CONSTRUCTION OF DISCRETE SERIES REPRESENTATIONS OF $SO_e(4,1)$ VIA ALGEBRAIC DIRAC INDUCTION

ANA PRLIĆ

ABSTRACT. The notion of algebraic Dirac induction was introduced by P. Pandžić and D. Renard. This is a construction which gives representations with prescribed Dirac cohomology. They proved that all holomorphic discrete series representations can be constructed via Dirac induction. All discrete series representations of the group $SO_e(4,1)$ are nonholomorphic. In this paper we prove that they can also be constructed using algebraic Dirac induction.

1. Introduction

The notion of Dirac cohomology was formulated by Vogan in 1997 [8]. Let $G$ be a connected real reductive Lie group with Cartan involution $Θ$ such that $K = G^Θ$ is a maximal compact subgroup of $G$ and let $g = t ⊕ p$ be the corresponding Cartan decomposition of the complexified Lie algebra $g$ of $G$. The algebraic version of the Dirac operator $D$ is defined in [8] as

$$D = \sum_\nu b_i \otimes d_i \in U(g) \otimes C(p),$$

where $U(g)$ is the universal enveloping algebra of $g$, $C(p)$ is the Clifford algebra of $p$ with respect to an invariant nondegenerate symmetric bilinear form $B$ on $g_0$, $b_i$ is a basis of $p$ and $d_i$ is the dual basis with respect to $B$. From the well known (and easy to prove) formula

$$D(1 \otimes x) + (1 \otimes x)D = -2x \otimes 1, \quad \text{for } x \in p,$$

it follows that understanding the $p$ action on the $(g, K)$–module $X$ comes down to understanding the action of the Dirac operator on $X \otimes S$ where $S$ is the spin module of $C(p)$. The Dirac cohomology of a Harish-Chandra module $X$ is defined as

$$H_D^0(X) = \ker D / \im D \cap \ker D.$$

It is a $\tilde{K}$–module, where $\tilde{K}$ is the spin double cover of $K$. In [8] Vogan conjectured and in [1] Huang and Pandžić proved that Dirac cohomology, if nonzero, determines the infinitesimal character of the representation. Namely, the following theorem holds: Let $\mathfrak{h} = t \oplus \mathfrak{a}$ be a fundamental Cartan subalgebra of $\mathfrak{g}$. We view $t^* \subset \mathfrak{h}^*$.

by extending functionals on \( t \) by 0 over \( a \). We fix compatible positive root systems \( R_+^g \) and \( R_+^\mathfrak{h} \) respectively \((\mathfrak{t}, t)\).

**Theorem 1.1.** Let \( X \) be a \((\mathfrak{g}, K)\)-module with infinitesimal character \( \Lambda \in \mathfrak{h}^* \). Assume that \( H^D_{\mathfrak{g}}(X) \) contains the irreducible \( K\)-module \( E_\tau \), with highest weight \( \gamma \in \mathfrak{t}^* \). Then

\[
\gamma + \rho_t = w\Lambda \text{ for some } w \in W_\mathfrak{g}.
\]

One of the consequences of the above theorem is the fact that unitary \((\mathfrak{g}, K)\)-modules with nonzero Dirac cohomology are exactly those for which Dirac inequality becomes equality on some \( \tilde{K} \)-types of \( X \otimes S \). Namely, Dirac inequality says that for a unitary \((\mathfrak{g}, K)\)-module \( X \) and an irreducible representation \( E_\gamma \) of \( K \) with the highest weight \( \tau \in \mathfrak{h}^* \) such that the multiplicity of the \( \tilde{K} \)-type \( E_\tau \) in \( X \otimes S \) is at least one, then

\[
||\tau + \rho_t|| \geq ||\Lambda||,
\]

where \( \Lambda \in \mathfrak{h}^* \) denotes the infinitesimal character of \( X \). Important examples of unitary modules with nonzero Dirac cohomology are discrete series representations, most of the more general unitary modules with strongly regular infinitesimal character, the so-called \( A_q(\lambda) \)-modules and many others. Classification of irreducible unitary \((\mathfrak{g}, K)\)-modules with nonzero Dirac cohomology is still an open problem.

In [4] the authors describe certain constructions which give representations with prescribed Dirac cohomology by tensoring the algebra \( U(\mathfrak{g}) \otimes C(p) \) with the Dirac cohomology over a certain subalgebra that contains the Dirac operator. Since the functor of Dirac cohomology admits no adjoint, two alternative definitions were proposed in [4], both of which coincide with the Vogan’s definition for unitary and finite dimensional \((\mathfrak{g}, K)\)-modules. They are called Dirac cohomology and homology. The functor of Dirac cohomology is left exact and admits a right adjoint, while the functor of Dirac homology is right exact and admits a left adjoint. These adjoints are called Dirac induction functors. For example, all holomorphic discrete series can be constructed by tensoring the algebra \( U(\mathfrak{g}) \otimes C(p) \) with the Dirac cohomology over the algebra generated by \( \mathfrak{t}_\Delta \), the ideal \( \mathcal{I} \subset (U(\mathfrak{g}) \otimes C(p))^K \) generated by the Dirac operator and \( C(p)^K \).

Let us review the definition and the main results about Dirac induction as defined in [4]. By composing the adjoint action of \( \mathfrak{t} \) on \( p \) with the embedding of the Lie algebra \( \mathfrak{so}(p) \) into the Clifford algebra \( C(p) \), we get a Lie algebra map \( \alpha : \mathfrak{t} \longrightarrow C(p) \).

Now we can embed the Lie algebra \( \mathfrak{t} \) diagonally into \( U(\mathfrak{g}) \otimes C(p) \), by

\[
X \mapsto X_\Delta = X \otimes 1 + 1 \otimes \alpha(X).
\]

We will denote the image of this embedding by \( \mathfrak{t}_\Delta \) and \( \mathcal{A} = U(\mathfrak{g}) \otimes C(p) \). Let \( \mathcal{I} \) be the two-sided ideal in the algebra of \( K \)-invariants \( \mathcal{A}^K \) generated by \( D \) and let \( \mathcal{B} \) be the \( K \)-invariant subalgebra of \( \mathcal{A} \) with unit, generated by \( \mathfrak{t}_\Delta \) and \( \mathcal{I} \).

**Definition 1.2.** Let \( X \) be a \((\mathfrak{g}, K)\)-module. Dirac cohomology of \( X \) is defined as

\[
H^D_{\mathfrak{g}}(X) = \{ v \in X \otimes S | av = 0, \forall a \in \mathcal{I} \},
\]

while the functor of the Dirac homology is defined as

\[
H_D(X) = X \otimes S/\mathcal{I}(X \otimes S).
\]

If the module \( X \) is finite-dimensional or unitary, then we have

\[
H^D_{\mathfrak{g}}(X) = H_D(X) = H^D_{\mathfrak{g}}(X) = \text{Ker}(D) = \text{Ker}(D^2).
\]
The functor of the Dirac cohomology \( H^D : \mathcal{M}(A, \tilde{K}) \to \mathcal{M}(\mathfrak{k}_\Delta, \tilde{K}) \) has a left adjoint, the functor

\[
\text{Ind}_D : W \mapsto A \otimes_{B} W,
\]

while the functor of the Dirac homology \( H^D : \mathcal{M}(A, \tilde{K}) \to \mathcal{M}(\mathfrak{k}_\Delta, \tilde{K}) \) has a right adjoint, the functor

\[
\text{Ind}^D : W \mapsto \text{Hom}_B(A, W)_{\tilde{K} - \text{finite}}.
\]
2. Discrete series representations of $SO_c(4,1)$

The (real) Lie algebra of the Lie group $G = SO_c(4,1)$ is $\mathfrak{g}_0 = \mathfrak{so}(4,1)$. We use the following basis of the complexification $\mathfrak{g}$ of $\mathfrak{g}_0$ (see [7]):

$$H_1 = i e_{12} - i e_{21}, \quad H_2 = i e_{34} - i e_{43},$$

$$E_1 = \frac{1}{2} (e_{13} - e_{24} - e_{23} - i e_{14} - e_{31} + e_{42} + i e_{32} + i e_{41}),$$

$$E_2 = \frac{1}{2} (e_{13} + e_{24} + i e_{23} + i e_{14} - e_{31} - e_{42} + i e_{32} - i e_{41}),$$

$$F_1 = -\frac{1}{2} (e_{13} - e_{24} + i e_{23} + i e_{14} - e_{31} + e_{42} - i e_{32} - i e_{41}),$$

$$F_2 = -\frac{1}{2} (e_{13} + e_{24} + i e_{23} - i e_{14} - e_{31} - e_{42} - i e_{32} + i e_{41}),$$

where $e_{ij}$ denotes the matrix with the $ij$ entry equal to 1 and all other entries equal to 0. The commutation relations are given by the following table (see [7]):

Let $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ be the Cartan decomposition of $\mathfrak{g}$ corresponding to the Cartan involution $\theta(X) = -X^\tau$. Then

$$\mathfrak{k} = \text{span}\{H_1, H_2, E_1, E_2, F_1, F_2\} \cong \mathfrak{so}(4,\mathbb{C}), \quad \mathfrak{p} = \text{span}\{E_3, E_4, F_3, F_4\}.$$

We have $\mathfrak{k} = \mathfrak{k}_1 \oplus \mathfrak{k}_2$, where

$$\mathfrak{k}_1 = \text{span}\{H_1 + H_2, E_1, F_1\} \cong \mathfrak{sl}(2,\mathbb{C}), \quad \mathfrak{k}_2 = \text{span}\{H_1 - H_2, E_2, F_2\} \cong \mathfrak{sl}(2,\mathbb{C}),$$

with $H_1 + H_2$, $E_1$ and $F_1$ (resp. $H_1 - H_2$, $E_2$ and $F_2$) corresponding to the standard basis of $\mathfrak{sl}(2,\mathbb{C})$. Algebras $\mathfrak{k}_1$ and $\mathfrak{k}_2$ mutually commute. In the standard positive root system, the compact positive roots are $\varepsilon_1 \pm \varepsilon_2$, and the noncompact positive roots are $\varepsilon_1, \varepsilon_2$. For a $\mathfrak{k}_1$–module $V$ and a $\mathfrak{k}_2$–module $W$, the external tensor product $V \otimes W$ is equal to the tensor product $V \otimes W$ as a vector space, and it is a $\mathfrak{k}$–module such that $\mathfrak{k}_1$ acts on $V$ and $\mathfrak{k}_2$ acts on $W$. We will denote by $V_m$ a finite dimensional $\mathfrak{sl}(2,\mathbb{C})$–module with the highest weight $m$. 

Table 1. commutator table
All discrete series representations are \( A_b(\lambda) \)-modules for some Borel subalgebra \( b \) and some \( \lambda \in \mathfrak{h}^* \) which is admissible for \( b \). Here we take
\[
b = \mathfrak{h} \oplus \mathfrak{g}_{\epsilon_1-\epsilon_2} \oplus \mathfrak{g}_{\epsilon_1+\epsilon_2} \oplus \mathfrak{g}_{\epsilon_1} \oplus \mathfrak{g}_{\epsilon_2}.
\]
From [3, Corollary 7.] it follows that the discrete series representation \( A_b(\lambda) \) of \( G \) has the following \( K \)-types
\[
V_{\lambda_1+\lambda_2+2+l+k} \otimes V_{\lambda_1-\lambda_2-l-k}, \quad k \in \mathbb{N}_0, l \in \{0, 1, \ldots, \lambda_1 - \lambda_2\}.
\]
Here \( V_n \otimes V_m \) denotes the \( \mathfrak{g} \)-module with highest weight \((n, m)\), such that \( H_1 + H_2 \) acts on the highest weight vector \( v_n \otimes v_m \) by \( n \) and \( H_1 - H_2 \) acts on the highest weight vector \( v_n \otimes v_m \) by \( m \). All of the above \( K \)-types are of multiplicity one. Let us denote the set \((2.1)\) by \( \Gamma(A_b(\lambda)) \). The next step is to find the action of the elements of \( \mathfrak{p} \) on the highest weight vector \( v_n \otimes v_m \) of each \( K \)-type \( V_n \otimes V_m \) in \( \Gamma(A_b(\lambda)) \).

**Figure 1.** \( K \)-types

\[
\begin{align*}
&\bullet\quad (m_0 + 2, n_0 + 2) & \bullet & \quad \vdots \\
&\bullet\quad (m_0 + 1, n_0 + 1) & \bullet & \quad (m_0 + 3, n_0 + 1) & \bullet \\
&\bullet\quad (m_0, n_0) & \bullet & \quad (m_0 + 2, n_0) & \bullet & \quad \vdots \\
&\bullet\quad (m_0 + 1, n_0 - 1) & \bullet & \quad (m_0 + n_0 + 1) & \bullet & \quad \vdots \\
&\bullet & \quad (m_0 + n_0 + 2, 2) & \bullet & \quad \vdots \\
&\bullet & \quad (m_0 + n_0 + 1, 1) & \bullet & \quad \vdots \\
&\bullet & \quad (m_0 + n_0, 0) & \bullet & \quad \vdots \\
\end{align*}
\]

In the above figure \( m_0 = \lambda_1 + \lambda_2 + 2 \) and \( n_0 = \lambda_1 - \lambda_2 \). The highest weight vector of the \( K \)-type \( \mathfrak{p} = \text{span}\{E_3, E_4, F_3, F_4\} \simeq V_1 \otimes V_1 \) in \( U(\mathfrak{g}) \) is \( E_3 \). The weights of the vectors \( E_4, F_3, F_4 \) are \((1, -1), (-1, -1), (-1, 1), \) respectively. The action map
It follows that 
\[ a : p \otimes (V_n \boxtimes V_m) \rightarrow p \cdot V_n \boxtimes V_m \] is $\mathfrak{t}$-equivariant. Furthermore, we have 
\[
(V_1 \boxtimes V_1) \otimes (V_n \boxtimes V_m) = (V_1 \otimes V_n) \boxtimes (V_1 \otimes V_m) = (V_{n+1} \oplus V_{n-1}) \boxtimes (V_{m+1} \oplus V_{m-1})
\]
\[= (V_{n+1} \boxtimes V_{m+1}) \oplus (V_{n+1} \boxtimes V_{m-1}) \oplus (V_{n-1} \boxtimes V_{m+1}) \oplus (V_{n-1} \boxtimes V_{m-1}).\]

It follows that 
\[ E_3 \cdot v_n \boxtimes v_m = \mu_{(n,m)} v_{n+1} \boxtimes v_{m+1}, \]
for some scalar $\mu_{(n,m)}$, where $v_{n+1} \boxtimes v_{m+1}$ is the highest weight vector of the $K$–type $V_{n+1} \boxtimes V_{m+1}$ of $A_b(\lambda)$. From now on, we will denote the $K$–type $V_n \boxtimes V_m$ by $(n,m)$.

**Lemma 2.1.** For each $K$–type $(n,m)$ of the discrete series $A_b(\lambda)$ we have $\mu_{(n,m)} \neq 0$, where $\mu_{(n,m)}$ is as above. Equivalently, $E_3 \cdot v_n \boxtimes v_m \neq 0$.

**Proof.** Let us fix some $K$–type $(n,m)$ of the discrete series $A_b(\lambda)$ with the highest weight vector $v_n \boxtimes v_m$. Since $A_b(\lambda)$ is an irreducible $(g,K)$–module, we have 
\[ A_b(\lambda) = U(g) \cdot v_n \boxtimes v_m. \]

It follows from the Poincaré-Birkhoff-Witt theorem that 
\[ A_b(\lambda) = U(\mathfrak{t}) \cdot \text{span}_C \{ F_1^a F_2^b F_3^c F_4^d \mid a,b,c,d \in \mathbb{N}_0 \} \cdot v_n \boxtimes v_m. \]

Let us assume that $\mu_{n,m} = 0$, i.e., $E_3 \cdot v_n \boxtimes v_m = 0$. Then we have

\begin{equation}
\lambda A_b(\lambda) = U(\mathfrak{t}) \cdot \text{span}_C \{ F_1^a F_2^b F_3^c F_4^d \mid a,b,c \in \mathbb{N}_0 \} \cdot v_n \boxtimes v_m.
\end{equation}

The weight of the vector $F_1^a F_2^b F_3^c F_4^d \cdot v_n \boxtimes v_m$ is equal to $(n+c-b-a, m-c-b+a)$. Since the $K$–type $(n+1, m+1)$ contributes to $A_b(\lambda)$, then it follows from (2.2) that

\begin{align*}
n+1 &= n + c - b - a \\
m+1 &= m - c - b + a
\end{align*}

for some $a, b, c \in \mathbb{N}_0$. It follows that $b = -1$, a contradiction. Hence $\mu_{(n,m)} \neq 0$. \hfill $\square$

Since the weights of the vectors $E_4$, $F_3$ and $F_4$ are $(1,-1)$, $(-1,-1)$ and $(-1,1)$ respectively, it follows that

\begin{align*}
E_4 \cdot v_n \boxtimes v_m &= \alpha_{(n,m)} F_2 \cdot v_{n+1} \boxtimes v_{m+1} + \beta_{(n,m)} v_{n+1} \boxtimes v_{m-1} \\
F_3 \cdot v_n \boxtimes v_m &= \gamma_{(n,m)} F_1 F_2 \cdot v_{n+1} \boxtimes v_{m+1} + \delta_{(n,m)} F_1 \cdot v_{n+1} \boxtimes v_{m-1} + \epsilon_{(n,m)} F_2 \cdot v_{n-1} \boxtimes v_{m+1} + \eta_{(n,m)} v_{n-1} \boxtimes v_{m-1} \\
F_4 \cdot v_n \boxtimes v_m &= \rho_{(n,m)} v_{n-1} \boxtimes v_{m+1} + \zeta_{(n,m)} F_1 \cdot v_{n+1} \boxtimes v_{m+1},
\end{align*}

where $v_n \boxtimes v_m, v_{n+1} \boxtimes v_{m+1}, v_{n+1} \boxtimes v_{m-1}, v_{n-1} \boxtimes v_{m+1}$ and $v_{n-1} \boxtimes v_{m-1}$ are the highest weight vectors of the $K$–types $(n,m), (n+1,m+1), (n+1,m-1), (n-1,m+1)$ and $(n-1,m-1)$ in $A_b(\lambda)$. If some of these $K$–types do not contribute to $A_b(\lambda)$, then the corresponding scalar in the above equations equals 0.
The black dots in the above figure represent the highest weight vectors of the corresponding $K$–types while the white dots represent lower vectors.

**Lemma 2.2.** Let us fix some $K$–type $(n, m)$ in $A_b(\lambda)$. With notation as above, we have $\beta_{(n,m)} \neq 0$ if the $K$–type $(n+1, m-1)$ belongs to $A_b(\lambda)$.

**Proof.** Let us assume that the $K$–type $(n+1, m-1)$ belongs to $A_b(\lambda)$ and $\beta_{(n,m)} = 0$. From that assumption it follows that $\alpha_{(n,m)} \neq 0$. Otherwise we would have $E_4 \cdot v_n \boxtimes v_m = 0$ and then $E_3 \cdot v_n \boxtimes v_m = 0$, since $E_3 = [E_2, E_4]$, which contradicts the previous lemma. Furthermore we have

\[
E_4 \cdot v_n \boxtimes v_m = [F_3, E_1] \cdot v_n \boxtimes v_m = -E_1 F_3 \cdot v_n \boxtimes v_m = -E_1 \gamma_{(n,m)} F_1 F_2 \cdot v_{n+1} \boxtimes v_{m+1} + \delta_{(n,m)} F_1 \cdot v_{n+1} \boxtimes v_{m-1} + \epsilon_{(n,m)} F_2 \cdot v_{n-1} \boxtimes v_{m+1} + \eta_{(n,m)} v_{n-1} \boxtimes v_{m-1}) = -\gamma_{(n,m)} E_1 F_1 F_2 \cdot v_{n+1} \boxtimes v_{m+1} - \delta_{(n,m)} E_1 F_1 \cdot v_{n+1} \boxtimes v_{m-1},
\]
This contradicts the assumption (2.3).

From where it follows $\delta(n, m) = 0$ and then
\[
p \cdot V_n \boxtimes V_m \subset (V_{n+1} \boxtimes V_{m+1}) \oplus (V_{m-1} \boxtimes V_{m+1}) \oplus (V_{n-1} \boxtimes V_{m-1}).
\]
Since the $K$–type $(n + 1, m + 1)$ is in $A_b(\lambda)$, we have
\[
E_4 \cdot v_{n+1} \boxtimes v_{m+1} = \alpha(n+1, m+1) F_2 \cdot v_{n+2} \boxtimes v_{m+2} + \beta(n+1, m+1) v_{n+2} \boxtimes v_m.
\]

If the $K$–type $(n - 1, m - 1)$ is in $A_b(\lambda)$, then we have
\[
E_4 \cdot v_{n-1} \boxtimes v_{m-1} = \alpha(n-1, m-1) F_2 \cdot v_n \boxtimes v_m + \beta(n-1, m-1) v_n \boxtimes v_{m-2}.
\]
Furthermore, we have
\[
E_4 \cdot v_{n+1} \boxtimes v_{m+1} = E_4 \left( \frac{1}{\mu(n,m)} E_3 \cdot v_n \boxtimes v_m \right)
\]
\[
= \frac{1}{\mu(n,m)} (E_3 E_4 - 2E_1) \cdot v_n \boxtimes v_m
\]
\[
= \frac{\alpha(n,m)}{\mu(n,m)} (E_3 F_2) \cdot v_{n+1} \boxtimes v_{m+1}
\]
\[
= \frac{\alpha(n,m)}{\mu(n,m)} (-E_4 + F_2 E_3) \cdot v_{n+1} \boxtimes v_{m+1},
\]
from which it follows
\[
\left(1 + \frac{\alpha(n,m)}{\mu(n,m)}\right) E_4 \cdot v_{n+1} \boxtimes v_{m+1} = \frac{\alpha(n,m)}{\mu(n,m)} \mu(n+1, m+1) F_2 \cdot v_{n+2} \boxtimes v_{m+2}.
\]
Since $\alpha(n,m) \neq 0$, $\mu(n,m) \neq 0$, $\mu(n+1, m+1) \neq 0$ and $E_2 \cdot v_{n+2} \boxtimes v_{m+2} \neq 0$, then from the equation above it follows that $1 + \frac{\alpha(n,m)}{\mu(n,m)} \neq 0$. From here and (2.3) we get $\beta(n+1, m+1) = 0$. Similar calculation shows that if the $K$–type $(n - 1, m - 1)$ is in $A_b(\lambda)$, then $\beta(n-1, m-1) = 0$. Since $\beta(n+1, m+1) = \beta(n-1, m-1) = 0$, then
\[
\delta(n+1, m+1) = \delta(n-1, m-1) = 0.
\]

From the previous conclusions we get
\[
\text{span}_C \{ F_a^b E_3^d E_4 E_3^d | a, b, c, d \in \mathbb{N}_0 \} \cdot V_n \boxtimes V_m \subset \bigcup_{k \leq l \leq n} V_k \boxtimes V_l.
\]
This contradicts the assumption $(n + 1, m - 1) \in \Gamma(A_b(\lambda))$. \hfill \Box

**Theorem 2.3.** The set
\[
\{ F_1^a F_2^b E_3^c E_4^d \cdot v_{\lambda_1+\lambda_2+2} \boxtimes v_{\lambda_1-\lambda_2} | k \in \mathbb{N}_0, l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\},
\]
\[
a \in \{0, 1, \cdots, \lambda_1 + \lambda_2 + 2 + k + l\},
\]
\[
b \in \{0, 1, \cdots, \lambda_1 - \lambda_2 + k - l\}\}
\]
is a basis of the discrete series representation $A_b(\lambda)$.

**Proof.** Let us introduce the following notation
\[
S_t = \{ F_1^a F_2^b E_3^c E_4^d \cdot v_{\lambda_1+\lambda_2+2} \boxtimes v_{\lambda_1-\lambda_2} | k \in \mathbb{N}_0, l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}, k + l \leq t,
\]
\[
a \in \{0, 1, \cdots, \lambda_1 + \lambda_2 + 2 + k + l\},
\]
\[
b \in \{0, 1, \cdots, \lambda_1 - \lambda_2 + k - l\}\},
\]
for $t \in \mathbb{N}_0$. From lemma 2.1 and lemma 2.2 it easily follows that the set $S_t$ is a spanning set of the vector space

$$Z_t = \bigoplus_{(\lambda_1, \lambda_2, +2 + r, y) \in \Gamma(A_b(\lambda))} V_{\lambda_1 + \lambda_2 + 2 + r} \otimes V_y,$$

It is easy to see that

$$Z_t = \bigoplus_{r=0}^{t} V_{m_0 + r} \otimes (V_{n_0 + r} \oplus V_{n_0 + r - 2} \oplus \cdots \oplus V_{|n_0 - r|}),$$

where $m_0 = \lambda_1 + \lambda_2 + 2$ and $n_0 = \lambda_1 - \lambda_2$. The dimension of that space is

$$\sum_{r=0}^{t} (m_0 + r + 1)(\dim V_{m_0 + r} + \dim V_{n_0 + r - 2} + \cdots + \dim V_{|n_0 - r|})$$

$$= \sum_{r=0}^{t} (m_0 + r + 1)(r + 1)(n_0 + 1)$$

$$= \frac{1}{6} (n_0 + 1)(3m_0 + 2t + 3)(t^2 + 3t + 2),$$

and the cardinality of the set $S_t$ is

$$\sum_{l=0}^{n_0} \sum_{k=0}^{t-l} (m_0 + k + l + 1)(n_0 + k - l + 1) = \frac{1}{6} (n_0 + 1)(3m_0 + 2t + 3)(t^2 + 3t + 2).$$

From this it follows that $S_t$ is a basis of $Z_t$ and hence, the set (2.3) is a basis of the discrete series $A_b(\lambda)$. $\square$

3. Dirac cohomology and the induced module

The algebra $A^K$ is generated by Casimir elements for $\mathfrak{t}_1$ and $\mathfrak{t}_2$, by one generator from $C(p)^K$, by the Dirac operator

$$D = E_3 \otimes F_3 + E_4 \otimes F_4 + F_3 \otimes E_3 + F_4 \otimes E_4,$$

and by the $\mathfrak{t}$–Dirac operator

$$D_1 = E_1 \otimes \alpha(2F_1) + E_2 \otimes \alpha(2F_2) + F_1 \otimes \alpha(2E_1) + F_2 \otimes \alpha(2E_2)$$

$$+ (H_1 - H_2) \otimes \alpha(H_1 - H_2) + (H_1 + H_2) \otimes \alpha(H_1 + H_2).$$

(3.1)

For more details about the structure of the algebra $A^K$ see [7]. The spin module is

$$S = \text{span}\{1, E_3, E_4, E_3 \wedge E_4\}.$$

The $C(p)$–module $S$ can be viewed as a $\mathfrak{t}$–module (see [2 Section 2]). We will denote by $V_{(n, m)}$ the irreducible finite dimensional $\mathfrak{t}$–module with highest weight $(n, m)$ such that $H_1$ acts by $n$ on the highest weight vector, while $H_2$ acts by $m$ on the highest weight vector. As a $\mathfrak{t}$–module $S$ is equal to

$$S = V_{(\frac{1}{2}, \frac{1}{2})} \oplus V_{(\frac{1}{2}, -\frac{1}{2})},$$

where

$$V_{(\frac{1}{2}, \frac{1}{2})} \cong V_1 \otimes V_0 = \text{span}\{E_3 \wedge E_4, 1\}$$

$$V_{(\frac{1}{2}, -\frac{1}{2})} \cong V_0 \otimes V_1 = \text{span}\{E_3, E_4\}.$$
Since the lowest $K$–type of the discrete series representation $A_b(\lambda)$ is
\[ V_{\lambda_1,\lambda_2 + 2} \cong V_{(\lambda_1 + 1, \lambda_2 + 1)}, \]
then by [2, Corollary 7.4.5.] it follows that the Dirac cohomology $H^D(A_b(\lambda))$ is
a single $\tilde{K}$–type with the highest weight equal to $(\lambda_1 + 1, \lambda_2 + 1) - \rho_n$, where
$\rho_n = \rho - \rho_{\ell} = \frac{1}{2}(1, 1)$ is the half sum of the noncompact positive roots. Therefore,
the Dirac cohomology of $A_b(\lambda)$ is the $\tilde{K}$–type $V_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2})}$, from where it follows
that the Dirac cohomology is contained in the tensor product of the lowest $K$–type of $A_b(\lambda)$ and
the $K$–type $V_{(\frac{1}{2}, \frac{1}{2})} \cong V_1 \otimes V_0 = \text{span}\{E_4 \wedge E_4, 1\}$ in $S$. Now, using the fact
that the highest weight vector of $H^D(A_b(\lambda))$ is annihilated by the elements $(E_1)_\Delta$ and $(E_2)_\Delta$,
it is easy to check that $H^D(A_b(\lambda))$ is the $\tilde{K}$–type with the highest weight vector equal to
\[ w(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2}) = (v_{\lambda_1 + \lambda_2} \otimes v_{\lambda_1 - \lambda_2}) \otimes E_3 \wedge E_4 + 2(\lambda_1 + \lambda_2 + 2)(v_{\lambda_1 + \lambda_2 + 2} \otimes v_{\lambda_1 - \lambda_2}) \otimes 1. \]
The Dirac cohomology is
\[ H^D(A_b(\lambda)) = \text{span}\{w(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - s) | s \in \{0, 1, \cdots, \lambda_1 + \lambda_2 + 1\}, t \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}\}, \]
where
\[ w(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - s) = (F_1)^{t}_{\Delta} \otimes (F_2)^{t}_{\Delta} w(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2}) \]
\[ = (v_{\lambda_1 + \lambda_2 - 2s} \otimes v_{\lambda_1 - \lambda_2 - 2t}) \otimes E_3 \wedge E_4 + 2(\lambda_1 + \lambda_2 + 2 - s)(v_{\lambda_1 + \lambda_2 + 2 - 2s} \otimes v_{\lambda_1 - \lambda_2 - 2t}) \otimes 1. \]

Let $x_s$ denote $\lambda_1 + \frac{1}{2} - s$ and let $y_t$ denote $\lambda_2 + \frac{1}{2} - t$. We describe a spanning set
of $(A, \tilde{K})$–module $\text{Ind}_D(W) = A \otimes_{\mathcal{B}} W$, where $W = H^D(A_b(\lambda))$. Let us denote
\[ Z = \text{span}_C\{ab \otimes w - a \otimes bw | a \in A, b \in \mathcal{B}, w \in W\}. \]

We are going to reduce the obvious spanning set of $A \otimes_{\mathcal{B}} W$ given by
\[ \{a \otimes w + Z | a \in A, w \in W\}. \]

As in [6], it is easy to show that we can “remove” $U(\mathfrak{t})$. For $x \in \mathfrak{t}$, $y \in C(\mathfrak{p})$ and
$w \in W$ we have
\[ (x \otimes y) \otimes w = ((1 \otimes y) \cdot (x_\Delta - 1 \otimes \alpha(x))) \otimes w = \]
\[ = ((1 \otimes y) \cdot x_\Delta) \otimes w - (1 \otimes y \cdot \alpha(x)) \otimes w = \]
\[ = \underbrace{((1 \otimes y) \cdot x_\Delta) \otimes w - (1 \otimes y) \otimes x_\Delta w + (1 \otimes y) \otimes x_\Delta w}_{\in Z} \]
\[ - (1 \otimes y \cdot \alpha(x)) \otimes w \]
\[ \in (1 \otimes C(\mathfrak{p})) \otimes W + Z. \]

From here it follows:
\[ (U(\mathfrak{t}) \otimes C(\mathfrak{p})) \otimes W \subset (1 \otimes C(\mathfrak{p})) \otimes W + Z. \]

Now, we are going to describe the structure of the algebra $U(\mathfrak{g})$ using the results
from [7]. The next proposition and its proof are similar to [6, Proposition 4.2.] and
its proof, but we recall it for the reader convenience.
Proposition 3.1. We have
\[(3.3)\]
\[U(g) = \text{span}_C \{ x(E_3F_3 + E_4F_4)^t y | x \in \{(adF_1)^a(adF_2)^b(E_3^k) | k \in \mathbb{N}_0, a, b \in \{0, \ldots, k\}, t \in \mathbb{N}_0, y \in U(\mathfrak{t})\}\].

Proof. Let \(T\) be the right side of (3.3). We will show by induction that \(U_t(g) \subset T\) for all \(l \in \mathbb{N}_0\). The claim is obvious for \(l = 0\) and \(l = 1\). Let us assume that the claim is true for \(l \in \mathbb{N}_0\) less than or equal to some fixed \(t \geq 1\). By the Poincare-Birkhoff-Witt’s theorem, it is enough to prove that elements of the form \(E_3^p E_4^q F_3^r F_4^s\), \(p, q, r, s \in \mathbb{N}_0, p + q + r + s = t + 1\) are in \(T\). From [7] p. 278 it follows that
\[S^n(p) = V_{(n,0)} \oplus (E_3F_3 + E_4F_4)S^{n-2}(p),\]
for all \(n \in \mathbb{N}, n \geq 2\), where \(V_{(n,0)}\) is the irreducible \(\mathfrak{t}\)-module with the highest weight vector \(E_3^n\) and the highest weight \((n,0)\) (more precisely \(H_1\) acts by \(n\) and \(H_2\) acts by zero on \(E_3^n\)). Now we have
\[E_3^p E_4^q F_3^r F_4^s \in (\text{span}_C \{(adF_1)^a(adF_2)^b(E_3^{t+1}) | k \in \mathbb{N}_0, a, b \in \{0, \ldots, t + 1\}\})\]
\[\oplus \text{span}_C \{ E_3^m E_4^n F_3^{r+1} F_4^s | m, n, r, s \in \mathbb{N}_0, m + n + r + s = t - 1 \} \oplus U_t(g).\]
Therefore, it is enough to show that \(E_3^m E_4^n F_3^{r+1} F_4^s + E_3^m E_4^{n+1} F_3^r F_4^{s+1}\) \(\in T\) for \(m, n, r, s \in \mathbb{N}_0, m + n + r + s = t - 1\). By induction on \(r\) and \(s\) it can be easily seen that
\[E_3^m E_4^n F_3^{r+1} F_4^s + E_3^m E_4^{n+1} F_3^r F_4^{s+1} \subset U_{t-1}(g)(E_3F_3 + E_4F_4) + U_t(g),\]
and the proposition follows. \(\square\)

Furthermore, we have
\[(3.4)\]
\[(E_3F_3 + E_4F_4) \otimes 1 = -\frac{1}{2}D_2 + D_t + (H_1 + H_2).\]
which implies that
\[((E_3F_3 + E_4F_4) \otimes 1) \otimes w \in (U(\mathfrak{t}) \otimes C(\mathfrak{p})) \otimes W + Z.\]

By (3.2), proposition 3.1 and (3.4) we see that the vector space \(\mathcal{A} \otimes W\) is spanned by the elements of the form \((x \otimes y) \otimes w\) where
\[x \in \{(adF_1)^a(adF_2)^b(E_3^k) | k \in \mathbb{N}_0, a, b \in \{0, 1, \ldots, k\}\}, y \in C(\mathfrak{p}), w \in W.\]
The next step is to reduce a part of the algebra \(C(\mathfrak{p})\).

Lemma 3.2. If \(T \in \text{End}_C(S) \cong C(\mathfrak{p})\) is any linear operator such that
\[T(1) = T(E_3 \wedge E_4) = 0,\]
then \(T = Tp'\), where \(p'\) is the projection on \(\text{span}_C \{E_3, E_4\}\).
Proof. For $s \in \text{span}_C\{E_3, E_4\}$ we have $p'(s) = s$ and then $Tp'(s) = T(s)$. Furthermore, $T(1) = T(E_3 \wedge E_4) = 0 = Tp'(1) = Tp'(E_3 \wedge E_4)$. Since

$$S = \text{span}_C\{1, E_3, E_4, E_3 \wedge E_4\}$$

it follows that $T = Tp'$.

In the spin module $S$, the following identities hold

$$E_3 F_4 \cdot 1 = 0, \quad E_3 F_4 \cdot E_3 \wedge E_4 = E_3 \cdot (2E_3) = 0,$$

$$E_4 F_3 \cdot 1 = 0, \quad E_4 F_3 \cdot E_3 \wedge E_4 = E_4 \cdot (-2E_4) = 0,$$

$$(E_3 F_3 - E_4 F_4) \cdot 1 = 0, \quad (E_3 F_3 - E_4 F_4) \cdot E_3 \wedge E_4 = E_3 \cdot (-2E_4) - E_4 \cdot (2E_3) = 0.$$ By lemma 3.2 we have $E_3 F_3 p' = E_4 F_4$, $E_4 F_3 p' = E_4 F_3$ and $(E_3 F_3 - E_4 F_4)p' = (E_3 F_3 - E_4 F_4)$. Since $(1 \otimes p')w = 0$ for $w \in W$, we get that for any $a \in A$ and $s \in \text{span}_C\{E_3 F_4, E_4 F_3, (E_3 F_3 - E_4 F_4)\}$

$$(a(1 \otimes s)) \otimes w = (a(1 \otimes s)) \otimes w = (a(1 \otimes s)(1 \otimes p')) \otimes w = (a(1 \otimes s)) \otimes (1 \otimes p')w \in Z.$$ It follows that

$$(U(g) \otimes C(p) E_3 F_4) \otimes W \subset Z$$

$$(U(g) \otimes C(p) E_4 F_3) \otimes W \subset Z$$

$$(U(g) \otimes C(p)(E_3 F_3 - E_4 F_4)) \otimes W \subset Z.$$

From (3.2), (3.5), (3.6) and

$$(\text{ad}F_i)^a E^b_3 \in \text{span}\{F_i^m E^k_3 F^n_i \mid m + n = a\}, \quad i = 1, 2$$

it follows that the vector space $A \otimes g W$ is spanned by the set

$$(3.7) \quad \{(x \otimes y) \otimes w \mid x \in \{F_1^a F_2^b E_3^k \mid k \in \mathbb{N}_0, a, b \in \{0, \ldots, k\}\},$$

$$y \in \{1, E_3, E_4, F_3, F_4, E_3 E_4, E_3 F_3, F_3 F_4\}, w \in W\}.$$ Furthermore, one can easily check that

$$D \cdot (1 \otimes E_3 F_4) - (1 \otimes E_3 F_4) \cdot D = -2(E_3 \otimes F_4 - F_4 \otimes E_3);$$

$$D \cdot (1 \otimes F_4 F_3) - (1 \otimes F_4 F_3) \cdot D = -2(E_4 \otimes F_3 - F_3 \otimes E_4);$$

$$D \cdot (1 \otimes (E_3 F_3 - E_4 F_4)) - (1 \otimes (E_3 F_3 - E_4 F_4)) \cdot D = -2D + 4(E_4 \otimes F_4 + F_3 \otimes E_3);$$

$$D - (E_4 \otimes F_4 + F_3 \otimes E_3) = (E_3 \otimes F_3 + E_4 \otimes E_4).$$

From (3.8), (3.6) and $D \otimes W \subset Z$ we get

$$E_3 \otimes F_4 - F_4 \otimes E_3 \otimes w \in Z$$

$$E_4 \otimes F_3 - F_3 \otimes E_4 \otimes w \in Z$$

$$(E_4 \otimes F_4 + F_3 \otimes E_3) \otimes w \in Z$$

$$(E_3 \otimes F_3 + F_4 \otimes E_4) \otimes w \in Z.$$ Proposition 3.3. For $s \in \{0, 1, 2, \ldots, \lambda_1 + \lambda_2\}$ and $t \in \{0, 1, 2, \ldots, \lambda_1 - \lambda_2\}$ we have

$$(1 \otimes F_4) \otimes (\lambda_1 + \lambda_2 + 1 - s) w_{(x_t, y_t)} \in (1 \otimes E_3) \otimes (F_1) w_{(x_t, y_t)} + Z.$$
Proof. For \( w \in W \) we have
\[
(F_1)_\Delta (1 \otimes E_3) \otimes w \in (1 \otimes E_3) \otimes (F_1)_\Delta w + (1 \otimes F_4) \otimes w + Z.
\]
Furthermore, using (3.6) we get
\[
(F_1)_\Delta (1 \otimes E_3) \otimes w \in (F_1 \otimes E_3) \otimes w + Z.
\]
From (3.9), and \( D \otimes W \subset Z \) we get
\[
(F_1 \otimes E_3) \otimes w = -\frac{1}{2} ([F_3, F_4] \otimes E_3) \otimes w
= -\frac{1}{2} ([F_3 F_4 \otimes E_3] \otimes w - (F_3 F_4 \otimes E_3) \otimes w]
\in -\frac{1}{2} ([F_3 E_3 \otimes F_4] \otimes w + (F_4 E_4 \otimes F_4) \otimes w] + Z
= -\frac{1}{2} ([F_3 E_3 + F_4 E_4] \otimes F_4 \otimes w] + Z.
\]
From (3.11), we get
\[
(F_3 E_3 + F_4 E_4) \otimes 1 = -\frac{1}{2} D^2 + D_\Delta - (H_1 + H_2).
\]
A straightforward calculation shows that \( D_\Delta \) acts on \( W \) by \((-\lambda_1 - \lambda_2 - 4)\). The proof follows from (3.10), (3.11), (3.12), (3.13) and from
\[
((H_1 + H_2) \otimes F_4) \otimes w_{(x,y)} = (1 \otimes F_4)((H_1 + H_2)_\Delta \otimes w_{(x,y)}
= -1 \otimes \alpha(H_1 + H_2) \otimes w_{(x,y)})
= (\lambda_1 + \lambda_2 - 2s)(1 \otimes F_4) \otimes w_{(x,y)} + Z.
\]

\( \square \)

Corollary 3.4. For \( s \in \{1, 2, \cdots, \lambda_1 + \lambda_2\} \) and \( t \in \{0, 1, 2, \cdots, \lambda_1 - \lambda_2\} \) we have
\[
(1 \otimes E_4 F_3) \otimes (\lambda_1 + \lambda_2 + 1 - s)w_{(x,y)} \in (1 \otimes E_4 E_3) \otimes (F_1)_\Delta w_{(x,y)} + Z,
(1 \otimes F_3 F_4) \otimes (\lambda_1 + \lambda_2 + 1 - s)w_{(x,y)} \in (1 \otimes F_3 E_3) \otimes (F_1)_\Delta w_{(x,y)} + Z,
(1 \otimes F_3) \otimes (\lambda_1 + \lambda_2 + 1 - s)w_{(x,y)} \in -(1 \otimes E_4) \otimes (F_1)_\Delta w_{(x,y)} + Z.
\]

Proof. The first two claims follow from the previous lemma. Furthermore, we have
\[
(1 \otimes E_4 F_3 F_4) \otimes (\lambda_1 + \lambda_2 + 1 - s)w_{(x,y)}
\in (1 \otimes E_4 F_3 E_3) \otimes (F_1)_\Delta w_{(x,y)} + Z
\]
The proof follows from \( E_4 F_3 E_3 = -2E_4 + E_3 E_4 F_3, E_4 F_3 F_4 = 2F_3 + F_4 E_4 F_3 \) and \( (U(g) \otimes C(p)E_4 F_3) \otimes W \subset Z. \)

\( \square \)

From Proposition 3.3 and Corollary 3.4 and from the previous conclusions it follows that the vector space \( A \otimes gW \) is spanned by the set
\[
\{(x \otimes E_3) \otimes w_{(x,y)}, (x \otimes E_4) \otimes w_{(x,y)}),
(x \otimes 1) \otimes w_{(x,y)}, (x \otimes E_3) \otimes w_{(x,y)},
(x \otimes F_3) \otimes w_{(x_1 + \lambda_2 + 1, y)}, (x \otimes F_4) \otimes w_{(x_1 + \lambda_2 + 1, y)},
(x \otimes E_4 F_3) \otimes w_{(x_1 + \lambda_2 + 1, y)}, (x \otimes F_3 F_4) \otimes w_{(x_1 + \lambda_2 + 1, y)},
x \in \{ F_1^a F_2^b E_3^k \mid k \in \mathbb{N}_0, a, b \in \{0, 1, \cdots, k\}, s \in \{0, 1, \cdots, \lambda_1 + \lambda_2 + 1\}, t \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}\}.
\]
Proposition 3.5. For \( s \in \{0, 1, \ldots, \lambda_1 + \lambda_2\}, \ t \in \{0, 1, \ldots, \lambda_1 - \lambda_2\} \) and for any nonnegative integer \( k \) we have
\[
(F_1 E_3^k \otimes E_3) \otimes w_{(x, y_t)} \in \text{span}_C \{(E_3^{k-2} \otimes E_3) \otimes (E_2) \Delta w_{(x, y_t)}, (E_3^k \otimes E_3) \otimes (F_1) \Delta w_{(x, y_t)}\} + Z,
\]
where \( E_3^{-1} = E_3^{-2} = 0. \)

**Proof.** One can easily show by induction that for each \( k \in \mathbb{N} \)
\[
(F_1 E_3^k) = -k(k - 1)E_3^{k-2}E_2 + kE_3^{k-1}F_4 + E_3^k F_1.
\]
Furthermore, using \( \alpha(E_2) = -\frac{1}{2}E_3 F_4 \) and \( \alpha(F_1) = \frac{1}{2}F_3 F_4 \) and previous conclusions we get
\[
(E_2 \otimes E_3) \otimes w_{(x, y_t)} \in (1 \otimes E_3) \otimes (E_2) \Delta w_{(x, y_t)} + Z,
\]
and
\[
(F_1 \otimes E_3) \otimes w_{(x, y_t)} \in \frac{\lambda_1 + \lambda_2 + 2 - s}{\lambda_1 + \lambda_2 + 1 - s} \{(E_3 \otimes E_3) \otimes (F_1) \Delta w_{(x, y_t)} + Z.
\]
From (3.14) and Proposition (3.3) we get
\[
(F_4 \otimes E_3) \otimes w_{(x, y_t)} = (E_3 \otimes F_4) \otimes w_{(x, y_t)}
\]
\[
\in \frac{1}{\lambda_1 + \lambda_2 + 1 - s} \{(E_3 \otimes E_3) \otimes (F_1) \Delta w_{(x, y_t)} + Z.
\]
The proof follows from (3.14), (3.15), (3.16) and (3.17). \(\square\)

Proposition 3.6. For any \( t \in \{0, 1, \ldots, \lambda_1 - \lambda_2\} \) and for any nonnegative integer \( k \) we have
\[
(F_1 E_3^k \otimes E_3) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)} \in \text{span}_C \{(E_3^{k-2} \otimes E_3) \otimes (E_2) \Delta w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}, (E_3^k \otimes F_4) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}\} + Z,
\]
where \( E_3^{-1} = E_3^{-2} = 0. \)

**Proof.** The proof follows from (3.14), (3.15) and from
\[
(F_1 \otimes E_3) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)} \in (1 \otimes F_4) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)} + Z
\]
\[
(F_4 \otimes E_3) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)} = (E_3 \otimes F_4) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}.
\]
\(\square\)

Finally, from propositions 3.5 and 3.6 and previous conclusions we get

**Theorem 3.7.** One spanning set of the vector space \( A \otimes B W \) is given by
\[
\{ (F_2 E_3^k \otimes E_3) \otimes w_{(x, y_t)}, (F_2 E_3^k \otimes E_3) \otimes w_{(x, y_t)}, \}
\]
\[
(F_2 E_3^k \otimes 1) \otimes w_{(x, y_t)}, (F_2 E_3^k \otimes E_3) \otimes w_{(x, y_t)}, \}
\]
\[
(x \otimes F_3) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}, (x \otimes F_3) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}, \}
\]
\[
(x \otimes E_3 F_3) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}, (x \otimes F_3 F_4) \otimes w_{(x_{\lambda_1 + \lambda_2 + 1}, y_t)}, \}
\]
\[
x \in \{F_2 E_3^k | k \in \mathbb{N}_0, a, b \in \{0, 1, \ldots, k\}, c \in \{0, 1, \ldots, k\},
\]
\[
s \in \{0, 1, \ldots, \lambda_1 + \lambda_2 + 1\}, t \in \{0, 1, \ldots, \lambda_1 - \lambda_2\} \}. \)
We will show that the above spanning set is also a basis of $A \otimes B W$ a bit later.

In the figure below $c \in \{0, 1, \cdots, k\}$ and $t \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}$.

**Figure 3. Basis**

![Diagram showing basis elements and relations](image)
4. Construction of the discrete series representations of the group $SO_e(4,1)$ via Dirac induction

Our goal is to get a basis of $X \otimes S$ which is similar to the spanning set from the theorem 3.7. The first step is to “remove” $E_4$ from Theorem 2.3. Since

$$(\text{ad} F_2) E_3^k = k E_3^{k-1} E_4 - k(k-1) E_3^{k-2} E_1,$$

one can easily show by induction that for all $k \in \mathbb{N}_0$ and for all $l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}$ we have

$$(\text{ad} F_2)^l E_3^{k+l} v_{\lambda_1 + \lambda_2 + 2} \otimes v_{\lambda_1 - \lambda_2} = (k+l)(k+l-1) \cdots (k+1) E_4^l v_{\lambda_1 + \lambda_2 + 2} \otimes v_{\lambda_1 - \lambda_2}.$$
One basis of the vector space \( Z_t \) (see (2.3)) is given by
\[
S^1_t = \{ F_1^a F_2^b (\text{ad} F_2)^l E_3^{k+l} \cdot v_{\lambda_1 + \lambda_2 + 2} \otimes v_{\lambda_1 - \lambda_2} \mid k \in \mathbb{N}_0, l \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 \}, k + l \leq t, a \in \{ 0, 1, \cdots, \lambda_1 + \lambda_2 + 2 + k + l \}, b \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 + k - l \} \}.
\]
(4.1)

Furthermore, we have
\[
(\text{ad} F_2)^l E_3^{k+l} \in \text{span}\{ F_2^a E_3^{k+l} F_2^b \mid s + t' = l \}.
\]
(4.2)

From (4.1) and (4.2) it easily follows that the set
\[
S^2_t = \{ F_1^a F_2^b E_3^{k+l} F_2^d \cdot v_{\lambda_1 + \lambda_2 + 2} \otimes v_{\lambda_1 - \lambda_2} \mid k \in \mathbb{N}_0, l \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 \}, k + l \leq t, a \in \{ 0, 1, \cdots, \lambda_1 + \lambda_2 + 2 + k + l \}, b \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 + k - l \} \}
\]
(4.3)
is a spanning set of the vector space \( Z_t \). Since the sets \( S^1_t \) and \( S^2_t \) have the same cardinality, the set \( S^2_t \) is a basis of \( Z_t \). If we denote \( r = k + l \) it follows that one basis of the vector space \( Z_t \otimes E_3 \) is given by
\[
(S_t)_E = \{ F_1^a F_2^b E_3^t \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2})} \mid r \in \{ 0, \cdots, t \}, l \in \{ 0, 1, \cdots, \min\{ \lambda_1 - \lambda_2, r \} \}, a \in \{ 0, 1, \cdots, \lambda_1 + \lambda_2 + 2 + r \}, b \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 + r - 2l \} \}
\]
(4.4)

To prove what we claim we need the following lemma.

**Lemma 4.1.** For \( x, y \in \mathbb{N}_0 \) such that \( x > y \) and for \( l \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 \} \) we have
\[
F_2^x E_3^y \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2})} \in \text{span}\{ F_2^y E_3^z \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)} \mid p \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 \}, v \in \{ 0, 1, \cdots, y \}, z \leq v \}.
\]

**Proof.** It is sufficient to prove the claim for \( x = y + 1 \). The general case then follows easily by induction. The claim is obvious for \( y = 0 \). Let us assume that the claim is true for some \( y = k - 1 \). Then we have
\[
F_2^{k+1} E_3^k \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2})} = k E_4 F_2^k E_3^k \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)}
\]
(4.5)

where \( w_{(\lambda_1 + \frac{1}{2}, \lambda_2 - 1)} = 0 \) for \( l = \lambda_1 - \lambda_2 \). Furthermore, we have
\[
E_4 F_2^x E_3^y \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)} = F_2^y E_3^z E_4 \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)}
\]
\[
\in \text{span}\{ F_2^x (\text{ad} F_2)^{x+k} E_3^{k+1} \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)} \}
\]
\[
\in \text{span}\{ F_2^{x+1} E_3^{k+1} \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)} \}
\]
\[
+ F_2^{x+k+1} \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2} - p)} \}
\]
(4.6)

If \( z \leq v \leq k - 1 \) then \( z + 1 \leq v + 1 \leq k \). The proof follows from (4.3) and (4.4). \( \square \)

Let us consider the following set
\[
(S_t)_E = \{ F_1^a F_2^b E_3^t \otimes E_3 \cdot w_{(\lambda_1 + \frac{1}{2}, \lambda_2 + \frac{1}{2})} \mid r \in \{ 0, \cdots, t \}, l \in \{ 0, 1, \cdots, \lambda_1 - \lambda_2 \}, a \in \{ 0, 1, \cdots, \lambda_1 + \lambda_2 + 2 + r \}, b \in \{ 0, 1, \cdots, r \} \}
\]
(4.7)
It follows from lemma 4.1 that the set \((S_t)^2_{E_3} \subset Z_t \otimes E_3\) is a spanning set of \(Z_t \otimes E_3\). Since the cardinality of the set \((S_t)^2_{E_3}\) is
\[
\sum_{r=0}^{t} (m_0 + r + 1)(r + 1)(n_0 + 1),
\]
(where \(m_0 = \lambda_1 + \lambda_2 + 2, n_0 = \lambda_1 - \lambda_2\) and the dimension of the space
\[
Z_t \otimes E_3 = (V_{m+r} \oplus V_{n+r-2} \oplus \cdots \oplus V_{|n-r|}) \otimes E_3
\]
is
\[
\sum_{r=0}^{t} (m_0 + r + 1)(r + 1)(n_0 + 1),
\]
the set \((S_t)^2_{E_3}\) is a basis of \(Z_t \otimes E_3\).

The next proposition is an analogue to the proposition 3.5 in the space \(X \otimes S = A_b(\lambda) \otimes S\).

**Proposition 4.2.** For \(s \in \{0, 1, \cdots, \lambda_1 + \lambda_2\}, \ l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}\) and for any nonnegative integer \(k\) we have
\[
(F_1 E_3^k \otimes E_3) \cdot w(x, y_l) \in \text{span}_C \{(E_3^{s-2} \otimes E_3) \cdot w(x, y_{l-1}) , \}
\[
\quad (E_3^k \otimes E_3) \cdot w(x+1, y_l)\}
\]
where \(E_3^{-1} = E_3^{-2} = 0\).

**Proof.** For each \(k \in \mathbb{N}\)
\[
(4.8) \quad F_1 E_3^k = -k(k-1)E_3^{k-2}E_2 + kE_3^{k-1}F_4 + E_3^k F_1.
\]
Furthermore, we have
\[
(4.9) \quad (E_2 \otimes E_3) \cdot w(x, y_l) = l(\lambda_1 - \lambda_2 - l + 1)(1 \otimes E_3) \cdot w(x, y_{l-1}),
\]
and
\[
(4.10) \quad (F_1 \otimes E_3) \cdot w(x, y_l) = \frac{\lambda_1 + \lambda_2 + 2 - s}{\lambda_1 + \lambda_2 + 1 - s} (1 \otimes E_3) \cdot w(x+1, y_l).
\]
Since \((E_3 \otimes F_4 - F_4 \otimes E_3) \cdot w = 0\) for all \(w \in W\), we get
\[
(4.11) \quad (F_1 \otimes E_3) \cdot w(x, y_l) = (E_3 \otimes F_4) \cdot w(x, y_l)
\]
\[
= \frac{1}{\lambda_1 + \lambda_2 + 1 - s} (E_3 \otimes E_3) \cdot w(x+1, y_l).
\]
The proof follows from (4.8), (4.9), (4.10), (4.11).

The next proposition is an analogue to the proposition 3.6 in the space \(X \otimes S = A_b(\lambda) \otimes S\).

**Proposition 4.3.** For \(l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}\) and for any nonnegative integer \(k\) we have
\[
(F_1 E_3^k \otimes E_3) \cdot w(x_{\lambda_1+\lambda_2+1}, y_l) \in \text{span}_C \{(E_3^{s-2} \otimes E_3) \cdot w(x_{\lambda_1+\lambda_2+1}, y_{l-1}) , \}
\[
\quad (E_3^k \otimes F_4) \cdot w(x_{\lambda_1+\lambda_2+1}, y_l)\}
\]
where \(E_3^{-1} = E_3^{-2} = 0\).
Proof. The proof follows from (3.14), (4.9) and

\[(F_1 \otimes E_3) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)} = (1 \otimes F_4) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)};\]

\[(F_4 \otimes E_3) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)} = (E_4 \otimes F_4) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)}.\]

From propositions 4.2 and 4.3 we get that the set

\[(4.12) \quad (S_t)_{\text{final}} = \{(F_2^a E_3^k \otimes E_3) \cdot w_{(x, y)};\]

\[(F_1^a F_2^b E_3^k \otimes F_4) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)};\]

\[k \in \{0, 1, \cdots, t\}, \quad a, b \in \{0, 1, \cdots, k\},\]

\[s \in \{0, 1, \cdots, \lambda_1 + \lambda_2 + 1\}, \quad l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}\]

is a spanning set of \(Z_t \otimes E_3\). Since the cardinality of the set \((S_t)_{\text{final}}\) equals the cardinality of the set \((S_t)_{\text{final}}\) which is a basis of \(Z_t \otimes E_3\), we conclude that \((S_t)_{\text{final}}\) is a basis of \(Z_t \otimes E_3\). Finally, from the previous conclusions we get that one basis of the vector space \(X \otimes S\) is given by

\[{(F_2^a E_3^k \otimes E_3) \cdot w_{(x, y)}; (F_2^a E_3^k \otimes E_3) \cdot w_{(x, y)};\]

\[(F_2^a \otimes 1) \cdot w_{(x, y)}; (F_2^a E_3^k \otimes E_3) \cdot w_{(x, y)};\]

\[(x \otimes F_3) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)}; (x \otimes F_4) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)};\]

\[(x \otimes E_3 F_3) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)}; (x \otimes F_3 F_4) \cdot w_{(x_{\lambda_1 + \lambda_2 + 1}, y)};\]

\[x \in \{F_2^a F_3^k \otimes E_3; k \in \mathbb{N}_0, a, b \in \{0, 1, \cdots, k\}, c \in \{0, 1, \cdots, k\},\]

\[s \in \{0, 1, \cdots, \lambda_1 + \lambda_2 + 1\}, \quad l \in \{0, 1, \cdots, \lambda_1 - \lambda_2\}.\]

The action map \(\phi : A \otimes W \rightarrow X \otimes S\)

\[\phi(a \otimes w) = a \cdot w, \quad a \in A, w \in W\]

maps the spanning set of \(A \otimes_B W\) from Theorem 3.4 into the basis of the space \(X \otimes S\), which implies that this spanning set is a basis of the vector space \(A \otimes_B W\). Finally, we get:

**Theorem 4.4.** Let \(X\) be the vector space of the discrete series representation of the group \(SO_c(4, 1)\) and let \(W\) be the Dirac cohomology of \(X\). Then the \((A, \tilde{K})\)-module \(\text{Ind}_D(W) = A \otimes_B W\) is isomorphic to the \((A, \tilde{K})\)-module \(X \otimes S\).

**Remark 4.5.** There is one more positive root system that contains the fixed positive root system \(\{\epsilon_1 \pm \epsilon_2\}\) for \(\mathfrak{t}\). This positive root system is

\[\{\epsilon_1 \pm \epsilon_2, \epsilon_1, -\epsilon_2\}\]

and the corresponding Borel subalgebra is

\[\mathfrak{b}' = \mathfrak{h} \oplus \mathfrak{g}_{-\epsilon_2} \oplus \mathfrak{g}_{\epsilon_1 + \epsilon_2} \oplus \mathfrak{g}_{\epsilon_1} \oplus \mathfrak{g}_{-\epsilon_2}.\]

Discrete series of \(SO_c(4, 1)\) of the form \(A_{\mathfrak{b}'}(\lambda)\) for some \(\lambda\) which is admissible for \(\mathfrak{b}'\) can also be constructed via Dirac induction. The proof is similar.
