Optimal Parallelism Bound for Fully Asynchronous Coordinate Descent with Linear Speedup

Yun Kuen Cheung * Richard Cole Yixin Tao †
Singapore University of Technology and Design Courant Institute, NYU

Abstract

When solving massive optimization problems in areas such as machine learning, it is a common practice to seek speedup via massive parallelism. However, especially in an asynchronous environment, there are limits on the possible parallelism. Accordingly, we seek tight bounds on the viable parallelism in asynchronous implementations of coordinate descent.

We focus on asynchronous coordinate descent (ACD) algorithms on convex functions $F : \mathbb{R}^n \to \mathbb{R}$ of the form

$$F(x) = f(x) + \sum_{k=1}^{n} \Psi_k(x_k),$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is a smooth convex function, and each $\Psi_k : \mathbb{R} \to \mathbb{R}$ is a univariate and possibly non-smooth convex function.

Our approach is to quantify the shortfall in progress compared to the standard sequential stochastic gradient descent. This leads to a truly simple yet optimal analysis of the standard stochastic ACD in a partially asynchronous environment, which already generalizes and improves on the bounds in prior work. We also give a considerably more involved analysis for general asynchronous environments in which the only constraint is that each update can overlap with at most $q$ others, where $q$ is at most the number of processors times the ratio in the lengths of the longest and shortest updates. The main technical challenge is to demonstrate linear speedup in the latter environment. This stems from the subtle interplay of asynchrony and randomization. This improves Liu and Wright’s lower bound on the maximum degree of parallelism attaining linear speedup almost quadratically; the new bound is essentially optimal.

1 Introduction

We consider the problem of finding an (approximate) minimum point of a convex function $F : \mathbb{R}^n \to \mathbb{R}$ of the form

$$F(x) = f(x) + \sum_{k=1}^{n} \Psi_k(x_k),$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is a smooth convex function, and each $\Psi_k : \mathbb{R} \to \mathbb{R}$ is a univariate convex function, but may be non-smooth. Such functions occur in many data analysis and machine learning problems, such as linear regression (e.g., the Lasso approach to regularized least squares [36]) where $\Psi_k(x_k) = |x_k|$, logistic regression [28], ridge regression [34] where $\Psi_k(x_k)$ is a quadratic function, and Support Vector Machines [16] where $\Psi_k(x_k)$ is often a quadratic function or a hinge loss (essentially, $\max\{0, x_k\}$).

Due to the enormous size of modern problems, there has been considerable interest in parallel algorithms for the problem in order to achieve speedup, ideally in proportion to the number of processors or cores at hand, called linear speedup. One of the most natural parallel algorithms is to simply have each of the multiple cores perform coordinate descent in an (almost) uncoordinated way. In this work, we analyze the natural parallel version of the standard stochastic version of coordinate descent: each core, at each of its iterations, chooses the next coordinate to update uniformly at random.$^1$

One important issue in parallel implementations is whether the different cores are all using up-to-date information for their computations. To ensure this requires considerable synchronization, locking, and consequent waiting. Avoiding the need for the up-to-date requirement, i.e., enabling asynchronous updating, was a significant advance. The advantage of asynchronous updating is it reduces and potentially eliminates the need for waiting. At the same time, as some of the data being used in calculating updates will be out of date, one has to ensure that the out-of-datedness is bounded in some fashion.

Modeling Asynchrony The study of asynchrony in parallel and distributed computing goes back to Chazan and Miranker [9] for linear systems and to Bertsekas and Tsitsiklis for a wider range of computations [6]. They obtained convergence results for both deterministic and stochastic algorithms along with rate of convergence results for deterministic algorithms. Subsequently, a different type of asynchronous method (often called “stateless algorithms”) and their stochastic variants were studied in the area of distributed computing; however, the meanings of “asynchrony” and “stochastic” are quite different from the usage in the optimization literature and in this paper, as we will discuss in the related work section.

The first analyses to prove rate of convergence bounds for stochastic asynchronous computations (as understood in the optimization literature) were those by Avron et al. [1] (for the Gauss-Seidel algorithm), and by Liu et al. [24] and Liu and Wright [23] (for coordinate descent). Liu et al. [24] imposed a “consistent read” constraint on the asynchrony; the other two works considered a more general “inconsistent read” model. Subsequent to Liu and Wright’s work, several overlooked issues were identified by Mania et al. [26] and Sun et al. [35]; we call them Undoing of Uniformity (UoU)$^3$ and No-Common-Value.

---

$^1$There are also versions of the sequential algorithm in which different coordinates can be selected with different probabilities.

$^2$“Consistent read” mean that all the coordinates a core reads may have some delay, but they must appear simultaneously at some moment. Precisely, the vector of $\tilde{x}$ values used by the update at time $t$ must be $x^{1-c}$ for some $c \geq 1$. “Inconsistent reads” mean that the $\tilde{x}$ values used by the update at time $t$ can be any of the $(x_1^{t-c_1}, \ldots, x_n^{t-c_n})$, where each $c_j \geq 1$ and the $c_j$’s can be distinct.

$^3$In [1], the authors also raised a similar issue about their asynchronous Gauss-Seidel algorithm.
In brief, as the asynchrony assumptions were relaxed, the bounds that could be shown, particularly in terms of achievable speedup, became successively weaker. In this work we ask the following question:

**Can we achieve both linear speedup and full asynchrony when applying coordinate descent to non-smooth functions $F$?**

Our answer to this question is “yes”, and we obtain the maximum possible parallelism while maintaining linear speedup (up to at most a constant factor). Our results match the best speedup, namely linear speedup with up to $\Theta(\sqrt{n})$ processors as in [24], but with no constraints on the asynchrony, beyond a requirement that unlimited delays do not occur. Specifically, as in [23], we assume there is a bounded amount of overlap between the various updates. We now state our results for strongly convex functions informally.

**Theorem 1 (Informal).** Let $q$ be an upper bound on how many other updates a single update can overlap. $L_{\text{res}}$ and $L_{\text{max}}$ are Lipschitz parameters defined in Section 2. Let $F$ be a strongly convex function with strongly convex parameter $\mu_F$. If $q = O\left(\frac{\sqrt{n}L_{\text{max}}}{L_{\text{res}}}\right)$ then $\mathbb{E}\left[F(x_{T+1}) - F^*\right] \leq \left(1 - \frac{1}{3}\frac{\mu_F}{nL_{\text{max}}}\right)^T \cdot \left(F(x_1) - F^*\right)$.

Standard sequential analyses [25, 33] achieve similar bounds with the $\frac{1}{3}$ replaced by 1; i.e., up to a factor of 3, this is the same rate of convergence. Furthermore, this bound is tight, as we show in a companion work [14].

**Asynchronicity Assumptions** The Uniformity assumption states that the start time ordering of the updates and their commit time ordering are identical. Undoing of Uniformity (UoU) arises because while each core initiates an update by choosing a coordinate uniformly at random, due to the possibly differing lengths of the different updates, and also due to various asynchronous effects, the commit time ordering of the updates may be far from uniformly distributed. The fact that this assumption had been made in earlier works was first pointed out in Mania et al. [26] — see their Section 3.1. In an experimental study, Sun et al. [35] showed that iteration lengths in coordinate descent problem instances varied by factors of 2 to 10, demonstrating that Undoing of Uniformity is likely.

The Common Value (CV) assumption states that the random choice of a coordinate to update does not affect the values read for that update. If coordinates are not being read on the same schedule, as seems likely for sparse problems, it would appear that this assumption too will be repeatedly violated. Again, the fact that this assumption had been used in earlier work was first pointed out in [26] — see their Assumption 5.1. The strong version of this assumption, the Strong Common Value (SCV) assumption, states that in addition, the values read in each previous gradient computation do not depend on which coordinate is selected by the current update. This too is implicitly assumed in [23, 24].

**Our Technical Contributions** There are two key contributions in our work. First, we identify an amortization approach for demonstrating convergence amid asynchrony. Briefly, each update yields a progress term, modulo an error cost which occurs due to asynchrony. A fraction of the progress per update is used to demonstrate overall progress, while in expectation the remaining fraction of the total progress can be shown to compensate for the error costs of all the updates. In short, it is the amortization of progress against errors that leads to our convergence analysis. With this perspective, it is intuitively clear why we need the bounded asynchrony assumption and the Lipschitz parameter bounds: the former to control how error blows up with the datedness of information being used, and the latter to control how one update affects the gradient measurements of other updates. When we use the SCV assumption as was done in [23], the amortization approach
leads to a clean and fairly short analysis, and also improves the parallelism bound given in \cite{23}; see Section 4.

While there is no short answer as to why our approach improves the parallel bound (partly because our analysis is substantially different from the one in \cite{23}), we point out a notable difference between our analysis and those in \cite{23} and \cite{26}. In the two prior works, error bounds are global in the sense that they involve distance terms between the current point and the optimal point (see equation (A.18) in \cite{23}, and all the lemmas in Appendix A.1 of \cite{26}). In contrast, all our error bounds can be kept local, i.e., they can be expressed only in terms of the magnitude of an update and its range of variation, and also of gradient changes due to updates, but the optimal point is not involved in the error bounds at all.

The second key contribution is to provide a rigorous analysis that removes the Uniformity and SCV assumptions. Here, we give a brief explanation of why this is technically challenging; we will discuss this further in Section 5. The standard stochastic analysis relies on showing an inequality of the following form: $\mathbb{E} \left[ F(x^t) \mid x^{t-1} \right] \leq (1 - \delta) \cdot F(x^{t-1})$ for some positive $\delta$. To remove the Uniformity assumption, Mania et al. \cite{26} ordered the updates by their starting time; this ensures that each update is equally likely to be to any of the $n$ coordinates, independently of all other updates. In order to analyze non-smooth functions, we need the additional property that for each coordinate, the update ordering be the same as the commit time ordering. This leads us to define a new ordering, called the **Single Coordinate Consistent Ordering**, the SCC ordering for short. We will define this ordering in Section 2. As in the start time ordering, in this ordering, at the moment when a core picks a random coordinate at some time $t$, the value of $x^{t-1}$, and possibly also of $x^\tau$ for some earlier times $\tau < t - 1$, need not be fully determined yet. The random choice made by the core, and the resulting subsequent computation can affect these values for a variety of reasons, including the possibly different lengths of the computations for different random choices, and conceivably, the possibly different read patterns and hence differing congestion patterns for the different choices. In sum, direct use of the standard stochastic analysis is not possible, since in our setting the “future” can affect the “past”. The SCV assumption guarantees that $x^{t-1}$ is the same regardless the choice of coordinate at time $t$, which is why it can lead to the aforementioned simple analysis. One key idea is to judiciously overestimate the error terms affecting the $t$-th update so that they do not depend on the choice of coordinate at time $t$, which then allows averaging of the error over this choice. A second observation is that these errors can be expressed in terms of a mutual recursion, which, with the right bounds on $q_i$, remains bounded.

Table 1 provides a comparison of our results with prior work in terms of the classes of functions they handle and the range of parallelism for which linear speedup is possible.

**Related Work**

Convex optimization is one of the most widely used methodologies in applications across multiple disciplines. Unsurprisingly, there is a vast literature studying convex optimization, with various assumptions and in various contexts. We refer readers to Nesterov’s text \cite{29} for an excellent overview of the development of optimization theory. Coordinate Descent is a method that has been widely studied; see Wright \cite{40} for a recent survey. Relevant works concerning sequential stochastic coordinate descent include Nesterov \cite{30}, Richtárik and Takác \cite{33} and Lu and Xiao \cite{25}.

Distributed and asynchronous computation has a long history in optimization, going back at least to the work of Chazan and Miranker \cite{9} in 1969, with subsequent milestones in the work of Baudet \cite{5}, and of Tsitsiklis, Bertsekas and Athans \cite{39, 6}; more recent results include \cite{8, 7}. See Avron et al. \cite{1} for an account of the development, and Frommer and Szyld \cite{19} for a fairly recent review.

In the last few years, there have been multiple analyses of various asynchronous parallel implementations of stochastic coordinate descent \cite{24, 23, 26, 35}. We have already mentioned the results
Table 1: Comparisons between the analyses of SACD. UoU stands for “Undoing of Uniformity”, SCV for “Strong Common Value”. See Definition 1 for the specifications of Lipschitz parameters $L$, $L_{\text{max}}$, $L_{\text{res}}$, and $L_{\text{res}}$; $\mu_f$ is the strong convexity parameter. When there is no non-smooth $\Psi_k$, the update increment is the computed gradient divided by $\Gamma$. Thus, the larger the $\Gamma$, the less aggressive the update. Mania et al. achieve linear speedup compared to the case $q = 1$ for $q = O(n^{1/6})$; however, the case $q = 1$ is slower by a factor of $\Theta(L^2/(\mu_f L_{\text{max}}))$ compared to a standard stochastic algorithm.

of Liu et al. [24] and Liu and Wright [23]. Both obtained bounds for both convex and “optimally” strongly convex functions, attaining linear speedup so long as there are not too many cores. Liu et al. [24] obtained bounds similar to ours (see their Corollary 2 and our Section 2), but the version they analyzed is more restricted than ours in two respects: first, they imposed the strong assumption of consistent reads, and second, they considered only smooth functions (i.e., no non-smooth univariate components $\Psi_k$). The version analyzed by Liu and Wright [23] is the same as ours, but their result requires both the Uniformity and Strong Common Value assumptions. Their bound degrades when the parallelism exceeds $\Theta(n^{1/4})$. Our bound has a similar flavor but with a limit of $\Theta(n^{1/2})$.

The analysis by Mania et al. [26] removed the Uniformity assumption and needs only the Common Value assumption (not the strong version). However, the maximum parallelism was much reduced (to at most $n^{1/6}$), and their results applied only to smooth strongly convex functions. We note that a major focus of their work concerned the analysis of HOGWILD!, an asynchronous stochastic gradient descent algorithm used for functions of the form $\sum_i f_i(x)$, where each of the $f_i$ is convex, and the bounds there were optimal.

The analysis in Sun et al. [35] removed the Common Value assumption and partially removed the Uniformity assumption. However, this came at the cost of achieving no parallel speedup. They also noted that a hard bound on the parameter $q$ could be replaced by a probabilistic bound, which in practice is more plausible.

Avron et al. [1] proposed and analyzed an asynchronous and randomized version of the Gauss-Seidel algorithm for solving symmetric and positive definite matrix systems. They pointed out that in practice delays depend on the random choice of direction (which corresponds to coordinate choice in our case), which is indeed one of the sources leading to Undoing of Uniformity. Their analysis bypasses this issue with their Assumption A-4, which states that delays are independent of

---

4This is a weakening of the standard strong convexity.

5This is expressed in terms of a parameter $\tau$, renamed $q$ in this paper, which is essentially the possible parallelism; the connection between them depends on the relative times to calculate different updates.
the coordinate being updated, but the already mentioned experimental study of Sun et al. indicates
that this assumption does not hold in general.

Another widely studied approach to speeding up gradient and coordinate descent is the use of
acceleration. Very recently, attempts have been made to combine acceleration and parallelism \cite{21,18,15}. But at this point, these results do not extend to non-smooth functions.

In statistical machine learning, the objective functions to be minimized typically have the form
\[
\sum_{e=1}^{N} f_e(x), \quad \text{where } x \in \mathbb{R}^n \text{ and each } f_e \text{ corresponds to a loss function for one training data instance.}
\]
Usually, \( f_e \) will only depend on a subset of entries in \( x \), and we denote this subset by \( S_e \). A well-known algorithm is Stochastic Gradient Descent (SGD), which proceeds by randomly sampling a number of training data instances, uses the corresponding \( f_e \)'s to compute an unbiased estimator of the accurate gradient, which in turn is used to make the standard gradient descent update. Niu et al. \cite{31} introduced HOGWILD!, the first asynchronous and lock-free SGD algorithm, in which cores sample training data instances and perform updates in an uncoordinated manner. Their algorithm does not preclude overwriting other cores' updates. HOGWILD! achieves linear speedup for \emph{sparse} problems, i.e., \( |S_e| \) is small for every \( e \), each \( i \in [n] \) appears only in a small number of \( S_e \)'s, and any fixed \( S_e \) intersects only a small number of other \( S_e \)'s. Many of the assumptions made for asynchronous SGD share similarities with our assumptions. For instance, Tsianos and Rabbat \cite{35} extended the analysis of Duchi et al. \cite{17} to analyze distributed dual averaging (DDA) with communication delay; the same authors \cite{32} studied DDA with heterogeneous systems, i.e., distributed computing units with different query and computing speeds. Langford et al. \cite{22} also studied problems with bounded communication delay.

In a similar spirit to our analysis, Cheung, Cole and Rastogi \cite{13} analyzed asynchronous taton-
nement in certain Fisher markets. This earlier work employed a potential function which drops continuously when there is no update and does not increase when an update is made.

In a companion work, Cheung and Cole \cite{11} analyzed asynchronous tatonnement in another family of Fisher markets, where tatonnement is equivalent to gradient descent. They gave worst-case analyses for a special family of convex functions arising in market analysis \cite{12}, while our work focus on stochastic analyses. The convex functions studied in \cite{11} do not have global Lipschitz parameters, so their update rule needs to be constrained to ensure that their analyses can proceed with local Lipschitz parameters.

(Stochastic) stateless algorithms have been studied in the area of distributed computing for a variety of problems, e.g., packing (positive) linear programming \cite{4}, flow \cite{20,3}, load balancing \cite{2}, and resource allocation \cite{27}. Most (if not all) of these algorithms presume no communication delay. “Asynchrony” refers to the uncoordinated update schedules for different variables, while “stochastic” means the updating schedules are chosen via (independent) random processes. But whenever an update is made in a round, it is always using the most up-to-date information available right before that round. Using the terminology of the optimization community, this is spiritually closer to \textit{synchronous} block descent, but where the block chosen in each round can be quite arbitrary.

\textbf{Organization of the Paper} In Section \ref{sec:2} we describe our model of asynchronous coordinate descent and state our results. In Section \ref{sec:3} we give a high-level sketch of the structure of our analysis. Then, in Section \ref{sec:4} we show that with the Strong Common Value assumption we can obtain a truly simple analysis for the Stochastic ACD (SACD for short); this analysis achieves the maximum possible speedup (i.e., linear speedup with up to \( \Theta(\sqrt{n}) \) processors). Note that this is the same assumption as in Mania et al.’s result \cite{26} and less restrictive than the assumptions in Liu and Wright’s analysis \cite{23}. We follow this with a discussion of some of the obstacles that need to be overcome in order to remove the Strong Common Value assumption, and some comments on how we achieve this. We then give the full analysis of SACD. All omitted proofs can be found in
the appendix. Also, for the reader’s convenience, at the end of this paper, we provide a table of the notation and parameters we use.

2 Model and Main Results

Recall that we are considering convex functions \( F : \mathbb{R}^n \to \mathbb{R} \) of the form \( F(x) = f(x) + \sum_{k=1}^n \Psi_k(x_k) \), where \( f : \mathbb{R}^n \to \mathbb{R} \) is a smooth convex function, and each \( \Psi_k : \mathbb{R} \to \mathbb{R} \) is a univariate and possibly non-smooth convex function. We let \( x^* \) denote a minimum point of \( F \) and \( X^* \) denote the set of all minimum points of \( F \). Without loss of generality, we assume that \( F^* \), the minimum value of \( F \), is 0.

We review some standard terminology. Let \( \vec{e}_j \) denote the unit vector along coordinate \( j \).

**Definition 1.** The function \( f \) is \( L \)-Lipschitz-smooth if for any \( x, \Delta x \in \mathbb{R}^n \), \( \| \nabla f(x + \Delta x) - \nabla f(x) \| \leq L \cdot \| \Delta x \| \). For any coordinates \( j, k \), the function \( f \) is \( L_{jk} \)-Lipschitz-smooth if for any \( x \in \mathbb{R}^n \) and \( r \in \mathbb{R} \), \( |\nabla_k f(x + r \cdot \vec{e}_j) - \nabla_k f(x)| \leq L_{jk} \cdot |r| \); it is \( L_{\text{res}} \)-Lipschitz-smooth if, for all \( j \), \( \| \nabla f(x + r \cdot \vec{e}_j) - \nabla f(x) \| \leq L_{\text{res}} \cdot |r| \). Let \( L_{\text{max}} := \max_{j,k} L_{jk} \); we note that if \( f \) is twice differentiable, then \( L_{\text{max}} = \max_j L_{jj} \). Let \( L_{\text{res}} := \max_k \left( \sum_{j=1}^n (L_{kj})^2 \right)^{1/2} \).

**The Difference Between \( L_{\text{res}} \) and \( L_{\text{res}} \)** In general, \( L_{\text{res}} \geq L_{\text{res}} \). \( L_{\text{res}} = L_{\text{res}} \) when the rates of change of the gradient are constant, as for example in quadratic functions such as \( x^T Ax + bx + c \). We need \( L_{\text{res}} \) because we do not make the Common Value assumption. We use \( L_{\text{res}} \) to bound terms of the form \( \sum_j |\nabla_j f(y^j) - \nabla_j f(x^j)|^2 \), where \( |y_k^j - x_k^j| \leq |\Delta_k| \), and for all \( h, i \), \( |y_k^h - y_i^h|, |x_k^h - x_i^h| \leq |\Delta_k| \), whereas in the analyses with the Common Value assumption, the term being bounded is \( \sum_j |\nabla_j f(y) - \nabla_j f(x)|^2 \), where \( |y_k - x_k| \leq |\Delta_k| \); i.e., our bound is over a sum of gradient differences along the coordinate axes for pairs of points which are all nearby, whereas the other sum is over gradient differences along the coordinate axes for the same pair of nearby points. Finally, if the convex function is \( s \)-sparse, meaning that each term \( \nabla_k f(x) \) depends on at most \( s \) variables, then \( L_{\text{res}} \leq \sqrt{s} L_{\text{max}} \). When \( n \) is huge, it seems plausible that the only feasible problems are going to be sparse ones.

By a suitable rescaling of variables, we may assume that \( L_{jj} \) is the same for all \( j \) and equals \( L_{\text{max}} \). This is equivalent to using step sizes proportional to \( L_{jj} \) without rescaling, a common practice.

Next, we define strong convexity.

**Definition 2.** Let \( f : \mathbb{R}^n \to \mathbb{R} \) be a convex function. \( f \) is strongly convex with parameter \( \mu_f > 0 \), if for all \( x, y \), \( f(y) - f(x) \geq \langle \nabla f(x), y - x \rangle + \frac{\mu_f}{2} \| y - x \|^2 \).

**The Update Rule** Recall that in a standard coordinate descent, be it sequential or parallel and synchronous, the update rule, applied to coordinate \( j \), first computes the accurate gradient \( g_j := \nabla_j f(x^t) \), and then performs the update given below.

\[
W_j(d, g, x) := gd + \Gamma d^2/2 + \Psi_j(x + d) - \Psi_j(x);
\]

\[
x_j^{t+1} \leftarrow x_j^t + \arg\min_d W_j(d, g_j, x_j^t) \equiv x_j^t + \tilde{d}_j(g_j, x_j^t),
\]

and \( \forall k \neq j \), \( x_k^{t+1} \leftarrow x_k^t \), where \( \Gamma \geq L_{\text{max}} \) is a parameter controlling the step size. We call this the update (that starts) at time \( t \).

However, in an asynchronous environment, an updating core (or processor) might retrieve outdated information \( \tilde{x}^t \) instead of \( x^t \), so the gradient the core computes will be \( \tilde{g}_j^t \equiv \tilde{g}_j := \nabla_j f(\tilde{x}^t) \),
instead of the accurate value $\nabla_j f(x^t)$. Our update rule, which is naturally motivated by its synchronous counterpart, is

$$x_j^{t+1} \leftarrow x_j^t + \hat{d}_j(\hat{g}_j, x_j^t) \equiv x_j^t + \Delta x_j^t \quad \text{and} \quad \forall k \neq j, \ x_k^{t+1} \leftarrow x_k^t. \quad \tag{1}$$

We let

$$\hat{W}_j(g,x) := -\min_d W(d,g,x) \equiv -W_j(\hat{d}_j(g,x), g, x).$$

Note that $W_j(0,g,x) = 0$; thus $\hat{W}_j(g,x) \geq 0$ always. It is well known that in the synchronous case, $\hat{W}_j(\nabla_j f(x^t), x_j^t)$ is a lower bound on the reduction in the value of $F$, which we treat as the progress. Finally, we let $k_t$ denote the coordinate being updated at time $t$.

**Algorithm 1 SACD Algorithm.**

**Input:** The initial point $x^1 = (x_1^1, x_2^1, \cdots, x_n^1)$. Multiple processors use a shared memory. Each processor iteratively repeats the following six-step procedure, with no global coordination among them:

- **Step 1:** Choose a coordinate $j \in \{1, 2, \cdots, n\}$ uniformly at random.
- **Step 2:** Retrieve coordinate values $\tilde{x}^t$ from the shared memory.
- **Step 3:** Compute the gradient $\nabla_j f(\tilde{x}^t)$.
- **Step 4:** Request a write lock on the memory that stores the value of the $j$-th coordinate.
- **Step 5:** Retrieve the most updated $j$-th coordinate value, then update it using rule (1).\footnote{Even if the processor had retrieved the value of the $j$-th coordinate from the shared memory in Step 2, the processor needs to retrieve it again here, because it needs the most updated value when applying update rule 1.}
- **Step 6:** Release the lock acquired in Step 4.

The SACD Algorithm The coordinate descent process starts at an initial point $x^1 = (x_1^1, x_2^1, \cdots, x_n^1)$. Multiple cores then iteratively update the coordinate values. We assume that at each time, there is exactly one coordinate update which is being written (in Step 5 of the SACD algorithm). In practice, since there will be little coordination between cores, it is possible that multiple coordinate values are updated at the same moment; but by using an arbitrary tie-breaking rule, we can immediately extend our analyses to these scenarios.

In Algorithm 1 we provide the complete description of SACD. The retrieval times for Step 2 plus the gradient-computation time for Step 3 can be non-trivial, and also in Step 4 a core might need to wait if the coordinate it wants to update is locked by another core. Thus, during this period of time other coordinates are likely to be updated. For each update, we call the period of time spent performing the six-step procedure the span of the update. We say that update $A$ interferes with update $B$ if the commit time of update $A$ lies in the span of update $B$.

Later in this section, we discuss why locking is needed and when it can be avoided; we also explain why the random choice of coordinate should be made before retrieving coordinate values.

Managing the Undoing of Uniformity: The Single Coordinate Consistent Ordering Before stating our result formally, we need to disambiguate our timing scheme. In every asynchronous iterative system, including our SACD algorithm, each procedure runs over a span of time rather than atomically. Generally, these spans are not consistent — it is possible for one update to start

\footnote{Instead of having a lock in lines 4–6, a compare-and-swap operation can be used to perform the update in Line 5. This has the effect of using the hardware lock that is part of the compare-and-swap operation.}
later than another one but to commit earlier. To create an analysis, we need a scheme that orders the updates in a consistent manner.

Using the commit times of the updates for the ordering seems the natural choice, since this ensures that future updates do not interfere with the current update. This is the choice made in many prior works. However, this causes uniformity to be undone. To understand why, consider the case when there are three cores and four coordinates, and suppose that the workload for updating $x_1$ is three times greater than those for updating $x_2, x_3, x_4$. If $k_t = 1$ for some $t$, then the probability distribution which the random variable $k_{t+1}$ follows is biased away from coordinate 1; precisely, $P[k_{t+1} = 1 | k_t = 1] < 1/4$. When there are many more cores and coordinates than the simple case we just considered, and when the other asynchronous effects\(^8\) are taken into account, it is highly uncertain what is the exact or even an approximate distribution for $k_{t+1}$ conditioned on knowledge of the history of $k_1, \cdots, k_t$. However, all prior analyses apart from [26] and [35] proceeded by making the idealized assumption that the conditional probability distribution remains uniform, while in fact it may be far from uniform. While it seems plausible that without conditioning, the $t$-th update to commit is more or less uniformly distributed, many prior analyses needed this property with the conditioning, and they needed it for every update without fail.

To bypass the above issue, we introduce the **Single Coordinate Consistent Ordering**, SCC for short, defined as follows. We begin from the updates ordered by start time. Then, for each coordinate separately, we rearrange the updates to this coordinate so that they are in commit order, while collectively occupying the same place in the start ordering. For example, if coordinate $x_1$ has updates $x_{1,2}^2, x_{1,8}^8, x_{1,11}^{11}$ that start at times 2, 8, and 11, resp., but they finish at times 9, 18 and 12, in the new ordering $x_{1,2}^2$ will be in position 2, $x_{1,11}^{11}$ will be in position 8, and $x_{1,8}^8$ will be in position 11. Henceforth, time will refer to the index $t$ in the SCC ordering.

Clearly the history has no influence on the choice of $k_{t+1}$. However, this raises a new issue: future updates can interfere with the current update. Here the term future is used w.r.t. the SCC ordering; recall that an update $U_1$ to one coordinate with an earlier starting time can commit later than another later starting update $U_2$ to a different coordinate, and therefore $U_2$ could interfere with $U_1$.

**The Strong Common Value Assumption** Since the retrievals of coordinate values are performed after choosing the coordinate $k_t$ to update, and since the schedule of retrievals depends on the choice of $k_t$, in general it is possible that the retrieved value $\tilde{x}$ in Step 2 of Algorithm 1 varies with $k_t$.

Also, a later starting update (update A) can affect updates with earlier starts (updates in B) if update A commits earlier than some of the updates in B. One scenario in which this is likely to occur if the iteration lengths are unequal. Suppose that at time $\tau$ a core $B$ chose coordinate $k_\tau \in B$ to update, and this update takes $2d$ time units to commit (where $d \geq 3$). Also, suppose the update is scheduled to read the value of coordinate $j$ at some time after $\tau + d + 2$. At time $\tau + 1$, core $A$ chooses a random coordinate to update. If it chooses coordinate $j$—Update A—and if this update takes $d$ time units to commit, then core $B$ will read the value updated by core $A$. On the other hand, if coordinate $j$ was not chosen recently, then core $B$ will surely read an earlier value of coordinate $j$.

More subtly, even if update A commits after all the updates in B, it can still affect the updates in B due to differential delays coming from the operating environment (see Footnote 8 for examples of such delays).

In [23], Liu and Wright implicitly used the Strong Common Value assumption, namely that the

\(^{8}\text{E.g., communication delays, interference from other computations (say due to mutual exclusion when multiple cores commit updates to the same coordinate), interference from the operating system and CPU scheduling.}\)
choice of coordinate for update $t$ does not affect the value of $\tilde{x}^t$ read in update $t$ nor the values read in earlier updates. This is the reason they can use the parameter $L_{\text{res}}$ to bound gradient differences. To avoid using the Strong Common Value assumption, we have introduced a new but similar parameter $L_{\text{res}}$.

2.1 Results

We assume that our algorithms are run until exactly $T$ coordinates are selected and then updated for some pre-specified $T$. The initial value of $x$ is denoted by $x^1$, and the first update is at time $t = 1$. (This is consistent with the update rule [1].) The commit times are constrained by the following assumption.

**Assumption 1.** There exists a non-negative integer $q$ such that the only updates that might interfere with the update at time $t$ are those that commit at times $t + 1, t + 2, \ldots, t + q$.

When asynchronous effects are moderate, and if the various gradients have a similar computational cost, the parameter $q$ will typically be bounded above by a small constant times the number of cores.

As we are using the SCC ordering, we need to express the constraint in terms of the latter ordering.

**Lemma 1.** The range of SCC times for coordinates that might interfere with an update at SCC time $t$ is $[t - 2q + 1, t + q - 1]$.

**Theorem 2 (SACD Upper Bound).** Given initial point $x^1$, Algorithm 1 is run for exactly $T$ iterations by multiple cores. Suppose that Assumption 1 holds, $\Gamma \geq L_{\text{max}}$, and $q \leq \min\{\sqrt{n}/102, \Gamma \sqrt{n}/102L_{\text{res}}\}$.

(i) If $F$ is strongly convex with parameter $\mu_F$, and $f$ is strongly convex with parameter $\mu_f$, then

$$\mathbb{E}[F(x^{T+1})] \leq \left[1 - \frac{1}{3n} \cdot \frac{\mu_F}{\mu_F + \Gamma - \mu_f}\right]^T \cdot F(x^1).$$

(ii) Now suppose that $F$ is convex. Let $R$ be the radius of the level set for $x^1$, Level$(x^1) = \{x | f(x) \leq f(x^1)\}$. Then

$$\mathbb{E}[F(x^{T+1})] \leq \frac{1}{1 + \min\left\{\frac{1}{12n}, \frac{F(x^1)}{24n R^2}\right\}} \cdot T \cdot F(x^1).$$

**Problem Instances with large $L_{\text{res}}$ and $L_{\text{res}}$** Both $L_{\text{res}}$ and $L_{\text{res}}$ can be as large as $\sqrt{n} \cdot L_{\text{max}}$. For problem instances of this type, the bound on $q$ becomes $O(1)$; i.e., they do not demonstrate any parallel speedup. We conjecture that this is inherent. Even if the conjecture holds, it is still conceivable that parallel speedup will occur in practice, but to provide a confirming analysis would require new assumptions on the asynchronous behavior, and we leave the devising of such assumptions as an open problem.

**Further Remarks about the SACD Algorithm** In many optimization problems, e.g., those involving sparse matrices, the number of coordinate values needed for computing the gradient in Step 3 of Algorithm 1 is much smaller than $n$, i.e., in Step 2, the core needs to retrieve only a tiny portion of the full set of coordinate values. Also, the sets of coordinate values needed for computing the gradients along different coordinates can be very different. Therefore, the random choice of coordinate for update $t$ does not affect the value of $\tilde{x}^t$ read in update $t$ nor the values read in earlier updates. This is the reason they can use the parameter $L_{\text{res}}$ to bound gradient differences. To avoid using the Strong Common Value assumption, we have introduced a new but similar parameter $L_{\text{res}}$.

\(^9\text{Necessarily, } \Gamma \geq \mu_f.\)
coordinate (in Step 1) has to be made ahead of the process of retrieving required information from the shared memory.

If the convex function $F$ does not have the univariate non-smooth components, each update simply adds a number, which depends only on the computed gradient, to the current value in the memory. Then the update can be done atomically (e.g., by fetch-and-add\footnote{The fetch-and-add CPU instruction atomically increments the contents of a memory location by a specified value.}), and no lock is required.

However, for general scenarios with univariate non-smooth components, the update to $x_j$ must depend on the value of $x_j$ in memory right before the update (see \footnote{The standard birthday paradox result states that if $\epsilon \sqrt{n}$ cores each chooses a random coordinate among $[n]$ uniformly, the probability for a collision to occur is $\Theta(\epsilon^2)$.}). Then the update cannot be done atomically, and a lock is necessary. We note that when the number of cores is far fewer than $n$, say when it is $\epsilon \sqrt{n}$ for some $\epsilon < 1$, delays due to locking can occur, but are unlikely to be significant\footnote{The standard birthday paradox result states that if $\epsilon \sqrt{n}$ cores each chooses a random coordinate among $[n]$ uniformly, the probability for a collision to occur is $\Theta(\epsilon^2)$.} As already mentioned, even if the update is carried out using a Compare-and-Swap operation, the lock is still present within the hardware implementation of this operation.

### 3 The Basic Framework

Let $k_t$ denote the index of the coordinate that is updated at time $t$, $g_{k_t}^t := \nabla_{k_t} f(x^t)$ denote the value of the gradient along coordinate $k_t$ computed at time $t$ using up-to-date values of the coordinates, and $\hat{g}_{k_t}^t$ denote the actual value computed, which may use some out-of-date values.

The classical analysis of stochastic (synchronous) coordinate descent proceeds by first showing that for any chosen $k_t$, $F(x^t) - F(x^{t+1}) \geq \hat{W}_{k_t}(g_{k_t}^t, x_{k_t}^t)$. Taking the expectation yields

$$
\mathbb{E} \left[ F(x^t) - F(x^{t+1}) \right] \geq \frac{1}{n} \sum_{j=1}^{n} \hat{W}_j(g_j^t, x_j^t).
$$

By \footnote{The fetch-and-add CPU instruction atomically increments the contents of a memory location by a specified value.} Lemmas 4,6], the RHS of the above inequality is at least $\frac{1}{n} \cdot \frac{\mu_F}{\mu_F + \mu_j} \cdot F(x^t)$; for completeness, we provide a proof of this result in Appendix A.2. Let $\alpha := \frac{\mu_F}{\mu_F + \mu_j}$. Then $\mathbb{E} \left[ F(x^{t+1}) \right] \leq (1 - \frac{\alpha}{n}) \cdot \mathbb{E} \left[ F(x^t) \right]$; iterating this inequality yields $\mathbb{E} \left[ F(x^{t+1}) \right] \leq (1 - \frac{\alpha}{n})^t \cdot F(x^1)$.

To handle the case where inaccurate gradients are used, we employ the following two lemmas.

**Lemma 2.** If $\Gamma \geq L_{\max}$, $F(x^t) - F(x^{t+1}) \geq \hat{W}_{k_t}(g_{k_t}^t, x_{k_t}^t) - \frac{1}{\Gamma} \cdot (g_{k_t}^t - \hat{g}_{k_t}^t)^2$.

**Lemma 3.** If $\Gamma \geq L_{\max}$, $F(x^t) - F(x^{t+1}) \geq \frac{1}{\Gamma} \cdot (\Delta x_{k_t}^t)^2 - \frac{1}{\Gamma} \cdot (g_{k_t}^t - \hat{g}_{k_t}^t)^2$.

Proving these results for smooth functions is straightforward. The version for non-smooth functions is less simple, and makes use of the SCC ordering. It follows from Lemma 19 in Appendix A.

Combining Lemma 2 with Lemma 3 yields

$$
F(x^t) - F(x^{t+1}) \geq \frac{1}{2} \cdot \hat{W}_{k_t}(g_{k_t}^t, x_{k_t}^t) + \frac{\Gamma}{8} \cdot (\Delta x_{k_t}^t)^2 - \frac{1}{\Gamma} \cdot (g_{k_t}^t - \hat{g}_{k_t}^t)^2. \tag{2}
$$

The first term on the RHS of the above inequality, after taking the expectation, is more or less what is needed in order to demonstrate progress. To complete the analysis we need to show that in expectation,

$$
\sum_{t=1}^{T} \frac{\Gamma}{8} \cdot (\Delta x_{k_t}^t)^2 (1 - \frac{\alpha}{2n})^{T-t} \geq \sum_{t=1}^{T} \frac{1}{\Gamma} \cdot (g_{k_t}^t - \hat{g}_{k_t}^t)^2 \left( 1 - \frac{\alpha}{2n} \right)^{T-t} \tag{3}
$$

for then we can conclude that $\mathbb{E} \left[ F(x^{T+1}) \right] \leq (1 - \frac{\alpha}{2n})^T \cdot F(x^1)$. 

4 A Truly Simple Analysis for the Strongly Convex Case with the Strong Common Value Assumption

The following analysis already generalizes the results shown in [23] [24].

Suppose there are a total of $T$ updates. We view the whole stochastic process as a branching tree of height $T$. Each node in the tree corresponds to the moment when some core randomly picks a coordinate to update, and each edge corresponds to a possible choice of coordinate. We use $\pi$ to denote a path from the root down to some leaf of this tree. A superscript of $\pi$ on a variable will denote the instance of the variable on path $\pi$. Note that for each path $\pi$ we reorder the coordinate instances so that they are in the SCC ordering. All this does, for each path $\pi$ and for each coordinate $k$, is to reorder the instances of $x_k$ on path $\pi$. A double superscript of $(\pi, t)$ will denote the instance of the variable at time $t$ on path $\pi$, i.e., right before the $t$-th update. Finally $\pi(k,t)$ will denote the path with the time $t$ coordinate on path $\pi$ replaced by coordinate $k$. Note that $\pi(k_t, t) = \pi$.

Recall that $\pi^t_{\pi} x$ denotes the value of $x_j$ on path $\pi$ immediately prior to the $t$-th update in the SCC ordering. So $\pi^t_{k_t} x$ denotes the value of $x_{k_t}$ on path $\pi(k,t)$ immediately prior to the $t$-th update and $\pi^t_{k,s} x$ denotes the value of $x_{k_s}$ on path $\pi(k,t)$ immediately prior to the $s$-th update.

In this section, we give a simple proof which shows that the error term when reading out-of-date values, $\mathbb{E}_k[(g_k^{\pi(k,t), t} - g_k^{\pi(k,t), t})^2]$, can be bounded by $\frac{3qL^2}{n} \sum_{s \in [t-2q+1, t+q-1] \setminus \{t\}} \mathbb{E}_k[(\Delta x_{k_s}^{\pi, s})^2]$, where $\Delta x_{k_s}^{\pi, s}$ denotes the update on path $\pi$ at time $s$, and $k_s$ is the index of the coordinate chosen at time $s$. Note that by the Strong Common Value assumption, when $s \neq t$, the values $\Delta x_{k_s}^{\pi(k,t), s}$ are the same for all $n$ paths obtained by varying $k$.

Lemma 4. With the Strong Common Value assumption,

$$
\mathbb{E}_k[(g_k^{\pi(k,t), t} - g_k^{\pi(k,t), t})^2] \leq \frac{3qL^2}{n} \sum_{s \in [t-2q+1, t+q-1] \setminus \{t\}} \mathbb{E}_k[(\Delta x_{k_s}^{\pi(k,t), s})^2].
$$

Proof. By definition, $g_k^{\pi(k,t), t} = \nabla_k f(x^{\pi(k,t), t})$, the gradient of up-to-date point $x^{\pi(k,t), t}$, and $g_k^{\pi(k,t), t} = \nabla_k f(\tilde{x}^{\pi(k,t), t})$, the gradient of the point actually read from memory, out-of-date point $\tilde{x}^{\pi(k,t), t}$. By the definition of $q$, we see that the difference between $x^{\pi(k,t), t}$ and $\tilde{x}^{\pi(k,t), t}$ is a subset of the updates in the time interval $[t-2q+1, t+q-1] \setminus \{t\}$.\footnote{Lemma states that the updates before time $t - 2q + 1$ have been written into memory before the update at time $t$ starts.}

We denote this subset by $U$: $U = \{t_1, t_2, \ldots, t_{|U|}\}$.

Viewing $\Delta x_{k_{t_i}}^{\pi(k,t), t}$ as an $n$-vector of with a non-zero entry for coordinate $k_{t_i}$ and no other, we have:

$$
x^{\pi(k,t), t} = \tilde{x}^{\pi(k,t), t} + \sum_{i=1}^{|U|} \left\{ \begin{array}{ll}
\Delta x_{k_{t_i}}^{\pi(k,t), t} & \text{if } t_i < t; \\
-\Delta x_{k_{t_i}}^{\pi(k,t), t} & \text{if } t_i > t. 
\end{array} \right.
$$

For simplicity, we define:

$$
x^{\pi(k,t), t}[j] = \tilde{x}^{\pi(k,t), t} + \sum_{i=1}^j \left\{ \begin{array}{ll}
\Delta x_{k_{t_i}}^{\pi(k,t), t} & \text{if } t_i < t; \\
-\Delta x_{k_{t_i}}^{\pi(k,t), t} & \text{if } t_i > t. 
\end{array} \right.
$$
Then, $x^{\pi(k,t),t}[0] = \tilde{x}^{\pi(k,t),t}$ and $x^{\pi(k,t),t}[U] = x^{\pi(k,t),t}$. By the definition of $L_{\text{res}}$ and the triangle inequality, we obtain:

$$
\|\nabla f(\tilde{x}^{\pi(k,t),t}) - \nabla f(x^{\pi(k,t),t})\|^2 \leq \left( \sum_{j=0}^{[U]-1} \left| \nabla f(x^{\pi(k,t),t}[j+1]) - \nabla f(x^{\pi(k,t),t}[j]) \right| \right)^2 \\
\leq \left( \sum_{t=1}^{[U]} L_{\text{res}} \left| \Delta x^{\pi(k,t),t}_t \right| \right)^2 \\
\leq 3q \sum_{s\in\{t-2q,t+q\}\{t\}} L_{\text{res}}^2 \left( \Delta x^{\pi(k,t),s}_{k,s} \right)^2.
$$

(4)

The last inequality followed from applying the Cauchy-Schwarz inequality to the RHS, relaxing $U$ to $[t - 2q + 1, t + q - 1] \setminus \{t\}$.

Note that by the Strong Common Value assumption, for any $k$ and $k'$, $\tilde{x}^{\pi(k',t),t} = \tilde{x}^{\pi(k,t),t}$ and $x^{\pi(k',t),t} = x^{\pi(k,t),t}$; consequently, $\|\nabla_{k'} f(\tilde{x}^{\pi(k',t),t}) - \nabla_{k'} f(x^{\pi(k',t),t})\|^2 = \|\nabla_{k'} f(\tilde{x}^{\pi(k,t),t}) - \nabla_{k'} f(x^{\pi(k,t),t})\|^2$. Thus,

$$
\mathbb{E}_k \left[ (\pi^{\pi(k,t),t}_k - \tilde{g}_k^{\pi(k,t),t})^2 \right] = \frac{1}{n} \mathbb{E}_k \left[ \|\nabla f(\tilde{x}^{\pi(k,t),t}) - \nabla f(x^{\pi(k,t),t})\|^2 \right].
$$

The result follows on applying (4). □

To demonstrate the bound in (3), it suffices that $\frac{6q^2L_2^2}{n}(1 - \alpha)3q \leq \frac{t^2}{8}$. The bound in Theorem 1 then follows readily (with $L_{\text{res}}$ replaced by $L_{\text{res}}$).

5 Comments on Achieving the Full Result

Although the analysis in the previous section is simple, it is not obvious how to obtain a similar bound without the Strong Common Value (SCV) assumption. We want to have a similar relationship between $\mathbb{E}_{k_t}[(\pi^{\pi(k_t,t),t}_k - \tilde{g}_k^{\pi(k_t,t),t})^2]$ and $\sum_{s\in\{t-2q+1, t+q\}\{t\}} (\Delta x^{\pi(k_t,t),s}_{k,s})^2$. We mention several of the challenges we face when we drop the SCV assumption.

1. Without the SCV assumption, $\tilde{x}^{\pi(k_t,t),t}$ may depend on the coordinate being updated at time $t$. Now we need to bound

$$
\sum_{k_t} \left[ \nabla_{k_t} f(\tilde{x}^{\pi(k_t,t),t}) - \nabla_{k_t} f(x^{\pi(k_t,t),t}) \right]^2,
$$

while the first inequality in (3) need not bound this term.

2. In addition, without the SCV assumption, $x^{t} = x^{\pi(k_t,t),t}$ may also depend on the coordinate being updated at time $t$. For example, suppose the updates to coordinates $i$ and $j$ at time $t$ have different read schedules and this affects the timing of an earlier update to coordinate $k$ (because the update has to be atomic and so may be slightly delayed if there is a read). Then a read of coordinate $k$ by an update to coordinate $l$ may occur before $k$’s update in the scenario with the time $t$ update to coordinate $i$ and after in the scenario with the time $t$ update to coordinate $j$. If the update to coordinate $l$ occurs before time $t$ then $x^{t}$ could depend on the coordinate chosen at time $t$. While this may seem esoteric, to rule it out imposes unclear limitations on the asynchronous schedules.
To handle this issue, roughly speaking, for each path $\pi$, we bound the difference between the maximum and minimum possible updates over all asynchronous schedules in which these updates could affect the time $t$ update. Then, for any set of paths which differ only on the time $t$ update, these differences are identical over these paths, and consequently we can average the effects of these differences on the time $t$ update over these paths, bringing in an $L_{\text{max}}$ term; we can then amortize with these averaged values, and achieve an $O(\frac{2L_{\text{max}}^2}{n})$ bound. We emphasize that our analysis considers all possible asynchronous schedules, but the initial averaging is done over subsets of these schedules. We will prove Lemma 9, the analogue of Lemma 4.

We have introduced a term that is the difference between the maximum and minimum possible updates. It is bounded by a recursive formulation in terms of the actual updates and these same terms for nearby coordinates (no more than $3q$ distant in time). But this complicates the amortized analysis. Our (substantially) modified analysis appears in Section 6.

3. Without the SCV assumption, a simple bound is that

$$
(g_{\pi}^t - \tilde{g}_{k,t}^\pi)^2 \leq 2q \sum_{s \in \{t-2q+1, t+q-1\}\{q\}} L_{k,s}^2 (\Delta x_{k,s}^\pi)^2 \leq 3q L_{\text{max}}^2 \sum_{s \in \{t-q, t+q\}\{q\}} (\Delta x_{k,s}^\pi)^2.
$$

This is essentially the bound in Sun et al. [35] (except that they use $L$ rather than $L_{\text{max}}$, and the start time rather than the SCC ordering). But this bound does not enable any parallel speedup because of the $q$ factor.

4. Without the SCV assumption, the first term on the RHS of (2) becomes

$$
\mathbb{E}_{k,t} \left[ \frac{1}{2} \cdot \hat{W}_{k_t} (g_{\pi(k,t), t}, x_{\pi(k,t), t}) \right] = \mathbb{E}_{k} \left[ \frac{1}{2} \cdot \hat{W}_{k} (g_{\pi(k,t), t}, x_{\pi(k,t), t}) \right].
$$

[33, Lemmas 4,6] does not apply to this expression. Instead, we want the following expression on the RHS of (2): $\mathbb{E}_{j} \left[ \mathbb{E}_{k} \left[ \frac{1}{2} \cdot \hat{W}_{k} (g_{\pi(j,t), t}, x_{\pi(j,t), t}) \right] \right]$; in fact, we can only achieve $\frac{1}{2}$ rather than $\frac{1}{3}$, but this suffices. The two expectations would be the same if the SCV assumption held. Our remedy is to devise new shifting lemmas to bound the cost of changing the arguments in $\hat{W}_k$, namely Lemma 5 and Lemma 7. These shifting Lemmas introduce some additional “error” terms.

6 Full SACD Analysis

In order to analyze both the strongly convex and merely convex cases, we apply the following theorem regarding rates of convergence. This theorem uses amortization terms $A^+$ and $A^-$, which could also be viewed as a Lyapunov function. This is a generalization of the methodology used in the simple argument above. We note that the same result, but without the amortization terms $A^+$ and $A^-$, can be found in [33].

**Theorem 3.** Suppose that $\Gamma \geq L_{\text{max}}$. Let $q$ be a fixed integer parameter. Let $A^+(t)$, $A^-(t)$ be non-negative functions with $A^+(1) = 0$, and let $H(t) := F(x^t) + A^+(t) - A^-(t)$. Suppose that

a. $H(t) \geq 0$ for all $t \geq 1$;

b. for all $t \geq 1$, $H(t + 1) \leq H(t)$, i.e., $H(t)$ is a decreasing function of $t$;
c. there exist constants $\alpha, \beta > 0$ such that for any $t \geq 1$,

$$H(t) - H(t + 1) \geq \frac{\alpha}{n} \sum_{k=1}^{n} \hat{W}_k(\nabla_k f(x^t), x^t_k) + \frac{\beta}{n} \cdot A^+(t).$$

(i) If $F$ is strongly convex with parameter $\mu_F$ and $f$ has strongly convex parameter $\mu_f$, then for all $T \geq 0$,

$$H(T + 1) \leq \left[1 - \min \left\{ \frac{\alpha}{2n} \cdot \frac{\mu_F}{\mu_F + \Gamma - \mu_f}, \frac{\beta}{2n} \right\} \right]^T \cdot F(x^1).$$

(ii) Now suppose that $F$ is convex. Let $\mathcal{R}$ be the radius of the level set for $x^1$. Formally, let $X = \{x \mid F(x) \leq F(x^1)\}$; then $\mathcal{R} = \sup_{x \in X} \inf_{x^* \in X^*} \|x - x^*\|$. Then, for all $T \geq 0$,

$$H(T + 1) \leq \frac{F(x^1)}{1 + \min \left\{ \frac{\beta}{2nF(x^1)}, \frac{\alpha}{4nF(x^1)}, \frac{\alpha}{8nF^2} \right\} : F(x^1) : T}.$$

This result also holds in expectation.

In fact, as $\hat{W}_k \geq 0$ and $A^+(t) \geq 0$, condition (c) implies condition (b), and as $A^-(T + 1) = 0$, $H(T + 1) \geq 0$, which together with condition (b) implies condition (a).

The first step in our analysis is to generalize Lemma 4 to settings in which the Strong Common Value Assumption does not hold. To facilitate this analysis we will need some additional notation.

### 6.1 Important Concepts and Notation

At this point, it is helpful to clarify the concept of a history. Suppose $\pi^t$ is a path of length $t$, and let $\mathcal{N}$ be $\pi^t$’s final node. What had really happened before $\mathcal{N}$, or in other words, what is the history before $\mathcal{N}$? Lemma 4 ensures that all updates with SCC time $t' \leq t - 2q$ have committed before $\mathcal{N}$, and thus all information about such updates belongs to the history. Also, the coordinates $k_s$ for $s \in [t - 2q + 1, t - 1]$ were already chosen, so their identities belong to the history; however, some or all of their updated values might not yet belong to the history.

The main novelty in our analysis is to achieve a bound on the difference between the computed gradient and the “up-to-date” gradient. The resulting bound is given below in Lemma 9. To fully understand this bound, new notation is needed, as defined below. We then use this bound to obtain the desired amortized progress.

#### The range of values for the updates

In order to achieve a good bound, we need to average the error over different paths. But for different paths, the values of $\Delta x_{k_s}$ need not be equal, which implies the error this update can induce on other updates can be different on different paths. To resolve this issue, our approach is to bound its range of values: we introduce the values $\Delta_{\min}^{t,R,S} x_{k_s}$ and $\Delta_{\max}^{t,R,S} x_{k_s}$, which will be identical for the paths over which we average, where $R$ and $S$ are two sets of times whose purpose we explain next.

Because the “future” (w.r.t. the SCC times) may affect the “past”, the natural formulation for bounding the range of $\Delta x_{k_s}$ involves a mutually recursive definition of the $\Delta x_{k_s}$ terms. To help sort this out, we introduce the term $\Delta_{\max}^{t} x_{k_s}$, which is intended to be the maximum value $x_{k_s}$ can take on when it can be an input for the update to $x_{k_s}^t$, as reflected in the following definition.

Our definition introduces a further constraint, namely ruling out a set of times $R$ of possible inputs; as

---

13 i.e., for all $x, y \in \mathbb{R}^n$ and $F'(x)$ which is any subgradient of $F$ at $x$, $F(y) \geq F(x) + (F'(x), y - x) + \frac{1}{2}\mu_F \|y - x\|^2$. 

14
Then we define the maximum value that \( \Delta x_{k_s}^{\pi,s} \) can assume when the first \((t-2q)\) updates on path \( \pi \) have been fixed, the update does not read any of the variable values updated at (SCC) times after \( s \), and \( t,R \) bounds on the range of values for this update; \( \Delta x_{k_s}^{\pi,s} \) when the first \((t-2q)\) updates on path \( \pi \) have been fixed, the update does not read any of the variable values updated at times after \( s \) and \( t \). Also, \( \Delta x_{k_s}^{\pi,s} \) is needed because of the univariate components of the underlying convex function \( F \).

Some of these definitions specify new notation in which max is a subscript; the analogous notation with max replaced by \( \min \) is being implicitly defined at the same time.

For any set \( R \subseteq [t-2q, t+q] \) and \( S \subseteq \{ u \mid k_u = k_s \text{ and } t-2q \leq u \leq s-1 \} \), let

\[
\Delta_{\max}^{t,R,S} x_{k_s}^{\pi,s} := \max_S \Delta_{\max}^{t,R} x_{k_s}^{\pi,s}.
\]

Note that for \( t > s \), \( \Delta_{\max}^{t,R} x_{k_s}^{\pi,s} \leq \Delta_{\max}^{s,R} x_{k_s}^{\pi,s} \) and \( \Delta_{\min}^{t,R} x_{k_s}^{\pi,s} \geq \Delta_{\min}^{s,R} x_{k_s}^{\pi,s} \), since the update does not read any of the variable values updated at times after \( s \) and \( q \). Also, \( \Delta_{\max}^{t,R} x_{k_s}^{\pi,s} \leq \Delta_{\max}^{t,\emptyset} x_{k_s}^{\pi,s} \) and \( \Delta_{\min}^{t,\emptyset} x_{k_s}^{\pi,s} \geq \Delta_{\min}^{t,R} x_{k_s}^{\pi,s} \), for all \( R \).

Also, an input \( x_{k_s} \) for the update \( \Delta x_{k_s}^{\pi,t} \) will be fixed if \( t \leq s \). Accordingly, we define

\[
\overline{\Delta}_{\max} x_{k_s}^{\pi,s} := \max_{t:s-q \leq t \leq s+2q} \Delta_{\max}^{t,\emptyset} x_{k_s}^{\pi,s} = \max_{s-q \leq t \leq s} \Delta_{\max}^{t,\emptyset} x_{k_s}^{\pi,s}.
\]

Let \( \overline{\Delta}_{\max} x_{k_s}^{\pi,s} \) denote the value of \( g_{k_s}^{\pi,s} \) used to evaluate \( \overline{\Delta}_{\max} x_{k_s}^{\pi,s} \); let \( \overline{\Delta}_{\max} x_{k_s}^{\pi,s} \) denote the maximum value of \( g_{k_s}^{\pi,s} \) when the first \((u-2q)\) updates on path \( \pi \) have been fixed, and the update does not read any of the variable values updated at times after \( u \); let \( \overline{\Delta}_{\max} x_{k_s}^{\pi,s} := \max_{s-q \leq u \leq s} \overline{\Delta}_{\max} x_{k_s}^{\pi,s} \).

We let \( \Delta_{\min}^{u,R} x_{k_s}^{\pi,s} \) denote the range of values for this update; \( \Delta_{\max}^{u,R} x_{k_s}^{\pi,s} \) is denoted by \( \Delta_{\min}^{u,R} x_{k_s}^{\pi,s} \). It’s clear that if \( u \subseteq [s-q, s] \), then

\[
\Delta_{\min}^{u,R} x_{k_s}^{\pi,s} \subseteq \overline{\Delta}_{\max} x_{k_s}^{\pi,s}.
\]

Similarly, we let \( g_{\min,k_s}^{\pi,s} = g_{\pi,k_s}^{\pi,s} - g_{\pi,k_s}^{\pi,s} \).

We also let \( (D_t)^2 := E_{\pi} \left( \overline{\Delta}_{\max} x_{k_t}^{\pi,t} - \overline{\Delta}_{\min} x_{k_t}^{\pi,t} \right)^2 \) and \( (D_t^X)^2 := E_{\pi} \left( \overline{\Delta}_{\min} x_{k_t}^{\pi,t} \right)^2 \).

Since exactly \( T \) updates are made, we assume that \( (D_t)^2, (D_t^X)^2 \equiv 0 \) for all \( t \leq 0 \) and \( t \geq T+1 \) throughout the analysis.

Advantage of the new notation There are several advantages to using \( \Delta_{\max}^{u,R} x_{k_t}^{\pi,t} \): a) the actual update, \( \Delta_{k_t}^{\pi,t} \), lies in the range \( \bigcup_{t-q \leq u \leq t} \left[ \Delta_{\min}^{u,\{t\}} x_{k_t}^{\pi,t}, \Delta_{\max}^{u,\{t\}} x_{k_t}^{\pi,t} \right] \), which allows us to give an upper bound on the range of values for this update; b) if \( \pi \neq \pi' \), if \( \pi \) and \( \pi' \) differ only at time \( t \), \( \Delta_{\max}^{u,\{t\}} x_{k_t}^{\pi,t} = \Delta_{\max}^{u,\{t\}} x_{k_t}^{\pi',t} \), which allows us to average over these paths.
With the notation in hand we can state the lemmas we will use when the parameters to $\hat{W}$ are changed.

**Lemma 5** ($\hat{W}$ Shifting on $g$ parameter). For any $g_j, g_j'$,

$$\hat{W}_j(g_j, x_j) \geq \frac{2}{3} \cdot \hat{W}_j(g_j', x_j) - \frac{4}{31} \cdot (g_j - g_j')^2.$$ 

**Lemma 6.** For any $g_1, g_2, x \in \mathbb{R}$ and $\Gamma \in \mathbb{R}^+$, $|\hat{d}(g_1, x_1) - \hat{d}(g_2, x_2)| \leq |x_1 - x_2| + \frac{1}{\Gamma} \cdot |g_1 - g_2|$, and hence

$$\left(\hat{d}(g_1, x_1) - \hat{d}(g_2, x_2)\right)^2 \leq 2(x_1 - x_2)^2 + \frac{2}{\Gamma^2} \cdot (g_1 - g_2)^2.$$ 

If $\Psi$ is the zero function, the upper bound on $|\hat{d}(g_1, x_1) - \hat{d}(g_2, x_2)|$ can be improved to $\frac{1}{\Gamma} \cdot |g_1 - g_2|$.

Lemma 7 bounds the change to $\hat{W}$ when we shift the $x$ value at time $t$. Before we state the lemma, we need to introduce some further notation.

Recall that at the beginning of the $t$-th update, $x_{k-2q}$ is already fixed when a core chooses $k$. However, if there are some updates to coordinate $k$ over the time interval $[t - 2q, t - 1]$, the value of $x_k$ will be modified during this time interval. A subtle observation is that how $x_k$ is modified might depend on the choice of $k$ (and also of $k_{t+1}, k_{t+2}, \ldots, k_{t+q-1}$). More concretely, depending on the coordinate choices for the time span $[t, t+q]$, and depending on various unpredictable asynchronous effects, the value of $x^t$ might not be the same. This is in contrast to the classical stochastic and synchronous case, where $x^t$ is already fixed by the history when bounding the relevant conditional expectation.

To avoid algebraic clutter, we write $\pi(k), t \equiv \pi(k, t), t$ in the remainder of this subsection.

**Lemma 7.** Suppose there are $\ell$ updates to coordinate $k$ over the time interval $[t - 2q + 1, t - 1]$. Then

$$\begin{align*}
\text{if } \ell = 0, \quad &\hat{W}(g_k^0, x_k^{\pi(k), t}) = \hat{W}(g_k^0, x_k^{\pi, t}) \\
\text{if } \ell > 0, \quad &\hat{W}(g_k^{\pi, t}, x_k^{\pi(k), t}) \geq \hat{W}(g_k^{\pi, t}, x_k^{\pi, t}) - \frac{3}{2\Gamma} \cdot (g_k^{\pi, \text{prev}(t,k)} - g_k^{\pi, t})^2 \\
&\quad - 2\Gamma(x_k^{\pi, t} - x_k^{\pi(k), t})^2 - \frac{3\Gamma}{2} \cdot (\Delta x_k^{\pi, \text{prev}(t,k)})^2,
\end{align*}$$

where $\text{prev}(t,k)$ denote the time of the most recent update to coordinate $k$, if any, in the time range $[t - 2q + 1, t - 1]$; otherwise, we set it to $t$.

We will also use the following observation.

**Lemma 8.** Suppose there are $\ell$ updates to coordinate $k$ over the time interval $[t - 2q, t - 1]$. Then,

$$\left(x_k^{\pi, t} - x_k^{\pi(k), t}\right)^2 \leq \sum_{1 \leq i \leq \ell} \Delta_{\text{span}}^{l, t, \pi, t_i} + \Delta_{\text{span}}^{l, \pi, t_i} + \Delta_{\text{span}}^{l, \pi, t_i} \leq 4q \sum_{1 \leq i \leq \ell} \left(\Delta_{\text{span}}^{l, t, \pi, t_i}\right)^2 + \left(\Delta_{\text{span}}^{l, t, \pi(k), t_i}\right)^2. \quad (6)$$
6.3 Gradient Bounds

We will need to bound \((g_{k_t}^{\pi,t} - \tilde{g}_{k_t}^{\pi,t})^2\). Unfortunately, \(g_{k_t}^{\pi,t}\) might not be in \([g_{\min,k_t}^{\pi,t}, g_{\max,k_t}^{\pi,t}]\). The reason is that \(T_{k_t}^{\pi,t}\) is a function of \(x^{(k_t),t}\), and this up-to-date \(x\) value could depend on the value of the time \(t\) update; for recall that the update at time \(t\) might finish before some updates with earlier SCC times, and the latter updates could then read the updated value of the coordinate being updated at time \(t\). As already explained, there are also other ways that the choice of update at time \(t\) could affect earlier updates. To handle this difficulty we introduce \(g_{k_t}^{S,\pi,t}\), the gradient at the point \(x^{\pi,t}\) if the updates from time \(t - 2q + 1\) to \(t - 1\) were performed as in the sequential algorithm; i.e., each one is using up-to-date information. Clearly,

\[
(g_{k_t}^{\pi,t} - \tilde{g}_{k_t}^{\pi,t})^2 \leq 2 \left( g_{k_t}^{\pi,t} - g_{k_t}^{S,\pi,t} \right)^2 + 2 \left( g_{k_t}^{S,\pi,t} - \tilde{g}_{k_t}^{\pi,t} \right)^2.
\]  

(7)

In Section 6.3.1 and Section 6.3.2 we will upper bound both \((g_{k_t}^{S,\pi,t} - \tilde{g}_{k_t}^{\pi,t})^2\) and \((g_{k_t}^{\pi,t} - \tilde{g}_{k_t}^{\pi,t})^2\) in terms of \((D_s)^2\) and \((\Delta_s^X)^2\).

6.3.1 Upper bound on \((g_{k_t}^{S,\pi,t} - \tilde{g}_{k_t}^{\pi,t})^2\)

It is clear that \((g_{k_t}^{S,\pi,t} - \tilde{g}_{k_t}^{\pi,t})^2\) is smaller than \((g_{\min,k_t}^{\pi,t} - g_{\max,k_t}^{\pi,t})^2 \leq (g_{\text{span},k_t}^{\pi,t})^2\). We bound the latter term as follows.

**Lemma 9.** Let \(\nu_1 := 12q^2/n\) and \(\nu_2 = 16q^2l^2/n^2\). Then

\[
\mathbb{E}_\pi \left[ \frac{2}{\Gamma} \left( g_{\text{span},k_t}^{\pi,t} \right)^2 \right] \leq \frac{\nu_1}{q} \sum_{s \in [t - 3q, t] \setminus \{t\}} \Gamma \cdot \left( (D_s)^2 + (\Delta_s^X)^2 \right), \text{ and}
\]

\[
\Gamma \cdot (D_t)^2 \leq \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t - 3q, t] \setminus \{t\}} \Gamma \cdot \left( (D_s)^2 + (\Delta_s^X)^2 \right).
\]

(8)

**Proof.** First, we review which updates can create differences in the values of \(g_{\max,k_t}^{\pi,t}\) and \(g_{\min,k_t}^{\pi,t}\). We claim that the computation of these gradients may differ due to reading different values for \(x_{k,s}^{\pi,s}\), or reading an older value of the coordinate, for some or all of \(t - 3q + 1 \leq s \leq t + q\), and only for this range of \(s\). To see why; note that in the definitions of \(g_{\max,k_t}^{\pi,t}\) and \(g_{\min,k_t}^{\pi,t}\) as given in (5), for all the relevant \(u\), the first \((u - 2q)\) updates are already fixed, so the first \((t - q) - 2q = t - 3q\) updates are fixed; also, an update to \(x_{k,t}^{\pi,t}\) will only consider updates up to time \(t + q\).

Further, for each \(s\), if \(x_{k,s}^{\pi,s}\) is an input, direct or indirect, for the update to \(x_{k,t}^{\pi,t}\), the change to the previous value of the variable due to the update yielding \(x_{k,s}^{\pi,s}\) will lie in the range \(\Delta_{\min,k_t}^{u_t} \leq x_{k,s}^{\pi,s} \leq \Delta_{\max,k_t}^{u_t} \) for a suitable span of \(u\) values, specified next. First, we are concerned only with \(u \in [t - q, t]\) because \(s\) is the range of \(u\) for \(\Delta_{\max,k_t}^{u_t}\) and \(\Delta_{\min,k_t}^{u_t}\). Second, as for \(s < u\), \(\Delta_{\max,k_t}^{x_{k,s}^{\pi,s}} \leq \Delta_{\max,k_t}^{x_{k,s}^{\pi,s}}\), and similarly \(\Delta_{\min,k_t}^{x_{k,s}^{\pi,s}} \geq \Delta_{\min,k_t}^{x_{k,s}^{\pi,s}}\), we can safely reduce the range \([s, \max\{s, t\}]\) to \(s\). Finally, as no variables updated at times \(v > u + q\) are read here, we have that \(s \leq u + q\), or \(s - q \leq u\). So the range for \(u\) is \(T_u := \max\{s - q, t - q\}, \min\{s, t\}\) ∪ \{\}. Thus, by Lemma 6 (to show the first inequality), and by two uses of the Cauchy-Schwartz inequality (for the second and the fourth inequalities), Also we define

\[
\Delta_{\text{var},k_t}^{x_{k,s}^{\pi,s}} = \max \left\{ \max_{u \in T_u} \Delta_{\max,k_t}^{u_t} x_{k,s}^{\pi,s} - \min_{u \in T_u} \Delta_{\min,k_t}^{u_t} x_{k,s}^{\pi,s}, \max_{u \in T_u} \Delta_{\max,k_t}^{u_t} x_{k,s}^{\pi,s}, \min_{u \in T_u} \Delta_{\min,k_t}^{u_t} x_{k,s}^{\pi,s} \right\}.
\]

17
This is maximal possible difference in the contribution from update \(s\) to the value for the coordinate \(k_s\) that the update at time \(t\) reads, where the terms \(\max_{u \in T_{st}} \Delta_{\max^{x_k}_{s}}\) and \(\min_{u \in T_{st}} \Delta_{\min^{x_k}_{s}}\) occur due to the different values of coordinate \(k_s\) if the update at time \(s\) has and hasn’t committed when the update at time \(t\) reads coordinate \(k_s\).

\[
\left( \Delta_{\text{span}^{x_{k_s}}_{k_t}} \right)^2 = \left( \delta_{\max^{x_{k_s}}_{k_t}} - \delta_{\min^{x_{k_s}}_{k_t}} \right)^2 \\
\leq 2 \left( \sum_{s \in [t-3q,t-1] \setminus \{t\}, k_s = k_t} \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 + \frac{2}{n^2} \left( g_{\delta_{\max^{x_{k_t}}_{k_s}} - \delta_{\min^{x_{k_s}}_{k_t}}} \right)^2 \\
\leq 6q \sum_{s \in [t-3q,t-1] \setminus \{t\}, k_s = k_t} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 + \frac{2}{n^2} \left( g_{\delta_{\max^{x_{k_t}}_{k_s}} - \delta_{\min^{x_{k_s}}_{k_t}}} \right)^2 \\
= 6q \sum_{s \in [t-3q,t-1] \setminus \{t\}, k_s = k_t} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 + \frac{2}{n^2} \left( g_{\delta_{\max^{x_{k_t}}_{k_s}} - \delta_{\min^{x_{k_s}}_{k_t}}} \right)^2 \\
\leq 6q \sum_{s \in [t-3q,t-1] \setminus \{t\}} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 + \frac{8q}{n^2} \sum_{s \in [t-3q,t+q] \setminus \{t\}} L_{k_t}^2 \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2.
\]

Now we average over all \(n\) choices of \(k_t\); consequently, \(\pi\) is now being viewed as a random variable where \(k_t\) on \(\pi\) is being chosen uniformly at random, while the coordinates at times other than \(t\) are fixed. Using the definition of \(L_{\text{res}}\) yields

\[
\mathbb{E} \left[ \left( \Delta_{\text{span}^{x_{k_t}}_{k_t}} \right)^2 \right] \leq \frac{6q}{n} \sum_{s \in [t-3q,t-1] \setminus \{t\}} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 + \frac{8qL_{\text{res}}^2}{n^2} \sum_{s \in [t-3q,t+q] \setminus \{t\}} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2.
\]

This averaging is legitimate because on the RHS the paths \(\pi\) being considered in the averaging all have the same values for \(\Delta_{\max^{x_{k_s}}_{k_t}}\) and \(\Delta_{\min^{x_{k_s}}_{k_t}}\) as their computation does not involve the update to \(x_{k_t}^t\), and because at most the first \((t-2q)\) updates have been fixed in any of these terms, none of the updates that could affect the update to \(x_{k_t}^t\) have been fixed.

On defining \(\Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} = \max \left\{ \Delta_{\text{span}^{x_{k_s}}_{k_t}} : \Delta_{\max^{x_{k_s}}_{k_t}}, \Delta_{\min^{x_{k_s}}_{k_t}} \right\} \), we obtain

\[
\mathbb{E} \left[ \left( \Delta_{\text{span}^{x_{k_t}}_{k_t}} \right)^2 \right] \leq \frac{6q}{n} \sum_{s \in [t-3q,t-1] \setminus \{t\}} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 + \frac{8qL_{\text{res}}^2}{n^2} \sum_{s \in [t-3q,t+q] \setminus \{t\}} \left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2,
\]

which is clear as \(\Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \geq \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \); since \(T_{s,t} \subseteq [s-q,s]\).

Additionally, \(\Delta x_{k_s}^{\pi_{s}} \in [\Delta_{\min^{x_{k_s}}_{k_t}}, \Delta_{\max^{x_{k_s}}_{k_t}}]\), thus \(\Delta x_{k_s}^{\pi_{s}} \leq \Delta_{\min^{x_{k_s}}_{k_t}} + \Delta_{\text{span}^{x_{k_s}}_{k_t}}\).

It follows that \(\left( \Delta_{\min^{x_{k_s}}_{k_t}} \right)^2, \left( \Delta_{\max^{x_{k_s}}_{k_t}} \right)^2 \leq 2 \left( \Delta x_{k_s}^{\pi_{s}} \right)^2 + 2 \left( \Delta_{\text{span}^{x_{k_s}}_{k_t}} \right)^2\). So, \(\left( \Delta_{\text{var}^{x_{k_s}}_{\pi_{s}}} \right)^2 \leq 2 \left( \Delta x_{k_s}^{\pi_{s}} \right)^2 + 2 \left( \Delta_{\text{span}^{x_{k_s}}_{k_t}} \right)^2\).
Thus

\[
E \left[ \left( \Delta_{\text{span}x_{k_t}} \right)^2 \right] \leq \frac{12q}{n} \sum_{s \in [t-3q,t-1]} \left[ \left( \Delta_{\text{span}x_{k_s}} \right)^2 + \left( \Delta_{x_{k_s}} \right)^2 \right] \\
+ \frac{16qI_2}{n\Gamma^2} \sum_{s \in [t-3q,t+q]} \left[ \left( \Delta_{\text{span}x_{k_s}} \right)^2 + \left( \Delta_{x_{k_s}} \right)^2 \right].
\]

Recall that \((\mathcal{D}_s)^2 := E_\pi \left[ \left( \Delta_{\text{span}x_{k_s}} \right)^2 \right]\). Also, \((\Delta_s)^2 := E_\pi \left[ \left( \Delta_{x_{k_s}} \right)^2 \right]\). And recall that \(\nu := \frac{12q^2}{n}\) and \(\nu_2 = \frac{16q^2I_2}{n\Gamma^2}\). Then

\[
\Gamma \cdot (\mathcal{D}_t)^2 \leq \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q,t+q]} \Gamma \cdot (\mathcal{D}_s)^2 + \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q,t+q]} \Gamma \cdot (\Delta_s)^2.
\]

On tracing back the calculations starting from (9), we see we have also shown:

\[
E_\pi \left[ \frac{2}{\Gamma} \left( g_{\text{span},k_t} \right)^2 \right] \leq \frac{\nu_2}{q} \sum_{s \in [t-3q,t+q]} \Gamma \cdot (\mathcal{D}_s)^2 + (\Delta_s)^2.
\]

6.3.2 Upper Bound on \((g_{k_t} - g_{S,\pi,t})^2\)

Before proceeding, we point out one crucial difference between this subsection and the previous one, which will explain why we need a significantly different approach here. In the previous subsection, we dealt with the squared difference \((\Delta_{\text{span}x_{k_t}})^2\). As is clear from their definitions, both gradients are generated with the update at time \(t\) reading neither its own update, nor any other update that reads the update at time \(t\). However, in the generation of \(g_{k_t}^t\), it is possible that some update at time \(s < t\) reads the update at time \(t\) — in other words, we cannot exclude any non-empty \(R\) in performing the analysis, while in the previous subsection we could clearly exclude the set \(\{t\}\). It turns out that deriving an upper bound under these conditions is considerably more challenging.

We give an upper bound in terms of \((\mathcal{D}_s)^2\) and \((\Delta_s)^2\). Let \(\Lambda = \max \left\{ \frac{I_{\pi,s}}{\nu_3}, 1 \right\}, \ r := \frac{72q^2\Lambda^2}{n}, \ \nu_3 := \frac{q^2}{8(1-r)}\) and \(\nu_4 := \frac{6r}{1-r}\).

**Lemma 10.** If \(q^2 \leq \frac{n^2}{144I_{\pi,s}}\) and \(q^2 \leq \frac{n}{144}\), then

\[
E \left[ \frac{1}{\Gamma} \left( g_{k_t} - g_{S,\pi,t} \right)^2 \right] \leq \frac{\nu_2\Gamma}{2q} \sum_{s \in [t-3q,t+q]} (\mathcal{D}_s)^2 + (\Delta_s)^2 \leq \frac{\nu_4\Gamma}{2} \left[ (\mathcal{D}_t)^2 + (\Delta_t)^2 \right].
\]

Applying (7) and (11) yields the following lemma.
Lemma 11. If $r < 1$, then
\[
\mathbb{E} \left[ \frac{1}{\Gamma} \left( g_{k_t} - g_{k_t}^\pi \right)^2 \right] \leq \frac{\nu_2 \Gamma}{q} \sum_{s \in [t-3q,t-q]} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
+ \frac{\nu_3 \Gamma}{q} \sum_{s \in [t-4q,t-q]} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
+ \nu_4 \Gamma \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q,t-q]} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] + \nu_4 \Gamma (\Delta_t^X)^2.
\]

In order to show Lemma 10, we first upper bound $\left( g_{k_t}^t - g_{k_t}^{\pi, t} \right)^2$ by
\[
\left( \sum_{l_0 \in [t-2q,t-1]} L_{k_l, k_t}^2 \Delta_{\text{span} \pi, l_0}^t \right)^2.
\]

The challenge is that changing either coordinate $k_{l_0}$ or $k_t$ may change the value of $\Delta_{\text{span} \pi, l_0}^t = \left( \Delta_{\text{max} \pi, k_{l_0}}^t - \Delta_{\text{min} \pi, k_{l_0}}^t \right)$ which implies that a simple averaging of the terms $L_{k_{l_0}, k_t}^2$ to obtain a term $L_{\text{res}}^2$ is not possible. We will proceed by bounding this term recursively.

Lemma 12. If $r < 1$, then for any $u \in [t-2q, t]$, 
\[
\mathbb{E} \left[ q \sum_{l_0 \in [t-2q,t]} L_{k_{l_0}, k_u}^2 \left( \Delta_{\text{span} \pi, l_0}^t \right)^2 \right] \\
\leq \frac{\nu_2 \Gamma^2}{4q} \sum_{s \in [t-4q,t-q]} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] + \frac{\nu_4 \Gamma^2}{4} \left[ (D_u)^2 + (\Delta_u^X)^2 \right].
\]

To prove the above lemma, we will make use of a recursive bound on
\[
\left( \sum_{l_0 \in [t-2q,t+q]} L_{k_{l_0}, k_u} \left( \Delta_{\text{span} \pi, l_0}^t \right)^2 \right),
\]
which is presented in the next lemma.
Lemma 13. For $t - 2q \leq u \leq t$,

$$
E \left[ \sum_{l_0 \in [t-2q,t-1]} \left( \sum_{l_1,l_2,\ldots,l_{m-1} \in [t-2q,t+q]} \left( \prod_{l_s \in R_{m-1}\setminus S_{m-1}} \frac{L_{k_{l_s}^u,k_{l_s-1}^u}}{\Gamma^2} \right) \right) \right] 
$$

$$
\leq E \left[ 8 \cdot 2^q \sum_{l_0 \in [t-2q,t-1]} \left( \sum_{l_1,l_2,\ldots,l_{m-1} \in [t-2q,t+q]} \left( \prod_{l_s \in R_{m-1}\setminus S_{m-1}} \frac{L_{k_{l_s}^u,k_{l_s-1}^u}}{\Gamma^2} \right) \right) \right] 
$$

$$
+ E \left[ 4 \cdot 2^q \sum_{l_0 \in [t-2q,t-1]} \left( \sum_{l_1,l_2,\ldots,l_{m-1} \in [t-2q,t+q]} \left( \prod_{l_s \in R_{m-1}\setminus S_{m-1}} \frac{L_{k_{l_s}^u,k_{l_s-1}^u}}{\Gamma^2} \right) \right) \right] 
$$

$$
+ E \left[ \sum_{s \in [t-4q,t+q] \setminus \{u\}} \frac{40q^2 (3^2)^{m-1}(3q)^{m-1}(2q)^m}{\eta^m+1} \left( \Delta_{t,R_{m-1}\cup\{u\} \setminus S_{m-1}} x_{k_{l_s}^u} \right)^2 \right] 
$$

$$
+ E \left[ 16L_{\max}^2 \frac{(3^2)^{m-1}(3q)^{m-1}(2q)^m}{\eta^m} \left( \Delta_{t,R_{m-1}} x_{k_{l_s}^u} \right)^2 \right] 
$$

$$
+ E \left[ 32L_{\max}^2 \frac{(3^2)^{m-1}(3q)^{m-1}(2q)^m}{\eta^m} \left( \Delta_{t,R_{m-1}} x_{k_{l_s}^u} \right)^2 \right] 
$$

The proof of Lemma 13 is deferred to Appendix A.4.

Proof of Lemma 12. Note that the first two terms on the RHS of Lemma 13 have a similar structure to the LHS, but with $m$ increased by 1. In fact, in combination, ignoring the constant multiplier
(of resp. 16q and 24q), they form the term on the LHS with \( m \) increased by 1. Let

\[
\mathcal{V}_{m-1} := E \left[ \sum_{l_0 \in [t-2q-1]} \left( \sum_{\substack{\text{for any } l_1,l_2,\ldots,l_{m-1} \in [t-2q,t+q] \\ \text{which are distinct and not equal to } \{u,l_0\} \\ \text{for any } S_{m-1} \subseteq \{l_i | k_i = k_{i-1}\} }} \prod_{l_s \in R_{m-1} \setminus S_{m-1} \text{ where } R_{m-1} = \{l_1,l_2,\ldots,l_{m-1}\}} \left( \frac{L_{k_i,k_{i+1}}^2}{\Gamma^2} \right) L_{k_{i+1},k_0}^2 \left( \Delta_{\text{span}}^{t,R_{m-1} \setminus \{l_{m-1}\}} x_{k_{m-1}}^{\pi,l_{m-1}} \right)^2 \right) \right].
\]

Note that \( \mathcal{V}_0 = 0 \) and \( \mathcal{V}_0 = E \left[ \sum_{l_0 \in [t-2q,t-1]} L_{k_0,k_{l_0}}^2 \left( \Delta_{\text{span}}^{t,R_0} x_{l_0}^{\pi,l_0} \right)^2 \right]. \)

By Lemma 13,

\[
\mathcal{V}_{m-1} \leq (24q) \mathcal{V}_m
\]

\[
+ E \left[ \sum_{s \in [t-4q,t+q] \setminus \{t\}} 40q \Gamma^2 \left( \frac{\Lambda_2^{m+1}(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta_{\text{span}}^{t,R_{m-1} \cup \{u\}} x_{k_s}^{\pi,u} \right)^2 \right]
\]

\[
+ E \left[ 16L_{\text{max}}^2 \left( \frac{\Lambda_2^m(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta_{\text{span}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \right)^2 \right]
\]

\[
+ E \left[ 32L_{\text{max}}^2 \left( \frac{\Lambda_2^m(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta_{\text{span}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \right)^2 \right]
\]

\[
+ E \left[ 32L_{\text{max}}^2 \left( \frac{\Lambda_2^m(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta_{\text{span}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \right)^2 \right].
\]

Since \( \Delta_{\text{max}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \leq \Delta_{\text{max}} x_{k_u}^{\pi,u} \), \( \Delta_{\text{min}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \geq \Delta_{\text{min}} x_{k_u}^{\pi,u} \), and

\[
\left( \Delta_{\text{max}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \right)^2 \leq 2 \left( \Delta_{\text{span}}^{t,R_{m-1} \setminus \{u\}} x_{k_u}^{\pi,u} \right)^2 + 2 \left( \Delta x_{k_u}^{\pi,u} \right)^2,
\]

we obtain

\[
\mathcal{V}_{m-1} \leq (24q) \mathcal{V}_m + E \left[ \sum_{s \in [t-4q,t+q] \setminus \{t\}} 160q^2 \Gamma^2 \left( \frac{\Lambda_2^2(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta_{\text{span}}^{t,R_0} x_{k_s}^{\pi,s} \right)^2 \cdot \left( \Delta_{\text{span}}^{t,R_0} x_{k_u}^{\pi,u} \right)^2 \right]
\]

\[
+ E \left[ 96L_{\text{max}}^2 \left( \frac{\Lambda_2^m(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta_{\text{span}}^{t,R_0} x_{k_u}^{\pi,u} \right)^2 \right]
\]

\[
+ E \left[ 64L_{\text{max}}^2 \left( \frac{\Lambda_2^m(3q)^{m-1}(2q)}{n^m} \right) \left( \Delta x_{k_u}^{\pi,u} \right)^2 \right].
\]
By applying this bound recursively, we obtain

\[
\mathbb{E} \left[ q \sum_{l_0 \in [t-2q,t-1]} L_{k_{l_0,k_u}}^2 \left( \Delta_{\text{span}}^x \pi_{l_0} \right)^2 \right] = q \cdot \mathcal{V}_0 \\
\leq (1 + r + r^2 + \cdots). \\
\mathbb{E} \left( \sum_{s \in [t-4q,t+q] \setminus \{u\}} \frac{160q^3 \Gamma^2 (\Lambda^2)^2}{n^2} \left( (\Delta_{\text{span}}^x \pi_s)^2 + (\Delta x_{k_s})^2 \right) \right. \\
\left. + \frac{96q^2 (\Lambda^2) L_{\text{max}}}{n} \left( (\Delta_{\text{span}}^x \pi_u)^2 + (\Delta x_{k_u})^2 \right) \right),
\]

where \( r = \frac{24q(3q) \Lambda^2}{n} = \frac{72q^2 \Lambda^2}{n} \).

As \( r < 1 \) and since \( \Gamma \geq L_{\text{max}} \),

\[
\mathbb{E} \left[ q \sum_{l_0 \in [t-2q,t-1]} L_{k_{l_0,k_u}}^2 \left( \Delta_{\text{span}}^x \pi_{l_0} \right)^2 \right] \\
\leq \frac{\Gamma^2}{1 - r} \cdot \mathbb{E} \left( \frac{1}{q} \sum_{s \in [t-4q,t+q] \setminus \{u\}} \frac{r^2}{32} \left( (\Delta_{\text{span}}^x \pi_s)^2 + (\Delta x_{k_s})^2 \right) + \frac{3}{2} r \left( (\Delta_{\text{span}}^x \pi_u)^2 + (\Delta x_{k_u})^2 \right) \right) \\
\leq \frac{r^2 \Gamma^2}{32(1 - r)q} \sum_{s \in [t-4q,t+q] \setminus \{u\}} \left( (D_s)^2 + (\Delta X_s)^2 \right) + \frac{3r \Gamma^2}{2(1 - r)} \left( (D_u)^2 + (\Delta X_u)^2 \right).
\]

\[
\square
\]

6.4 SACD Amortized Analysis

In this section, we want to prove the following progress lemma, from which we will be able to deduce our convergence bounds.

**Lemma 14.**

\[
\mathbb{E}_\pi \left[ F(x^t) - F(x^{t+1}) \right] \\
\geq \frac{1}{3n^2} \mathbb{E}_\pi \left[ \sum_{k=1}^{n} \sum_{k_t=1}^{n} \hat{W}_k (g_k^{\pi(k_t,t),t}, x_k^{\pi(k_t,t),t}) \right] + \left( \frac{1}{8} - \frac{10r}{1 - r} \right) \Gamma \cdot (\Delta t)^2 \\
- \frac{1}{q} \left[ \frac{r^2}{2} + \frac{5q^2}{1 - r} + \frac{r^2}{144} + \frac{r^3}{12(1 - r)} \right] \Gamma \cdot \sum_{s \in [t-5q,t+q]} \left( (D_s)^2 + (\Delta X_s)^2 \right).
\]

**Proof.** Recall that we write \( \pi(k,t) \) to denote the path in which coordinate \( k_t \) at time \( t \) is replaced by coordinate \( k \), and to reduce clutter here we abbreviate this as \( \pi(k) \). Note that \( \pi(k_t) = \pi \). Recall that we let \( \text{prev}(t,k) \) denote the time of the most recent update to coordinate \( k \), if any, in the time
range $[t - 2q, t - 1]$; otherwise, we set it to $t$. From (2),

$$E_{\pi} \left[ F(x^t) - F(x^{t+1}) \right]$$

$$\geq \frac{1}{2n} E_{\pi} \left[ \sum_{k_t=1}^{n} \widehat{W}_k(g_{k_t}(x_{k_t}, x_{k_t}^{(k_t)}), x_{k_t}^{(k_t)} \pi) \right] + \frac{\Gamma}{8} (\Delta_t^X)^2 - \frac{1}{\Gamma} E_{\pi} \left[ (\pi_t^{(k_t)} - \pi_t^{(k_t)})^2 \right]$$

$$= \frac{1}{2n} E_{\pi} \left[ \sum_{k=1}^{n} \sum_{k_t=1}^{n} \left( \frac{1}{3} \widehat{W}_k(g_k(x_k(x_k^{(k_t)}), x_k^{(k_t)} \pi), x_k^{(k_t)} \pi) \right) - \frac{4}{3\Gamma} \left( (g_k^{(k_t)} - g_k^{(k_t)})^2 \right) \right]$$

$$+ \frac{1}{\Gamma} E_{\pi} \left[ (\pi_t^{(k_t)} - \pi_t^{(k_t)})^2 \right] \quad \text{(by Lemma 5)}$$

$$\geq \frac{1}{3n^2} E_{\pi} \left[ \sum_{k=1}^{n} \sum_{k_t=1}^{n} \widehat{W}_k(g_k(x_k(x_k^{(k_t)}), x_k^{(k_t)} \pi) \right]$$

$$- \frac{1}{3n^2} E_{\pi} \left[ \sum_{t-2q \leq s < t} \sum_{k_t=1}^{n} \left( \frac{3}{2\Gamma} (g_{k_s}^{(k_t)} - g_{k_s}^{(k_t)})^2 \right) \right]$$

$$+ 2\Gamma \left( x_{k_s}^{(k_t)} - x_{k_s}^{(k_t)} \right) + \frac{3\Gamma}{2} (\Delta x_{k_s}^{(k_t)})^2 \right]$$

$$+ \frac{1}{n^2} \sum_{k=1}^{n} \sum_{k_t=1}^{n} \left( \frac{2}{3\Gamma} (g_k^{(k_t)} - g_k^{(k_t)})^2 \right) + \frac{\Gamma}{8} (\Delta_t^X)^2$$

$$- \frac{1}{\Gamma} E_{\pi} \left[ (\pi_t^{(k_t)} - \pi_t^{(k_t)})^2 \right] \quad \text{(by Lemma 7).}$$

Observe that terms $A$, $D$ and $E$ are expectations of gradient differences; they can be bounded using Lemmas 9, 11 along with Lemma 12 which provides a bound stemming from the recursive formulation mentioned earlier. The upper bounds on the three terms are all of the form

$$O(\nu_1, \nu_2, \nu_3, \nu_4) \cdot \Gamma \cdot \sum_s [(D_s)^2 + (\Delta_s^X)^2] + O(\nu_4) \cdot \Gamma (\Delta_t^X)^2,$$

where $s$ runs over a neighborhood of $t$ of length $O(q)$. In the appendix, we compute these upper bounds precisely (see Claims 5, 9 and 7).

Terms $B$ and $C$ are bounded as follows.

**Claim 4.** (Bounding Term B)

$$E_{\pi} \left[ \frac{2}{3n^2} \sum_{t-2q \leq s < t} \sum_{k_t=1}^{n} \left( x_{k_s}^{(k_t)} - x_{k_s}^{(k_t)} \pi_t^{(k_t)}\right)^2 \right] \leq \frac{2\nu_1}{9q} \sum_{s \in [t-2q, t-1]} \Gamma \cdot (D_s)^2.$$

24
Bounding Term $C$

\[
\mathbb{E}_{\pi} \left[ \frac{\Gamma}{2n^2} \sum_{t-2q \leq s < t} \sum_{k_t=1}^{n} \left( \Delta x_{k_s}^{(k_t),s} \right)^2 \right] \leq \frac{\Gamma}{2n} \sum_{t-2q \leq s \leq t-1} \left( \Delta s \right)^2.
\]

Summing up these bounds yields

\[
\mathbb{E}_{\pi} \left[ F(x^t) - F(x^{t+1}) \right] \geq \frac{1}{3n^2} \mathbb{E}_{\pi} \left[ \sum_{k=1}^{n} \sum_{k_t=1}^{n} \hat{W}_k (g_k^{\pi(k_t),t}, x_k^{\pi(k_t),t}) \right] + \left( \frac{1}{8} - \frac{5\nu_4}{3} \right) \Gamma \left( \Delta t \right)^2
\]

\[
- \max \left\{ \frac{2\nu_1}{9q}, \frac{1 + 2\nu_4}{2n} \right\} + (\nu_2 + \nu_3 + \nu_4 (\nu_1 + \nu_2)) \left( \frac{2}{n} + \frac{5}{3q} \right)
\]

\[
\cdot \Gamma \sum_{s \in [t-5q,t+q]} \left( (D_s)^2 + (\Delta s)^2 \right). \tag{12}
\]

With a little calculation, presented in Claim 8, we obtain that the expression $G$ above can be bounded by

\[
\frac{1}{q} \left[ \frac{r}{2} + \frac{5r^2}{1-r} + \frac{r^2}{144} + \frac{r^3}{12(1-r)} \right]
\]

and that $\frac{5\nu_4}{3} \leq \frac{10r}{1-r}$, which implies the bound stated in the lemma. \hfill \Box

Let $\varpi, \varrho$ denote the two coefficients in Lemma 14

\[
\varpi = \frac{1}{q} \left[ \frac{r}{2} + \frac{5r^2}{1-r} + \frac{r^2}{144} + \frac{r^3}{12(1-r)} \right] \quad \text{and} \quad \varrho = \frac{1}{8} - \frac{10r}{1-r}. \tag{13}
\]

Then

\[
\mathbb{E}_{\pi} \left[ F(x^t) - F(x^{t+1}) \right] \geq \frac{1}{3n^2} \mathbb{E}_{\pi} \left[ \sum_{k=1}^{n} \sum_{k_t=1}^{n} \hat{W}_k (g_k^{\pi(k_t),t}, x_k^{\pi(k_t),t}) \right] + (\varrho - \varpi) \Gamma \left( \Delta t \right)^2
\]

\[
- \varpi \Gamma \sum_{s \in [t-5q,t+q]} \left( (D_s)^2 + (\Delta s)^2 \right) - \varpi \Gamma (D_t)^2. \tag{14}
\]

The term $(\Delta s)^2$ and $(D_s)^2$ will be paid for by the progress terms from time $s$ by means of an amortization. Also, we will account for the term $(D_t)^2$ using the bound Lemma 9

\[
\Gamma \cdot (D_t)^2 \leq \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q,t+q]} \Gamma \cdot \left( (D_s)^2 + (\Delta s)^2 \right). \tag{15}
\]

For the purpose of amortizing the $(D_s)^2$ terms, for some constant $\gamma > 0$ which we will specify later, we add terms $+\gamma \Gamma (D_t)^2 - \gamma \Gamma (D_t)^2$ to (14), and then we use (15) to bound $(\gamma + \varpi) \Gamma (D_t)^2$, which
Lemma 15. If $5q < n$, $d_1 = 5q$, $d_2 = q$, $c_1 = c_2 = \varpi + \bar{\varpi}(\frac{\nu_1}{q^2} + \frac{\nu_2}{q})$, $\gamma = \frac{1}{45}$, $\Lambda = \max\{\frac{t_2}{t_1^2}, 1\}$, $r = \frac{t_2^2\Lambda^2}{n} \leq \frac{1}{144}$, and

$$A^+(t) = \sum_{s = t - d_1}^{t-1} \sum_{v = t}^{s + d_1} \frac{1}{2n} t_{v-t+1} \left[ c_1 (D_s)^2 + c_2 (\Delta_s X)^2 \right],$$

$$A^-(t) = \sum_{s = t - d_2}^{t-1} \sum_{v = t}^{s + d_2} \left[ c_1 (D_v)^2 + c_2 (\Delta_v X)^2 \right].$$

Then (18) holds.
We are now ready to conclude the proof of our main result.

**Proof of Theorem 2.** By Lemma 15, if \( r \leq \frac{1}{144} \), the conditions for applying Theorem 3 hold (see the choice of parameter values below). As \( A^{-1}(T + 1) = 0 \), we conclude that \( F(x^{T+1}) \leq H(T + 1) \); this inequality also holds in expectation, thus we are done.

We apply Theorem 3 with \( \beta = \frac{1}{3} \) and \( \alpha = \frac{1}{3} \), which yields the stated results. Recall that \( r = \frac{72q^2 \max\left\{ \frac{L^2}{102}, 1 \right\}}{n} \). Thus, to achieve \( r \leq \frac{1}{144} \) it suffices to have \( q \leq \min\left\{ \frac{\Gamma \sqrt{n} 102L}{102}, \frac{\sqrt{n} 102}{102} \right\} \). \( \square \)

Note that we have not sought to fully optimize the constants.

**Acknowledgment** We thank several anonymous reviewers for their helpful and thoughtful suggestions regarding earlier versions of this paper.

**References**

We begin with the proof of Lemma 1. In Appendix A.1 we prove Lemma 2 and Lemma 3, the basic progress lemmas. In Appendix A.2 we prove Theorem 3 which provides the conditions for demonstrating rates of convergence. Then, in Appendix A.3 we give several bounds on how much.
\( \hat{W} \) can change when one of its arguments is altered. These bounds are used in the general analysis, which does not make the Strong Common Value assumption. We follow this in Appendix A.4 with the proof of the recursive bound given in Lemma [13]. Finally, in Appendix A.5, we give the proofs of the claims from the amortization analysis.

**Proof of Lemma [17]** We first observe that for each update, the difference between the SCC time and the start time lies in the range \([- (q - 1), (q - 1)]\). For the commit time of one update is the start time of the next update chosen by the core executing the update. As there are at most \(q\) interfering coordinates, these two times are at most \(q + 1\) apart. For a coordinate to receive an SCC time differing from its start time, either its interval from start to commit time contains the interval for another update to the same coordinate, or its interval is contained in another such interval. Either way, the two start times differ by at most \(q - 1\).

Now, we prove the bound on the range.

Consider an update \(U'\) with start time \(t'\) which receives SCC time \(t \geq t'\). It’s commit time does not change; it is still at most \(t' + q + 1\). Also, \(t \leq t' + q - 1\). Likewise, any update that interferes with \(U'\) must still have commit time in the range \([t' + 1, t' + q]\), and hence SCC time in the range \([t' - q, t' + q - 1] \subseteq [t + 1, t + q - 1]\).

While if \(t < t'\), this means that the update \(U\) with start time \(t\) had a later commit time than \(U'\), but this commit time was at most \(t + q + 1\), and therefore \(U'\) had commit time at most \(t + q\). Again, the interfering updates had commit times in the range \([t' + 1, t + q - 1]\), and hence SCC times in the range \([t' - q, t + q - 2] \subseteq [t + 1, t + q - 2]\).

Let \([n]\) denote the set of coordinates \(\{1, 2, \ldots, n\}\). In this proof, \(\Psi\) will always denote a function \(\mathbb{R} \rightarrow \mathbb{R}\) which is univariate, proper, convex and lower semi-continuous. Recall the definition of \(L_{kk}\) in Definition [1]. As is conventional, we write \(L_k \equiv L_{kk}\).

It is well-known that for any \(k \in [n]\), \(x \in \mathbb{R}^n\) and \(r \in \mathbb{R}\),

\[
f(x + r\hat{e}_k) \leq f(x) + \nabla_k f(x) \cdot r + \frac{L_k}{2} \cdot r^2. \tag{19}
\]

### A.1 The Basic Progress Lemmas

We recall two known results.

**Lemma 16** (Three-Point Property, [10], Lemma 3.2). For any proper, convex and lower semi-continuous function \(Y : \mathbb{R} \rightarrow \mathbb{R}\) and for any \(d^- \in \mathbb{R}\), let \(d^+ := \arg \max_{d \in \mathbb{R}} \{-Y(d) - \Gamma(d - d^-)^2\}\). Then for any \(d' \in \mathbb{R}\),

\[
Y(d') + \Gamma(d' - d^-)^2 \geq Y(d^+) + \Gamma(d^+ - d^-)^2 + \Gamma(d' - d^+)^2.
\]

**Lemma 17** ([37], Lemma 4). For any \(g_1, g_2, x \in \mathbb{R}\) and \(\Gamma \in \mathbb{R}^+\),

\[
|\hat{d}(g_1, x) - \hat{d}(g_2, x)| \leq \frac{1}{\Gamma} \cdot |g_1 - g_2|.
\]

We can now lower bound \(\hat{W}(g, x)\) in terms of \(\hat{d}(g, x)\).

**Lemma 18.** For any \(g, x \in \mathbb{R}\) and \(\Gamma \in \mathbb{R}^+\), \(\hat{W}(g, x) \geq \frac{\Gamma}{2} \left(\hat{d}(g, x)\right)^2\).

**Proof.** We apply Lemma [16] with \(d^- = d' = 0\) and \(Y(d) = gd - \Psi(x) + \Psi(x + d)\). Then \(W(d, g, x, \Gamma, \Psi) = -Y(d) - \Gamma d^2/2\), and hence \(d^+\), as defined in Lemma [16] equals \(\hat{d}(g, x)\). These yield

\[
Y(0) \geq Y(\hat{d}(g, x)) + \Gamma \cdot \left(\hat{d}(g, x)\right)^2.
\]

30
Since \( Y(0) = 0 \) and \( -Y(\tilde{d}(g, x, \Gamma, \Psi)) = \tilde{W}(g, x, \Gamma, \Psi) + \frac{\Gamma}{2} \left( \tilde{d}(g, x, \Gamma, \Psi) \right)^2 \), we are done. \( \square \)

We are now ready to show Lemmas \([2] \) and \([3] \) they follow directly from Lemma \([19] \) below.

**Lemma 19.** Suppose there is an update to coordinate \( j \) at time \( t \) according to rule \([1] \), and suppose that \( \Gamma \geq L_{\text{max}} \). Let \( g_j = \nabla_j f(x^t) \) and \( \tilde{g}_j = \nabla_j f(\tilde{x}) \). Then

\[
F(x^t) - F(x^{t+1}) \geq \tilde{W}(\tilde{g}_j, x^t_j) - (g_j - \tilde{g}_j) \tilde{d}_j.
\]

**Proof.** To avoid clutter, we use the shorthand \( \tilde{d}_j := \tilde{d}_j(g_j, x^t_j) \) and \( \tilde{d}_j := \tilde{d}_j(\tilde{g}_j, x^t_j) \). By update rule \([1] \), \( \tilde{d}_j = \Delta x_{j,t} \).

\[
F(x^{t+1}) = f(x^{t+1}) + \Psi_j(x^{t+1}_j) + \sum_{k \neq j} \Psi_k(x^{t+1}_k) \\
\leq f(x^t) + g_j \tilde{d}_j + \frac{\Gamma}{2} (\tilde{d}_j)^2 + \Psi_j(x^t_j + \tilde{d}_j) + \sum_{k \neq j} \Psi_k(x^t_k) \\
\quad \text{(By } [19], [1], \text{ and the assumption } \Gamma \geq L_{\text{max}} \geq L_j) \\
= F(x^t) + \tilde{g}_j \tilde{d}_j + \frac{\Gamma}{2} (\tilde{d}_j)^2 - \Psi_j(x^t_j) + \Psi_j(x^t_j + \tilde{d}_j) + (g_j - \tilde{g}_j) \tilde{d}_j \\
= F(x^t) - \tilde{W}(\tilde{g}_j, x^t_j) + (g_j - \tilde{g}_j) \tilde{d}_j.
\]

Hence, 
\[
F(x^t) - F(x^{t+1}) \geq \tilde{W}(\tilde{g}_j, x^t_j) - (g_j - \tilde{g}_j) \tilde{d}_j.
\]

Then we can apply Lemma \([18] \) to prove the first inequality in Lemma \([19] \)

\[
F(x^t) - F(x^{t+1}) \geq \tilde{W}(\tilde{g}_j, x^t_j) - (g_j - \tilde{g}_j) \tilde{d}_j \geq \tilde{W}_j(d_j, \tilde{g}_j, x^t_j) - (g_j - \tilde{g}_j) \tilde{d}_j \\
\geq \frac{\Gamma}{2} (\tilde{d}_j)^2 - \frac{1}{2} \left[ \frac{2}{\Gamma} \cdot (g_j - \tilde{g}_j)^2 + \frac{\Gamma}{2} (\tilde{d}_j)^2 \right] \\
= \frac{\Gamma}{4} (\tilde{d}_j)^2 - \frac{1}{\Gamma} \cdot (g_j - \tilde{g}_j)^2.
\]

We prove the second inequality in Lemma \([19] \) as follows:

\[
F(x^t) - F(x^{t+1}) \geq \tilde{W}(\tilde{g}_j, x^t_j) - (g_j - \tilde{g}_j) \tilde{d}_j \geq W_j(d_j, \tilde{g}_j, x^t_j) - (g_j - \tilde{g}_j) \tilde{d}_j \\
= W_j(d_j, g_j, x^t_j) + (g_j - \tilde{g}_j) \tilde{d}_j - (g_j - \tilde{g}_j) \tilde{d}_j \\
= \tilde{W}_j(g_j, x^t_j) + (g_j - \tilde{g}_j)(d_j - \tilde{d}_j) \geq \tilde{W}_j(g_j, x^t_j) - |g_j - \tilde{g}_j| \cdot |d_j - \tilde{d}_j| \\
\geq \tilde{W}_j(g_j, x^t_j) - \frac{1}{\Gamma} (g_j - \tilde{g}_j)^2. \quad \text{(By Lemma } [17] \text{)}
\]

\( \square \)
\section{The Proof of Theorem 3}

The following lemma is key to the demonstration of progress in both the strongly convex and convex cases.

For any $t \geq 1$, we define the following:

$$\text{PRG}(t) := \sum_{k=1}^{n} \hat{W}_k(\nabla_k f(x^t), x^t_k).$$

We will use the following lemma from \cite{33} Lemmas 4,6). The version we present here is slightly different from the one in \cite{33}, but the proofs are essentially the same.

\begin{lemma}[\cite{33} Lemmas 4,6]
\begin{enumerate}[(a)]
  \item Suppose that $f, F$ are strongly convex with parameters $\mu_f, \mu_F > 0$ respectively, and suppose that $\Gamma \geq \mu_f$. Then

  $$\text{PRG}(t) \geq \frac{\mu_F}{\mu_F + \Gamma - \mu_f} \cdot F(x^t).$$

  \item Suppose that $f, F$ are convex functions. Suppose that $R := \min_{x^* \in X} \|x^t - x^*\| < \infty$. Then

  $$\text{PRG}(t) \geq \min \left\{ \frac{1}{2}, \frac{F(x^t)}{2 \Gamma R^2} \right\} \cdot F(x^t).$$
\end{enumerate}
\end{lemma}

\textbf{Proof of Theorem 3}. We begin by showing (i). By the second assumption and Lemma 20,

$$H(t) - H(t + 1) \geq \left[ \frac{\alpha}{n} \cdot \text{PRG}(t) + \frac{\beta}{n} \cdot A^+(t) \right] \geq \left[ \frac{\alpha}{n} \cdot \frac{\mu_F}{\mu_F + \Gamma - \mu_f} \cdot F(x^t) + \frac{\beta}{n} \cdot A^+(t) \right] \geq \delta \cdot H(t),$$

where $\delta := \min \left\{ \frac{\alpha}{n} \cdot \frac{\mu_F}{\mu_F + \Gamma - \mu_f}, \frac{\beta}{n} \right\}$.

Thus $H(t + 1) \leq (1 - \delta) H(t)$ for all $t \geq 1$. Iterating the above inequality $T$ times yields $H(T + 1) \leq (1 - \delta)^T H(1)$.

To finish the proof note that since $A^+(1) = 0$ and $A^-(1) \geq 0$, $H(1) \leq F(x^1)$.

Now we show (ii). By the second assumption and Lemma 20,

$$H(t) - H(t + 1) \geq \left[ \frac{\alpha}{n} \cdot \text{PRG}(t) + \frac{\beta}{n} \cdot A^+(t) \right] \geq \left[ \frac{\alpha}{n} \cdot \min \left\{ \frac{1}{2}, \frac{F(x^t)}{2 \Gamma R^2} \right\} \right] \cdot F(x^t) + \frac{\beta}{n} \cdot A^+(t).$$

We consider two cases:

- If $F(x^t) \leq A^+(t)$, then $A^+(t) \geq \frac{H(t)}{2}$, thus

  $$\frac{\alpha}{n} \cdot \min \left\{ \frac{1}{2}, \frac{F(x^t)}{2 \Gamma R^2} \right\} \cdot F(x^t) + \frac{\beta}{n} \cdot A^+(t) \geq \frac{\beta}{2n} \cdot H(t).$$

- If $F(x^t) > A^+(t)$, then $F(x^t) \geq \frac{H(t)}{2}$, thus

  $$\frac{\alpha}{n} \cdot \min \left\{ \frac{1}{2}, \frac{F(x^t)}{2 \Gamma R^2} \right\} \cdot F(x^t) + \frac{\beta}{n} \cdot A^+(t) > \frac{\alpha}{2n} \cdot \min \left\{ \frac{1}{2}, \frac{H(t)}{4 \Gamma R^2} \right\} \cdot H(t).$$
Since $H$ is a decreasing function, $H(t) \leq H(1) \leq F(x^1)$. Thus, unconditionally,
\[
\frac{\alpha}{n} \cdot \min \left\{ \frac{1}{2} \cdot \frac{F(x^1)}{2T \Gamma R^2}, F(x^1) \right\} \cdot F(x^1) + \frac{\beta}{n} \cdot A^+(t) \geq \min \left\{ \frac{\beta}{2n}, \frac{\alpha \cdot H(t)}{4n \cdot 8n \Gamma R^2} \right\} \cdot H(t)
\geq \min \left\{ \frac{\beta}{2n \cdot F(x^1)}, \frac{\alpha}{4n}, \frac{\alpha}{8n \Gamma R^2} \right\} \cdot H(t)^2.
\]

Note that the term $\min \left\{ \frac{\beta}{2n \cdot F(x^1)}, \frac{\alpha}{4n}, \frac{\alpha}{8n \Gamma R^2} \right\}$ is independent of $t$. We denote it by $\varepsilon$. Thus, $H(t) - H(t + 1) \geq \varepsilon H(t)^2$. Dividing both sides by $H(t) \cdot H(t + 1)$ yields
\[
\frac{1}{H(t + 1)} - \frac{1}{H(t)} \geq \varepsilon \frac{H(t)}{H(t + 1)} \geq \varepsilon.
\]

Iterating the above inequality $T$ times yields
\[
\frac{1}{H(T + 1)} - \frac{1}{H(1)} \geq \varepsilon T,
\]
and hence
\[
\frac{1}{H(T + 1)} \geq \varepsilon T + \frac{1}{H(1)} \geq \varepsilon T + \frac{1}{F(x^1)} \quad \text{(since $H(1) \leq F(x^1)$)}
\]
(ii) follows by taking reciprocal on both sides of the above inequality.

It is straightforward to see that taking expectations leaves the proof unchanged. \hfill \Box

A.3 Bounding How Much $\hat{W}$ and $\hat{d}$ Vary as a Function of Their Arguments

We first present the proofs of Lemma 5 and 6. To prove Lemma 7, we will need two additional lemmas, to be presented below. We finish with the proof of Lemma 8.

**Proof of Lemma 5**

\[
\hat{W}(g_1, x) = \max_{d \in \mathbb{R}} W(d, g_1, x) \geq W(\hat{d}(g_2), g_1, x)
\]
\[
= -g_1 \cdot \hat{d}(g_2) - \Gamma \cdot (\hat{d}(g_2))^2/2 + \Psi(x) - \Psi(x + \hat{d}(g_2))
\]
\[
= -g_2 \cdot \hat{d}(g_2) - \Gamma \cdot (\hat{d}(g_2))^2/2 + \Psi(x) - \Psi(x + \hat{d}(g_2))
\]
\[
+ (g_2 - g_1) \cdot [\hat{d}(g_1) + (\hat{d}(g_2) - \hat{d}(g_1))]
\]
\[
\geq \hat{W}(g_2, x) - |g_1 - g_2| \cdot |\hat{d}(g_1)| - |g_1 - g_2| \cdot |\hat{d}(g_2) - \hat{d}(g_1)|
\]
\[
\geq \hat{W}(g_2, x) - |g_1 - g_2| \cdot |\hat{d}(g_1)| - \frac{1}{\Gamma} (g_1 - g_2)^2 \quad \text{(By Lemma 17)}
\]
\[
\geq \hat{W}(g_2, x) - \frac{1}{\Gamma} (g_1 - g_2)^2 - \frac{1}{\Gamma} (\hat{d}(g_1))^2 - \frac{1}{\Gamma} (g_1 - g_2)^2 \quad \text{(AM-GM ineq.)}
\]
\[
\geq \hat{W}(g_2, x) - \frac{2}{\Gamma} (g_1 - g_2)^2 - \frac{1}{2} \hat{W}(g_1, x). \quad \text{(By Lemma 18)}
\]

Next, we demonstrate Lemma 6. it is a simple corollary of Lemma 17 and the following lemma.

**Lemma 21.** For any $g, x_1, x_2 \in \mathbb{R}$, $|\hat{d}(g, x_1) - \hat{d}(g, x_2)| \leq |x_1 - x_2|$.  

33
Proof. For \( i = 1, 2 \), let \( d_i := \ddot{d}(g, x_i) \). By the definition of \( \ddot{d} \), for \( i = 1, 2 \), there exists a subgradient \( \Psi'(x_i + d_i) \) such that
\[
g + \Gamma \cdot d_i + \Psi'(x_i + d_i) = 0.
\]

If \( d_1 = d_2 \), we are done. If \( d_1 > d_2 \), then \( \Psi'(x_1 + d_1) < \Psi'(x_2 + d_2) \). Since \( \Psi \) is convex, \( x_1 + d_1 \leq x_2 + d_2 \) and hence \( 0 < d_1 - d_2 \leq x_2 - x_1 \).

If \( d_2 > d_1 \), by the same argument as above we have \( 0 < d_2 - d_1 \leq x_1 - x_2 \). \( \square \)

The next two lemmas will be needed to prove Lemma \ref{lem:7}.

\textbf{Lemma 22 (\( \hat{W} \) Shifting on x parameter).} Let \( \hat{W}(g, x_1) = W(\ddot{d}_1, g, x_1) \) and \( \hat{W}(g, x_2) = W(\ddot{d}_2, g, x_2) \). Then
\[
\hat{W}(g, x_1) + \Psi(x_2) - \Psi(x_1) \geq \hat{W}(g, x_2) - g(x_2 - x_1) - \Gamma \ddot{d}_2(x_2 - x_1) - \frac{\Gamma}{2} \cdot (x_2 - x_1)^2.
\]

Proof. We use Lemma \ref{lem:6} with \( d^- = 0 \), and \( Y(d) = gd - \Psi(x_1) + \Psi(x_1 + d) \). Then we have
\[
Y(d') + \frac{\Gamma}{2} \cdot (d')^2 \geq -\hat{W}(g, x_1) + \frac{\Gamma}{2} \cdot (d' - \ddot{d}_1)^2.
\]
The above inequality holds for any \( d' \). In particular, we pick \( d' = x_2 - x_1 + \ddot{d}_2 \), yielding
\[
\hat{W}(g, x_1) \geq -g(x_2 - x_1 + \ddot{d}_2) + \Psi(x_1) - \Psi(x_2 + \ddot{d}_2) - \frac{\Gamma}{2} \cdot (x_2 - x_1 + \ddot{d}_2)^2 + \frac{\Gamma}{2} \cdot (x_2 - x_1 + \ddot{d}_2 - \ddot{d}_1)^2.
\]

By adding \( \Psi(x_2) - \Psi(x_1) \) to both sides, we obtain
\[
\hat{W}(g, x_1) + \Psi(x_2) - \Psi(x_1)
\geq -g(x_2 - x_1 + \ddot{d}_2) + \Psi(x_2) - \Psi(x_2 + \ddot{d}_2) - \frac{\Gamma}{2} \cdot (x_2 - x_1 + \ddot{d}_2)^2 + \frac{\Gamma}{2} \cdot (x_2 - x_1 + \ddot{d}_2 - \ddot{d}_1)^2
\]
\[
= \hat{W}(g, x_2) - g(x_2 - x_1) - \Gamma \ddot{d}_2(x_2 - x_1) - \frac{\Gamma}{2} \cdot (x_2 - x_1)^2 + \frac{\Gamma}{2} \cdot (x_2 - x_1 + \ddot{d}_2 - \ddot{d}_1)^2
\]
\[
\geq \hat{W}(g, x_2) - g(x_2 - x_1) - \Gamma \ddot{d}_2(x_2 - x_1) - \frac{\Gamma}{2} \cdot (x_2 - x_1)^2.
\]
\( \square \)

\textbf{Lemma 23 (\( \Psi \) Shifting).} Let \( \hat{W}(g_1, x_1) = W(\ddot{d}_1, g_1, x_1) \) and \( \hat{W}(g_2, x_2) = W(\ddot{d}_2, g_2, x_2) \). Then
\[
\Psi(x_2 + \ddot{d}_2) - \Psi(x_1 + \ddot{d}_1) \leq g_2(x_1 - x_2 + \ddot{d}_1 - \ddot{d}_2) + \frac{\Gamma}{2} \cdot (x_1 - x_2 + \ddot{d}_1)^2.
\]

Proof. By the definition of \( \ddot{d}_2 \), we have the following inequality, which directly implies the one stated in the lemma.
\[
-g_2 \ddot{d}_2 - \frac{\Gamma}{2} \cdot (\ddot{d}_2)^2 - \Psi(x_2 + \ddot{d}_2) \geq -g_2(x_1 - x_2 + \ddot{d}_1) - \frac{\Gamma}{2} \cdot (x_1 - x_2 + \ddot{d}_1)^2 - \Psi(x_1 + \ddot{d}_1).
\]
\( \square \)
Proof. (of Lemma 7) Suppose the latest update to coordinate $k$ occurred at time $\hat{t}$. Also suppose that

- the changes to $x_k$ from $x_k^{\pi(k),t}$ to $x_k^{a(t),t}$ are $d_{11}, d_{12}, \ldots, d_{1\ell}$;
- the changes to $x_k$ from $x_k^{\pi(k),t}$ to $x_k^{\pi,\hat{t}}$ are $d_{21}, d_{22}, \ldots, d_{2\ell}$; furthermore, let

$$g_k^a := \nabla_k f(x_k^{\pi,\hat{t}}) \quad \text{and} \quad \hat{d} := \arg\max_d W(d, g_k^a, x_k^{\pi,\hat{t}}).$$

In other words, $x_k^{\pi(k),t} = x_k^{\pi,\hat{t}} + \sum_{r=1}^\ell d_{1r}$ and $x_k^{\pi,\hat{t}} = x_k^{\pi(k),t} + \sum_{r=1}^\ell d_{2r}$.

By Lemma 23,

$$\hat{W}(g_k^a, x_k^{\pi(k),t}) + \Psi(x_k^{\pi,\hat{t}}) - \Psi(x_k^{\pi(k),t}) \geq \hat{W}(g_k^a, x_k^{\pi,\hat{t}}) - g_k^a \cdot (x_k^{\pi,\hat{t}} - x_k^{\pi(k),t}) - \Gamma \hat{d} \cdot (x_k^{\pi,\hat{t}} - x_k^{\pi(k),t})^2 - \frac{\Gamma}{2} \cdot (x_k^{\pi(k),t} - x_k^{\pi,\hat{t}} - d_{2\ell})^2. \tag{20}$$

On the other hand, let $g_k^b$ be the gradient used to compute the update $d_{2\ell}$. By Lemma 23 on setting $x_2 = x_k^{\pi,\hat{t}} - d_{2\ell}$ and $x_1 = x_k^{\pi(k),\hat{t}} - d_{1\ell}$, and noting that $\hat{d}_1 = d_{1\ell}$ and $\hat{d}_2 = d_{2\ell}$, we obtain

$$\Psi(x_k^{\pi,\hat{t}}) - \Psi(x_k^{\pi(k),\hat{t}}) \leq g_k^b (x_k^{\pi(k),\hat{t}} - x_k^{\pi,\hat{t}}) + \frac{\Gamma}{2} (x_k^{\pi(k),\hat{t}} - x_k^{\pi,\hat{t}} + d_{2\ell})^2.$$

Combining the above two inequalities, and letting $\delta := x_k^{\pi,\hat{t}} - x_k^{\pi(k),\hat{t}}$, yields

$$\hat{W}(g_k^a, x_k^{\pi(k),\hat{t}}) \geq \hat{W}(g_k^a, x_k^{\pi,\hat{t}}) + (g_k^b - g_k^a) \cdot \delta - \Gamma \hat{d} \cdot \delta - \frac{\Gamma}{2} \cdot \delta^2 - \frac{\Gamma}{2} \cdot (d_{2\ell} - \delta)^2$$

$$\geq \hat{W}(g_k^a, x_k^{\pi,\hat{t}}) - \frac{1}{2\Gamma} \cdot (g_k^b - g_k^a)^2 - \frac{3}{2} \cdot \Gamma \delta^2 - \frac{\Gamma}{2} \cdot (d_{2\ell})^2 - \Gamma |\hat{d} - d_{2\ell}| \cdot |\delta|$$

$$\geq \hat{W}(g_k^a, x_k^{\pi,\hat{t}}) - \frac{1}{2\Gamma} \cdot (g_k^b - g_k^a)^2 - 2\Gamma \delta^2 - \frac{\Gamma}{2} \cdot (d_{2\ell})^2 - \frac{\Gamma}{2} \cdot (d_{2\ell} - \delta)^2.$$

By Lemma 6,

$$\frac{\Gamma}{2} \cdot (d_{2\ell} - \delta)^2 \leq \Gamma \cdot (d_{2\ell})^2 + \frac{1}{\Gamma} \cdot (g_k^a - g_k^b)^2.$$

Thus,

$$\hat{W}(g_k^a, x_k^{\pi(k),\hat{t}}) \geq \hat{W}(g_k^a, x_k^{\pi,\hat{t}}) - \frac{3}{2\Gamma} \cdot (g_k^b - g_k^a)^2 - 2\Gamma \delta^2 - \frac{3\Gamma}{2} \cdot (d_{2\ell})^2. \tag{20}$$

Proof of Lemma 8 To see the first inequality, note that

$$x_k^{\pi,\hat{t}} - x_k^{\pi(k),\hat{t}} - 2q \in \left[ \sum_{1 \leq i \leq \ell} \Delta^{t\pi(k),t_i} x_k^{\pi(k),t_i}, \sum_{1 \leq i \leq \ell} \Delta^{t\pi,\hat{t}} x_k^{\pi,\hat{t}} \right],$$

$$x_k^{\pi(k),\hat{t}} - x_k^{\pi(k),\hat{t}} - 2q \in \left[ \sum_{1 \leq i \leq \ell} \Delta^{t\pi(k),t_i} x_k^{\pi(k),t_i}, \sum_{1 \leq i \leq \ell} \Delta^{t\pi,\hat{t}} x_k^{\pi,\hat{t}} \right],$$

and the above two intervals overlap, as the synchronous update $\Delta^{tS\pi,\hat{t}} x_k^{\pi,\hat{t}} = \Delta^{tS\pi(k),t_i} x_k^{\pi(k),t_i}$ lies in both intervals.

The second inequality follows by applying the Cauchy-Schwartz inequality.
A.4 The Recursive Analysis (proof of Lemma 13)

Proof of Lemma 13. Let \( \Delta_{\text{var}}^{(t),R} x_{\pi,s} \) = \( \max \{|\Delta_{\text{max}}^{t,R} x_{\pi,s}^{k_s} - \Delta_{\text{min}}^{t,R} x_{\pi,s}^{k_s}|, |\Delta_{\text{max}}^{t,R} x_{\pi,s}^{k_s} - \Delta_{\text{min}}^{t,R} x_{\pi,s}^{k_s}|\} \). First, let’s expand the term

\[
\left( \Delta_{\text{span}}^{t,R_{m-1}\setminus\{l_{m-1}\}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2 = \left( \Delta_{\text{max}}^{t,R_{m-1}\setminus\{l_{m-1}\}} x_{\pi,l_{m-1}^{k_{m-1}}} - \Delta_{\text{min}}^{t,R_{m-1}\setminus\{l_{m-1}\}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2
\]

for \( l_m \in [t-2q,t+q] \), and \( R_{m-1} \) which contains \( l_{m-1} \). As in the proof of Lemma 9, by Lemma 6,

\[
\left( \Delta_{\text{span}}^{t,R_{m-1}\setminus\{l_{m-1}\}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2 \leq 2 \sum_{l_m \in \max\{l_{m-1}-2q,t-2q\} \setminus \{l_{m-1}\} \setminus R_{m-1} \text{ and } k_{m-1} = k_{m-1} \} \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2
\]

\[
+ \frac{2}{\Gamma^2} \left( \sum_{l_m \in \max\{l_{m-1}-2q,t-2q\} \setminus \{l_{m-1}\} \setminus R_{m-1} \text{ and } k_{m-1} = k_{m-1} \} \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2.
\]

(21)

By the Cauchy-Schwarz inequality, the first term on the RHS of (21) can be bounded as follows:

\[
2 \left( \sum_{l_m \in \max\{l_{m-1}-2q,t-2q\} \setminus \{l_{m-1}\} \setminus R_{m-1} \text{ and } k_{m-1} = k_{m-1} \} \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2 \leq 4 \cdot \left( \sum_{l_m \in \max\{l_{m-1}-2q,t-2q\} \setminus \{l_{m-1}\} \setminus R_{m-1} \text{ and } k_{m-1} = k_{m-1} \} \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2 + 4 \cdot 1_{k_{m-1} = k_{u}} \left( \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,u^{k_{u}}} \right)^2
\]

Also, by the Cauchy-Schwarz inequality, the second term on the RHS of (21) can be bounded as follows:

\[
\frac{2}{\Gamma^2} \left( \sum_{l_m \in \max\{l_{m-1}-2q,t-2q\} \setminus \{l_{m-1}\} \setminus R_{m-1} \text{ and } k_{m-1} = k_{m-1} \} \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2 \leq 4(3q) \left( \sum_{l_m \in \max\{l_{m-1}-2q,t-2q\} \setminus \{l_{m-1}\} \setminus R_{m-1} \text{ and } k_{m-1} = k_{m-1} \} \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,l_{m-1}^{k_{m-1}}} \right)^2
\]

\[
+ 4 \cdot L_{k_{m-1},k_{m-1}}^2 \left( \Delta_{\text{var}}^{(t),R_{m-1}} x_{\pi,u^{k_{u}}} \right)^2.
\]
As \( \Delta_{\text{max}}^{t,R_{m-1}\cup\{u\}} x_{\pi,s} \in \left[ \Delta_{\text{min}}^{t,R_{m-1}} x_{\pi,s}, \Delta_{\text{max}}^{t,R_{m-1}} x_{\pi,s} \right] \), we know that for any \( s \leq t + q \), \( (\Delta_{\text{max}}^{t,R_{m-1}} x_{\pi,s})^2 \),

\[
(\Delta_{\text{max}}^{t,R_{m-1}} x_{\pi,s})^2 \leq \left[ \Delta_{\text{max}}^{t,R_{m-1}} x_{\pi,s} + \Delta_{\text{max}}^{t,R_{m-1}\cup\{u\}} x_{\pi,s} \right]^2,
\]

and consequently

\[
(\Delta_{\text{var}}^{t,R_{m-1}} x_{\pi,s})^2 \leq 2 \left( \Delta_{\text{span}}^{t,R_{m-1}} x_{\pi,s} \right)^2 + 2 \left( \Delta_{\text{max}}^{t,R_{m-1}\cup\{u\}} x_{\pi,s} \right)^2.
\]

Similarly,

\[
(\Delta_{\text{var}}^{t,R_{m-1}} x_{\pi,u})^2 \leq 2 \left( \Delta_{\text{span}}^{t,R_{m-1}} x_{\pi,u} \right)^2 + 2 \left( \Delta_{\text{max}}^{t,R_{m-1}\cup\{u\}} x_{\pi,u} \right)^2.
\]

Additionally, for any \( s < t - 2q \), \( \Delta_{\text{min}}^{t,R_{m-1}} x_{\pi,s} = \Delta_{\text{max}}^{t,R_{m-1}} x_{\pi,s} \), so

\[
(\Delta_{\text{var}}^{t,R_{m-1}} x_{\pi,s})^2 = \left( \Delta_{\text{max}}^{t,R_{m-1}\cup\{u\}} x_{\pi,s} \right)^2.
\]

In summary, \([21]\) yields

\[
(\Delta_{\text{span}}^{t,R_{m-1\cup\{l_{m-1}\}} x_{\pi,l_{m-1}}}^2)^2 
\leq 4 \cdot (4q) \sum_{l_m \in [t-2q,t+q]\setminus\{(u)\cup R_{m-1}\}} \text{ for any } l_m \in [t-2q,t+q]\setminus\{(u)\cup R_{m-1}\}
\leq 4 \cdot 1_{k_{l_{m-1}} = k_u} \left( \Delta_{\text{max}}^{t,R_{m-1\cup\{u\}} x_{\pi,u}} \right)^2 + \left( \Delta_{\text{max}}^{t,R_{m-1}\cup\{u\}} x_{\pi,u} \right)^2
\]

\[
+ \frac{4(3q)^2}{\Gamma^2} \left( \sum_{l_m \in [t-2q,t+q]\setminus\{(u)\cup R_{m-1}\}} \Delta_{\text{span}}^{L_{k_{l_{m-1}}} x_{\pi,l_{m}}} \right)^2
\]

\[
+ \frac{8}{\Gamma^2} L_{k_{l_{m-1}}}^2 \left( \Delta_{\text{span}}^{t,R_{m-1\cup\{u\}} x_{\pi,u}} \right)^2 + \left( \Delta_{\text{max}}^{t,R_{m-1\cup\{u\}} x_{\pi,u}} \right)^2.
\]

Note that the term \([22]\) is zero for \( l_m < t - 2q \).

Next, we bound the LHS of the inequality in Lemma \([13]\) using the above inequality. To do so, we multiply this inequality by a series of terms \( \frac{L_{k_{l_{m}}}^2}{\Gamma^2} \) on both sides, sum up over all choices of \( l_1, l_2, \ldots, l_{m-1} \in [t-2q,t+q] \), and then take the expectation over all choices of \( k_{l_0}, \ldots, k_{l_{m-1}} \) and \( k_u \). This results in five expectation terms that come from the RHS of \([23]\). We bound the second to the fifth of these terms below.

Recall that \( \Lambda^2 = \max \left\{ \frac{L_{k_{l_{0}}}^2}{\Gamma^2}, 1 \right\} \). The second expectation term is bounded as follows:

\[
E \left[ \sum_{l_0 \in [t-2q,t+1]} \left( \prod_{l_m \in R_{m-1}\cup\{u\}} \sum_{l_{m-1} \in [t-2q,t+1]} \left( \frac{L_{k_{l_{m-1}}}^2}{\Gamma^2} \right) \right) \right]
\leq E \left[ 8 \frac{L_{\text{max}}^2}{\Gamma^2} (\Lambda^2)^{m-1}(3q)^{m-1}(2q)^{m-1} \left( \Delta_{\text{max}}^{t,R_{m-1\cup\{u\}} x_{\pi,u}} \right)^2 \right].
\]
as $L_{k_0,k_u}^2$ can be bounded by $L_{\max}^2$, we can then average, in turn, over $k_0$, $k_1$, $\ldots$, $k_{m-1}$, each of which provides a $\frac{1}{n}$ or an $\frac{1}{n} \cdot \frac{L_{\max}^2}{L_{k_0,k_0}}$ term, depending on whether $l_s$ is in $S_{m-1}$ or not. To elaborate, the factor $\frac{(\Lambda^2)^{m-1} (3q)^{m-1} (2q)}{n^m}$ on the RHS is due to a combination of the following observations:

- the $m-1$ factors of $\frac{\max \left\{ \frac{L_{\max}^2}{L_{k_0,k_0}}, 1 \right\} \cdot 3q}{n} = \frac{\Lambda^2 \cdot 3q}{n}$ are due to the expectation over the $\frac{L_{k_0,k_0}}{L_{k_0,k_0}}$ terms, and then summing over all possible values of $l_{s-1}$ (if $l_s \in S_{m-1}$, we have $k_{l_s} = k_{l_s-1}$, and thus taking the expectation yields an $1/n$ factor);
- the extra $n$ factor in the denominator is due to the expectation of $1_{k_{m-1} = k_u}$;
- the $2q$ factor comes from the enumeration of $l_0$.

Note that the third and the fifth expectation terms can be bounded similarly. For the fourth expectation term, as $\left( \Delta_{\max}^{t_R m-1 \cup \{u \}} \gamma_{\pi,s} \right)^2$ is fixed over all paths $\pi$ obtained by varying $k_u$, we can
do the averaging without needing to introduce the $4L_{\text{max}}^2$ term. We obtain

$$E \left[ \sum_{l_0 \in [t-2q,t-1]} \left( \sum_{\text{for any } l_1, l_2, \ldots, l_{m-1} \in [t-2q,t+q] \text{ \ which are distinct and not equal to } \{u, l_0\} \text{ \ for any } S_{m-1} \subseteq \{l_i | k_{i_s} = k_{i_{s-1}} \}} \left( \prod_{l_s \in R_{m-1} \setminus S_{m-1}} \frac{L_{k_{l_s}, k_{l_{s-1}}}^2}{\Gamma^2} \right) \right) \right]$$

$$\leq E \left[ 8 \cdot 2q \sum_{l_0 \in [t-2q,t-1]} \left( \sum_{\text{for any } l_1, l_2, \ldots, l_{m} \in [t-2q,t+q] \text{ \ which are distinct and not equal to } \{u, l_0\} \text{ \ for any } S_{m-1} \subseteq \{l_i | k_{i_s} = k_{i_{s-1}} \text{ \ and } s \leq m-1\}; \text{ \ where } K_m = k_{i_{m-1}} \cdot \left( \prod_{l_s \in R_{m-1} \setminus S_{m-1}} \frac{L_{k_{l_s}, k_{l_{s-1}}}^2}{\Gamma^2} \right) \right) \right]$$

$$+ E \left[ \sum_{s \in [t-4q,t+q] \setminus \{u\}} 8(2q) \frac{(A^2)^m + (3q)^{m-1}(2q)}{m^{m+1}} \frac{(A_{\text{max}} t_{R_{m-1} \cup \{u\}} x_{k_s}^2)}{m^{m+1}} \right]$$

$$+ E \left[ 8L_{\text{max}}^2 \frac{(A^2)^m(3q)^{m-1}(2q)}{m^{m+1}} \left( \frac{(A_{\text{span}} x_{k_u}^2)}{m^{m+1}} \right) \left( \frac{(A_{\text{span}} x_{k_u}^2)}{m^{m+1}} \right) \right]$$

$$+ E \left[ 4(3q)^2 \sum_{l_0 \in [t-2q,t-1]} \left( \sum_{\text{for any } l_1, l_2, \ldots, l_{m} \in [t-2q,t+q] \text{ \ which are distinct and not equal to } \{u, l_0\} \text{ \ for any } S_{m-1} \subseteq \{l_i | k_{i_s} = k_{i_{s-1}} \text{ \ and } s \leq m-1\}; \right) \right]$$

$$\left( \prod_{l_s \in R_{m-1} \setminus S_{m-1}} \frac{L_{k_{l_s}, k_{l_{s-1}}}^2}{\Gamma^2} \right) \frac{L_{k_m, k_{m-1}}^2}{\Gamma^2} \frac{(A_{\text{span}} x_{k_m}^2)}{m^{m+1}} \right]$$

$$+ E \left[ \sum_{s \in [t-4q,t+q] \setminus \{u\}} 4(3q)^2 \frac{(A^2)^m + (3q)^{m-1}(2q)}{m^{m+1}} \frac{(A_{\text{max}} t_{R_{m-1} \cup \{u\}} x_{k_s}^2)}{m^{m+1}} \right]$$

$$+ E \left[ 8L_{\text{max}}^2 \frac{(A^2)^m(3q)^{m-1}(2q)}{m^{m+1}} \left( \frac{(A_{\text{span}} x_{k_u}^2)}{m^{m+1}} \right) \left( \frac{(A_{\text{span}} x_{k_u}^2)}{m^{m+1}} \right) \right]$$

$$+ E \left[ 8L_{\text{max}}^2 \frac{(A^2)^m(3q)^{m-1}(2q)}{m^{m+1}} \left( \frac{(A_{\text{span}} x_{k_u}^2)}{m^{m+1}} \right) \left( \frac{(A_{\text{span}} x_{k_u}^2)}{m^{m+1}} \right) \right]$$

Note that $\left( \frac{A_{\text{max}} t_{R_{m-1}} x_{k_u}^2}{m^{m+1}} \right) \leq 2 \left( \frac{A_{\text{span}} x_{k_u}^2}{m^{m+1}} \right)^2 + 2 \left( \frac{A_{\text{span}} x_{k_u}^2}{m^{m+1}} \right)^2$; the result now follows. $\square$
A.5 Proofs for the Amortized Analysis, Section 6.4: Lemma 15, Claims 5–8

Proof of Lemma 15

By calculation,

\[ A^+(t) - A^+(t + 1) = \sum_{s = t - d_1}^{t-1} \frac{1}{(1 - \frac{1}{2n})} \left[ c_1 (D_s)^2 + c_2 (\Delta_s^X)^2 \right] + \sum_{s = t - d_1 + 1}^{s + d_1} \sum_{v = t + 1}^{1 - \frac{1}{2n}} \left[ c_1 (D_s)^2 + c_2 (\Delta_s^X)^2 \right] \]

\[ \left[ 1 - \frac{1}{2n} \right] A^+(t) - A^-(t) = A^+(t + 1) - A^-(t + 1) \]

\[ = \sum_{s = t - d_1}^{t-1} \left[ c_1 (D_s)^2 + c_2 (\Delta_s^X)^2 \right] - \sum_{v = t + 1}^{t + d_1} \left[ c_1 (D_v)^2 + c_2 (\Delta_v^X)^2 \right] \]

\[ + \sum_{v = t + 1}^{t + d_2} \left[ c_1 (D_v)^2 + c_2 (\Delta_v^X)^2 \right] - \sum_{s = t - d_2}^{s = t - 2} \left[ c_1 (D_s)^2 + c_2 (\Delta_s^X)^2 \right] \]

\[ = \sum_{s = t - 2}^{t-q} \left[ c_1 (D_s)^2 + c_2 (\Delta_s^X)^2 \right] \]

\[ \left( \sum_{v = t + q}^{t + q + 1} \left( 1 - \frac{1}{2n} \right)^{\frac{1}{v - t}} + d_2 \right) \left[ c_1 (D_t)^2 + c_2 (\Delta_t^X)^2 \right] \]

In order to achieve 18, we compare the coefficients of each of the terms \( c_1 (D_t)^2, c_2 (\Delta_t^X)^2, c_1 (D_s)^2, c_2 (\Delta_s^X)^2 \) in (18) and (24). Since \( c_1 = c_2 = \varpi + (\gamma + \varpi) \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \) the coefficient of \( (D_s)^2 \) and \( (\Delta_s^X)^2 \) in (24) is bigger than (18). Therefore, it suffices to have the coefficients of \( (D_t)^2 \) and \( (\Delta_t^X)^2 \) satisfy the following inequalities:

\[ \gamma \geq \frac{1}{q} \left[ q \varpi + (\gamma + \varpi) (\nu_1 + \nu_2) \right] \cdot \left[ \sum_{i=1}^{d_1} \frac{1}{1 - \frac{1}{2n}} + d_2 \right] \]

\[ = \frac{1}{q} \left[ q \varpi + (\gamma + \varpi) (\nu_1 + \nu_2) \right] \cdot \left[ 2n \left( \frac{1}{(1 - \frac{1}{2n})^{d_1+1}} - \frac{1}{1 - \frac{1}{2n}} \right) + d_2 \right] \]
Then it suffices that
\[ \varrho - \varpi \geq \frac{1}{q} \left[ q\varpi + (\gamma + \varpi)(\nu_1 + \nu_2) \right]. \]

If \( d_1 = 5q \leq n - 1 \), then by the fact that \((1 + x)^r \leq 1 + \frac{rx}{1-(r-1)x}\) for any \( x < \frac{1}{r-1} \) and \( r \geq 1 \),
\[
2n \left( \frac{1}{1 - \frac{1}{2n}} d_1 \right) - \frac{1}{1 - \frac{1}{2n}} \right) + d_2 \leq 2n \left( \frac{1}{1 - \frac{1}{2n}} d_1 + 1 \right) - \frac{2n}{2n - 1} + d_2
\]
\[
\leq 2n \left[ 1 + \frac{(d_1 + 1) (\frac{2n - 1}{2n - 1} - 1) + d_2 \right]
\]
\[
\leq 2n \left( \frac{d_1 + 1}{2n - 1 - d_1} \right) + d_2 \leq 2d_1 + 2 + d_2,
\]
if \( \frac{2n}{2n - 1 - d_1} \leq 2 \), i.e., if \( 5q \leq n - 1 \).

Then it suffices that
\[ \gamma \geq \frac{1}{q} \left[ q\varpi + (\gamma + \varpi)(\nu_1 + \nu_2) \right] (11q + 2) \]
and
\[ \varrho - \varpi \geq \frac{1}{q} \left[ q\varpi + (\gamma + \varpi)(\nu_1 + \nu_2) \right] (11q + 2). \]

Recall that \( \nu_1 = \frac{12q^2}{n} \leq \frac{r}{6} \) and \( \nu_2 = \frac{16q^2 r}{n} \leq \frac{r}{4} \) (see Lemma 9), \( \varrho = \frac{1}{8} - \frac{10r}{1-r} \) (see 13), and \( \varpi = \frac{1}{q} \left[ \frac{r}{2} + \frac{r^2}{4} + \frac{r^3}{12(1-r)} \right] \). One choice of values that suffices is \( \gamma = \varrho - \varpi \) and \( r \leq \frac{1}{144} \).

Claim 5. [Bounding Term A]
\[
\mathbb{E}_\pi \left[ \sum_{t-2q\leq s\leq t \text{ and } s=\text{prev}(t,k_s)} \frac{1}{2n^2 \Gamma} \cdot \left( \hat{g}_{k_s} - \pi(k_s) \right)^2 \right]
\]
\[
\leq 2 \frac{q}{n \Gamma} \frac{\nu_2 \Gamma^2}{2q} \sum_{u \in \{t-5q,t+q\}} \left( (D_u)^2 + (\Delta_u)^2 \right)
\]
\[
+ 2 \frac{1}{2n \Gamma} \sum_{t-2q \leq s \leq t} \left( \nu_3 \Gamma^2 \sum_{u \in \{t-4q,t+4q\}} \left( (D_u)^2 + (\Delta_u)^2 \right) + \nu_4 \Gamma^2 \left( \Delta_u \right)^2 \right)
\]
\[
+ 2 \frac{q}{n \Gamma} \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{u \in \{t-5q,t+q\}} \left( (D_u)^2 + (\Delta_u)^2 \right)
\]
\[
+ \frac{\nu_2 \Gamma^2}{2q} \sum_{u \in \{t-2q-1\}} \left( (D_u)^2 + (\Delta_u)^2 \right).
\]

Proof. We begin by observing:
\[
\mathbb{E}_\pi \left[ \sum_{t-2q\leq s\leq t \text{ and } s=\text{prev}(t,k_s)} \frac{1}{2n^2 \Gamma} \cdot \left( \hat{g}_{k_s} - \pi(k_s) \right)^2 \right]
\]
\[
\leq \mathbb{E}_\pi \left[ \sum_{t-2q\leq s\leq t} \sum_{k_s=1}^{n} \frac{1}{2n^2 \Gamma} \cdot \left( \hat{g}_{k_s} - \pi(k_s) \right)^2 \right].
\] (25)
Now,

\[
\left( \tilde{g}_{k_s}^{\pi(k_t),s} - g_{k_s}^{\pi(k_t),t} \right)^2 \leq 2 \left( \tilde{g}_{k_s}^{\pi(k_t),s} - \tilde{g}_{k_s}^{S,\pi(k_t),s} \right)^2 + 2 \left( \tilde{g}_{k_s}^{S,\pi(k_t),s} - g_{k_s}^{\pi(k_t),t} \right)^2 ,
\]

where \( \tilde{g}_{k_s}^{\pi(k_t),s} \) is the gradient of coordinate \( k_s \) at the point \( \pi(k_t),s \) if the updates from time \( t - 2q \) to \( t \) were performed as in the sequential algorithm.

We bound the first term on the RHS as follows.

\[
\left( \tilde{g}_{k_s}^{\pi(k_t),s} - g_{k_s}^{\pi(k_t),s} \right)^2 \leq \left( g_{\text{span,}k_s}^{\pi(k_t),s} \right)^2 .
\]

Taking the expectation and using Lemma 9 yields

\[
\mathbb{E} \left[ \left( \tilde{g}_{k_s}^{\pi(k_t),s} - g_{k_s}^{S,\pi(k_t),s} \right)^2 \right] \leq \frac{\nu_2 \Gamma^2}{2q} \sum_{u \in \{s-3q, s+q\}} \left( \mathcal{D}_u^2 + (\Delta_u^X)^2 \right)
\]

\[
\leq \frac{\nu_2 \Gamma^2}{2q} \sum_{u \in \{t-5q, t+q\}} \left( \mathcal{D}_u^2 + (\Delta_u^X)^2 \right) .
\]

To bound the second term, we reason as follows. \( \Delta_{t,\{s\}}^{t,\emptyset} x_{k_u}^{\pi(k_t),u} \) is all smaller than \( |\Delta_{\text{span}}^{t,\emptyset} x_{k_u}^{\pi(k_t),u}| + |\Delta_{\text{span}}^{t,\{s\}} x_{k_u}^{\pi(k_t),u}| \), which implies \( |\Delta_{\text{span}}^{t,\emptyset} x_{k_u}^{\pi(k_t),u}| \) and \( |\Delta_{\text{span}}^{t,\{s\}} x_{k_u}^{\pi(k_t),u}| \) are all smaller than \( |\Delta_{\text{span}}^{t,\emptyset} x_{k_u}^{\pi(k_t),u}| + |\Delta_{\text{span}}^{t,\{s\}} x_{k_u}^{\pi(k_t),u}| \). Therefore,

\[
\left( \tilde{g}_{k_s}^{S,\pi(k_t),s} - g_{k_s}^{\pi(k_t),t} \right)^2 \leq \left( \sum_{u \in \{t-2q, t-1\}} L_{k_u,k_s} \left( |\Delta_{\text{span}}^{t,\emptyset} x_{k_u}^{\pi(k_t),u}| + |\Delta_{\text{span}}^{t,\{s\}} x_{k_u}^{\pi(k_t),u}| \right) \right)^2 .
\]
Then, applying the Cauchy-Schwartz inequality and taking the expectation yields

\[
E \left[ \left( \hat{g}_{k_u}^{S,\pi(k_t),u} - g_{k_u}^{\pi(k_t),t} \right)^2 \right] 
\leq E \left[ 4q \sum_{u \in [t-2q,t-1]} L_{k_u,k_s} \left( \Delta t, \pi \right)^2 \right] + 4q \sum_{u \in [t-2q,t-1]} \frac{I_{uu}^2}{n} \left( \Delta \max_{k-u} \pi(k_t)^2 \right) 
\leq E \left[ 4q \sum_{u \in [t-2q,t-1]} L_{k_u,k_s} \left( \Delta t, \pi \right)^2 \right] + 4q \sum_{u \in [t-2q,t-1]} \frac{I_{uu}^2}{n} \left( 2(D_u)^2 + 2(\Delta X_u)^2 \right) 
\leq \frac{\nu_3 \Gamma^2}{q} \sum_{u \in [t-2q,t+q]} \left( (D_u)^2 + (\Delta X_u)^2 \right) + \nu_4 \Gamma^2 \left( (D_u)^2 + (\Delta X_u)^2 \right) 
+ \frac{4qI_{uu}^2}{n} \sum_{u \in [t-2q,t-1]} \left( 2(D_u)^2 + 2(\Delta X_u)^2 \right) \quad \text{(by Lemma 12)}
\leq \frac{\nu_3 \Gamma^2}{q} \sum_{u \in [t-2q,t+q]} \left( (D_u)^2 + (\Delta X_u)^2 \right) + \nu_4 \Gamma^2 \left( (D_u)^2 + (\Delta X_u)^2 \right) 
+ \frac{4qI_{uu}^2}{n} \sum_{u \in [t-2q,t-1]} \left( 2(D_u)^2 + 2(\Delta X_u)^2 \right) \quad \text{(by Lemma 9)}
\leq \frac{\nu_3 \Gamma^2}{q} \sum_{u \in [t-2q,t+q]} \left( (D_u)^2 + (\Delta X_u)^2 \right) + \nu_4 \Gamma^2 \left( (D_u)^2 + (\Delta X_u)^2 \right) 
+ \frac{\nu_4 \Gamma^2}{4q} \sum_{u \in [t-2q,t-1]} \left( 2(D_u)^2 + 2(\Delta X_u)^2 \right).
\]

Combining (25), (26), (27) and (28) yields the result. □

**Proof of Claim 4**

We will be using the following observation. \( \Delta_{t,\max^{X}}^{t,\pi(k_t),u} \geq \Delta_{t,\max^{X}}^{t,\pi(k_t),u} \) and \( \Delta_{t,\min^{X}}^{t,\pi(k_t),u} \leq \Delta_{t,\min^{X}}^{t,\pi(k_t),u} \) because replacing \( k_u \) by \( k_t \) on path \( \pi \) allows more choices of input in calculating the update to \( x_{k_u} \).
From (29), we obtain:

\[
E_{\pi} \left[ \frac{2}{3n^2} \sum_{t-2q \leq s < t} \sum_{k_1 = 1}^{n} \sum_{k_t = 1}^{n} \Gamma \cdot (x_{k_s},t - x_{k_t},t)^2 \right] \\
\leq \frac{\Gamma \cdot 2}{3n^2} \cdot E \left[ \sum_{k_1 = 1}^{n} \sum_{t-2q \leq s < t} \sum_{k_1 = 1}^{n} \sum_{t-2q \leq u < t} \sum_{k_u = k_s} \left[ 2q \left( \Delta_{\max} x_{k_s} - \Delta_{\min} x_{k_s} \right)^2 \right] + 2q \left( \Delta_{\max} x_{k_s} u - \Delta_{\mid k_s} x_{k_s} \right)^2 \right] \\
\leq \frac{\Gamma \cdot 2}{3n^2} \cdot E \left[ \sum_{k_1 = 1}^{n} \sum_{t-2q \leq s < t} \sum_{k_1 = 1}^{n} \sum_{t-2q \leq u < t} \sum_{k_u = k_s} \left[ 2q \left( \Delta_{\max} x_{k_s} u - \Delta_{\mid k_s} x_{k_s} \right)^2 \right] + 2q \left( \Delta_{\mid k_s} x_{k_s} u - \Delta_{\mid k_s} x_{k_s} \right)^2 \right] \\
\leq \frac{\Gamma \cdot 2}{3n^2} \cdot E \left[ \sum_{k_1 = 1}^{n} \sum_{t-2q \leq s < t} \sum_{k_1 = 1}^{n} \sum_{t-2q \leq u < t} \sum_{k_u = k_s} \left[ 2q \left( \Delta_{\max} x_{k_s} u - \Delta_{\mid k_s} x_{k_s} \right)^2 \right] + 2q \left( \Delta_{\mid k_s} x_{k_s} u - \Delta_{\mid k_s} x_{k_s} \right)^2 \right] \\
\leq \frac{8q}{3n} \sum_{u \in [t-2q, t-1]} \Gamma \cdot (D_u)^2 = \frac{2\nu_1}{9q} \sum_{s \in [t-2q, t-1]} \Gamma \cdot (D_s)^2 \\
(\text{see Lemma 9 for the definition of } \nu_1).
\]

\[\square\]

**Claim 6. [Bounding Term D]**

\[
E_{\pi} \left[ \frac{2}{3Gn^2} \sum_{k=1}^{n} \sum_{k_t=1}^{n} \left( g_{k}^{\pi(k),t} - g_{k}^{\pi(k),t} \right)^2 \right] \\
\leq \frac{\nu_2 \Gamma}{6q} \sum_{s \in [t-2q, t-1]} \left[ (D_s)^2 + (\Delta_{k}^X)^2 \right] + \frac{2\nu_3 \Gamma}{3q} \sum_{s \in [t-4q, t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_{k}^X)^2 \right] \\
+ \frac{2}{3\nu_4} \cdot \Gamma \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q, t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_{k}^X)^2 \right] + \frac{2}{3} \nu_4 \cdot \Gamma \left( \Delta_{k}^X \right)^2.
\]

**Proof.** We bound the term \(E_{\pi} \left[ \frac{2}{3n^2} \sum_{k=1}^{n} \sum_{k_t=1}^{n} \left( g_{k}^{\pi(k),t} - g_{k}^{\pi(k),t} \right)^2 \right] \). We will use the term \(g_{k}^{S_{\pi(k)},t} \) as an intermediary to allow us to compare values on two different paths, as follows.

\[
\left( g_{k}^{\pi(k),t} - g_{k}^{\pi(k),t} \right)^2 \leq 2 \left( g_{k}^{\pi(k),t} - g_{k}^{S_{\pi(k)},t} \right)^2 + 2 \left( g_{k}^{S_{\pi(k)},t} - g_{k}^{\pi(k),t} \right)^2 \\
\leq 2 \left( g_{k}^{\pi(k),t} - g_{k}^{S_{\pi(k)},t} \right)^2 + 2 \left( g_{k}^{S_{\pi(k)},t} - g_{k}^{\pi(k),t} \right)^2, \tag{29}
\]

as \(g_{k}^{S_{\pi(k)},t} = g_{k}^{S_{\pi(k)},t} \) since the gradients evaluated in synchronous order do not depend on the time \(t \) update.

44
For the first term on the RHS of (29), we first apply Lemma [10] and then apply Lemma [9] to bound the \((\Delta_t^E)^2\) term which is generated by Lemma [10] as follows.

\[
\mathbb{E}_\pi \left[ \left( \hat{g}_{k}^{\pi(k),t} - \tilde{g}_{k}^{\pi(k),t} \right)^2 \right] \\
\leq \frac{\nu_3 \Gamma^2}{2q} \sum_{s \in [t-4q,t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] + \frac{\nu_4 \Gamma^2}{2} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
\leq \frac{\nu_3 \Gamma^2}{2q} \sum_{s \in [t-4q,t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
+ \frac{\nu_4 \Gamma}{2} \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q,t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] + \frac{\nu_4}{2} \Gamma^2 \left( \Delta_t^X \right)^2. 
\]

(30)

For the second term on the RHS of (29),

\[
\left( \tilde{g}_{k}^{S,\pi(k),t} - g_{k}^{\pi(k),t} \right)^2 \leq 2q \sum_{s \in [t-2q,t-1]} L_{k,s,k}^2 \left( \Delta_{t,0} \pi(k_1),s - \Delta_{t,\max} \pi(k_1),s \right)^2 \\
= 2q \sum_{s \in [t-2q,t-1]} L_{k,s,k}^2 \left( \Delta_{\text{span}} \pi(k_1),s \right)^2.
\]

This yields

\[
\mathbb{E}_\pi \left[ \frac{1}{n^2} \sum_{k=1}^{n} \sum_{k_1=1}^{n} \left( \hat{g}_{k}^{\pi(k),t} - \tilde{g}_{k}^{\pi(k),t} \right)^2 \right] \\
\leq \mathbb{E}_\pi \left[ \frac{1}{n^2} \sum_{k_1=1}^{n} \sum_{k=1}^{n} 2q \sum_{s \in [t-2q,t-1]} L_{k,s,k}^2 \left( \Delta_{\text{span}} \pi(k_1),s \right)^2 \right] \\
\leq \frac{2q \Gamma^2}{n} \sum_{s \in [t-2q,t-1]} (D_s)^2 \leq \frac{\nu_2 \Gamma^2}{8q} \sum_{s \in [t-2q,t-1]} (D_s)^2. 
\]

(31)

Combining (29), (30) and (31) yields the result.

The following bound on term \(E\) is immediate by Lemma [11]

**Claim 7. ([Bounding Term \(E\)])**

\[
\frac{1}{\Gamma} \mathbb{E}_\pi \left[ \left( g_{k_1}^{\pi(t),t} - \hat{g}_{k_1}^{\pi(t),t} \right)^2 \right] \leq \frac{\nu_2 \Gamma}{q} \sum_{s \in [t-3q,t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
+ \frac{\nu_4 \Gamma}{q} \sum_{s \in [t-4q,t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
+ \nu_4 \cdot \Gamma \left( \frac{\nu_1}{q} + \frac{\nu_2}{q} \right) \sum_{s \in [t-3q,t+q] \setminus \{t\}} \left[ (D_s)^2 + (\Delta_s^X)^2 \right] \\
+ \nu_4 \cdot \Gamma^2 \left( \Delta_t^X \right)^2.
\]

This is more than \(\frac{3}{2}\) times the bound given in Claim [6]
Claim 8. The term $G$ in (12) is bounded by $\frac{1}{q} \left[ \frac{r}{2} + \frac{5r^2}{1-r} + \frac{r^2}{144} + \frac{r^3}{12(1-r)} \right].$

Proof. Recall that $r = \frac{72q^2}{n} \cdot \max\left\{ \frac{1}{12}, 1 \right\}$ (see the second paragraph of Section 6.3.2). As stated in Lemma 9, $\nu_1 = \frac{12q^2}{n} \leq \frac{r}{12}$, $\nu_2 = \frac{16q^2L_2}{n} \leq \frac{r}{6}$, and as stated in Lemma 10, $\nu_3 = \frac{r^2}{8(1-r)}$, $\nu_4 = \frac{6r}{1-r}$; also $\frac{1}{n} \leq \frac{r}{72q}$ as $q \geq 1$.

$$\left[ \max \left\{ \frac{2\nu_1}{9q}, \frac{1 + 2\nu_4}{2n} \right\} + (\nu_2 + \nu_3 + \nu_4 (\nu_1 + \nu_2)) \left( \frac{2}{n} + \frac{5}{3q} \right) \right]$$

$$\leq \frac{1}{q} \left[ \max \left\{ \frac{r}{27} + \frac{r^2}{12(1-r)} + \frac{6r}{1-r} \right\} + \left( \frac{r}{4} + \frac{r^2}{8(1-r)} + \frac{6r}{1-r} \left( \frac{r}{6} + \frac{r}{4} \right) \right) \left( \frac{r}{36} + \frac{5}{3} \right) \right]$$

$$\leq \frac{1}{q} \left[ \frac{r}{27} + \frac{r^2}{12(1-r)} + \left( \frac{r}{4} + \frac{r^2}{8(1-r)} + \frac{6r}{1-r} \left( \frac{r}{36} + \frac{5}{3} \right) \right) \right]$$

$$= \frac{1}{q} \left[ \frac{r}{27} + \frac{5}{12} + \frac{r^2}{1-r} \left( \frac{1}{12} + \frac{5}{24} + \frac{25}{6} \right) + \frac{r^2}{144} + \frac{r^3}{1-r} \left( \frac{1}{288} + \frac{5}{72} \right) \right]$$

$$\leq \frac{1}{q} \left[ \frac{r}{2} + \frac{5r^2}{1-r} + \frac{r^2}{144} + \frac{r^3}{12(1-r)} \right].$$

</table>
For any set $R \subseteq [t - 2q, t + q]$ and $S \subseteq \{u \mid k_u = k_s$ and $t - 2q \leq u \leq s - 1\}$, the maximum value that $\Delta x_{\pi_{k_s}}^{R,S}$ can assume when the first $(t - 2q)$ updates on path $\pi$ have been fixed, the update does not read any of the variable values updated at (SCC) times $R \cup S$ and (SCC) times after $t + q$; furthermore, none of the updates at times $R \cup S$ are used in the computation of the updates in $[t - 2q, t + q] \setminus (R \cup S)$. 

$\Delta_{\text{max}} x_{\pi_{k_s}}^{R,S} :=$ the maximum value of $g_{k_s}^{\pi_{k_s}}$ when the first $(u - 2q)$ updates on path $\pi$ have been fixed, and the update does not read any of the variable values updated at times after $u + q$. 

$g_{\text{max}, k_s}^{\pi_{k_s}, u}$ :=
