TAUTOLOGICAL RELATIONS FOR STABLE MAPS TO A TARGET VARIETY

YOUNGHAH BAE

Abstract. We define tautological relations for the moduli space of stable maps to a target variety. Using the double ramification cycle formula for target varieties of Janda-Pandharipande-Pixton-Zvonkine [17], we construct non-trivial tautological relations parallel to Pixton’s double ramification cycle relations for the moduli of curves. Examples and applications are discussed.

1. Introduction

1.1. Tautological relations on the moduli space of stable curves. Let \( \overline{M}_{g,n} \) be the moduli space of stable curves of genus \( g \) with \( n \) marked points. It is a smooth Deligne-Mumford stack of dimension \( 3g - 3 + n \) and has both singular and Chow cohomology theories. Mumford [20] initiated the study of the subring of tautological classes

\[ R^*(\overline{M}_{g,n}) \subseteq A^*(\overline{M}_{g,n})_Q \]

of the Chow ring, which we now call the tautological ring – see [10, Section 1] for an introduction and basic definitions. One advantage of considering the tautological ring is that there is a canonical set of additive generators of \( R^*(\overline{M}_{g,n}) \) by boundary strata together with basic \( \psi \) and \( \kappa \) classes [14]. A fundamental goal is to find all linear relations among these additive generators – such relations are called tautological relations. For an excellent survey of this topic, see [26].

Because few tools exist to handle the geometry of moduli spaces of stable curves in higher genus, finding new tautological relations is not easy. A breakthrough appeared in Pixton’s note [27], which was inspired by the Faber-Zagier conjecture on tautological relations in \( A^*(M_g) \) proven in [24]. Pixton conjectured a systematic means of writing down tautological relations in terms of graph sums. His conjecture was proven in cohomology [23] using the theory of Witten’s 3-spin class and in Chow [15] using the equivariant Gromov-Witten theory of \( \mathbb{P}^1 \).

1.2. Tautological relations on the moduli space of stable maps. Let \( X \) be a nonsingular projective variety over \( \mathbb{C} \). For an effective curve class \( \beta \in H_2(X, \mathbb{Z}) \) and nonnegative integers \( g \) and \( n \), we consider the moduli space of stable maps \( \overline{M}_{g,n,\beta}(X) \). A closed point of the moduli space corresponds to a morphism from a connected nodal curve \( C \) of genus \( g \) with \( n \) marked points to \( X \),

\[ f : (C, x_1, \cdots, x_n) \to X, \quad f_*[C] = \beta. \]
By the stability condition, the data (1.1) is required to have only finitely many automorphisms – see [12] for a foundational treatment. Unlike $\mathcal{M}_{g,n}$, the moduli space of stable maps is typically not smooth and can have many connected components of different dimensions. Nevertheless, $\mathcal{M}_{g,n,\beta}(X)$ has a natural perfect obstruction theory of expected dimension
\[ \text{vdim} = (1 - g)(\dim_{\mathbb{C}} X - 3) + \int_{\beta} c_1(X) + n, \]

The first question that we pursue here is whether a ring of tautological classes can be defined in the rational Chow theory of $\mathcal{M}_{g,n,\beta}(X)$. In Section 2, we define tautological classes through fundamental classes and show that their span in the Chow group carries a natural product structure. Our tautological classes lie in $A_*(\mathcal{M}_{g,n,\beta}(X))$ and not in the operational Chow group because the virtual fundamental classes are cycles and not operational classes. The issue of the multiplication of tautological classes is delicate because we are considering cycles on a singular space $\mathcal{M}_{g,n,\beta}(X)$. In genus 0, tautological classes were studied earlier by Oprea [22] in cases where the moduli space of stable maps $\mathcal{M}_{0,n,\beta}(X)$ is smooth. Our definition agrees with [22] in the cases he considers.

Classical examples of tautological relations on $\mathcal{M}_{g,n,\beta}(X)$ come from tautological relations on $\mathcal{M}_{g,n}$ by pulling-back relations via the stabilization morphism
\[ st : \mathcal{M}_{g,n,\beta}(X) \to \mathcal{M}_{g,n}. \]
Formulae for the pull-back are presented in Section 2.2.

Our study is motivated by the following two basic questions concerning the structure of tautological relations on the moduli space of stable maps:

1. Can we find tautological relations on $\mathcal{M}_{g,n,\beta}(X)$ that are not obtained via pull-back from Pixton’s set of tautological relations on $\mathcal{M}_{g,n}$? More precisely, can we use the geometry of $X$ to construct relations among tautological classes not obtained via pull-back?

2. Can we use the tautological relations on $\mathcal{M}_{g,n,\beta}(X)$ to determine new relations among Gromov-Witten invariants?

For question (1), the answers should be in the form of general constructions which are valid for all $X$. As an example, in [19], the authors obtained tautological relations in $\text{Pic}((\mathcal{M}_{0,n,d}(\mathbb{P}^m)))$ to prove a reconstruction theorem for genus 0 quantum cohomology and quantum K-theory for $X \subseteq \mathbb{P}^m$.

Our main result here is a general construction of tautological relations for $\mathcal{M}_{g,n,\beta}(X)$ using the new double ramification cycle formula for target varieties of Janda-Pandharipande-Pixton-Zvonkine [17]. Because the construction essentially involves the geometry of $X$, the relations are not expected to be pull-backs. Examples and applications are provided in Section 4.

\footnote{For instance, if $X$ is a K3 surface, the virtual fundamental class of the moduli space of stable maps is zero if $\beta$ is nonzero. And it is not likely to be true that these relations come from tautological relations on $\mathcal{M}_{g,n}$. In this note we will not consider such cases.}
When $X$ is a point, the relations constructed here specialize to the double ramification cycle relations for $\overline{M}_{g,n}$ conjectured by Pixton \cite{28} and proven by Clader and Janda in \cite{7}. In fact, our proof follows the strategy of \cite{7}.

**Acknowledgements.** The author is indebted to Johannes Schmitt for his collaboration in proving Lemma 2.6, Longting Wu and Honglu Fan for their collaboration in computing Example 4.2, and Dragos Oprea for sharing his insights on tautological relations on the stable map spaces and pointing out an error in the first version of this paper. Special thanks to my Ph.D. advisor Rahul Pandharipande who suggested this problem to me. The author would also like to thank Felix Janda, Drew Johnson, Hyenho Lho, Georg Oberdieck, and Dmitri Zvonkine for helpful conversations. This project has received funding from the European Research Council (ERC) under the European Unions Horizon 2020 research and innovation programme (grant agreement No. 786580) and Korea Foundation for Advanced Studies.

2. **X-valued Tautological Ring**

2.1. **X-valued stable graphs.** Let $X$ be a nonsingular projective variety over $\mathbb{C}$ and let $C(X)$ be the semigroup of effective curve classes in $H_2(X, \mathbb{Z})$. For each element $\beta$ in $C(X)$, an Artin stack $\mathcal{M}_{g,n,\beta}$ exists that parametrizes genus $g$, $n$ marked prestable curves $C$ together with a labeling on each irreducible component of $C$ by an element of $C(X)$. The labeling must satisfy the stability condition and the degrees must sum to $\beta$ – see \cite{9, Section 2} for details. This space is called the moduli space of prestable curves with $C(X)$-structure. It is a smooth Artin stack and is étale over the moduli space of marked prestable curves $\mathcal{M}_{g,n}$.

Let us review the notion of $X$-valued stable graphs following \cite{17}.

**Definition 2.1.** An $X$-valued stable graph $\Gamma \in \mathcal{S}_{g,n,\beta}(X)$ consists of the data

$$\Gamma = (V, H, L, g : V \to \mathbb{Z}_{\geq 0}, v : H \to V, \iota : H \to H, \beta : V \to C(X))$$

satisfying the properties:

(i) $V$ is a vertex set with a genus function $g : V \to \mathbb{Z}_{\geq 0}$,

(ii) $H$ is a half-edge set equipped with a vertex assignment $v : H \to V$ and an involution $\iota$,

(iii) $E$ is defined by the 2-cycles of $\iota$ in $H$,

(iv) $L$ is defined by the fixed points of $\iota$ and corresponds to the set of $n$ markings,

(v) the pair $(V, E)$ defines a connected graph satisfying the genus condition

$$\sum_{v \in V} g(v) + h^1(\Gamma) = g,$$

(vi) for each vertex $v \in V$, the stability condition holds: if $\beta(v) = 0$, then

$$2g(v) - 2 + n(v) > 0,$$

where $n(v)$ is the valence of $\Gamma$ at $v$,

(vii) the degree condition holds:

$$\sum_{v \in V} \beta(v) = \beta.$$
An automorphism of $\Gamma \in \mathcal{S}_{g,n,\beta}(X)$ consists of automorphisms of the sets $V$ and $H$, which leaves invariant the structures $L, g, v, \iota$, and $\beta$. Let $\text{Aut}(\Gamma)$ denote the automorphism group of $\Gamma$.

For each $X$-valued stable graph $\Gamma$, consider a moduli space $\overline{\mathcal{M}}_\Gamma$ of stable maps of the prescribed degeneration together with the canonical morphism [17, Section 0.2],

$$j_\Gamma : \overline{\mathcal{M}}_\Gamma \to \overline{\mathcal{M}}_{g,n,\beta}(X).$$

To construct $j_\Gamma$, a universal family of stable curves over $\mathcal{M}_\Gamma$ is required [4]. The forgetful morphism from $\mathcal{M}_\Gamma$ to $\mathcal{M}_\Gamma$ carries a relative perfect obstruction theory.

The universal curve

$$(2.1) \quad \pi : C_{g,n,\beta}(X) \to \overline{\mathcal{M}}_{g,n,\beta}(X)$$

has $n$ sections $s_i$ and a universal evaluation morphism

$$(2.2) \quad f : C_{g,n,\beta}(X) \to X.$$ 

Next, the notion of the strata algebra can be extended to $X$-valued stable graphs.

**Definition 2.2.** A decorated $X$-valued stable graph $[\Gamma, \gamma]$ is an $X$-valued stable graph $\Gamma \in \mathcal{S}_{g,n,\beta}(X)$ together with the following data:

- each leg $i \in L$ is decorated with $ev_i^*\alpha_i$, $\alpha_i \in A^*(X)$,
- each half-edge $h \in H$ is decorated with a monomial $\psi_h^{[y][h]}$ for some $y[h] \in \mathbb{Z}_{\geq 0}$,
- each edge $e \in E$ is decorated with a monomial $ev_e^*\alpha_e$, $\alpha_e \in A^*(X)$,
- each vertex $v \in V$ is decorated with a product of twisted $\kappa$ classes

$$\kappa_{a_1, \ldots, a_m}(\alpha_1, \ldots, \alpha_m) = \pi_m(\psi_{n+1}^{a_1+1} ev_{n+1}^*\alpha_1 \cdots \psi_{n+m}^{a_m+1} ev_{n+m}^*\alpha_n)$$

where $\pi_m : \overline{\mathcal{M}}_{g,n+m,\beta}(X) \to \overline{\mathcal{M}}_{g,n,\beta}(X)$ is the morphism forgetting the last $m$ marked points, $a_1, \ldots, a_m \in A^*(X)$ and $a_1, \ldots, a_m \in \mathbb{Z}_{\geq -1}$.

We bound the degree of $\gamma$ by the virtual dimension of the moduli space

$$\text{deg}(\gamma) \leq \text{vdim} \overline{\mathcal{M}}_{g,n,\beta}(X).$$

Consider the $\mathbb{Q}$-vector space $\mathcal{S}_{g,n,\beta}(X)$ whose basis is given by the isomorphism classes of decorated $X$-valued stable graph $[\Gamma, \gamma]$. We give a product structure on $\mathcal{S}_{g,n,\beta}(X)$ as follows, see [14, 17]. Let

$$(\Gamma_A, \gamma_A), (\Gamma_B, \gamma_B) \in \mathcal{S}_{g,n,\beta}(X)$$

be two elements in $\mathcal{S}_{g,n,\beta}(X)$. The product of two elements is a finite linear combination of decorated $X$-valued graphs as follows:

1. Consider $\Gamma \in \mathcal{S}_{g,n,\beta}(X)$ with edges colored by $A$ or $B$ so that after contracting the edge not colored as $A$ (resp. $B$), we obtain $\Gamma_A$ (resp. $\Gamma_B$).
2. For each such $\Gamma$, we assign operational Chow classes by the following rules.
   - The operational Chow classes on legs are obtained by multiplying the corresponding leg monomials on $\gamma_A$ and $\gamma_B$.

\footnote{The virtual fundamental class obtained by the relative perfect obstruction theory coincides with the virtual fundamental class obtained by the Gysin pullback along the diagonal $\Delta : X \to X \times X$ at each edge.}

\footnote{It is allowed to color an edge both by $A$ and $B$.}
• The operational Chow classes on a half edge colored $A$ only or colored $B$ only is determined by $\gamma_A$ or $\gamma_B$ respectively. On an edge $e = (h, h')$ colored both $A$ and $B$, we multiply by
\begin{equation}
- (\psi_h + \psi_{h'})
\end{equation}
in addition to contributions from $\gamma_A$ and $\gamma_B$.
• The factors of edges coming from $\gamma_A$ and $\gamma_B$ descend to $\Gamma$.
• The factors on the vertex $v$ in $\Gamma_A$ (resp. $\Gamma_B$) are split in all possible ways among the vertices which collapse to $v$ as $\Gamma$ is contracted to $\Gamma_A$ and $\Gamma_B$. Then we multiply two vertex contributions.

The above product yields a $\mathbb{Q}$-algebra structure on $S_{g,n,\beta}(X)$. Push-forward along $j_\Gamma$ defines a $\mathbb{Q}$-linear map $q : S_{g,n,\beta}(X) \to A_*(\overline{M}_{g,n,\beta}(X))$,
\begin{equation}
q([\Gamma, \gamma]) = j_\Gamma^! (\gamma \cap [\overline{M}_{\Gamma}]^{vir}) \in A_*(\overline{M}_{g,n,\beta}(X)).
\end{equation}
An element of the kernel of $q$ is called a tautological relation for the target variety $X$. Unlike in [25], there is no intersection product on the Chow group of $A_*(\overline{M}_{g,n,\beta}(X))$, so there is no obvious reason why the kernel of the map $q$ is an ideal of $S_{g,n,\beta}(X)$. However, we can use the perfect obstruction theory on $\overline{M}_{g,n,\beta}(X)$ to prove that the kernel of $q$ is an ideal.

Lemma 2.3. The kernel of $q$ is an ideal in $S_{g,n,\beta}(X)$.

Proof. From the splitting axiom, the map $q$ factors through the following diagram
\begin{equation}
\begin{array}{ccc}
S_{g,n,\beta}(X) & \xrightarrow{q_0} & A^*(\overline{M}_{g,n,\beta}(X)) \\
& \xrightarrow{q} & A_*(\overline{M}_{g,n,\beta}(X)) \\
& \xrightarrow{\gamma} & A_*(\overline{M}_{g,n,\beta}(X)).
\end{array}
\end{equation}
The map $q_0$ assigns $[\Gamma, \gamma]$ to an operational Chow class on $\overline{M}_{g,n,\beta}(X)$ as follows. For each scheme $U$ and a morphism $u : U \to \overline{M}_{g,n,\beta}(X)$, consider the following fiber diagram
\begin{equation}
\begin{array}{ccc}
U' & \xrightarrow{j_u} & U \\
\downarrow \quad \downarrow u' & & \downarrow u \\
\overline{M}_\Gamma & \xrightarrow{j_\Gamma} & \overline{M}_{g,n,\beta}(X) \\
\downarrow & & \downarrow \\
\mathfrak{M}_\Gamma & \xrightarrow{\xi_\Gamma} & \mathfrak{M}_{g,n,\beta},
\end{array}
\end{equation}
where $\mathfrak{M}_\Gamma$ is the moduli space of prestable curves with prescribed degeneration defined by $\prod_{v \in V(\Gamma)} \mathfrak{B}_{g(v),n(v),\beta(v)}$ and $\xi_\Gamma$ is the gluing morphism. The class
\begin{equation}
q_0([\Gamma, \gamma])(s) : A_*(U) \to A_{*-|E|-\deg(\gamma)}(U)
\end{equation}
assigns $V \in A_*(U)$ to $j_*(u^*(\gamma) \cap \xi_\Gamma^! V)$. Parallel argument in [13] Appendix shows that the map $q_0$ is a ring homomorphism. Therefore the kernel of $q$ is an ideal in $S_{g,n,\beta}(X)$. \qed
From the above, the image of the map \( q \) has a \( \mathbb{Q} \)-algebra structure. We call this ring as the tautological ring of the moduli space of stable maps to \( X \) and write \( R^*(\overline{\mathcal{M}}_{g,n,\beta}(X)) \).

2.2. **Tautological relations from Pixton’s 3-spin relations.** We briefly review the tautological relations on \( \overline{\mathcal{M}}_{g,n,\beta}(X) \) coming from the tautological relations on the moduli space of stable curves via the stabilization morphism (1.2). We assume \( 2g - 2 + n > 0 \) throughout this section.

**Definition 2.4.** Let \( \mathfrak{M} \) be an Artin stack over \( \mathbb{C} \). For any integer \( p \), define an operational Chow class \( \alpha \in A^p(\mathfrak{M}) \) as follows: For each scheme \( U \) and morphism \( U \rightarrow \mathfrak{M} \), we assign a linear map \( \alpha_U : A^*(U) \rightarrow A^{*+p}(U) \) which is compatible with proper push-forward, flat pull-back, l.c.i pull-back, and Chern classes, see [11, Chapter 17].

Because the ground field is of characteristic 0, \( A^*(\mathfrak{M}) \) is a commutative ring. For example, tautological classes on \( \mathfrak{M}_{g,n} \) can be naturally extended to a notion of tautological classes on operational classes capped with the virtual fundamental class of \( \mathfrak{M}_{g,n,\beta}(X) \).

The following lemma illustrates the pull-back formula under the stabilization morphism.

**Lemma 2.5.** (with Johannes Schmitt) Let \( st : \overline{\mathcal{M}}_{g,n,\beta}(X) \rightarrow \overline{\mathcal{M}}_{g,n} \) be the stabilization morphism in (1.2). The following formulas hold:

1. Let \( [\Gamma] \) be a boundary class in \( R^*(\overline{\mathcal{M}}_{g,n}) \). Then,
   \[
st^* \frac{1}{|\text{Aut}(\Gamma)|} [\Gamma] = \sum_{\Gamma'} \frac{1}{|\text{Aut}(\Gamma')|} [\Gamma']
   \]
   The sum is over all \( X \)-valued stable graphs \( \Gamma' \) where the graph of \( \Gamma' \) is equal to \( \Gamma \) but the degree map \( \beta(v) \) can vary.

2. \( st^* \psi_i = \psi_i - [D_i] \), where \( D_i \) is an \( X \)-valued stable graph with one edge connecting two vertices \( v_1 \) and \( v_2 \) with \( g(v_1) = g \) so that the only leg attached to \( v_2 \) is the \( i \)-th leg.

3. The pull-back of \( \kappa \) classes are tautological.

**Proof.** It is sufficient to prove the lemma for the stabilization morphism \( \mathfrak{M}_{g,n,\beta} \rightarrow \overline{\mathcal{M}}_{g,n} \). Proof of (1) and (2) are well known, see [4].

Proof of (3). The pull-back formula follows from the fact that the log canonical sheaf \( \omega_{\log} \) does not change under the stabilization for semistable curves. Consider the following diagram

\[
\begin{array}{ccc}
\mathfrak{M}_{g,n+1,\beta} & \xrightarrow{st} & \mathcal{C} \\
\downarrow \pi_1 & & \downarrow \pi_2 \\
\mathfrak{M}_{g,n,\beta}, & \xrightarrow{st} & \mathcal{C}
\end{array}
\]

where \( \mathcal{C} \) it the pull-back of the universal curve over \( \overline{\mathcal{M}}_{g,n} \) under the stabilization morphism and \( st : \mathfrak{M}_{g,n+1,\beta} \rightarrow \mathcal{C} \) is the fiberwise stabilization. Let \( \omega_i = \omega_{\log,\pi_i} \), \( i = 1, 2 \), be the log canonical sheaves for each projections. Then,

\[
st^* c_1(\omega_2) = c_1(\omega_1) - [D],
\]
where D is the sum of stable graphs with one edge connecting two vertex \( v_1 \) and \( v_2 \) where \( g(v_1) = g(v_2) = 0 \) and the only leg adjacent to \( v_2 \) is the \( n+1 \)-th leg. Because the morphism \( st \) is birational,

\[
st^* \kappa_n = \pi_1^*(c_1(\omega_1) - D)^{n+1}.
\]

After expanding the right hand side, we get the pull-back formula. □

**Example 2.6.** From the above lemma, we get

\[
st^* \kappa_1 = \kappa_1 + [D]
\]

in \( R^1(\overline{\mathcal{M}}_{g,n,\beta}(X)) \) where \( D \) is the \( X \)-valued stable graph in the proof of (3).

It is natural to find tautological relations on \( \mathcal{M}_{g,n} \) directly because the pull-back of tautological classes can be complicated. We can try to find tautological relations on \( \mathcal{M}_{g,n} \) from tautological relations on \( \overline{\mathcal{M}}_{g,n} \) as follows. Consider the smooth atlas

\[
\bigsqcup_{m \geq 0} \overline{\mathcal{M}}_{g,n+m} \to \mathcal{M}_{g,n}
\]

defined by forgetting the last \( m \) marked points. Images of \( \overline{\mathcal{M}}_{g,n+m} \) give a *good filtration* on \( \mathcal{M}_{g,n} \) in the sense of [21, Definition 5]. Suppose we have a finite degree operational Chow class on \( \mathcal{M}_{g,n} \) which pulls back to a tautological relation on \( \overline{\mathcal{M}}_{g,n+m} \) for sufficiently large \( m \). Then we can try to prove that the relation holds in \( \mathcal{M}_{g,n} \).

3. **Tautological relations from double ramification cycles**

3.1. **Twisted double ramification relations.** Let \( S \to X \) be a line bundle and let \( k \in \mathbb{Z} \) be an integer. A vector \( A = (a_1, \ldots, a_n) \in \mathbb{Z}^n \) of \( k \)-twisted double ramification data for a target variety is defined by the condition

\[
\int_{\beta} c_1(S) + k(2g - 2 + n) - \sum_{i=1}^{n} a_i = 0.
\]

Under this condition, we define \( k \)-twisted double ramification relations as follows. For each genus \( g \), \( n \) pointed nodal curve \( (C, x_1, \ldots, x_n) \), let

\[
\omega_{\log} = \omega_C(x_1 + \cdots + x_n)
\]

be the log canonical line bundle. In (2.1) and (2.2), we defined the universal curve and the universal evaluation map

\[
\begin{align*}
\mathcal{C}_{g,n,\beta}(X) & \xrightarrow{f} X \\
\pi & \xrightarrow{} \overline{\mathcal{M}}_{g,n,\beta}(X).
\end{align*}
\]

The following tautological classes are obtained from the above diagram

- \( \xi_i = c_1(s_i^* f^* S) \),
- \( \xi = f^* c_1(S) \),
- \( \eta_{a,b} = \pi^*((c_1(\omega_{\log}))^a c_1(f^* S)^b) \).

\footnote{However, we do not know that the pullback \( A^d(\mathcal{M}_{g,n}) \to A^d(\overline{\mathcal{M}}_{g,n+m}) \) is injective.}
The subscript \(i\) corresponds to the \(i\)-th marked point and \(a, b\) are nonnegative integers. We will use 
\[ \eta = \pi_* (\xi^2) \]
for the notational convention. To state the double ramification (DR) vanishing formula, we recall the definition of weights for \(X\)-valued stable graphs.

**Definition 3.1.** Let \(\Gamma \in \mathcal{S}_{g,n,\beta}(X)\) be an \(X\)-valued stable graph. A \(k\)-weighting mod \(r\) of \(\Gamma\) is a function on the set of half edges, 
\[ w : H(\Gamma) \rightarrow \{0, 1, \cdots, r - 1\} \]
which satisfies:

1. \(\forall i \in L(\Gamma), \) corresponding to \(i\)-th marking,
   \[ w(i) = a_i \mod r, \]
2. \(\forall e \in E(\Gamma), \) corresponding to half edges \(h, h'\),
   \[ w(h) + w(h') = 0 \mod r, \]
3. \(\forall v \in V(\Gamma), \)
   \[ \sum_{e(h)=v} w(h) = \int_{\beta(v)} c_1(S) + k(2g(v) - 2 + n(v)) \mod r, \]
where the sum is over all half-edges incident to \(v\).

We denote \(W_{\Gamma, r, k}\) be the set of all \(k\)-weightings mod \(r\) of \(\Gamma\).

Let \(A\) be a vector of \(k\)-twisted ramification data for genus \(g\). For each positive integer \(r\), let \(P_{d, r, g, A, \beta, k}\) be the degree \(d\) component of the class
\[
\sum_{\Gamma \in \mathcal{S}_{g,n,\beta}(X)} \sum_{w \in W_{\Gamma, r, k}} r^{-h^1(\Gamma)} |\text{Aut}(\Gamma)| \prod_{i=1}^n \exp \left( \frac{1}{2} a_i^2 \psi_i + a_i \xi_i \right) \times \prod_v \exp \left( -\frac{1}{2} \eta(v) - k \eta_{1,1}(v) - \frac{1}{2} k^2 \kappa_1(v) \right) \prod_{e=(h,h')} \frac{1 - \exp(-\frac{w(h)w(h')}{2} (\psi_h + \psi_{h'}))}{\psi_h + \psi_{h'}}. 
\]

The class \(P_{d, g, n, \beta, k}\) is polynomial in \(r\) for sufficiently large \(r\) and we denote \(P_{d, g, n, \beta, k}\) to be the constant term.

3.2. The vanishing result. In this section, we closely follow Clader-Janda [7] and Janda-Pandharipande-Pixton-Zvonkine [17]. We first outline the constructions in [17]. For each positive integer \(r\), we consider the moduli space \(\overline{M}_{g,A,\beta}(X,S)\) of stable maps \((f : (C, x_1, \cdots, x_n) \rightarrow X)\) with an \(r\)-th root of the line bundle
\[ f^* S \otimes \omega_{\log}^k(-a_i x_i). \]

Let \(\mathcal{M}_{g,n,\beta}^{n,n,0}\) be the stack of prestable twisted curves with a degree 0 line bundle and let \(\mathcal{M}_{g,n}^{Z}\) be the stack of prestable curves with a degree 0 line bundle. We have a morphism
\[
\overline{M}_{g,n,\beta}(X) \rightarrow \mathcal{M}_{g,n,\beta}^{n,n,0}, \quad [f] \rightarrow (C, f^* S \otimes \omega_{\log}^k(-a_i x_i)).
\]
and a fiber diagram
\[
\begin{array}{ccc}
\mathcal{M}_{g,A,\beta}(X,S) & \xrightarrow{\epsilon} & \mathcal{M}_{g,n,\beta}(X)
\\ \downarrow & & \downarrow
\\ \mathcal{M}_{g,n}^{r,L} & \xrightarrow{\epsilon} & \mathcal{M}_{g,n}^{r,L^{'},n},
\end{array}
\]

where \( \epsilon: \mathcal{M}_{g,n}^{r,L} \to \mathcal{M}_{g,n}^{r,L^{'},n} \) is the morphism forgetting the stacky structure.

As in \([7]\), it is sufficient to prove the vanishing of (3.2) when exactly one \( a_i \) is negative. Assume that \( a_1 < 0 \) and \( a_i \geq 0 \) for all \( i \geq 2 \). Choose a positive number \( r > \max\{|a_i|\} \) and take \( A' = (a'_1, \cdots, a'_n) = (a_1 + r, a_2, \cdots, a_n) \). The constraint (3.1) is still valid modulo \( r \) and the constant term of (3.2) is invariant under the translation. Let \( \mathcal{M}_{g,n}^{r,L} \) be the stack of prestable curves together with a degree \(-r\) line bundle, and \( \mathcal{M}_{g,n}^{r,L^{'},n} \) be the stack of prestable twisted curves together with a degree \(-1\) line bundle. There is a universal twisted curve
\[
(3.5) \quad \pi: \mathcal{C}_{r,L^{'},n} \to \mathcal{M}_{g,n}^{r,L^{'},n}
\]
and the universal line bundle \( \mathcal{L}^{'},A^{'},n \to \mathcal{C}_{r,L^{'},n} \).

**Theorem 3.2.** If \( d > g \), and \( n \geq 1 \), then \( P^d_{g,A,\beta,k} = 0 \in \text{Av}_{\text{dim}-d}(\mathcal{M}_{g,n,\beta}(X)) \).

**Proof.** We follow the three basic steps of the vanishing argument of \([7]\).

*Step 1.* Use the polynomiality of \( P^d_{g,A,\beta,k} \). From the polynomiality of \( P^d_{g,A,\beta,k} \) in \( k \), we may assume that \( k \) is a negative number. Since \( X \) is a projective variety, \( S \) can be written as a difference of two ample line bundles \( S_1 \) and \( S_2 \). Introduce new variables \( x, y \) and write \( S = S_1^{\otimes x} \otimes S_2^{\otimes y} \). We can view the expression \( P^d_{g,A,\beta,k}(S) \) as a polynomial in \( x, y, a'_1, \cdots, a'_{n-1} \), after substituting (3.1). The polynomiality ensures that it suffices to prove vanishing for \( x, y \ll 0 \).

*Step 2.* Use stability and the degree analysis of \([7]\) Lemma 4.2]. Consider the morphism (3.5). The degree of the orbifold line bundle \( \mathcal{L}^{'},A^{'},n \) restricted to each fiber on the irreducible component \( C_v \) is
\[
\frac{1}{r} \left[ \int_{\beta_v} c_1(S) + k(2g_v - 2 + n_v) - \sum_{i=1}^{n_v} a'_i \right].
\]
If \( \beta_v \) is 0, \( 2g_v - 2 + n_v > 0 \) and the degree of the line bundle is negative. If \( \beta_v \) is nonzero, \( 2g_v - 2 + n_v \) can be negative. However, we assumed that \( x, y \ll 0 \) so the degree of the line bundle is also negative. The proof of \([7]\) Lemma 4.2] implies \(-R\pi_* \mathcal{L}^{'},A^{'},n \) is a locally free sheaf of rank \( g \).

*Step 3.* Use the Grothendieck-Riemann-Roch formula in \([7]\) Section 2]. From the computation in \([7]\) Corollary 11], \( r^{-2g+2d+1} \epsilon_c(-R\pi_* \mathcal{L}^{'},A^{'},n) \) is obtained by substituting \( r = 0 \) into the degree \( d \) part of
\[
\sum_{\Gamma \in \mathcal{S}^r_{g,n,\beta}(X), w \in \text{Wr}_{r,k}} \sum_{\Gamma} \frac{r^{-h^1(\Gamma)}}{|\text{Aut}(\Gamma)|} j_{r^*}[\prod_v \exp(-\frac{1}{2} \eta(v) - k\eta,1(v) - \frac{1}{2} k^2 \kappa_1(v))]
\]
\[
\prod_{v \in \psi(h,h')} \left[ 1 - \exp\left(-\frac{w(h,w,h')}{2} \right) \left( \psi_h + \psi_{h'} \right) \right],
\]

(3.6)
Twisting by $\omega^{\otimes k}_{\log}$ produces additional terms in (3.6). The above formula vanishes for all $d$ greater than $g$. By the pull-back formula in \cite[Lemma 4]{17}, we obtain the vanishing result on $\M_{g,n,\beta}(X)$. □

In \cite{17}, the untwisted double ramification cycle formula for the target variety was proven via relative/orbifold Gromov-Witten theory (the cycle $\text{DR}_{g,n,\beta}(X,S)$ was defined in \cite[Definition 1]{17}).

**Theorem 3.3.**  \((\cite{17} \text{Theorem 2})\) Let $k = 0$. Then, we have

$$\text{DR}_{g,n,\beta}(X,S) = P_{g,A,\beta}^{g} \in A_{\text{vir}}(\M_{g,n,\beta}(X)),$$

Moreover, the proof of Theorem 3.2 for untwisted cases was already implicitly stated in \cite{17}.

**Theorem 3.4.** If $d > g$, then $P_{d,A,\beta}^{g} = 0 \in R_{d}(\M_{g,n,\beta}(X))$.

**Proof.** The proof follows from the localization formula in \cite[Section 3]{17}. For $l \geq 1$, consider the class

$$\text{(3.7)} \quad \text{Coeff}_{l} \left[ \epsilon_{*}(t^{l} \chi_{g,A,\beta}([\M_{g,n,\beta}(X), D_{\infty}])^{\text{vir}}) \right]$$

in $A_{*}(\M_{g,n,\beta}(X))$. From \cite[Proposition 9]{17} and the localization formula, (3.7) is a Laurent polynomial in $r$. The coefficient of $r^{1-l}$ of (3.7), should vanish for all $l \geq 1$. If $l = 1$, we prove Theorem 3.3 and if $l \geq 2$, we get the vanishing result $P_{g,A,\beta}^{g+l-1} = 0$. □

### 3.3. R-matrix interpretation.

In \cite[Section 5]{7}, DR relations are packaged into cohomological field theory (CohFT). Similarly, there is a way to understand $X$-valued DR relations by using the $X$-valued CohFT, first illustrated in \cite[Appendix A.]{23}. We follow the notation in \cite{23}, but unlike in \cite{23}, we use the full R-matrix action on the CohFT. Let $V_{0}$ be a $\mathbb{Q}$-vector space spanned by $\zeta_{0}, \cdots, \zeta_{r-1}$. Let $V = V_{0} \otimes H^{*}(X)$ and let

$$\eta: V \otimes V \to H^{*}(X)$$

be a map defined by

$$\eta(\zeta_{i} \otimes 1, \zeta_{j} \otimes 1) = \begin{cases} 1 & \text{if } i + j \equiv 0 \pmod{r} \\ 0 & \text{otherwise} \end{cases}$$

and $H^{*}(X)$-linearly extended. For $k$ twisted theory, let $1 = \zeta_{k} \otimes 1$ be the distinguished element in $V$. For given $v_{1}, \cdots, v_{n} \in H^{*}(X)$ and a sequence of integers $A = (a_{1}, \cdots, a_{n})$, consider the following system of maps

$$\text{(3.9)} \quad \omega_{g,n,\beta}: V^{\otimes n} \to H_{*}(\M_{g,n,\beta}(X)),$$

where

$$\omega_{g,n,\beta}(v_{1} \otimes \zeta_{a_{1}}, \cdots, v_{n} \otimes \zeta_{a_{n}}) = r^{g} \epsilon_{*}(v_{1}) \cdots \epsilon_{*}(v_{n})[\M_{g,n,\beta}(X)]^{\text{vir}}$$

if $A$ satisfies the condition (3.1) and 0 otherwise. Following \cite{17}, let $R^{r}(z)$ be the exponential of diagonal $r \times r$ matrix:

$$\text{(3.10)} \quad \exp \begin{pmatrix} -\frac{r^{2}B_{1}(0)}{2} z \\ -\frac{r^{2}B_{1}(1)}{2} z \\ \vdots \\ -\frac{r^{2}B_{1}(r-1)}{2} z \end{pmatrix},$$
where $B'_2(x) = x^2 - x + \frac{1}{4}$.

The $R$-matrix action on $\omega_{g,n,\beta}$ is defined by a sum over $X$-valued stable graphs:

\[ R \omega_{g,n,\beta}(w_1, \cdots, w_n) = \sum_{\Gamma} \frac{1}{|\text{Aut}(\Gamma)|} j^*_{\Gamma} \left( \prod_{v \in V(\Gamma)} \sum_{k=0}^{\infty} \pi_* \omega_{g(v),n(v)+k}(\cdots) \right), \]

where
- The sum is over all $\Gamma \in S_{g,n,\beta}(X)$.
- $j_{\Gamma} : M_{\Gamma} \rightarrow M_{g,n,\beta}(X)$ is the canonical morphism obtained by prescribing degeneration of the domain.
- $\pi : M_{g(v),n(v)+k,\beta} \rightarrow M_{g(v),n(v),\beta}$ forgets the last $k$ markings.
- $\iota_{\Gamma}$ is the refined Gysin map

\[ A_* \left( \prod_{v \in V(\Gamma)} M_{g(v),n(v),\beta(v)} \right) \rightarrow A_*(M_{\Gamma}). \]

- For each argument corresponding to a marking $l$, put $R^{-1}(\psi_l)$, where $\tilde{\psi}_l$ denotes

\[ \psi_l + \frac{2\xi_l}{w(l)} \]

- For each edge $e = (h, h')$, put the bivector

\[ \frac{\Id \otimes \Id - R^{-1}(\psi_h) \otimes R^{-1}(\psi_{h'})}{\psi_h + \psi_{h'}} \]

- At each of the additional legs for each vertex, put

\[ \tilde{\psi}(\Id - R^{-1}(\psi)))1. \]

Following the computation in [7, Lemma 5.3], it is straightforward to check that

\[ P_{g,A,\beta,k} = R.\omega_{g,n,\beta}\big|_{r=0}. \]

4. Examples

From the double ramification cycle relations, tautological relations on the moduli space of stable maps to a target $X$ were constructed. Returning back to the questions in the introduction, it is natural to ask whether these relations can be obtained from tautological relations on $\mathcal{M}_{g,n}$. Consider a system of ideals

\[ I_{g,n,\beta} \subset S_{g,n,\beta}(X), \]

which is the smallest system satisfying three conditions:

1. $I_{g,n,\beta}$ contains pull-back of tautological relations on $\mathcal{M}_{g,n}$.
2. $I_{g,n,\beta}$ is closed under the map $S_{g,n+1,\beta}(X) \rightarrow S_{g,n,\beta}(X)$.
3. Each $X$-valued stable graph $\Gamma$ gives a map

\[ \prod_{v \in V(\Gamma)} S_{g(v),n(v),\beta(v)}(X) \rightarrow S_{g,n,\beta}(X). \]

Then, the system of ideals \{ $I_{g,n,\beta}$ \} is closed under these maps for all $\Gamma$.

---

5Take a unique representative of $w(l)$ modulo $r$ so that $1 \leq w(l) \leq r$. 
We say a class $R \in S_{g,n,\beta}(X)$ is obtained from moduli spaces of curves if $R$ is a class in $I_{g,n,\beta}$.

In many cases, it is difficult to prove that a tautological relation in $\overline{M}_{g,n,\beta}(X)$ does not come from moduli spaces of curves. On the other hand, we will see that some DR relations are obtained from moduli spaces of curves in nontrivial ways.

4.1. Genus 0 case. The following genus 0 computation was done with H. Fan and L. Wu. Let $S \to X$ be a line bundle over a nonsingular projective variety $X$. For each integer $d$ greater than $g$, we have the vanishing result $P_{g,A,\beta}^d = 0$ proven in the previous section. In this section, we extract tautological relations for the space $X$ by using the polynomiality of $P_{g,A,\beta}^d$. The class $P_{g,A,\beta}^d$ is polynomial in the ramification data $A$. Moreover, the degree constraint

$$\int_{\beta} c_1(S) - \sum_{i=1}^n a_i = 0$$

has a scale invariance

$$a_i \mapsto ma_i, \quad S \mapsto S \otimes m$$

for $m \in \mathbb{Z}$. This implies that the constant term of $P_{g,mA,\beta}^d$ is polynomial in $m$. If the degree $d$ is greater than $g$, each coefficient of monomials in $A$ and $m$ must be zero after we substitute (4.2) to the relation $P_{g,A,\beta}^d = 0$.

Notation 4.1. In the following examples, the symbol

$\circ$

denotes a vertex with genus $g$ with degree $\beta$. If the genus of the vertex is 0, we omit 0. We write

$$\begin{bmatrix} 1 & 2 \\ \circ & \circ \end{bmatrix}$$

to indicate the sum over all possible stable splittings $\beta_1 + \beta_2 = \beta$. Also, we use the notation $b = \int_{\beta} c_1(S)$ and $b_i = \int_{\beta(v_i)} c_1(S)$.

Example 4.2. Let $g = 0$, $n = 2$, $d = 1$. We show that all relations can be obtained from the moduli space of prestable curves. There are three prestable graphs with at most one edge. The constant term $P_{0,A,\beta}^1$ is equal to

$$(-\frac{1}{2} \eta + \frac{1}{2} a_1^2 \psi_1 + \frac{1}{2} a_2^2 \psi_2 + a_1 \xi_1 + a_2 \xi_2) \begin{bmatrix} 1 & 2 \\ \circ & \circ \end{bmatrix} - \frac{b_2^2}{2} \begin{bmatrix} 1 & 2 \\ \circ & \circ \end{bmatrix} - \frac{(b_1 - a_1)^2}{2} \begin{bmatrix} 1 & 2 \\ \circ & \circ \end{bmatrix}$$

After substituting $a_2 = b - a_1$ in $P_{0,A,\beta}^1 = 0$, the following vanishing holds:

- Coefficient of $a_1^2$:

$$\psi_1 + \psi_2 - \begin{bmatrix} 1 & 2 \\ \circ & \circ \end{bmatrix} = 0,$$
• Coefficient of $a_1$:

$$\xi_1 - \xi_2 - b\psi_2 + b_1 \begin{array}{c}
1
\end{array} \begin{array}{c}
2
\end{array} = 0,$$

• Coefficient of $a_1^0$:

$$-\eta + b^2\psi_2 + 2b\xi_2 - b_2^2 \begin{array}{c}
1
\end{array} \begin{array}{c}
2
\end{array} - b_1^2 \begin{array}{c}
1
\end{array} \begin{array}{c}
2
\end{array} = 0.$$

For more markings, relations can be obtained by pull-back via the morphism $\overline{\mathcal{M}}_{0,n,\beta}(X) \to \overline{\mathcal{M}}_{0,2,\beta}(X)$. The first two relations recover the Lee-Pandharipande relation [19]. The first relation is independent of the target $X$. In fact, the relation

$$\psi_1 + \psi_2 - \begin{array}{c}
1
\end{array} \begin{array}{c}
2
\end{array} = 0$$

holds in $A^1(\mathcal{M}_{0,2})$. The second relation is a consequence of the following relation

$$\psi_2 - \begin{array}{c}
1
\end{array} \begin{array}{c}
2
\end{array} = 0$$

on $A^1(\mathcal{M}_{0,3})$. After pulling back the relation to $\overline{\mathcal{M}}_{0,3,\beta}(X)$, multiplying with $\xi_3$ and pushing-forward to $\overline{\mathcal{M}}_{0,2,\beta}$ by forgetting the third marked point, we get the second relation. The third relation is a consequence of the second relation. The pull-back of the second relation to $\overline{\mathcal{M}}_{0,3,\beta}(X)$ is

$$\xi_1 - \xi_2 - b\psi_2 + b \binom{2}{3} \begin{array}{c}
1
\end{array} \begin{array}{c}
2
\end{array} + \sum_{\beta_2 \neq 0} b_1 \binom{1}{3} \begin{array}{c}
2
\end{array} + \sum_{\beta_2 \neq 0} b_2^2 \binom{1}{2} \begin{array}{c}
3
\end{array}.$$

Take a cup product this relation with $\xi_1$ and push-forward to $\overline{\mathcal{M}}_{0,2,\beta}(X)$ which forgets the first marking. After relabelling the third marking to the first marking, the relation is exactly the third relation.

4.2. **Genus 1 case.** In genus 1 cases, it is useful to replace $\psi$ classes with boundary strata.

**Example 4.3.** Let $g = 1, n = 1, d = 2$. We substitute $a_1 = b$ in $P^2_{1,A,\beta}$:
• Coefficient of $m^4$:

\[ 0 = (\eta^2 - 2b^2\eta\psi_1 + 4b\eta\xi_1 + b^4\psi_1^2 + 4b^2\xi_1^2 + 4b^3\psi_1\xi_1) \]

\[ + (2b^2_1\eta_1 + 2b^2_2\eta_2 - 2b^2_1b^2_2\psi_1 - 4bb^2_2\xi_1) \]

\[ + (2b^2_1\eta_1 + 2b^2_1\eta_2 - 2b^2_1b^2_1\psi_1 - 4bb^2_1\xi_1) \]

\[ + 2(b - b_1)^2b^2_3 \]

\[ + 2b^2_3(b - b_2)^2 \]

\[ \times \left( \begin{array}{ccc} 1 \\ \psi_h \\ \psi_h' \end{array} \right) \]

\[ \times \left( \begin{array}{c} \eta_1 \\ \xi_2 \\ \xi_3 \\ \xi_4 \\ \xi_5 \end{array} \right) \]

\[ - \left( \begin{array}{ccc} 1 \\ \psi_h + \psi_h' \end{array} \right) \]

\[ \times \left( \begin{array}{c} \eta_1 \\ \xi_2 \\ \xi_3 \\ \xi_4 \\ \xi_5 \end{array} \right) \]

\[ \times \left( \begin{array}{ccc} 1 \\ \psi_1 \end{array} \right) \]

• Coefficient of $m^2$:

\[ (-\eta + 2b\xi_1) \]

\[ - b^2_2 \]

\[ + 2(b^2 - b^2_1) \]

\[ + 2b^2_2 \]

\[ \times \left( \begin{array}{c} \eta_1 \end{array} \right) \]

\[ \times \left( \begin{array}{c} \xi_2 \end{array} \right) \]

\[ \times \left( \begin{array}{c} \xi_3 \end{array} \right) \]

\[ \times \left( \begin{array}{c} \xi_4 \end{array} \right) \]

\[ \times \left( \begin{array}{c} \xi_5 \end{array} \right) \]

\[ = 0 \]

• Coefficient of $m^0$:

\[ (\psi_h + \psi_h') \]

\[ - 2 \]

\[ = 0 \]

On $M_{1,5,\beta}(X)$, there is a simple form $R'$ which pushed downed to the first relation. In particular, we can write $R'$ as

\[ R' = \sum \left[ \Gamma, \xi_2\xi_3\xi_4\xi_5 \right] \]

where $\Gamma$ are strata classes on $M_{1,5,\beta}$. After removing all $\psi$ classes at the genus one vertices from the relation, there are terms

\[ \left[ \begin{array}{c} 1 \\ \psi_1 \end{array} \right] \]

which cannot be obtained from tautological relations on $M_{1,5,\beta}$. On the other hand, the second and the third relation comes from tautological relations on moduli spaces of curves.

**Example 4.4.** Let $g = 1, n = 2, d = 2$. There are 26 prestable graphs with at most two edges. The degree of $m$ can be 0, 2, or 4. We prove that the relation which does not contain $\eta$ classes can be obtained from tautological relations on genus 0 prestable curves. The coefficient of $m^4$ and $a_3^1$ is the most complicated example. For 

\[ ^6 \text{However, we can ask if there is a suitable tautological relation on } M_{1,5,\beta} \text{ which implies the given relation.} \]
simplicity, let $\delta$ be the codimension one boundary strata of $\overline{M}_{1,2,\beta}(X)$ associated to the one loop $X$-valued stable graph. After simplification, the relation becomes

$$0 = b(\psi_1^2 - \psi_2^2) + 2(\psi_1 + \psi_2)(\xi_1 - \xi_2)$$

$$+ (-2b_2\psi_1 + 2b_1\psi_2 - 2\xi_1 + 2\xi_2 + (b_1 - b_2)(\psi_h + \psi_{h'})) \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$$

$$+ (-2b_1\psi_1 + 2b_2\psi_2 - 2\xi_1 + 2\xi_2 + (b_2 - b_1)(\psi_h + \psi_{h'})) \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$$

$$+ (-2b_1 + 2b_3) \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} + (2b_1 - 2b_3) \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$$

$$+ (-2b_1 + 2b_3) \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix}.$$ 

On $\overline{M}_{1,n,\beta}(X)$, we have

$$\psi_1 = \frac{1}{12}\delta + \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} + \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix},$$

and similarly for $\psi_2$. The class $b(\psi_1^2 - \psi_2^2)$ is equal to

$$b \left[ \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} - \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} + \frac{1}{6}\begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} - \frac{1}{6}\begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} \right].$$

The excess intersection formula gives

$$\begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix}^2 = -\psi_h, \psi_{h'} \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} + 2 \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix}.$$ 

Using the $g = 0, n = 2$ relation,

$$\psi_1 + \psi_2 - \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} = 0,$$

the equation is equivalent to

$$4(\xi_1 - \xi_2) \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} + \frac{b_2}{3} \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} - \frac{b_2}{3} \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} = 0.$$

From the $g = 0$ DR relations, $\xi_1 - \xi_2$ can be written in terms of boundary strata.

$$\xi_1 - \xi_2 = b\psi_2 - b_1 D(1|2)$$
where \( D(1|2) \) is the sum over all codimension one boundary strata which splits the first and the second marked points. Using the relation

\[
\begin{bmatrix}
1 & 2 & 3 \\
\end{bmatrix} = \begin{bmatrix}
1 & 3 & 2 \\
\end{bmatrix} = \begin{bmatrix}
2 & 3 & 1 \\
\end{bmatrix}
\]

in \((g,n) = (0,3)\), the left hand side is equal to zero. This computation shows that the original relation is obtained from curves.

### 4.3. Further directions

From the previous examples, we see that tautological relations are much richer than the relations pulled-back from tautological relations on the moduli spaces of stable curves. Since Theorem 3.3 produces relations uniformly for all target \( X \), it is likely that, for a given \( X \), further relations could also hold. The following questions are some possible directions for further studies.

1. **Lower genus cases.** From lower degree computations, Oprea conjectures that all tautological relations on \( \overline{M}_{0,n,\beta}(X) \) come from tautological relations on the moduli space of genus 0 curves \([22]\). However, tautological relations on \( \mathcal{M}_{0,n} \) have not been investigated much yet and we do not know if there is a finite number of relations which replace the role of the WDVV equation in \( \overline{M}_{0,n} \). In genus 1 cases, tautological relations are generated by the WDVV relation and the Getzler’s relation on \( \overline{M}_{1,4} \) \([13]\). When the genus is equal to 0 or 1, can we find a finite number of relations which generate all tautological relations for the moduli spaces of stable maps to \( X \)?

2. **Generalization of the Pixton’s 3-spin relations.** In \([27]\ [25]\), a system of tautological relations on \( \overline{M}_{g,n} \) was obtained from the study of Witten’s 3-spin classes. These relations contain all known tautological relations on the moduli spaces of stable curves, see \([25]\). We can try to apply the argument in \([13]\) to produce tautological relations for a target space \( X \) as follows. Consider a split vector bundle \( V \) over \( X \) and its projectivization \( \mathbb{P}(V) \). By torus localization in the fiber direction, the equivariant GW theory of \( \mathbb{P}(V) \) is relatively semisimple over \( X \) \([5]\ [8]\). We speculate that the localization formula can be organized into Givental’s R-matrix formalism where the R-matrix action is twisted by Chern characters of \( V \). From this observation, we can expect to get variants of Pixton’s 3-spin relations on \( \overline{M}_{g,n,\beta}(X) \) twisted by Chern characters of \( V \).
