THE STRONG MASSEY VANISHING CONJECTURE FOR
FIELDS WITH VIRTUAL COHOMOLOGICAL DIMENSION AT
MOST 1

AMBRUS PÁL AND ENDRE SZABÓ

Abstract. We show that the strong vanishing conjecture for n-fold Massey
products holds for fields of virtual cohomological dimension at most 1 using a
theorem of Haran.

1. Introduction

Definition 1.1. Let $C^*$ be a differential graded associative algebra with product $\cup$, differential $\delta : C^* \to C^{*+1}$, and cohomology $H^* = \text{Ker}(\delta)/\text{Im}(\delta)$. Choose an integer $n \geq 2$ and let $a_1, a_2, \ldots, a_n$ be a set of cohomology classes in $H^1$. A defining system for the n-fold Massey product of $a_1, a_2, \ldots, a_n$ is a set $a_{ij}$ of elements of $C_1$ for $1 \leq i < j \leq n+1$ and $(i, j) \neq (1, n+1)$ such that

$$\delta(a_{ij}) = \sum_{k=i+1}^{j-1} a_{ik} \cup a_{kj}$$

and $a_1, a_2, \ldots, a_n$ is represented by $a_{12}, a_{23}, \ldots, a_{n,n+1}$. We say that the n-fold Massey product of $a_1, a_2, \ldots, a_n$ is defined if there exists a defining system. The n-fold Massey product $\langle a_1, a_2, \ldots, a_n \rangle a_{ij}$ of $a_1, a_2, \ldots, a_n$ with respect to the defining system $a_{ij}$ is the cohomology class of

$$\sum_{k=2}^{n} a_{1k} \cup a_{k,n+1}$$

in $H^2$. Let $\langle a_1, a_2, \ldots, a_n \rangle$ denote the subset of $H^2$ consisting of the n-fold Massey products of $a_1, a_2, \ldots, a_n$ with respect to all defining systems. We say that the n-fold Massey product of $a_1, a_2, \ldots, a_n$ vanishes if $\langle a_1, a_2, \ldots, a_n \rangle$ contains zero.

Notation 1.2. Now let $k$ be a field whose characteristic is not 2, let $\Gamma$ denote the absolute Galois group of $k$, and let $C^*$ be now the differential graded algebra of $Z/2$-cochains of $\Gamma$ in continuous group cohomology. The cohomology of $C^*$ is $H^* = H^*(\Gamma, Z/2)$. Following Mináč and Tǎn in [8], we say that the strong Massey vanishing conjecture holds for $k$ if for every integer $n \geq 3$ and $a_1, a_2, \ldots, a_n \in H^1(\Gamma, Z/2)$ such that $a_i \cup a_{i+1} = 0$ for every $1 \leq i < n$, the n-fold Massey product of $a_1, a_2, \ldots, a_n$ vanishes.

There is quite a bit of beautiful work on this fascinating conjecture (see for example [2], [3], [6], [7], and [8]), but it remains open in general. Our aim is to prove this conjecture for a new class of fields whose definition we recall next.

Definition 1.3. Recall that a field $k$ has virtual cohomological dimension $\leq 1$ if there is a finite separable extension $K/k$ with $cd(K) \leq 1$ where $cd$ denotes the cohomological dimension as defined in [11]. Since the only torsion elements in the absolute Galois group of $k$ are the involutions coming from the orderings of $k$, it is equivalent (by a theorem in [11]) to require $cd(K) \leq 1$ for any fixed finite separable extension $K$ of $k$ without orderings, for example for $K = k(i)$, where $i = \sqrt{-1}$. In particular, if $k$ itself cannot be ordered (which is equivalent to $-1$ being a sum of squares in $k$), this condition is equivalent to $cd(k) \leq 1$.

Examples 1.4. Examples of fields $k$ which can be ordered with $cd(k(i)) \leq 1$ include real closed fields, function fields in one variable over any real closed ground field, the field of Laurent series in one variable over any real closed ground field, and the field $\mathbb{Q}^{ab} \cap \mathbb{R}$ which is the subfield of $\mathbb{R}$ generated by the numbers $\cos\left(\frac{2\pi n}{m}\right)$, where $n \in \mathbb{N}$.

The main result of this paper is the following

Theorem 1.5. The strong Massey vanishing conjecture holds for fields $k$ with $cd(k(i)) \leq 1$.

The proof is an easy application of earlier work of Haran and Dwyer. After we review the latter, we give a quick proof of our main result in the next section.

2. The strong Massey vanishing conjecture for fields with virtual cohomological dimension at most 1

Definition 2.1. An embedding problem for a profinite group $G$ is the left hand side diagram:

$$
\begin{array}{ccc}
G & \xrightarrow{\phi} & A, \\
\downarrow{\phi} & & \downarrow{\phi} \\
B & \xrightarrow{\alpha} & A, \\
\end{array}
$$

where $A, B$ are finite groups, the solid arrows are continuous homomorphisms and $\alpha$ is surjective. A solution of this embedding map is a continuous homomorphism $\tilde{\phi} : G \rightarrow B$ which makes the right hand side diagram commutative. We say that the embedding problem above is real if for every involution $t \in G$ with $\phi(t) \neq 1$ there is an involution $b \in B$ with $\alpha(b) = \phi(t)$. Following Haran and Jarden (see [5]) we say that a profinite group $G$ is real projective if $G$ has an open subgroup without 2-torsion, and if every real embedding problem for $G$ has a solution.

Theorem 2.2 (Haran). A profinite group $G$ is real projective if and only if $G$ has an open subgroup $G_0$ of index $\leq 2$ with $cd(G_0) \leq 1$, and every involution $t \in G$ is self-centralizing, that is, we have $C_G(t) = \{1, t\}$.

Proof. This is Theorem A of [4] on page 219. □
Since by classical Artin–Schreier theory every involution in the absolute Galois group of a field is self-centralising, we get the following

**Corollary 2.3.** The absolute Galois group of a field \( k \) is real projective if and only if \( k \) satisfies \( \text{cd}(k(1)) \leq 1 \). \[\square\]

We also need to recall Dwyer’s theorem relating the vanishing of Massey products to certain embedding problems.

**Definition 2.4.** Let \( e_{ij} : \text{Mat}_n(\mathbb{Z}/2) \to \mathbb{Z}/2 \) be the function taking an \( n \times n \) matrix with coefficients in \( \mathbb{Z}/2 \) to its \((i,j)\)-entry. Let

\[ U_n = \{ U \in \text{Mat}_n(\mathbb{Z}/2) \mid e_{ii}(U) = 1, \ e_{ij}(U) = 0 \ (\forall \ i > j) \} \]

be the group of upper triangular \( n \times n \) invertible matrices with coefficients in \( \mathbb{Z}/2 \). Let \( \Gamma \) and \( C^\ast \) be the same as in Notation 1.2. Then \( H^1 \) is naturally isomorphic to the group of continuous homomorphisms \( \text{Hom}(\Gamma, \mathbb{Z}/2) \), and we will indentify these two groups in all that follow. Given \( n \) continuous homomorphisms

\[ a_i : \Gamma \longrightarrow \mathbb{Z}/2 \quad (i = 1, 2, \ldots, n), \]

let \( E(a_1, a_2, \ldots, a_n) \) denote the embedding problem:

\[ \begin{array}{c}
\Gamma \\
\downarrow \psi \\
U_{n+1} \\
\downarrow \phi \\
(\mathbb{Z}/2)^n,
\end{array} \]

where \( \phi \) is given by the rule \( U \mapsto (e_{12}(U), e_{23}(U), \ldots, e_{nn+1}(U)) \).

**Theorem 2.5** (Dwyer). The \( n \)-fold Massey product \( \langle a_1, a_2, \ldots, a_n \rangle \) vanishes if and only if the embedding problem \( E(a_1, a_2, \ldots, a_n) \) has a solution.

**Proof.** See Theorem 2.4 of [1]. \[\square\]

**Proof of Theorem 2.5.** By Haran’s theorem it will be enough to show that every such embedding problem with \( a_i \cup a_{i+1} = 0 \) for every \( i = 1, 2, \ldots, n - 1 \) is real, in other words the restriction of the embedding problem to any subgroup of order two has a solution. In other words, by Artin-Schreier theory, we reduced the claim to the case when \( k \) is real closed, i.e. when \( \Gamma = \mathbb{Z}/2 \). Now let \( a_1, a_2, \ldots, a_n \in \text{Hom}(\Gamma, \mathbb{Z}/2) \) be a set of cohomology classes in \( H^1 \) such that \( a_i \cup a_{i+1} = 0 \) for every \( i = 1, 2, \ldots, n - 1 \). Let \( g \in \Gamma \) be the generator.

**Lemma 2.6.** For every \( i = 1, 2, \ldots, n - 1 \) the following holds: if \( a_i(g) = 1 \) then \( a_{i+1}(g) = 0 \).

**Proof.** Since for every \( a, b \in H^1 \) the 2-fold Massey product \( \langle a, b \rangle \) is the singleton \( a \cup b \), by Theorem 2.3 we get that the embedding problem:

\[ \begin{array}{c}
\Gamma \\
\downarrow \psi_i \\
U_3 \\
\downarrow \phi \\
(\mathbb{Z}/2)^2,
\end{array} \]
has a solution \( \psi_i \). Assume now that \( a_i(g) = a_{i+1}(g) = 1 \). Then either

\[
\tilde{\psi}_i(g) = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{or} \quad \tilde{\psi}_i(g) = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.
\]

However neither of these matrices has order two, which is a contradiction. \( \square \)

In plain English the lemma above means that we can break up the row vector

\[
(a_1(g) \ a_2(g) \ldots \ a_n(g))
\]

to single entries of 1-s separated by zeros. By the above it is enough to construct a matrix \( A \in U_n \) such that \( A^2 \) is the identity matrix, and

\[
\phi(A) = a_1 \times a_2 \times \cdots \times a_n(g).
\]

In fact the matrix \( A = (a_{ij})_{i,j=1}^{n+1} \) with

\[
a_{ij} = \begin{cases} 
1, & \text{if } i = j, \\
1, & \text{if } i + 1 = j \text{ and } a_i(g) = 1, \\
0, & \text{otherwise},
\end{cases}
\]

will do. Indeed it is a block matrix whose off-diagonal terms are zero matrices, and the diagonal terms are either the \( 1 \times 1 \) matrix \((1)\) or the \( 2 \times 2 \) matrix \((\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix})\). These have order dividing two, so the same holds for \( A \), too. \( \square \)
