^2 I + P \Psi}{\sigma_n^2 + \text{Tr}(\mathbf{F}^H \tilde{\mathbf{F}}^H \Psi)}, \) \hspace{1cm} (125)

For the final matrix inequality, we have the following lower bound of the right-hand side term, i.e.,

\[
\tau \frac{\sigma_n^2 + P \lambda_{\text{min}}(\Psi)}{\sigma_n^2 + P \lambda_{\text{max}}(\Psi)} I \leq \tau \frac{\sigma_n^2 I + P \Psi}{\sigma_n^2 + \text{Tr}(\mathbf{F}^H \tilde{\mathbf{F}}^H \Psi)},
\]

where the equality holds when \( \Psi \propto I. \) Based on the lower bound in (126), for the Pareto optimal solutions of the following optimization problem, the corresponding objective is a lower bound of that in (123)

\[
\max_{\mathbf{F}} \mathbf{F}^H \tilde{\mathbf{H}}^H \tilde{\mathbf{F}}(\sigma_n^2 I + P \Psi)^{-\frac{1}{2}} \tilde{\mathbf{F}}^H \tilde{\mathbf{H}} \tilde{\mathbf{F}}(\sigma_n^2 I + P \Psi)^{-\frac{1}{2}} \tilde{\mathbf{F}},
\]

s.t. \( \text{Tr}(\mathbf{F}^H \tilde{\mathbf{F}}^H) \leq P, \quad \mathbf{F} \tilde{\mathbf{F}}^H \leq \tau \frac{\sigma_n^2 + P \lambda_{\text{min}}(\Psi)}{\sigma_n^2 + \text{Tr}(\mathbf{F}^H \tilde{\mathbf{F}}^H \Psi)} I, \) \hspace{1cm} (127)

It is obvious that based on Lemma 2 the Pareto optimal solutions of (127) satisfy the following structure

\[
\tilde{\mathbf{F}} = \mathbf{V}_H \mathbf{A}_F U_{\text{Arb}}^H,
\]

where the unitary matrix \( \mathbf{V}_H \) is defined based on the SVD

\[
\tilde{\mathbf{H}}(\sigma_n^2 I + P \Psi)^{-\frac{1}{2}} = \mathbf{U}_H \mathbf{A}_H \mathbf{V}_H^H, \text{ with } \mathbf{A}_H \succ 0.
\]

(129)

The diagonal elements of the rectangular diagonal matrix \( \mathbf{A}_H \) are smaller than \( \sqrt{\tau(\sigma_n^2 + P \lambda_{\text{min}}(\Psi))}/(\sigma_n^2 + P \lambda_{\text{max}}(\Psi)). \)

Based on the definition in (124), \( \mathbf{F} \) equals

\[
\mathbf{F} = \frac{\sigma_n^2 \tilde{\Psi}^{-\frac{1}{2}} \mathbf{V}_H \mathbf{A}_F U_{\text{Arb}}^H}{(1 - \text{Tr}(\tilde{\Psi}^{-\frac{1}{2}} \Psi \tilde{\Psi}^{-\frac{1}{2}} \mathbf{V}_H \mathbf{A}_F \mathbf{A}_F^H \mathbf{V}_H^H)^{\frac{1}{2}})},
\]

\[
\tilde{\Psi} = \sigma_n^2 I + P \Psi.
\]
