Abstract: Mantel’s Theorem asserts that a simple n vertex graph with more than $\frac{1}{4}n^2$ edges has a triangle (three mutually adjacent vertices). Here we consider a rainbow variant of this problem. We prove that whenever $G_1, G_2, G_3$ are simple graphs on a common set of n vertices and $|E(G_i)| > \left(\frac{26-2\sqrt{7}}{81}\right)n^2 \approx 0.2557n^2$ for $1 \leq i \leq 3$, then there exist distinct vertices $v_1, v_2, v_3$ so that (working with the indices modulo 3) we have $v_i v_{i+1} \in E(G_i)$ for $1 \leq i \leq 3$. We provide an example to show this bound is best possible. This also answers a question of Diwan and Mubayi. We include a new short proof of Mantel’s Theorem we obtained as a byproduct.

Key words and phrases: Mantel’s theorem, triangle, rainbow, extremal graph theory

1 Introduction

Throughout we shall assume that all graphs are simple. For a positive integer r we let $K_r$ denote a complete graph on r vertices and we let $K_{r,r}$ denote a balanced complete bipartite graph with r vertices in each part. A triangle in a graph G is a subgraph isomorphic to $K_3$. The starting point for this work is the following classical theorem, one of the first results in extremal graph theory.
Theorem 1.1 (Mantel [10]). If $G$ is a graph on $n$ vertices with $|E(G)| > \frac{1}{4}n^2$, then $G$ contains a triangle.

To see that this bound is best possible, observe that when $n$ is even, the complete bipartite graph $K_{\frac{n}{2}, \frac{n}{2}}$ has $\frac{n^2}{4}$ edges but no triangle.

In this article we consider a colourful variant of the above. Let $G_1, G_2, G_3$ be three graphs on a common vertex set $V$ and think of each graph as having edges of a distinct colour. Define a rainbow triangle to be three vertices $v_1, v_2, v_3 \in V$ so that $v_iv_{i+1} \in E(G_i)$ (where the indices are treated modulo 3). We will be interested in determining how many edges force the existence of a rainbow triangle. Is it true that if $|E(G_i)| > \frac{1}{4}n^2$ for $1 \leq i \leq 3$, then there exists a rainbow triangle? By taking $G_1 = G_2 = G_3$ we return to the setting of Mantel’s Theorem. In general, however, the answer to the former question is negative, as shown by the following construction.

Let $n$ be an integer and let $0 < t < \frac{1}{4}$ have the property that $tn$ is an integer. Let $V$ be a set of $n$ vertices, and partition $V$ into $\{A, B, C\}$ where $|B| = |C| = tn$ and $|A| = (1 - 2t)n$. Construct three graphs $G_1, G_2, G_3$ on $V$ as follows: Let $G_1$ consist of a clique on $A$ plus a clique on $B$, let $G_2$ consist of a clique on $A$ plus a clique on $C$, and let $G_3$ consist of all edges except for those with both ends in $A$ (see Figure 1). A simple check reveals that there is no rainbow triangle for this triple of graphs. Furthermore $|E(G_1)| = |E(G_2)| = \left(\frac{n-2tn}{2}\right) + \left(\frac{tn}{2}\right) = \frac{2-8t+10t^2}{4}n^2 - \frac{1-2t}{2}n$ while $|E(G_3)| = \left(\frac{n}{2}\right) - \left(\frac{n-2tn}{2}\right) = \frac{8t-8t^2}{4}n^2 - tn$.

It is easy to verify that $2 - 8t + 10t^2 > 1$ and $8t - 8t^2 > 1$ whenever $t$ satisfies $\frac{1}{2} - \frac{1}{2\sqrt{2}} < t < 0.155 < \frac{2 - \sqrt{3/2}}{5}$. Thus, if we pick $0.147 < t < 0.155$, then for every sufficiently large $n$ (such that $tn$ is an integer) there are graphs $G_1, G_2, G_3$ on a common set of $n$ vertices without a rainbow triangle that satisfy $|E(G_i)| > \frac{1}{4}n^2$ for $1 \leq i \leq 3$. However, a slight increase in the number of edges forces the occurrence of a rainbow triangle. Throughout the paper we fix the value $\tau = \frac{4-\sqrt{3}}{9}$, so $\tau^2 \approx 0.0226$, and $\frac{1+\tau^2}{4} = \frac{26-2\sqrt{7}}{81} \approx 0.2557$.

Theorem 1.2. Let $G_1, G_2, G_3$ be graphs on a common set of $n$ vertices. If $|E(G_i)| > \frac{1+\tau^2}{4}n^2$ for $1 \leq i \leq 3$, then there exists a rainbow triangle.

Only after finishing the paper we have learned about work of A. Diwan and D. Mubayi [6] (see also https://faculty.math.illinois.edu/~west/regs/turancol.html). They consider two-colored
variants of Turán’s theorem, prove a couple of them and pose a problem about three-colored version of Mantel’s theorem. Thus, the above theorem is an asymptotically tight solution to their problem.

Theorem 1.2 is sharp in the sense that $\tau^2$ cannot be replaced by a smaller constant. To see this, note that $t = \tau$ is the unique solution to the quadratic equation $2 - 8t + 10t^2 = 8t - 8t^2$ with $0 < t < \frac{1}{4}$. For this number $\tau$ both sides of this quadratic equation are equal to $1 + \tau^2$. It follows by the construction showed above (taking $n$ large and $t$ close to $\tau$) that for every $\varepsilon > 0$ there exist simple graphs $G_1, G_2, G_3$ on a common set of $n$ vertices without a rainbow triangle that satisfy $|E(G_i)| > (\frac{1+\tau^2}{4} - \varepsilon)n^2$ for $1 \leq i \leq 3$.

We were also able to use some of the ideas in our proof to obtain a new short proof of Mantel’s Theorem. We include this proof at the beginning of the main section since it provides a nice example of a technique later used to prove Theorem 1.2.

Since $\tau^2$ is not rational, there does not exist a graph $G$ with $|V(G)| = n$ and $|E(G)| = \frac{1+\tau^2}{4}n^2$, and thus there is no finite tight example for our problem. This inconvenience is removed in the setting of graph limits and graphons: a growing sequence constructed as in the previous paragraph would converge to three graphs, each with density $\frac{1+\tau^2}{2}$ and without a rainbow triangle. In this setting, Razborov’s flag algebra machinery may give an alternative proof of our result, and be useful in extending it. Indeed, a flag-algebra proof has already been obtained (independently from us) by E. Culver, B. Lidický, F. Pfender, and J. Volec [4]. Their proof even gives a precise characterization of all extremal configurations with sufficiently large number of vertices. To further explore this area of “rainbow extremal graph theory” each approach has its pluses and minuses, ours has the advantage of being verifiable by hand. We suggest some potential interesting directions to proceed with the following problems.

**Problem 1.3.** For what real numbers $\alpha_1, \alpha_2, \alpha_3 > 0$ is it true that every triple of graphs $G_1, G_2, G_3$ satisfying $|E(G_i)| > \alpha_i n^2$ must have a rainbow triangle?

Turán’s Theorem generalizes Mantel’s Theorem by proving that for every integer $r \geq 2$, a simple $n$ vertex graph with more than $(1 - \frac{1}{r-1})\frac{n^2}{2}$ edges has a $K_r$ subgraph. Analogously, one may consider the following.

**Problem 1.4.** For every positive integer $r$, what is the smallest real number $\delta_r$ so that whenever $G_1, \ldots, G_{\binom{r}{2}}$ are graphs on a common set of $n$ vertices with $|E(G_i)| \geq \delta_r n^2$ for every $1 \leq i \leq \binom{r}{2}$, there exists a rainbow $K_r$, i.e., a set of $r$ vertices and one edge from each $G_i$ that together form a clique on this set of vertices.

We can also consider this problem for the number of graphs (colours) being different from $\binom{r}{2}$, with an appropriately modified notion of “rainbow”. For $r = 3$ and more than three graphs the answer is $\delta_r = 1/4$ with the extremal configuration being all graphs identical complete biparite (Theorem 1.2 of [9]). When the number of graphs is less than $\binom{r}{2}$, one can study the existence of other colour patterns. For $r = 3$ and two graphs a problem with such a flavor was considered in [5].

We will finish this section by a sample of other results and conjectures that can be described as rainbow. Perhaps historically first is a result of Bárany [3] in combinatorial geometry. He obtained a rainbow (also termed colourful) version of Carathéodory’s theorem; see also [8].

More recent, and closer to our present topic, is the study of rainbow Erdős-Ko-Rado theorems. Let us use $f(n, r, k)$ to denote the EKR number – the smallest $m$ such that every $r$-uniform hypergraph with $n$ vertices and $m$ edges has a matching of size $k$. (Recall that the classical Erdős-Ko-Rado theorem states...
that $f(n, r, 2) = \binom{n-1}{r-1}$ whenever $n \geq 2r$. Aharoni and Howard [1] conjecture the following rainbow version:

**Conjecture 1.5** (Aharoni, Howard). Let $H_1, \ldots, H_k$ be $r$-uniform hypergraphs on the same set of $n$ vertices, each having $f(n, r, k)$ hyperedges. Then there is a rainbow matching: a matching $\{e_1, \ldots, e_k\}$ such that $e_i \in E(H_i)$ for $i = 1, \ldots, k$.

In [1] this conjecture is discussed for hypergraphs that are balanced $r$-partite and it is proved there with this restriction for $r = 3$. We finish with a conjecture motivated by Dirac’s condition for hamiltonicity.

**Conjecture 1.6** (Aharoni). Given graphs $G_1, \ldots, G_n$ on the same vertex set of size $n$, each having minimum degrees at least $n/2$, there exists a rainbow Hamilton cycle: a cycle with edge-set $\{e_1, \ldots, e_n\}$ such that $e_i \in E(G_i)$ for $i = 1, \ldots, n$.

## 2 Proof

A key idea in the proof of Theorem 1.2 will be to analyze the structure of the subgraphs induced by pairs of edges in a matching of a graph. We can use a similar (but simpler) approach to obtain a short proof of Mantel’s Theorem.

**Lemma 2.1.** Let $G$ be a graph and $P$ be the set of pairs of distinct vertices $\{x, y\} \subseteq V(G)$ such that $N(x) \cap N(y) \neq \emptyset$. If $M$ is a maximal matching in $G$, then $|P| \geq |E(G)| - |M|$.

**Proof.** Let $M = \{e_1, e_2, \ldots, e_k\}$ be a maximal matching of $G$. Since $M$ is maximal, we know that every edge $e \in E(G)$ has at least one endpoint in common with an edge of $M$. For $e \in E(G) \setminus M$, let $s(e)$ be the smallest integer such that $e \cap e_{s(e)} \neq \emptyset$, and take $f(e) = e \Delta e_{s(e)}$. It is easy to see that $f : E(G) \setminus M \to P$ is an injective function, and the result follows. \qed

**Proof of Theorem 1.1.** Let $G$ be a triangle-free graph and $M$ a maximum matching of $G$. Since $G$ has no triangles then $|P| + |E(G)| \leq \binom{n}{2}$, and by Lemma 2.1 we have $|E(G)| - \frac{1}{4}n \leq |E(G)| - |M| \leq |P|$. By combining these inequalities, we get $2|E(G)| \leq \binom{n}{2} + \frac{1}{4}n$, and so $|E(G)| \leq \frac{1}{4}n^2$. \qed

There are a great many proofs of Mantel’s Theorem and we borrow ideas from a few. In particular, the following lemma we require is a variant of an “entropy minimizing” proof ([7], see also [2]). For a graph $G$ and a set $X \subseteq V(G)$ we let $G[X]$ denote the subgraph of $G$ induced on $X$ and we let $e_G(X) = |E(G[X])|$. If $Y \subseteq V(G)$ is disjoint from $X$ we let $e_G(X, Y) = \{|xy \in E(G) | x \in X \text{ and } y \in Y\}$. As usual, if the graph $G$ is clear from context, we drop the subscript $G$.

**Lemma 2.2.** Let $G$ be a graph and let $\{Z_0, Z_1\}$ be a partition of $V(G)$. If for $i = 0, 1$, every $z \in Z_i$ has the property that $N(z) \cap Z_{1-i}$ is a clique, then

$$e(Z_0, Z_1) \leq e(Z_0) + e(Z_1) + \frac{1}{2}(|Z_0| + |Z_1|).$$

**Proof.** We say that two vertices $z, z' \in Z_i$ ($i = 0, 1$ is the same for both $z$, $z'$) are twins if they have the same closed neighbourhood, $N[z] = N[z']$. Observe that being twins is an equivalence relation. Now we choose a graph $G$ so that
A RAINBOW VERSION OF MANTEL’S THEOREM

(1) \( e(Z_0, Z_1) − e(Z_0) − e(Z_1) \) is maximum; and

(2) the total number of pairs of vertices that are twins is maximum (subj. to (1)). Recall that if a pair of vertices are twins, then they both are in \( Z_0 \) or both in \( Z_1 \).

Observe that it is sufficient to verify the desired bound for this \( G \). Now we fix \( i = 0, 1 \) and let \( w', w'' \in Z_i \) be adjacent. Consider the graph \( G' (G'') \) obtained from \( G \) by deleting \( w' (w'') \) and adding a new vertex and making it a twin of \( w' (w'') \). It is immediate from this construction that both \( G' \) and \( G'' \) satisfy the condition that \( N(z) \cap Z_{1−j} \) is a clique for every \( j = 0, 1 \) and \( z \in Z_j \). If one of \( G' \) or \( G'' \) is superior to the original graph \( G \) for the first optimization criterion (1) we have a contradiction with the choice of \( G \). It follows that all three graphs \( G, G', G'' \) are tied relative to this criterion. If \( w' \) and \( w'' \) are not twins, then one of \( G' \) or \( G'' \) is superior to \( G \) relative to the second optimization criterion (2). To see this, observe that if \( x, y \in Z_{1−j} \) are twins in \( G \), then they are also twins in \( G' \) and in \( G'' \). If the twin-equivalence class of \( w' (w'') \) has \( a' (a'' \text{ elements}) \), then \( G' \) loses \( a' − 1 \) twin-pairs and gains \( a'' \) new ones; thus if \( a'' \geq a' \), then \( G' \) is superior to \( G \), a contradiction to the choice of \( G \). (If \( a' > a'' \), we use \( G'' \).) It follows that \( w' \) and \( w'' \) must be twins.

As being twins is an equivalence relation, we conclude that the graph \( G \) is a disjoint union of complete graphs. Consider a component \( H \) of \( G \) with \( |V(H) \cap Z_0| = \ell \) and \( |V(H) \cap Z_1| = m \). In this case the sets

\[
C = E(H) \cap E(Z_0, Z_1) \text{ and } D = E(H) \setminus C
\]

satisfy

\[
|D| − |C| = \binom{\ell}{2} + \binom{m}{2} − \ell m = \frac{1}{2} (\ell − m)^2 − \ell + m \geq −\ell + m
\]

and the lemma follows by summing these inequalities over each component. \( \square \)

Any counterexample to Theorem 1.2 would immediately imply the existence of large counterexamples by way of “blowing up” vertices. More precisely, suppose that \( G_1, G_2, G_3 \) contradict the theorem, and let \( k \) be a positive integer. Now replace every vertex \( v \) by a set \( X_v \) consisting of \( k \) isolated vertices, and for each graph \( G_i \), replace every edge \( uv \) by all possible edges between the sets \( X_u \) and \( X_v \). This operation magnifies the number of vertices by a factor of \( k \) and the number of edges in each \( G_i \) by a factor of \( k^2 \), and thus yields another counterexample. Moreover, if \( \min_{1 \leq i \leq 3} \frac{|E(G_i)|}{n^2} - \frac{1 + \tau^2}{4} = \varepsilon \) then this property will also be preserved. So, the resulting graph on \( kn \) vertices will exceed the bound by \( \varepsilon k^2 n^2 \) edges (\( \varepsilon \) is positive, as \( \tau^2 \) is irrational). The condition in Theorem 1.2 implies \( |E(G_i)| + |E(G_j)| \geq \frac{1 + \tau^2}{2} n^2 \) for all \( 1 \leq i < j \leq 3 \). Hence, by the above observation, to prove Theorem 1.2 it suffices to establish the following result.

**Lemma 2.3.** Let \( G_1, G_2, G_3 \) be graphs on a common set \( V \) of \( n \geq 1 \) vertices. If

\[
|E(G_i)| + |E(G_j)| \geq \frac{1 + \tau^2}{2} n^2 + \frac{3}{2} n
\]

holds for every \( 1 \leq i < j \leq 3 \), then there exists a rainbow triangle.

The statement of the above lemma replaces a bound on the number of edges in each graph \( G_i \) by a bound on the sum of the number of edges in any two such graphs. This adjustment will allow us to forbid certain types of induced subgraphs of a possible minimal counterexample, as demonstrated by Lemma 2.4 below.
To proceed, we need some further notation. For the remainder of this article we will be focusing on the proof of Lemma 2.3, so we will always have three graphs $G_1, G_2, G_3$ on a common set of vertices $V$. Abbreviating our usual notation, if $X \subseteq V$ and $1 \leq i \leq 3$ we will let $e_i(X) = e_{G_i}(X)$ and we define $e(X) = e_1(X) + e_2(X) + e_3(X)$. Similarly, if $Y \subseteq V$ is disjoint from $X$, then we let $e_i(X,Y) = e_{G_i}(X,Y)$ and we define $e(X,Y) = e_1(X,Y) + e_2(X,Y) + e_3(X,Y)$. We also let $E_i = E(G_i)$.

**Lemma 2.4.** A counterexample to Lemma 2.3 with $n$ minimum does not contain a nonempty proper subset of vertices $X$ for which $G[X]$ has a perfect matching for all $1 \leq i \leq 3$.

**Proof.** Let $G_1, G_2, G_3$ be a minimal counterexample to Lemma 2.3. Suppose (for a contradiction) that there is a set of vertices $X$, such that every colour induces a graph with a perfect matching on $X$. Let $|X| = \ell$ and let $M$ be a perfect matching in the graph $G_3[X]$. If $xx' \in M$ and $y \in V \setminus \{x, x'\}$, then $e_1(y, \{x, x'\}) + e_2(y, \{x, x'\}) \leq 2$ (otherwise there would be a rainbow triangle). Summing this over all edges of $M$ and $y \in V \setminus X$ gives us $e_1(X, V \setminus X) + e_2(X, V \setminus X) \leq \ell(n - \ell)$.

If $uu', vv' \in M$ and $uv \in E_1 \cap E_2$, then $uv', uu' \notin E_1 \cup E_2$. This implies that $e_1(\{u, u'\}, \{v, v'\}) + e_2(\{u, u'\}, \{v, v'\}) \leq 4$ and thus, on average, an edge in $E(X) \setminus M$ contributes at most 1 to $e_1(X) + e_2(X)$; obviously an edge of $M$ contributes at most 2. Hence $e_1(X) + e_2(X) \leq \frac{\ell}{2} + \binom{\ell}{2} = \frac{\ell^2}{2}$. Therefore

$$|E(G_1 - X)| + |E(G_2 - X)| \geq |E(G_1)| + |E(G_2)| - \ell(n - \ell) - \frac{\ell^2}{2}$$

$$\geq \frac{1+\frac{\ell}{2}n}{2}^2 n^2 + \frac{3}{2}n - \ell n + \frac{\ell^2}{2}$$

$$\geq \frac{1+\frac{\ell}{2}(n - \ell)}{2}^2 (n - \ell)^2 + \frac{3}{2}(n - \ell).$$

It follows from the same argument applied to the other two pairs of colours that the graphs $G_1 - X$, $G_2 - X$, and $G_3 - X$ form a smaller counterexample, contradicting minimality. \hfill \square

![Figure 2: The three situations described in the first instance of Observation 2.5. Colors $i$, $j$ and $k$ are depicted by green, red and blue respectively. If an edge is not depicted it means that the edge is not present, if it is dashed it indicates that it may be present.](image)

**Observation 2.5.** Let $G_1, G_2, G_3$ be a counterexample to Lemma 2.3 for which $n$ is minimum and let $X, X' \subseteq V$ be disjoint sets with $|X| = |X'| = 2$. Suppose also that $n \geq 5$. If $e(X) = e(X') = 2$ and $\{i, j, k\} = \{1, 2, 3\}$ then we have:
The first part follows from the observation that the graph induced on $X \cup X'$ cannot have two nonadjacent edges of colour $k$ (otherwise Lemma 2.4 would be violated) and a straightforward case analysis (leaning on the assumption that there is no rainbow triangle).

To show the second part, recall that Lemma 2.4 implies there is no pair of vertices adjacent in all three colors. We make a similar case analysis, obtaining that the only configuration with $e(X, X') = 5$ is the one depicted in Figure 3 (b).

\section*{Proof of Lemma 2.3} Suppose (for a contradiction) that Lemma 2.3 is false, and choose a counterexample $G_1, G_2, G_3$ with common vertex set $V$ so that $n = |V|$ is minimum. It follows that $n > 5$ (otherwise the given bound on $|E(G_i)| + |E(G_j)|$ is greater than $2 \binom{n}{2}$). Recall that by Lemma 2.4 there does not exist a pair of vertices adjacent in all three graphs $G_1, G_2, G_3$. Say that a set $X \subseteq V$ with $|X| = 2$ is a digon if $e(X) = 2$. Now, choose a maximum sized collection $M$ of pairwise disjoint digons. For $1 \leq i < j \leq 3$ define $M_{i,j}$ to be the subset of $M$ consisting of those digons $X$ so that $e_i(X) = e_j(X) = 1$. For every $1 \leq i < j \leq 3$ let $X_{i,j}$ be the union of the digons in $M_{i,j}$ and let $D = V \setminus (X_{1,2} \cup X_{1,3} \cup X_{2,3})$.

\textbf{Claim 1.} The set $D$ satisfies the following.

1. If $x, x' \in D$ then $e(x, x') \leq 1$.

2. If $X \in M_{i,j}$ and $y \in D$ satisfy $e(X, y) \geq 3$, then $e_k(X, y) = 0$ (with $\{i, j, k\} = \{1, 2, 3\}$).
3. For every $X \in M$ there is at most one vertex $y \in D$ for which $e(X, y) = 4$.

Proof of Claim 1. The first part follows from the maximality of $M$. For the second part, if $X = \{x, x'\}$ and, say, $xy \in E_i$ then $x'y \notin E_i \cup E_j$, thus $e(X, y) \leq 2$. For the last part, assume again $X = \{x, x'\} \in M_{i,j}$. For contradiction, suppose there are distinct $y, y' \in D$ such that $e(X, y) = e(X, y') = 4$. As no edge is contained in all three subgraphs, both $\{x, y\}$ and $\{x', y\}$ are digons, so we may use them in $M$ instead of $\{x, x'\}$, contradicting the maximality of $M$. □

The plan for the rest of the proof is to use our understanding of the structure of minimal counterexample (as given by Observation 2.5 and by Claim 1) to derive several inequalities for $|X_{1,2}|, |X_{2,3}|, |X_{1,3}|$ and $|D|$. These inequalities will appear as (1)–(3) below. As we will show they have no solution, we will reach our desired contradiction.

In order to simplify calculations we now replace the graphs $G_i$ by graphs having simpler structure (and possibly several rainbow triangles). First off, for every $X \in M$, if there exists $y \in D$ with $e(X, y) = 4$, then delete one edge between $X$ and $y$. (Note that by the above claim this removes at most $\frac{n}{2}$ edges in total.) Next suppose that $\{i, j, k\} = \{1, 2, 3\}$ and $X, X' \in M_{i,j}$ satisfy $e(X, X') > 0$. In this case we delete all edges between $X$ and $X'$ (in all three graphs) and then add back three edges between $X$ and $X'$ in $G_i$ and three such edges in $G_j$. Note that for this operation the first part of Observation 2.5 implies that the sum of the edge-count for any two of the graphs does not decrease. Let $G'_1, G'_2, G'_3$ be the graphs resulting from applying these operations whenever possible. By the above,

$$\min_{1 \leq i < j \leq 3} |E(G'_i)| + |E(G'_j)| \geq \frac{1+\varepsilon^2}{2}n^2 + n.$$ 

Note that the sets $M, M_{i,j}, X_{i,j}$ and $D$ do not change by going to $G'_1, G'_2, G'_3$. The graphs $G'_1, G'_2, G'_3$ may have a rainbow triangle. However, each such triangle involves an edge between two digons $X, X'$ in the same set $M_{i,j}$ for which $e_{G'_i}(X, X') = e_{G'_j}(X, X') = 3$.

Before making our next modification, we pause to construct an auxiliary graph. For every $1 \leq i \leq 3$ let $\{i, j, k\} = \{1, 2, 3\}$ and construct a simple graph $H$ with vertex set $M_{i,j} \cup M_{i,k}$ by the following rules:

- If $X, X' \in M_{i,j}$ are distinct, we add an edge between them if $e_{G'_i}(X, X') \leq 3$. We do the same with $k$ in place of $j$.
- If $X \in M_{i,j}$ and $X' \in M_{i,k}$, we add an edge between them if $e'_i(X, X') = 5$ (using $e'_i = e_{G'_1} + e_{G'_2} + e_{G'_3}$).

Claim 2. The graph $H$ satisfies the hypothesis of Lemma 2.2 with $Z_0 = M_{i,j}$ and $Z_1 = M_{i,k}$.

Proof of Claim 2. For the sake of contradiction assume that there are digons $X, X' \in M_{i,j}$ and $Y \in M_{i,j}$ such that both $YX$ and $YX'$ are edges of $H$, but $XX'$ is not. It follows that $e_{G'_i}(X, X') = 4$, so the edges between $X$ and $X'$ have not been modified when constructing graphs $G'_1, G'_2, G'_3$. Moreover, as $e'_i(X, Y) = e'_j(X', Y) = 5$, the second part of Observation 2.5 describes precisely the structure of edges between $X \cup X'$ and $Y$, and we find a rainbow triangle (not only in $G'$, but also in $G$). □

By Lemma 2.2 we have $e_H(Z_0) + e_H(Z_1) \geq e_H(Z_0, Z_1) - (|M_{i,j}| + |M_{i,k}|)/2$. Note that by the definition of $H$, $e_H(Z_0)$ is at most the number of missing edges of colour $j$ in $X_{i,j}$, and $e_H(Z_1)$ is at most the number
of missing edges of colour $k$ in $X_{i,k}$. Also, $e_H(Z_0, Z_1)$ is the number of pairs $(X, X')$ where $X \in M_{i,j}$ and $X' \in M_{i,k}$ that satisfy $e(X, X') = 5$.

Based on this observation, we now construct a new triple of graphs. For each $i = 0, 1, 2$ and for $j < k$ such that $\{i, j, k\} = \{0, 1, 2\}$ we modify the induced subgraphs of $G'_1, G'_2, G'_3$ on $X_{i,j} \cup X_{i,k}$:

For every $X \in M_{i,j}$ and $X' \in M_{i,k}$ we modify the graph between $X$ and $X'$ as follows: If $e(X, X') = 5$ (so, by Lemma 2.2, $e_j(X, X') = 3$ and $e_j(X, X') = 1 = e_k(X, X')$) then delete the edges between $X$ and $X'$ of colours $j$ and $k$ and then add back one new edge of colour $j$ or $k$ (to be chosen later) so that the new edge is not parallel to any of the three edges of colour $i$. Otherwise, if $e(X, X') \leq 4$ we rearrange the edges between $X$ and $X'$ so that every $x \in X$ and $x' \in X'$ satisfy $e(x, x') \leq 1$. Next, we add to $X_{i,j}$ all missing edges of colour $j$ and to $X_{i,k}$ all missing edges of colour $k$. We let $\text{loss}(j, i)$ denote the decrease of the number of edges of $G'_j$ (thus $\text{loss}(j, i)$ is negative, if the number of edges of $G'_j$ has increased). Similarly for $k$ in place of $j$. It follows from Lemma 2.2 and the above discussion that $\text{loss}(j, i) + \text{loss}(k, i) \leq (|M_{i,j}| + |M_{i,k}|)/2 \leq n/4$.

Moreover, we can choose whether to decrease the number of edges of $G'_j$ or $G'_k$. Thus, we may ensure that $\text{loss}(j, i) < 0$ only if $\text{loss}(k, i) \leq 0$ (and vice versa). Consequently, we have

$$\text{loss}(j, i) \leq n/4 \quad \text{and} \quad \text{loss}(k, i) \leq n/4.$$ 

Summing up, we may arrange the modification process so that each colour class of edges decreases in size by at most $\frac{n}{2}$. So, if we let $G''_1, G''_2, G''_3$ be the graphs resulting from our operation, we have:

$$\min_{1 \leq i < j \leq 3} |E(G''_i)| + |E(G''_j)| > \frac{1 + \tau^2}{2} n^2.$$ 

To complete the proof, we will now show that the above density condition is incompatible with the structure of the graphs $G''_i$. Let $G'' = \bigcup_{i \leq 3} G''_i$. Below we use the notation $e(S)$, $e(S, S')$, $e_i(S)$ for the parameters in the graph $G''$. The construction of the graphs $G''_i$ implies:

Claim 3. 1. The subgraph of $G''$ induced on $X_{i,j}$ is complete in colours $i$ and $j$ and empty in the remaining colour.

2. If $x \in X_{i,j}$ and $x' \in X_{i,k}$ where $j \neq k$, then $e(x, x') \leq 1$.

3. If $x, x' \in D$ then $e(x, x') \leq 1$.

4. If $X \in M_{i,j}$ and $y \in D$ then $e(X, y) \leq 3$ and if $e(X, y) = 3$, then all edges between $X$ and $y$ have colour $i$ or colour $j$.

Let $a, b, c, d$ be such that $an = |X_{1,2}|$, $bn = |X_{1,3}|$, $cn = |X_{2,3}|$, and $dn = |D|$. We shall assume (without loss of generality) that $a \geq b \geq c$, and we note that $a + b + c + d = 1$. Next, we will apply our density bounds to get some inequalities relating $a, b, c,$ and $d$. For the purposes of these calculations, it is convenient to introduce a density function. For any graph $H$ we define $d(H) = \frac{2|E(H)|}{|V(H)|^2}$. Note that with this terminology we have

$$\min_{1 \leq i < j \leq 3} d(G''_i) + d(G''_j) > 1 + \tau^2.$$ 

ADVANCES IN COMBINATORICS, 2020:2, 12pp.
First, we consider just colours 2 and 3. Note that if \(x, y \in V\) are adjacent in both \(G_2'\) and \(G_3''\), then either \(x, y \in X_{2,3}\) or one of these vertices is in \(X_{2,3}\) and the other is in \(D\). Furthermore, in this last case, if say \(y \in D\) and \(x \in X_{2,3}\) has \(X = \{x, y\} \subseteq M_{2,3}\), then \(e_2(X, y) + e_3(X, y) \leq 3\). It follows from this that
\[
|E(G_2')| + |E(G_3'')| \leq \binom{n}{2} + \binom{m}{2} + \frac{1}{2}cdn^2 \leq \frac{3}{2}n^2 + c^2d^2 + c(d) \leq 2.5.
\]
Multiplying this equation through by \(\frac{2}{n^2}\) then gives the useful bound
\[
c^2 + cd \geq d(G_2') + d(G_3'') - 1 \geq \tau^2. \tag{2.1}
\]
Next, we will count edges of \(G_1'\) twice, edges of \(G_2'\) twice, and edges of \(G_3''\) three times. An edge within \(X_{1,2}\) is counted four times in total, edge within \(X_{1,3}\) or within \(X_{2,3}\) five times in total. Edge between \(X_{1,2}\) and \(X_{2,3}\) (etc.) at most three times. Finally, for \(y \in D\) and \(x \in M_{2,3}\), we count the two edges between \(y\) and \(X\) at most \(2 + 3 + 3\) times, thus we have at most \(4|D||X_{2,3}|\) edges here. The same count applies for \(M_{1,3}\) in place of \(M_{2,3}\); for \(M_{1,2}\) we get at most \(3|D||X_{1,2}|\). This implies
\[
2|E(G_1')| + 2|E(G_2')| + 3|E(G_3'')| - 3\binom{n}{2} \leq \binom{an}{2} + \binom{bn}{2} + \binom{cn}{2} + bdn^2 + cdn^2,
\]
giving us the bound
\[
a^2 + 2b^2 + 2c^2 + 2bd + 2cd \geq 2d(G_1') + 2d(G_2') + 3d(G_3'') - 3.
\]
We can express the right hand side as \(\frac{1}{2}(d(G_1') + d(G_2')) + \frac{3}{2}(d(G_1') + d(G_3'')) + \frac{3}{2}(d(G_2') + d(G_3'')) - 3\) and use the lower bound for each of the sum of two densities, yielding
\[
a^2 + 2b^2 + 2c^2 + 2bd + 2cd \geq \frac{1}{2} + \frac{3}{2} \tau^2. \tag{2.2}
\]
Finally, \(|E(G_1')| + |E(G_2')| + |E(G_3'')| - \binom{n}{2} \leq \binom{an}{2} + \binom{bn}{2} + \binom{cn}{2} + \frac{1}{2}(a + b + c)d^2n^2\) gives us the inequality (strict one, as \(\tau^2\) is irrational)
\[
a^2 + b^2 + c^2 + d(a + b + c) > \frac{1}{2} + \frac{3}{2} \tau^2. \tag{2.3}
\]
We claim that there do not exist nonnegative real numbers \(a, b, c, d\) with \(a \geq b \geq c\) and \(a + b + c + d = 1\) satisfying the inequalities \(2.1\), \(2.2\), and \(2.3\). To prove this, first note that inequality \(2.1\) (and the quadratic formula) imply
\[
c \geq \frac{-d + \sqrt{d^2 + 4 \tau^2}}{2}. \tag{2.4}
\]
Now \(b \geq c\) and inequality \(2.4\) imply \(b + c + d \geq \sqrt{d^2 + 4 \tau^2}\). This gives us the following useful upper bound on \(a\)
\[
a \leq 1 - \sqrt{d^2 + 4 \tau^2} \leq 1 - 2 \tau. \tag{2.5}
\]
To get a lower bound on \(a\), observe that \(a \geq b \geq c\) and inequality \(2.3\) give us \(\frac{1}{2} + \frac{3}{2} \tau^2 < a^2 + b^2 + c^2 + d(1 - d) \leq 3a^2 + \frac{1}{4}\). It follows that \(a \geq \sqrt{\frac{1}{12} + \frac{3}{2} \tau^2} \geq 2 \tau\). Combining this lower bound on \(a\) with the upper bound \(2.5\) gives the following useful inequality
\[
a^2 + (1 - a)^2 \leq 1 - 4 \tau + 8 \tau^2.
\]
The above bound together with (2.2) implies
\begin{equation*}
\frac{1}{2} + \frac{7}{2} \tau^2 \leq a^2 + (1 - a)^2 + b^2 + c^2 - 2bc - d^2 \leq 1 - 4\tau + 8\tau^2 + (b - c)^2 - d^2.
\end{equation*}
However, \( \tau \) satisfies the equation \( \frac{1}{2} + \frac{7}{2} \tau^2 = 1 - 4\tau + 8\tau^2 \) so the above simplifies to give
\begin{equation*}
b - c \geq d. \quad (2.6)
\end{equation*}
Note that since \( b \geq d \) we have \( 1 \geq a + b + d \geq 3d \) and thus \( d \leq \frac{1}{3} \). At this point we have \( c \geq \frac{-d + \sqrt{d^2 + 4\tau^2}}{2} \) and \( b \geq \frac{d + \sqrt{d^2 + 4\tau^2}}{2} \) and we will show that this contradicts (2.3). To see this, note that under the assumption \( a \geq b \geq c \) and \( a + b + c = 1 - d \) the quantity \( a^2 + b^2 + c^2 \) is maximized when \( b \) and \( c \) are as small as possible and \( a \) is as large as possible. Thus
\begin{equation*}
\frac{1}{2} + \frac{3}{2} \tau^2 < a^2 + b^2 + c^2 + d(1 - d)
\end{equation*}
\begin{equation*}
\leq (1 - d - \sqrt{d^2 + 4\tau^2})^2 + (d + \sqrt{d^2 + 4\tau^2})^2 + (d + \sqrt{d^2 + 4\tau^2})^2 + d(1 - d)
\end{equation*}
\begin{equation*}
= 1 + 2d^2 - d + 6\tau^2 - 2(1 - d)\sqrt{d^2 + 4\tau^2}.
\end{equation*}
Using the identity \( \frac{1}{2} + \frac{9}{2} \tau^2 = 4\tau \) and rearranging gives us
\begin{equation*}
2(1 - d)\sqrt{d^2 + 4\tau^2} < 4\tau + 2d^2 - d. \quad (2.7)
\end{equation*}
The above equation immediately implies \( d > 0 \). From here a straightforward calculation gives the contradiction \( d > \frac{1 - 2\tau^2 + \sqrt{(1 - 2\tau^2)^2 + 16(1 - 23\tau^2)}}{8} \approx 0.485 > \frac{1}{3} \). (To check this by hand, square both sides of (2.7) and observe that the left and right sides are degree 4 polynomials in \( d \) with matching highest order terms and matching constants; cancel these terms, divide by \( d \), apply the quadratic formula and use the fact \( 9\tau^2 - 8\tau + 1 = 0 \) for simplification.)
