Generalized Harmonic Progression

Jose Risomar Sousa

September 14, 2020

Abstract

This paper presents formulae for the sum of the terms of a harmonic progression of order $k$ with integer parameters, $HP_k(n)$, for the partial sums of two Fourier series associated with them, $C^m_k(a, b, n)$ and $S^m_k(a, b, n)$, and for the partial sums of the Lerch’s $\Phi$ and the polylogarithm functions. (Here, “harmonic progression” is being used loosely, as for some parameter choices, $a$ and $b$, the sequence might not be a harmonic progression). These new formulae are a generalization of the formulae created in a previous paper, and were achieved using a slightly modified version of the reasoning employed before.

5.3 $C^m_{2k+1}(n)$ and $C^m_{2k+1}(a, b, n)$

5.4 $S^m_{2k}(n)$ and $S^m_{2k}(a, b, n)$

6 Lerch’s $\Phi$ and the polylogarithm

6.1 Partial Lerch’s $\Phi$ sums

6.2 Partial polylogarithm sums
1 Introduction

Building upon the results of [3], *Generalized Harmonic Numbers Revisited*, this new paper demonstrates how to obtain exact formulae for the sum of the first \( n \) terms of a harmonic progression of order \( k \) with integer parameters, \( a \) and \( b \):

\[
HP_k(n) = \sum_{j=1}^{n} \frac{1}{(aj + b)^k}
\]

Even though formulae for \( HP_k(n) \) can probably be created using the digamma function, \( \psi \), the ones derived here are arguably more interesting, and they must be the first such formulae other than \( \psi \).

We also create formulae for the partial sums of two Fourier series associated with \( HP_k(n) \):

\[
C_m^k(a, b, n) = \sum_{j=1}^{n} \frac{1}{(aj + b)^k} \cos \frac{2\pi (aj + b)}{m}, \text{ and } S_m^k(a, b, n) = \sum_{j=1}^{n} \frac{1}{(aj + b)^k} \sin \frac{2\pi (aj + b)}{m}
\]

My first manuscript\(^2\) received some criticism for including too many details, so in this one we omit unnecessary details, which can be easily understood from a reading of [3], for the interested reader. It also received criticism for being long and repetitive. In all honesty, that’s because it was my very first paper, and I’m neither an academic nor a professor (having an advisor must make a big difference when it comes to formatting a paper). So, it turns out that the first paper wasn’t suitable for an academic publication, but I hope these findings may be useful and find an application in some important problem someday. Although not excellent in exposition, paper [3] was about novelty, not about presentation.

This new manuscript, however, is concise and succinct, it focuses solely on closed-forms for \( HP_k(n) \), \( C_m^k(a, b, n) \) and \( S_m^k(a, b, n) \). The question on the limits of these expressions as \( n \) approaches infinity is addressed in [4] and [5].

We make use again of Faulhaber’s formula\(^2\) for the sum of the \( i \)-th powers of the first \( n \) positive integers:

\[
\sum_{k=1}^{n} k^i = \sum_{j=0}^{i} \frac{(-1)^j i! B_j n^{i+1-j}}{(i+1-j)! j!},
\]

where \( B_j \) are the Bernoulli numbers.

Since odd Bernoulli numbers are always 0, except for \( B_1 \), we can simplify the above formula for even and odd powers as follows:

\[
\sum_{k=1}^{n} k^{2i} = \frac{n^{2i}}{2} + \sum_{j=0}^{i} \frac{(2i)! B_{2j} n^{2i+1-2j}}{(2j)! (2i+1-2j)!}
\]

\(^1\)In a stricter sense, closed-forms don’t include integrals.
\[ \sum_{k=1}^{n} k^{2i+1} = \frac{n^{2i+1}}{2} + \sum_{j=0}^{i} \frac{(2i+1)!B_{2j}n^{2i+2-2j}}{(2j)!(2i+2-2j)!} \]  

(2)

2 Lagrange’s Identities

In [3] we introduced an indicator function, \( k \) divides \( n \) \((1_{k|n})\), and its analog as key elements of the method used to solve the harmonic numbers. For the harmonic progression, we need to modify those functions and obtain their Taylor series, though unlike in the first paper here we focus on only one of them, as the other one has an analogous behavior.

The below is the function we’re interested in, for the odd case. We can write this sum as a closed-form using Lagrange’s trigonometric identities:

\[
\sum_{j=1}^{k} \sin \frac{2\pi n(a_j + b)}{k} = -\frac{1}{2} \sin \frac{2\pi bn}{k} + \frac{1}{2} \sin 2\pi n \left( a + \frac{b}{k} \right) + \sin \pi n \left( a + \frac{2b}{k} \right) \sin \pi an \cot \frac{\pi an}{k}
\]

Now, we can derive a power series for the left-hand side of the above equation with the employment of (2), and through comparison we can deduce the following power series for each function on the right-hand side (they hold for all real \( n, a \) and \( b \) and for all integer \( k > 0 \)):

\[
\sum_{i=0}^{\infty} (-1)^i \left( \frac{2\pi bn}{k} \right)^{2i+1} \sum_{j=0}^{i} \left( \frac{(ak/b)^{2j}}{(2j)!} + \frac{(ak/b)^{2j+1}}{(2j + 1)!(2i - 2j)!} \right) = \sin 2\pi n \left( a + \frac{b}{k} \right)
\]

(3)

\[
\sum_{i=0}^{\infty} (-1)^i \left( \frac{2\pi bn}{k} \right)^{2i+1} \sum_{j=0}^{i} \left( \frac{(a/b)^{2j}}{(2i+1 - 2j)!} \sum_{p=0}^{j} \frac{B_{2p}k^{2j+1-2p}}{(2j+1-2p)!(2p)!} + \frac{(a/b)^{2j+1}}{(2j+1)!(2i - 2j)!} \sum_{p=0}^{j} \frac{B_{2p}k^{2j+2-2p}}{(2j+2-2p)!(2p)!} \right) = \sin \pi n \left( a + \frac{2b}{k} \right) \sin \pi an \cot \frac{\pi an}{k}
\]

(4)

For the harmonic progressions of even order, the analogous function is:

\[
\sum_{j=1}^{k} \cos \frac{2\pi n(a_j + b)}{k} = -\frac{1}{2} \cos \frac{2\pi bn}{k} + \frac{1}{2} \cos 2\pi n \left( a + \frac{b}{k} \right) + \cos \pi n \left( a + \frac{2b}{k} \right) \sin \pi an \cot \frac{\pi an}{k}
\]

3 Approach based on sine

The rationale to build a formula for \( HP_k(n) \) is to use the Taylor series expansion of \( \sin 2\pi(a_j + b), \) and exploit the fact that it’s 0 for all integer \( a_j + b \) (hence the need for \( a \)
and $b$ to be integers):

$$\sin 2\pi(a j + b) = 0 \Rightarrow 2\pi(a j + b) = -\sum_{i=1}^{\infty} \frac{(-1)^i}{(2i+1)!} (2\pi(a j + b))^{2i+1}$$  \hspace{1cm} (5)

If we divide both sides of (5) by $2\pi(a j + b)^2$, we end up with a power series for $1/(a j + b)$ that only holds for integer $a j + b$.

Besides, on the right-hand side of the resulting equation the exponents of $a j + b$ are positive integers, allowing us to apply the Faulhaber’s formula mentioned in the introduction. By doing so we end up with a very convoluted power series that can be turned into integrals by means of equations (3) and (4), which in turn were derived using Lagrange’s identities. That about sums up the logic.

### 3.1 Harmonic Progression

We start by dividing both sides of (5) by $2\pi(a j + b)^2$:

$$\frac{1}{a j + b} = \sum_{i=0}^{\infty} \frac{(-1)^i(2\pi b)^{2i+2}(2i + 1)!}{b(2i + 3)!} \sum_{j=0}^{i} \left(\frac{(an/b)^{2j}}{(2j)!(2i + 1 - 2j)!} + \frac{(an/b)^{2j+1}}{(2j+1)!(2i - 2j)!}\right) + \\
\sum_{i=0}^{\infty} \frac{(-1)^i(2\pi b)^{2i+2}(2i + 1)!}{b(2i + 3)!} \sum_{j=0}^{i} \left(\frac{(a/b)^{2j}}{(2i + 1 - 2j)!} \sum_{p=0}^{j} \frac{B_{2p}n^{2j+2-2p}}{(2j+1-2p)!(2p)!} + \frac{(a/b)^{2j+1}}{(2i - 2j)!} \sum_{p=0}^{j} \frac{B_{2p}n^{2j+2-2p}}{(2j + 2 - 2p)!(2p)!}\right)$$

The above sums can be manipulated conveniently and then obtained from (3) and (4), the two equations we derived previously, by means of decompositions into linear combinations followed by integrations. Though we have omitted the details here, the reader can refer to the precursor paper\textsuperscript{2} for a more detailed description of the steps involved.

After all the appropriate calculations are performed, one ends up with:

$$\frac{1}{2b} \sum_{i=0}^{\infty} (-1)^i \frac{(2\pi b)^{2i+2}(2i + 1)!}{(2i + 3)!} \sum_{j=0}^{i} \left(\frac{(an/b)^{2j}}{(2j)!(2i + 1 - 2j)!} + \frac{(an/b)^{2j+1}}{(2j+1)!(2i - 2j)!}\right) = \frac{2\pi(a n + b) - \sin 2\pi(a n + b)}{4\pi(a n + b)^2}$$

$$\sum_{i=0}^{\infty} (-1)^i \frac{(2\pi b)^{2i+2}(2i + 1)!}{b(2i + 3)!} \sum_{j=0}^{i} \left(\frac{(a/b)^{2j}}{(2i + 1 - 2j)!} \sum_{p=0}^{j} \frac{B_{2p}n^{2j+1-2p}}{(2j+1-2p)!(2p)!} + \frac{(a/b)^{2j+1}}{(2i - 2j)!} \sum_{p=0}^{j} \frac{B_{2p}n^{2j+2-2p}}{(2j + 2 - 2p)!(2p)!}\right) = 2\pi \int_{0}^{1} (1 - u) \sin \pi a u \sin \pi (a n + 2b) u \cot \pi a u \, du$$
Now, summing up all the results (disregarding the sine of multiples of \( \pi \)), we arrive at a formula for \( HP(n) \):

\[
\sum_{j=1}^{n} \frac{1}{aj+b} = -\frac{1}{2b} + \frac{1}{2(an+b)} + 2\pi \int_{0}^{1} (1-u) \sin \pi(an+2b)u \sin \pi anu \cot \pi au \, du
\]

In the next sections we state a generalization of this result without getting into too much detail.

### 3.2 General Formula

If we keep dividing (6) by \( aj+b \), we obtain similar recursions to the ones we got for the generalized harmonic numbers. All the results presented next follow from analogous reasonings to those from reference [3].

### 3.3 Harmonic Progression of Order \( 2k \)

We have the following recursion for \( HP_{2k}(n) \):

\[
HP_{2k}(n) = -\frac{1}{2b^{2k}} \sum_{j=0}^{k} \frac{(-1)^j(2\pi b)^{2j}}{(2j+1)!} + \frac{1}{2(an+b)^{2k}} \sum_{j=0}^{k} \frac{(-1)^j(2\pi(an+b))^{2j}}{(2j+1)!}
\]

\[
-\sum_{j=1}^{k-1} \frac{(-1)^{k-j}(2\pi)^{2k-2j}}{(2k+1-2j)!} HP_{2j}(n) - \frac{(-1)^k(2\pi)^{2k}}{(2k)!} \int_{0}^{1} (1-u)^{2k} \cos \pi(an+2b)u \sin \pi anu \cot \pi au \, du
\]

Note that \( HP_0(n) = 0 \) for all positive integer \( n \) (just like \( H_0(n) = 0 \), previously). Therefore, from the recursion, we conclude that for all integer \( a \neq 0, b \neq 0 \) and \( k \geq 0 \):

\[
\sum_{j=1}^{n} \frac{1}{(aj+b)^{2k}} = -\frac{1}{2b^{2k}} + \frac{1}{2(an+b)^{2k}} + \\
-(-1)^k(2\pi)^{2k} \int_{0}^{1} \sum_{j=0}^{k} \frac{B_{2j}(2-2^{2j})}{(2j)!} (1-u)^{2k-2j} \cos \pi(an+2b)u \sin \pi anu \cot \pi au \, du
\]

And if we turn the product of cosine and sine into a sum of sines, we derive another, perhaps more useful, way to express this formula:

\[
\sum_{j=1}^{n} \frac{1}{(aj+b)^{2k}} = -\frac{1}{2b^{2k}} + \frac{1}{2(an+b)^{2k}} + \\
-\frac{(-1)^k(2\pi)^{2k}}{2} \int_{0}^{1} \sum_{j=0}^{k} \frac{B_{2j}(2-2^{2j})}{(2j)!} (1-u)^{2k-2j} \sin 2\pi(an+b)u - \sin 2\pi bu \cot \pi au \, du
\]

This formula also works for the generalized harmonic numbers \( (a = 1, b = 0) \), if the term \(-1/(2b^{2k})\) is disregarded. In fact, if we disregard any term of the equation that has a null denominator, the equation still holds.
3.4 Harmonic Progression of Order $2k+1$

We have the following recursion for $HP_{2k+1}(n)$:

$$
HP_{2k+1}(n) = - \frac{1}{2b^{2k+1}} \sum_{j=0}^{k} \frac{(-1)^j (2\pi b)^{2j}}{(2j+1)!} + \frac{1}{2(an+b)^{2k+1}} \sum_{j=0}^{k} \frac{(-1)^j (2\pi (an+b))^{2j}}{(2j+1)!} 
$$

$$
- \sum_{j=0}^{k-1} \frac{(-1)^{k-j} (2\pi)^{2k-2j}}{(2k+1-2j)!} HP_{2j+1}(n) + \frac{(-1)^k (2\pi)^{2k+1}}{(2k+1)!} \int_{0}^{1} (1-u)^{2k+1} \sin \pi (an+2b) u \sin \pi an u \cot \pi au \, du
$$

Therefore, for all integer $a \neq 0, b \neq 0$ and $k \geq 0$:

$$
\sum_{j=1}^{n} \frac{1}{(aj+b)^{2k+1}} = - \frac{1}{2b^{2k+1}} + \frac{1}{2(an+b)^{2k+1}} + \sum_{j=0}^{k} \frac{B_{2j} (2-2^{2j}) (1-u)^{2k+1-2j}}{(2j)!(2k+1-2j)!} \sin \pi (an+2b) u \sin \pi an u \cot \pi au \, du
$$

If we turn the product of sines into a sum of cosines, we obtain:

$$
\sum_{j=1}^{n} \frac{1}{(aj+b)^{2k+1}} = - \frac{1}{2b^{2k+1}} + \frac{1}{2(an+b)^{2k+1}} + \sum_{j=0}^{k} \frac{B_{2j} (2-2^{2j}) (1-u)^{2k+1-2j}}{(2j)!(2k+1-2j)!} (\cos 2\pi (an+b) u - \cos 2\pi bu) \cot \pi au \, du
$$

3.5 Generating functions

As seen in [3], the polynomials in $u$ within the integrals are generated by the functions:

$$
f(x) = \frac{x \cos x (1-u)}{\sin x} \Rightarrow f^{(2k)}(0) = \frac{(-1)^k \sum_{j=0}^{k} B_{2j} (2-2^{2j}) (1-u)^{2k-2j}}{(2j)!(2k-2j)!}, \text{ and}
$$

$$
f(x) = \frac{x \sin x (1-u)}{\sin x} \Rightarrow f^{(2k+1)}(0) = \frac{(-1)^k \sum_{j=0}^{k} B_{2j} (2-2^{2j}) (1-u)^{2k+1-2j}}{(2j)!(2k+1-2j)!}
$$

4 Approach based on exponential

This approach consists in using equation $e^{2\pi i (aj+b)} = 1$. It’s even better than the sine-based approach, since it yields a single formula for both odd and even powers.
For this one we can skip the step-by-step demonstration and go straight to the final result. If \( k \geq 0 \):

\[
\sum_{j=1}^{n} \frac{1}{(aj + b)^k} = -\frac{1}{2b^k} + \frac{1}{2(an + b)^k} + \frac{i(2\pi i)^k}{2} \int_0^1 \sum_{j=0}^{k} \frac{B_j(1-u)^{k-j}}{j!(k-j)!} \left( e^{2\pi i(\alpha n + b)u} - e^{2\pi i bu} \right) \cot \pi u \, du,
\]

where the generating function of the polynomial in \( u \) inside the integral is:

\[
f(x) = \frac{x e^{(1-u)}}{e^x - 1} \Rightarrow f^{(k)}(0) = \sum_{j=0}^{k} \frac{B_j(1-u)^{k-j}}{j!(k-j)!}
\]

### 5 The partial Fourier sums

Let’s briefly recall the formulae we found for \( C_k^m(n) \) and \( S_k^m(n) \), the partial sums of the Fourier series associated with the generalized harmonic numbers, \( H_k(n) \), from reference [3].

Next to each one we show their harmonic progression analogs, \( C_k^m(a, b, n) \) and \( S_k^m(a, b, n) \), which are based entirely on analogy.

The below expressions hold for all complex \( m, a \) and \( b \) (unlike the \( HP_k(n) \) formulae), and for all integer \( n \geq 1 \). As mentioned before, we can disregard any term that has zero in the denominator, and the equation still holds (technically, we take the limit as the parameter tends to 0). See (6.2), for an example.

Again, by definition \( H_0(n) = 0 \) and \( HP_0(n) = 0 \) for all positive integer \( n \), so they have no effect in the sums and to avoid confusion we skip them in the formulae.

#### 5.1 \( C_{2k}^m(n) \) and \( C_{2k}^m(a, b, n) \)

For all integer \( k \geq 1 \):

\[
\sum_{j=1}^{n} \frac{1}{j^{2k} \cos^2 \left( \frac{2\pi j}{m} \right)} = \frac{1}{2^{2k}} \cos \left( \frac{2\pi n}{m} \right)^2 \left( \cos \frac{2\pi n}{m} \sum_{j=0}^{k} \frac{(-1)^j (\frac{2\pi j}{m})^{2j}}{(2j)!} H_{2j}(n) \right) + \sum_{j=1}^{k} \frac{(-1)^{k-j} (\frac{2\pi j}{m})^{2k-2j}}{(2k-2j)!} \frac{H_{2j}(n)}{H_{2j}(n)} \]

\[
+ \frac{(-1)^k (\frac{2\pi}{m})^{2k}}{2(2k-1)!} \int_0^1 (1-u)^{2k-1} \sin \left( \frac{2\pi nu}{m} \right) \cot \frac{\pi u}{m} du
\]
5.2 \( S_{2k+1}^m(n) \) and \( S_{2k+1}^m(a, b, n) \)

For all integer \( k \geq 0 \):

\[
\sum_{j=1}^{n} \frac{1}{(a_j + b)^{2k}} \cos \frac{2\pi(a_j + b)}{m} = -\frac{1}{2^{2k}} \left( \cos \frac{2\pi b}{m} - \sum_{j=0}^{k} \frac{(-1)^j (2 \pi b)^{2j}}{(2j)!} \right) + \frac{1}{2(a_n + b)^{2k}} \left( \cos \frac{2\pi(a_n + b)}{m} - \sum_{j=0}^{k} \frac{(-1)^j (2 \pi (a_n + b))^{2j}}{(2j)!} \right) + \frac{1}{2} \left( \frac{-1)^{k-j} (2 \pi b)^{2k-2j}}{(2k-2j)!} \right) H P_{2j}(n)
\]

\[
\sum_{j=1}^{n} \frac{1}{(a_j + b)^{2k+1}} \sin \frac{2\pi(a_j + b)}{m} = -\frac{1}{2^{2k+1}} \left( \cos \frac{2\pi b}{m} - \sum_{j=0}^{k} \frac{(-1)^j (2 \pi b)^{2j+1}}{(2j+1)!} \right) + \frac{1}{2(a_n + b)^{2k+1}} \left( \cos \frac{2\pi(a_n + b)}{m} - \sum_{j=0}^{k} \frac{(-1)^j (2 \pi (a_n + b))^{2j+1}}{(2j+1)!} \right) + \frac{1}{2} \left( \frac{-1)^{k-j} (2 \pi b)^{2k-2j}}{(2k-2j)!} \right) H P_{2j}(n)
\]

5.3 \( C_{2k+1}^m(n) \) and \( C_{2k+1}^m(a, b, n) \)

For all integer \( k \geq 0 \):

\[
\sum_{j=1}^{n} \frac{1}{j^{2k+1}} \cos \frac{2\pi j}{m} = \frac{1}{2^{2k+1}} \left( \cos \frac{2\pi b}{m} - \sum_{j=0}^{k} \frac{(-1)^j (2 \pi b)^{2j}}{(2j)!} \right) + \frac{1}{2} \left( \frac{-1)^{k-j} (2 \pi b)^{2k-2j}}{(2k-2j)!} \right) H P_{2j+1}(n)
\]

\[
\sum_{j=1}^{n} \frac{1}{j^{2k+1}} \sin \frac{2\pi j}{m} = -\frac{1}{2^{2k+1}} \left( \cos \frac{2\pi b}{m} - \sum_{j=0}^{k} \frac{(-1)^j (2 \pi b)^{2j}}{(2j)!} \right) + \frac{1}{2} \left( \frac{-1)^{k-j} (2 \pi b)^{2k-2j}}{(2k-2j)!} \right) H P_{2j+1}(n)
\]
5.4 $S_{2k}^m(n)$ and $S_{2k}^m(a, b, n)$

For all integer $k \geq 1$:

$$
\sum_{j=1}^{n} \frac{1}{2j^{2k}} \sin \frac{2\pi j}{m} = \frac{1}{2n^{2k}} \left( \sin \frac{2\pi n}{m} - \sum_{j=0}^{k-1} \frac{(-1)^j(2\pi n)^{2j+1}}{(2j+1)!} \right) - \sum_{j=0}^{k-1} \frac{(-1)^{k-j} \frac{1}{2(2k-1)!} \int_{0}^{1} (1-u)^{2k-1} \left( \cos \frac{2\pi nu}{m} \right) + \sum_{j=1}^{k} m^{k-j} \frac{1}{2(k-1)!} \int_{0}^{1} (1-u)^{k-1} \left( e^{m(n+b)u} - e^{mbu} \right) \coth \frac{mu}{2} du \right)
$$

6 Lerch’s $\Phi$ and the polylogarithm

By making use of the formulae we created for the partial Fourier sums, we are able to deduce formulae for Lerch’s $\Phi$ and the polylogarithm functions at the positive integers (both of which are generalizations of the Riemann zeta function). One starts by obtaining their partial sums and from there their limits.

Here, however, we only present the final partial sum expressions in order to make this paper a compilation of these interrelated formulae. The demonstrations are given in [5].

6.1 Partial Lerch’s $\Phi$ sums

If we combine and transform the formulae from [5], we are able to derive a single formula for the partial sums of the Lerch’s $\Phi$ function. For all integer $k \geq 1$ and all complex $m$:

$$
\sum_{j=1}^{n} \frac{e^{m(j+b)}}{(j+b)^k} = -\frac{e^{mb}}{2b^k} + \frac{e^{m(n+b)}}{2(n+b)^k} + \frac{1}{2b^k} \sum_{j=0}^{k} \frac{(mb)^j}{j!} - \frac{1}{2(n+b)^k} \sum_{j=0}^{k} \frac{(m(n+b))^{j}}{j!} + \sum_{j=1}^{k} m^{k-j} \frac{1}{(k-j)!} HP_j(n) + \frac{m^{k}}{2(k-1)!} \int_{0}^{1} (1-u)^{k-1} \left( e^{m(n+b)u} - e^{mbu} \right) \coth \frac{mu}{2} du \tag{7}
$$

Note we assumed $a = 1$, that is, $HP_j(n) = \sum_{j=1}^{n} 1/(j+b)$. Lerch’s $\Phi$ is obviously the limit of the above expression when $n$ tends to infinity.
6.2 Partial polylogarithm sums

When $b = 0$, we have an interesting particular case, the partial sums of the polylogarithm function. Therefore, for all integer $k \geq 1$ and all complex $m$:

$$\sum_{j=1}^{n} \frac{e^{mj}}{j^k} = \frac{e^{mn}}{2n^k} - \frac{1}{2n^k} \sum_{j=0}^{k} \frac{(mn)^j}{j!} + \sum_{j=1}^{k} \frac{m^{k-j}}{(k-j)!} H_j(n)$$

$$+ \frac{m^k}{2(k-1)!} \int_{0}^{1} (1-u)^{k-1} (e^{mu} - 1) \coth \frac{mu}{2} du$$

To obtain this expression, we just take the limit of (7) as $b$ tends to 0:

$$\lim_{b \to 0} \frac{e^{mb}}{2b^k} + \frac{1}{2b^k} \sum_{j=0}^{k} \frac{(mb)^j}{j!} = 0$$
References
