EXISTENCE OF PSEUDOHEAVY FIBERS OF MOMENT MAPS

MORIMICHI KAWASAKI AND RYUMA ORITA

Abstract. In the present paper, we introduce the notion of pseudoheaviness of closed subsets of closed symplectic manifolds and prove the existence of pseudoheavy fibers of moment maps. In particular, we generalize Entov and Polterovich’s theorem, which ensures the existence of non-displaceable fibers. As its application, we provide a partial answer to a problem posed by them, which asks the existence of heavy fibers. Moreover, we obtain a family of singular Lagrangian submanifolds in $S^2 \times S^2$ with strange rigidities.

1. Introduction

1.1. Backgrounds. Let $(M,\omega)$ be a closed symplectic manifold. Let $C(M)$ (resp. $C^\infty(M)$) denote the set of continuous (resp. smooth) functions on $M$. Given a finite-dimensional Poisson-commutative subspace $\mathcal{A}$ of $C^\infty(M)$, the moment map $\Phi: M \to \mathcal{A}^*$ is given by $F(x) = \langle \Phi(x), F \rangle$ for $x \in M$ and $F \in \mathcal{A}$.

A subset $X$ of $M$ is called displaceable from a subset $Y \subset M$ if there exists a Hamiltonian $H: S^1 \times M \to \mathbb{R}$ such that $\varphi_H(X) \cap \overline{Y} = \emptyset$, where $\varphi_H$ is the Hamiltonian diffeomorphism generated by $H$ (i.e., the time-1 map of the isotopy $\{ \varphi^t_H \}_{t \in \mathbb{R}}$ associated with the Hamiltonian vector field $X_H$ defined by the formula $\iota_{X_H} \omega = -dH$, where $H_t = H(t,\cdot)$ for $t \in S^1 = \mathbb{R}/\mathbb{Z}$) and $\overline{Y}$ is the topological closure of $Y$. Otherwise, $X$ is called non-displaceable from $Y$.

Since Gromov’s famous work [13], it has been an important problem in symplectic geometry to find non-displaceable subsets. Biran, Entov, and Polterovich [4] proved that the standard moment map on the complex projective space has only one non-displaceable fiber using the Calabi quasi-morphism constructed in [8]. Entov and Polterovich [9] generalized that argument and proved the following theorem.

**Theorem 1.1** ([9, Theorem 2.1], see also [23, Theorem 6.1.8]). Let $(M, \omega)$ be a closed symplectic manifold and $A$ a finite-dimensional Poisson-commutative subspace of $C^\infty(M)$. Then, there exists $y_0 \in \Phi(M)$ such that $\Phi^{-1}(y_0)$ is non-displaceable from itself.

To prove Theorem 1.1, Entov and Polterovich [9] introduced the concept of partial symplectic quasi-state (see Definition 2.1). In [10], they introduced the notion of heaviness of closed subsets in terms of partial symplectic quasi-states.

**Definition 1.2** ([10, Definition 1.3]). Let $\zeta : C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$. A closed subset $X$ of $M$ is said to be $\zeta$-heavy (resp. $\zeta$-superheavy) if

$$\zeta(H) \geq \inf_X H \quad \text{(resp. } \zeta(H) \leq \sup_X H \text{)}$$

for any $H \in C(M)$.

Here we collect properties of (super)heavy subsets.

**Theorem 1.3** ([10, Theorem 1.4]). Let $\zeta : C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$.

1. Every $\zeta$-superheavy subset is $\zeta$-heavy.
2. Every $\zeta$-heavy subset is non-displaceable from itself.
3. Every $\zeta$-heavy subset is non-displaceable from every $\zeta$-superheavy subset. In particular, every $\zeta$-heavy subset intersects every $\zeta$-superheavy subset.

Entov and Polterovich posed the following problem relating to Theorem 1.1.

**Problem 1.4** ([10, Section 1.8.2], see also [7, Question 4.9]). Let $(M, \omega)$ be a closed symplectic manifold and $A$ a finite-dimensional Poisson-commutative subspace of $C^\infty(M)$. Let $\zeta : C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$ made from the Oh–Schwarz spectral invariant (see [27, 21]). Then, does there exist $y_0 \in \Phi(M)$ such that $\Phi^{-1}(y_0)$ is $\zeta$-heavy?

1.2. Main results. Let $(M, \omega)$ be a closed symplectic manifold. For an open subset $U$ of $M$, let $\mathcal{H}(U)$ be the subset of $C(M)$ consisting of all functions supported in $U$. We introduce the notion of pseudoheaviness of closed subsets.

**Definition 1.5.** Let $\zeta : C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$. A closed subset $X$ of $M$ is said to be $\zeta$-pseudoheavy (resp. $\zeta$-superheavy) if

$$\zeta(H) \geq \inf_X H \quad \text{(resp. } \zeta(H) \leq \sup_X H \text{)}$$

for any $H \in C(M)$.

By definition, every $\zeta$-heavy subset is $\zeta$-pseudoheavy. The following proposition tells us the reason why we call such subsets pseudoheavy (compare Theorem 1.3).

**Proposition 1.6** ([17]). Let $\zeta : C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$. If a closed subset $X$ of $M$ is $\zeta$-pseudoheavy, then $X$ is non-displaceable from itself and from every $\zeta$-superheavy subset.

We prove Proposition 1.6 in Section 2. Our main theorem is the following one which asserts the existence of a pseudoheavy fiber instead of heavy one.
Theorem 1.7 (Main Theorem). Let $(M, \omega)$ be a closed symplectic manifold and $\mathfrak{a}$ a finite-dimensional Poisson-commutative subspace of $C^\infty(M)$. Let $\zeta: C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$. Then, there exists $y_0 \in \Phi(M)$ such that $\Phi^{-1}(y_0)$ is $\zeta$-pseudoheavy.

As written in Proposition 1.6, any $\zeta$-pseudoheavy subset is non-displaceable from any $\zeta$-superheavy subset. Thus, we can see Theorem 1.7 as a relative version of Theorem 1.1. For another relative version of Theorem 1.1, see [16].

In Section 3, we will provide examples of closed subsets which are pseudoheavy, but not heavy. Moreover, we will point out that the positive answer to Problem 1.4 does not hold for a general partial symplectic quasi-state.

In Section 4, we introduce a notion of simplicity of partial symplectic quasi-states (Definition 1.2) and prove the following proposition.

Proposition 1.8. Let $\zeta: C(M) \to \mathbb{R}$ be a simple partial symplectic quasi-state on $(M, \omega)$. Then, every $\zeta$-pseudoheavy subset is $\zeta$-heavy.

As an application of Theorem 1.7 and Proposition 1.8, we have the following corollary which gives a partial answer to Problem 1.4.

Corollary 1.9. Let $(M, \omega)$ be a closed symplectic manifold and $\mathfrak{a}$ a finite-dimensional Poisson-commutative subspace of $C^\infty(M)$. Let $\zeta: C(M) \to \mathbb{R}$ be a simple partial symplectic quasi-state on $(M, \omega)$. Then, there exists $y_0 \in \Phi(M)$ such that $\Phi^{-1}(y_0)$ is $\zeta$-heavy.

For a closed symplectic manifold $(M, \omega)$, let $\zeta_M$ denote the partial symplectic quasi-state on $(M, \omega)$ made from the Oh–Schwarz spectral invariant with respect to the fundamental class $[M]$ of the quantum homology $\text{QH}_*(M; \mathbb{Z}/2\mathbb{Z})$ of $M$. Let $(S, \omega)$ be a closed Riemann surface $S$ with the symplectic form $\omega$. Then, it is known that $\zeta_S(F^2) = \max\{\zeta_S(F^3), \zeta_S(-F^2)\}$ for any function $F: S \to \mathbb{R}$ (see [9] for genus zero case, [15] for positive genus case). Under this condition, one can prove that the partial symplectic quasi-state $\zeta_S$ is simple. Among experts, it is an open conjecture for many years that every symplectic quasi-state (see [9] for the definition) made from the Oh–Schwarz spectral invariant is always simple. However, it is known to be difficult to prove that these symplectic quasi-states are actually simple when the dimension of $M$ is greater than two.

In Section 5, we obtain some singular Lagrangian submanifolds in $S^2 \times S^2$ with strange rigidities. To prove that strange rigidities, we use Theorem 2.6 which is the key theorem for proving Theorem 1.7. To be more precise, we define functions $J_1, H^1: S^2 \times S^2 \to \mathbb{R}$ by

$$J_1(p) = z_1 + z_2 \quad \text{and} \quad H^1(p) = x_1x_2 + y_1y_2 + z_1z_2,$$

for each $p = (x_1, y_1, z_1, x_2, y_2, z_2) \in S^2 \times S^2 \subset \mathbb{R}^3 \times \mathbb{R}^3$, respectively. Then, $\{J_1, H^1\} = 0$ (see Section 5) and the integrable system $\{J_1, H^1\}$ is called (a special case of) the coupled angular momenta [26, 19, 14]. We set $\Phi_1 = (J_1, H^1): S^2 \times S^2 \to \mathbb{R}^2$. Given $c \in [-1, -1/2]$, we set the Lagrangian submanifold $L_c = (\Phi_1)^{-1}(0, c)$ of $(S^2 \times S^2, \omega_1)$ (see Section 5 for the definition of $\omega_1$ and more details). Let $Z$ be a topological space obtained by pinching two disjoint meridians in the 2-torus $T^2$ as shown in Figure 0. Then, we have the following result.

Theorem 1.10. There exists a family $\{Z_c\}_{c \in [-1, -1/2]}$ of closed subsets of $S^2 \times S^2$ such that for any $c \in [-1, -1/2]$,

1. $Z_c$ is homeomorphic to $Z$ if $c \neq -1$,
2. $Z_c$ is non-displaceable from $Z_{c'}$ and from $L_d$ in $(S^2 \times S^2, \omega_1)$ for any $c' \in [-1, -1/2]$ and any $d \in [-1, c]$,
3. $Z_c$ is displaceable from $L_d$ in $(S^2 \times S^2, \omega_1)$ for any $d \in (c, -1/2)$.
We show Theorem 1.10 as a corollary of Theorem 5.5 in Section 5.2. In order to prove Theorem 1.10, we use the following partial symplectic quasi-states. For $c = -1$, Entov and Polterovich [10] constructed a partial symplectic quasi-state $\zeta_{-1}$ on $(S^2 \times S^2, \omega_1)$ such that the Lagrangian sphere $L_{-1}$ is $\zeta_{-1}$-superheavy. For every $c \in (-1, -1/2]$, Fukaya, Oh, Ohta, and Ono [11] constructed a partial symplectic quasi-state $\zeta_c$ on $(S^2 \times S^2, \omega_1)$ such that the Lagrangian torus $L_c$ is $\zeta_c$-superheavy (see also [6, 18] for the case $c = -1/2$).

Moreover, we deal with generalized coupled angular momenta (see [14, 12, 22]) in Section 5. We prove that some of them have at least two non-displaceable fibers (Corollary 5.1) using Proposition 1.6 and Theorem 1.7. Furthermore, we prove that another generalized coupled angular momentum has only one non-displaceable fiber (Theorem 5.2).

2. Proof of Theorem 1.7

In this section, we provide the definition of partial symplectic quasi-state and proofs of Proposition 1.6 and Theorem 1.7. Let $(M, \omega)$ be a closed symplectic manifold. Let Ham$(M, \omega)$ denote the group of Hamiltonian diffeomorphisms of $(M, \omega)$.

2.1. Partial symplectic quasi-states and pseudoheaviness.

Definition 2.1. A partial symplectic quasi-state on $(M, \omega)$ is a functional $\zeta : C(M) \to \mathbb{R}$ satisfying the following conditions.

**Normalization:** $\zeta(a) = a$ for any constant function $a$.

**Stability:** For any $H_1, H_2 \in C(M)$

$$\min_M(H_1 - H_2) \leq \zeta(H_1) - \zeta(H_2) \leq \max_M(H_1 - H_2).$$

In particular, **Monotonicity** holds: $\zeta(H_1) \leq \zeta(H_2)$ if $H_1 \leq H_2$.

**Semi-homogeneity:** $\zeta(sH) = s\zeta(H)$ for any $H \in C(M)$ and any $s > 0$.

**Hamiltonian Invariance:** $\zeta(H \circ \phi) = \zeta(H)$ for any $H \in C(M)$ and any $\phi \in \text{Ham}(M, \omega)$.

**Vanishing:** $\zeta(H) = 0$ for any $H \in C(M)$ whose support is displaceable from itself.

**Quasi-subadditivity:** $\zeta(H_1 + H_2) \leq \zeta(H_1) + \zeta(H_2)$ for any $H_1, H_2 \in C^\infty(M)$ satisfying $\{H_1, H_2\} = 0$.

Remark 2.2. In this paper, we adopted the properties listed in [23, Section 4.5] as the definition of partial symplectic quasi-state. There are different definitions of...
EXISTENCE OF PSEUDOHEAVY FIBERS OF MOMENT MAPS

partial symplectic quasi-state as in [9, Section 4] and [11, Definition 13.3]. One can confirm that our definition is more general than the latter. In addition, we note that the quasi-subadditivity is called “the triangle inequality” in [10, Theorem 3.6] and [11, Definition 13.3].

First we prove Proposition 1.6.

Proof of Proposition 1.6. Let \( X \) be a \( \zeta \)-pseudoheavy subset of \( M \). Assume, on the contrary, that \( X \) is displaceable either from itself or from a \( \zeta \)-superheavy subset \( Y \). Then, there exists an open neighborhood \( U \) of \( X \) that is displaceable either from itself or from \( Y \). If \( U \) is displaceable from itself, then by the vanishing of \( \zeta \), \( \zeta(F) = 0 \) for any \( F \in H(U) \). This contradicts the \( \zeta \)-pseudoheaviness of \( X \).

If \( U \) is displaceable from \( Y \), then we can choose \( \phi \in \text{Ham}(M,\omega) \) such that \( \phi(U) \cap Y = \emptyset \). Since \( Y \) is \( \zeta \)-superheavy, for any \( F \in H(\phi(U)) \) \( \zeta(F) \leq \sup_Y F = 0 \).

By the Hamiltonian invariance of \( \zeta \), it means that \( \zeta(G) \leq 0 \) for any \( G \in H(U) \). This contradicts the \( \zeta \)-pseudoheaviness of \( X \). Therefore, \( X \) is non-displaceable from itself and from every \( \zeta \)-superheavy subset. □

2.2. Proof of Theorem 1.7. Let \( \zeta: C(M) \to \mathbb{R} \) be a partial symplectic quasi-state on \((M,\omega)\). We need the following proposition to prove Theorem 2.5.

Proposition 2.3 ([10, Proposition 4.1]). Let \( X \) be a closed subset of \( M \).

1. \( X \) is \( \zeta \)-heavy if and only if \( \zeta(H) = 0 \) for any \( H \in C(M) \) satisfying \( H \leq 0 \) and \( H|_X \equiv 0 \).
2. \( X \) is \( \zeta \)-superheavy if and only if \( \zeta(H) = 0 \) for any \( H \in C(M) \) satisfying \( H \geq 0 \) and \( H|_X \equiv 0 \).

Given a finite-dimensional Poisson-commutative subspace \( \mathcal{A} \) of \( C^\infty(M) \), we recall that the moment map \( \Phi: M \to \mathcal{A}^* \) is given by \( F(x) = \langle \Phi(x), F \rangle \) for \( x \in M \) and \( F \in \mathcal{A} \). We define NPH-stems which generalize stems introduced in [9].

Definition 2.4. A closed subset \( X \) of \( M \) is called a \( \zeta \)-NPH-stem (resp. stem) if there exists a finite-dimensional Poisson-commutative subspace \( \mathcal{A} \) of \( C^\infty(M) \) satisfying the following conditions.

1. \( X = \Phi^{-1}(p) \) for some \( p \in \Phi(M) \).
2. Every non-trivial fiber of \( \Phi \), other than \( X \), is not \( \zeta \)-pseudoheavy (resp. is displaceable from itself).

Here NPH stands for “non-pseudoheavy.” By Proposition 1.6, every stem is a \( \zeta \)-NPH-stem for any partial symplectic quasi-state \( \zeta \). A crucial property of stems is the following.

Theorem 2.5 ([10, Theorem 1.8]). Every stem is \( \zeta \)-superheavy for any partial symplectic quasi-state \( \zeta \).

We generalize Theorem 2.5 as follows.

Theorem 2.6. Every \( \zeta \)-NPH-stem is \( \zeta \)-superheavy.

The proof of Theorem 2.6 is almost parallel to that of [10, Theorem 1.8], but we use the quasi-subadditivity instead of the partial quasi-additivity (see, for example, [23, Section 4.6]).

Proof of Theorem 2.6. Let \( X = \Phi^{-1}(p), \, p \in \Phi(M) \), be a \( \zeta \)-NPH-stem. Take any function \( H: \mathcal{A}^* \to \mathbb{R} \) which vanishes on an open neighborhood \( V \) of \( p \). First we claim that \( \zeta(\Phi^*H) \leq 0 \).
Consider a finite open cover \( \mathcal{U} = \{U_1, \ldots, U_d\} \) of \( \Phi(M) \setminus V \) so that each \( \Phi^{-1}(U_i) \) contains no \( \zeta \)-pseudoheavy fiber. Take a partition of unity \( \{\rho_1, \ldots, \rho_d\} \) subordinated to \( \mathcal{U} \). Namely, \( \sum_{i=1}^{d} \rho_i |_{\Phi(M) \setminus V} \equiv 1 \) and \( \text{supp}(\rho_i) \subset U_i \) for any \( i \). Since \( \text{supp}(\Phi^*(\rho_i H)) \subset \Phi^{-1}(U_i) \), by the definition of pseudoheaviness,

\[
\zeta(\Phi^*(\rho_i H)) \leq 0
\]

for any \( i \). Since \( \{\Phi^*(\rho_i H), \Phi^*(\rho_j H)\} = 0 \) for any \( i \) and \( j \), by the quasi-subadditivity,

\[
\zeta(\Phi^*H) = \zeta\left(\sum_{i=1}^{d} \Phi^*(\rho_i H)\right) \leq \sum_{i=1}^{d} \zeta(\Phi^*(\rho_i H)) \leq 0,
\]

and this completes the proof of the claim.

Now given any function \( G \in C(M) \) satisfying \( G \geq 0 \) and \( G|_V \equiv 0 \), one can find a function \( H: \mathbb{A}^* \to \mathbb{R} \) and an open neighborhood \( V \) of \( p \) with \( H|_{V} \equiv 0 \) such that \( G \leq \Phi^*H \). By the normalization, the monotonicity and the above claim,

\[
0 = \zeta(0) \leq \zeta(G) \leq \zeta(\Phi^*H) \leq 0.
\]

Hence \( \zeta(G) = 0 \). By Proposition \ref{prop:fiberproperty}, \( X \) is \( \zeta \)-superheavy.

Now we are in a position to prove our main theorem (Theorem \ref{mainthm}).

**Proof of Theorem \ref{mainthm}** Arguing by contradiction, assume that every fiber of \( \Phi \) is not \( \zeta \)-pseudoheavy. Then, every fiber is a \( \zeta \)-NPH-stem. Hence, by Theorem \ref{thm:main} every fiber is \( \zeta \)-superheavy. Since all fibers are mutually disjoint, it contradicts Theorem \ref{thm:main} (1) and (3).

**Remark** \ref{rem:nonvanishing}. In the proof of Theorem \ref{mainthm} we do not use the vanishing property of \( \zeta \).

3. **Examples of pseudoheavy, but not heavy fibers**

Here we provide examples of moment maps with no heavy fiber.

**Proposition** \ref{prop:example}. Let \((M, \omega)\) be a closed symplectic manifold and \( \mathbb{A} \) a finite-dimensional Poisson-commutative subspace of \( C^\infty(M) \). Let \( \zeta_1, \zeta_2: C(M) \to \mathbb{R} \) be partial symplectic quasi-states on \((M, \omega)\). Assume that there exist \( y_1, y_2 \in \Phi(M) \) such that \( y_1 \neq y_2 \) and \( \Phi^{-1}(y_i) \) is \( \zeta_i \)-superheavy for \( i = 1, 2 \). Then, the functional \( \frac{1}{2} (\zeta_1 + \zeta_2): C(M) \to \mathbb{R} \) is also a partial symplectic quasi-state on \((M, \omega)\) and

1. \( \Phi^{-1}(y_1) \cup \Phi^{-1}(y_2) \) is \( \frac{1}{2} (\zeta_1 + \zeta_2) \)-superheavy.
2. \( \Phi^{-1}(y_1) \) and \( \Phi^{-1}(y_2) \) are \( \frac{1}{2} (\zeta_1 + \zeta_2) \)-pseudoheavy.
3. \( \Phi \) does not admit any \( \frac{1}{2} (\zeta_1 + \zeta_2) \)-heavy fiber.

For examples of \((M, \omega)\), \( \zeta_1, \zeta_2 \) and \( \Phi \) satisfying the assumption listed in Proposition \ref{prop:example} see \cite{Kawasaki, Orta} and \cite{Watanabe}.

Let \( \Sigma_2 \) be a closed Riemann surface of genus 2 with an area form \( \omega \). Rosenberg \cite{Rosenberg} constructed a functional \( \zeta_P: C(\Sigma_2) \to \mathbb{R} \) from Py’s Calabi quasi-morphism defined in \cite{Py} and proved that \( \zeta_P \) is a partial symplectic quasi-state on \((\Sigma_2, \omega)\).

Let \( F_P: \Sigma_2 \to \mathbb{R} \) be a generic Morse function with exactly six critical points as shown in Figure \ref{fig:example2}. Let \( p_1, \ldots, p_6 \) be the critical points of \( F_P \) such that \( c_1 < \cdots < c_6 \), where \( c_i = F_P(p_i) \) for \( i = 1, \ldots, 6 \).

**Proposition** \ref{prop:example2}. Let \( \zeta_P \) as above. Then,

1. \( F_P^{-1}(c_3) \cup F_P^{-1}(c_4) \) is \( \zeta_P \)-superheavy.
2. \( F_P^{-1}(c_3) \) and \( F_P^{-1}(c_4) \) are \( \zeta_P \)-pseudoheavy.
3. \( F_P \) does not admit any \( \zeta_P \)-heavy fiber.

To prove Propositions \ref{prop:example} and \ref{prop:example2} we use the following lemma.
**Figure 2.** A generic Morse function on $\Sigma_2$ with exactly six critical points

**Lemma 3.3.** Let $(M, \omega)$ be a closed symplectic manifold and $\Lambda$ a finite-dimensional Poisson-commutative subspace of $C^\infty(M)$. Let $\zeta : C(M) \to \mathbb{R}$ be a partial symplectic quasi-state on $(M, \omega)$. Assume that there exist $y_1, y_2 \in \Phi(M)$ such that $y_1 \neq y_2$ and $\zeta(f \circ \Phi) = \frac{1}{2}(f(y_1) + f(y_2))$ for any continuous function $f \in C(\Lambda^*)$. Then,

1. $\Phi^{-1}(y_1) \cup \Phi^{-1}(y_2)$ is $\zeta$-superheavy.
2. $\Phi^{-1}(y_1)$ and $\Phi^{-1}(y_2)$ are $\zeta$-pseudoheavy.
3. $\Phi$ does not admit any $\zeta$-heavy fiber.

**Proof.** We fix an isomorphism $\Lambda^* \cong \mathbb{R}^k$ for some $k$. For a continuous function $H : M \to \mathbb{R}$, take a continuous function $h : \mathbb{R}^k \to \mathbb{R}$ such that $H \leq h \circ \Phi$ and

$$\max\{H(y_1), H(y_2)\} \leq \sup_{\Phi^{-1}(y_1) \cup \Phi^{-1}(y_2)} H.$$

Then, by the monotonicity of $\zeta$ and the assumption,

$$\zeta(H) \leq \zeta(h \circ \Phi) = \frac{1}{2}(h(y_1) + h(y_2)) \leq \sup_{\Phi^{-1}(y_1) \cup \Phi^{-1}(y_2)} H.$$

Since $H$ is arbitrary, we complete the proof of (1).

We show that $\Phi^{-1}(y_1)$ is $\zeta$-pseudoheavy. For any open neighborhood $U$ of $\Phi^{-1}(y_1)$ choose an open neighborhood $V$ of $y_1$ such that $y_2 \notin V$ and $\Phi^{-1}(V) \subset U$.

Take a function $f \in \mathcal{H}(V)$ such that $f(y_1) > 0$. Then,

$$\zeta(f \circ \Phi) = \frac{1}{2}f(y_1) > 0.$$

Since $f \circ \Phi \in \mathcal{H}(U)$, $\Phi^{-1}(y_1)$ is $\zeta$-pseudoheavy. Similarly, we can prove that $\Phi^{-1}(y_2)$ is also $\zeta$-pseudoheavy. This completes the proof of (2).

Let $y \in \Phi(M) \setminus \{y_1, y_2\}$. Since $\Phi^{-1}(y)$ is disjoint from the $\zeta$-superheavy subset $\Phi^{-1}(y_1) \cup \Phi^{-1}(y_2)$, by Theorem 1.3 (3), $\Phi^{-1}(y)$ is not $\zeta$-heavy. We show that $\Phi^{-1}(y_1)$ is not $\zeta$-heavy. Since $y_1 \neq y_2$, we can choose a function $G \in C(\mathbb{R}^k)$ such that $G(y_1) = 1$ and $G(y_2) = 0$. Set $G = G \circ \Phi \in C(M)$. Then,

$$\zeta(G) = \frac{1}{2}(G(y_1) + G(y_2)) = \frac{1}{2} < 1 = \inf_{\Phi^{-1}(y_1)} G.$$

Hence $\Phi^{-1}(y_1)$ is not $\zeta$-heavy. Similarly, we can prove that $\Phi^{-1}(y_2)$ is also not $\zeta$-heavy. This completes the proof of Lemma 3.3. $\square$
Proof of Proposition 3.2. To confirm that \(\frac{1}{2}(\zeta_1 + \zeta_2)\) is a partial symplectic quasi-state on \((M, \omega)\), we only check the stability since other properties follow from the definition. Since \(\zeta_i\) (\(i = 1, 2\)) satisfies the stability, for any \(H_1, H_2 \in C(M)\)
\[
\min_M(H_1 - H_2) \leq \zeta_i(H_1) \leq \zeta_i(H_2) \leq \max_M(H_1 - H_2).
\]
By summing up with \(i = 1, 2\) and dividing by 2,
\[
\min_M(H_1 - H_2) \leq \frac{1}{2}(\zeta_1(H_1) + \zeta_2(H_1)) = \frac{1}{2}(\zeta_1(H_2) + \zeta_2(H_2)) \leq \max_M(H_1 - H_2).
\]
Hence \(\frac{1}{2}(\zeta_1 + \zeta_2)\) also satisfies the stability.

Now we claim that for any continuous function \(f \in C(\mathbb{A}^+)\)
\[
\frac{1}{2}(\zeta_1 + \zeta_2)(f \circ \Phi) = \frac{1}{2}(f(y_1) + f(y_2)).
\]
Indeed, since \(\Phi^{-1}(y_i)\) (\(i = 1, 2\)) is \(\zeta_i\)-superheavy, by Theorem 1.3 (1),
\[
f(y_i) = \inf_{\Phi^{-1}(y_i)} f \circ \Phi \leq \zeta_i(f \circ \Phi) \leq \sup_{\Phi^{-1}(y_i)} f \circ \Phi = f(y_i).
\]
Thus, \(\zeta_i(f \circ \Phi) = f(y_i)\) and this shows the claim. Hence Lemma 3.3 yields Proposition 3.1. \(\square\)

To prove Proposition 3.2, we use the following theorem which is a special case of Py’s theorem.

**Theorem 3.4** (A special case of [24 Théorème 2], see also [25 Theorem 4.4]). Let \((\Sigma_2, \omega), \zeta_P\) and \(F_P\) as above. Then, \(\zeta_P(H) = \frac{1}{2}(H(p_3) + H(p_4))\) for any smooth function \(H: \Sigma_2 \to \mathbb{R}\) with \(H, F_P\) = 0.

**Proof of Proposition 3.2**. For any smooth function \(f: \mathbb{R} \to \mathbb{R}\), since \(\{f \circ F_P, F_P\} = 0\), Theorem 3.4 implies that
\[
\zeta_P(f \circ F_P) = \frac{1}{2}((f \circ F_P)(p_3) + (f \circ F_P)(p_4)) = \frac{1}{2}(f(c_3) + f(c_4)).
\]
By the stability of \(\zeta_P\), this equality still holds for any continuous function \(f\). Thus, \((\Sigma_2, \omega), \zeta_P, F_P, c_3\) and \(c_4\) satisfy the assumption of Lemma 3.3. Hence Proposition 3.2 follows from Lemma 3.3. \(\square\)

4. Simple partial symplectic quasi-states

Let \((M, \omega)\) be a closed symplectic manifold. Let \(\zeta: C(M) \to \mathbb{R}\) be a partial symplectic quasi-state on \((M, \omega)\). For a closed subset \(X\) of \(M\), we define a real number \(\tau_\zeta(X)\) by
\[
\tau_\zeta(X) = \inf\{ \zeta(a) \mid a: M \to [0, 1], \ a|_X \equiv 1 \}.
\]

**Remark 4.1.** When \(\zeta\) is a symplectic quasi-state in the sense of [11] or, more generally, a quasi-state in the sense of [1], then the above \(\tau_\zeta\) is a quasi-measure [1].

**Definition 4.2.** A partial symplectic quasi-state \(\zeta\) on \((M, \omega)\) is called simple if \(\tau_\zeta(X) = 0\) or \(\tau_\zeta(X) = 1\) for any closed subset \(X\) of \(M\).

**Remark 4.3.** When \(\zeta\) is a quasi-state, then our definition of simplicity is equivalent to that of [1].

To prove Proposition 1.8, we use the following lemmas.

**Lemma 4.4.** Let \(\zeta\) be a partial symplectic quasi-state on \((M, \omega)\) and \(X\) a closed subset of \(M\). If \(X\) is \(\zeta\)-pseudoheavy, then for any open neighborhood \(U\) of \(X\), \(\tau_\zeta(U) > 0\).
Proof. By the definition of pseudoheaviness, there exists a function $F \in \mathcal{H}(U)$ such that $\zeta(F) > 0$. By the monotonicity and the normalization of $\zeta$, $\max_M F \geq \zeta(F) > 0$. For any continuous function $a: M \to [0, 1]$ with $a|_U \equiv 1$, by the monotonicity and the semi-homogeneity of $\zeta$,

$$\zeta(F) \leq \zeta\left(\max_M F \cdot a\right) = \max_M F \cdot \zeta(a).$$

Thus, by the definition of $\tau_\zeta$,

$$\tau_\zeta(U) \geq \left(\max_M F\right)^{-1} \cdot \zeta(F) > 0.$$  

□

Lemma 4.5. Let $\zeta$ be a partial symplectic quasi-state on $(M, \omega)$ and $X$ a closed subset of $M$. Then, $\tau_\zeta(X) = 1$ if and only if $X$ is $\zeta$-heavy.

Proof. Assume that $\tau_\zeta(X) = 1$. Let $G: M \to \mathbb{R}$ be a continuous function such that $G > 0$. Define a continuous function $\mathcal{G}: M \to \mathbb{R}$ by

$$\mathcal{G}(x) = \min\{G(x), \inf_X G\}.$$  

Then, the function $(\inf_X G)^{-1} \cdot \mathcal{G}$ takes values in $[0, 1]$ and $(\inf_X G)^{-1} \cdot \mathcal{G}|_X \equiv 1$. Thus, by the definition of $\tau_\zeta$ and the semi-homogeneity of $\zeta$,

$$\inf_X G \cdot \tau_\zeta(X) \leq \inf_X G \cdot \zeta\left(\left(\inf_X G\right)^{-1} \cdot \mathcal{G}\right) = \zeta(\mathcal{G}).$$

By the monotonicity of $\zeta$ and $\tau_\zeta(X) = 1$,

$$\inf_X G = \inf_X G \cdot \tau_\zeta(X) \leq \zeta(\mathcal{G}) \leq \zeta(G).$$

Let $H: M \to \mathbb{R}$ be a continuous function. Take a positive number $r$ so that $H + r > 0$. Then, the above argument yields $\inf_X (H + r) \leq \zeta(H + r)$. By the stability of $\zeta$,

$$\zeta(H + r) - \zeta(H) \leq r.$$  

Therefore,

$$\inf_X H = \inf_X (H + r) - r \leq \zeta(H + r) - r \leq \zeta(H).$$

Since $H$ is arbitrary, $X$ is $\zeta$-heavy.

Conversely, assume that $X$ is $\zeta$-heavy. Let $a: M \to [0, 1]$ be a continuous function with $a|_X \equiv 1$. By the monotonicity and the normalization of $\zeta$, $\zeta(a) \leq 1$. On the other hand, since $X$ is $\zeta$-heavy,

$$\zeta(a) \geq \inf_X a = 1,$$

which concludes that $\zeta(a) = 1$. Since $a$ is arbitrary, $\tau_\zeta(X) = 1$.  

□

Lemma 4.6. Let $\zeta$ be a partial symplectic quasi-state on $(M, \omega)$ and $X$ a closed subset of $M$. If the closure of any sufficiently small open neighborhood of $X$ is $\zeta$-heavy (resp. $\zeta$-superheavy), then $X$ is also $\zeta$-heavy (resp. $\zeta$-superheavy).

Proof. Let $H \in C(M)$. For any $\varepsilon > 0$ choose an open neighborhood $U$ of $X$ whose closure is $\zeta$-heavy so that

$$0 \leq \inf_X H - \inf_{\overline{U}} H \leq \varepsilon.$$  

Since $U$ is $\zeta$-heavy,

$$\zeta(H) \geq \inf_{\overline{U}} H \geq \inf_X H - \varepsilon.$$  

Since $\varepsilon$ is arbitrary, $\zeta(H) \geq \inf_X H$ for all $H \in C(M)$. Thus $X$ is $\zeta$-heavy. We can prove the case of superheaviness similarly.  

□

Now we are in a position to prove Proposition 1.8.
Proposition 4.7. Let X be a \( \zeta \)-pseudoheavy subset of M. Let \( U \) be an open neighborhood of X. Then, by Lemma 4.4, \( \tau(\zeta, U) > 0 \). Since \( \zeta \) is simple, \( \tau(\zeta) = 1 \). Hence by Lemma 4.5, \( U \) is \( \zeta \)-heavy. Since the closure of any open neighborhood of \( X \) is \( \zeta \)-heavy, by Lemma 4.0, \( X \) is also \( \zeta \)-heavy. \( \Box \)

We can prove the converse of Proposition 1.8.

**Proposition 4.7.** Let \( \zeta \) be a partial symplectic quasi-state on \((M, \omega)\) such that every \( \zeta \)-pseudoheavy subset is \( \zeta \)-heavy. Then, \( \zeta \) is simple.

**Proof.** Choose arbitrary closed subset \( X \) of \( M \) such that \( \tau(\zeta, X) > 0 \). By the definitions of pseudoheaviness and \( \tau(\zeta) \), \( X \) is \( \zeta \)-pseudoheavy. By the assumption, \( X \) is \( \zeta \)-heavy and thus, by Lemma 1.5, \( \tau(\zeta) = 1 \). Since \( X \) is arbitrary, \( \zeta \) is simple. \( \Box \)

5. Generalized coupled angular momenta

In this section, we provide applications of Theorems 1.7 and 2.6. Let \( S^2 = \{(x, y, z) \in \mathbb{R}^3 \mid x^2 + y^2 + z^2 = 1\} \) be the two-sphere with the standard symplectic form \( \omega_{S^2} \). We consider the product \( S^2 \times S^2 \) with the symplectic form \( \omega_R = \pi_1^*\omega_{S^2} + R(\pi_2^*\omega_{S^2}) \), where \( R \) is a positive number and \( \pi_1, \pi_2 : S^2 \times S^2 \to S^2 \) are the first and second projections, respectively. Let \( f : [-1, 1]^2 \to \mathbb{R} \) be a smooth function. We define functions \( J_R, H_f : S^2 \times S^2 \to \mathbb{R} \) by the formulas

\[(1) \quad J_R(x_1, y_1, z_1, x_2, y_2, z_2) = z_1 + Rz_2,\]
\[(2) \quad H_f(x_1, y_1, z_1, x_2, y_2, z_2) = x_1x_2 + y_1y_2 + z_1z_2 - f(z_1, z_2),\]

respectively, and set \( \Phi_{R, f} = (J_R, H_f) : S^2 \times S^2 \to \mathbb{R}^2 \). Since the function \( H_f \) is conserved along the Hamiltonian vector field \( X_{J_R} \) associated to \( J_R \), Noether’s theorem implies that \( J_R \) and \( H_f \) are Poisson-commutative on \((S^2 \times S^2, \omega_R)\).

Let \( s \in \mathbb{R} \). We set \( H^s = H_f \) and \( \Phi_{R, f} = \Phi_{R, f} \) when \( f(z_1, z_2) = (1 - s)z_1z_2 \). Namely, for each \((x_1, y_1, z_1, x_2, y_2, z_2) \in S^2 \times S^2\),

\[(3) \quad H^s(x_1, y_1, z_1, x_2, y_2, z_2) = x_1x_2 + y_1y_2 + sz_1z_2.\]

5.1. Non-displaceable fibers of \( \Phi_{R, f} \). In the following corollary of Theorem 1.7 and Proposition 1.6, we set \( R = 1 \).

**Corollary 5.1.** If \( \|f\|_{L^\infty} < 1/4 \), then \( \Phi_{1, f} \) has at least two non-displaceable fibers.

**Proof.** Recall \( L_{-1/2} = (\Phi_1)^{-1}(0, -1/2) \) and \( L_{-1} = (\Phi_1)^{-1}(0, -1) \) in \( S^2 \times S^2 \). As pointed out in Section 1.2, \( L_c \) is \( \zeta_c \)-superheavy for each \( c = -1/2, -1 \). By Theorem 1.7, for each \( c = -1/2, -1 \) there exists \( w_c \in \Phi_{1, f}(S^2 \times S^2) \) such that \( \Phi_{1, f}(w_c) \) is \( \zeta_c \)-superheavy. Since \( L_c \) is \( \zeta_c \)-superheavy, by Proposition 1.6,

\[(4) \quad \Phi_{1, f}^{-1}(w_c) \cap L_c \neq \emptyset.\]

Let \((x_1, y_1, z_1, x_2, y_2, z_2) \in S^2 \times S^2\). Since \(|z_1| \leq 1 \) and \(|z_2| \leq 1 \),

\[|H^1(x_1, y_1, z_1, x_2, y_2, z_2) - H_f(x_1, y_1, z_1, x_2, y_2, z_2)| = |f(z_1, z_2)| \leq \|f\|_{L^\infty} < 1/4.\]

Thus,

\[H_f(L_{-1/2}) \subset \left(\begin{array}{c} -1/2 \quad -1/4 \quad -1/2 + 1/4 \\ -3/4 \quad -1/4 \end{array}\right) \]

and

\[H_f(L_{-1}) \subset \left(\begin{array}{c} -1 \quad -1/4 \quad -1 + 1/4 \\ -5/4 \quad -3/4 \end{array}\right).\]
Theorem 5.2. Let
\[ \Phi_{1,f}(L_{-1/2}) \subset \{0\} \times \left( -\frac{3}{4}, -\frac{1}{4} \right) \quad \text{and} \quad \Phi_{1,f}(L_{-1}) \subset \{0\} \times \left( -\frac{5}{4}, -\frac{3}{4} \right). \]

Therefore, by (4),
\[ w \psi \]
\[ \text{Example 5.4. If} \]

Lemma 5.3. Since
\[ \text{Proof of Lemma 5.3.} \]
that \( (\Phi_R, H^*) \) (recall (5) for the definition of \( H^* \)). Moreover, Theorem 5.2 means that \( (\Phi_R^*)^{-1}(0,0) \) is a stem.

Example 5.4. Assume that \( f(z_1, z_2) = (1 - s)z_1z_2 \) where \( s \geq 0 \). Then, \( F_{R,f}(z) = -sz^2 \). Since \(-1 \leq z \leq 1, m_{R,f} = -sR \) and \( M_{R,f} = 0 \). By Lemma 5.3, the fiber \( (\Phi_R^*)^{-1}(a, b) \) is displaceable from itself whenever \( (a, b) \notin \{0\} \times [-sR, 0] \), where \( \Phi_R^* = (J_R, H^*) \) (recall (5) for the definition of \( H^* \)).

Proof of Lemma 5.3 Since
\[ J_R(\psi(p)) = -z_1 - Rz_2 = -J_R(p) \]
for any \( p = (x_1, y_1, z_1, x_2, y_2, z_2) \in S^2 \times S^2 \),
\[ \Phi_{R,f} \left( \psi(\Phi_{R,f}^{-1}(a, b)) \right) \subset \{-a\} \times R. \]

Hence \( \psi \) displaces \( \Phi_{R,f}^{-1}(a, b) \) from itself whenever \( a \neq 0 \).

Thus, we consider the case \( a = 0 \). Let \( b \in R \) and \( p = (x_1, y_1, z_1, x_2, y_2, z_2) \in \Phi_{R,f}^{-1}(0, b) \). Then, \( z_1 = -Rz_2 \) and \( H_f(p) = b \). Hence
\[ H_f(\psi(p)) = -x_1x_2 - y_1y_2 + z_1z_2 - f(-z_1, -z_2) = -H_f(p) + 2z_1z_2 - f(z_1, z_2) - f(-z_1, -z_2) = -b - 2Rz_2^2 - f(-Rz_2, z_2) - f(Rz_2, -z_2). \]

By the definitions of \( M_{R,f} \) and \( m_{R,f} \),
\[ -b + 2m_{R,f} \leq H_f(\psi(p)) \leq -b + 2M_{R,f}. \]

Therefore, since \( J_R \left( \psi(\Phi_{R,f}^{-1}(0, b)) \right) = \{0\}, \)
\[ \Phi_{R,f} \left( \psi(\Phi_{R,f}^{-1}(0, b)) \right) \subset \{0\} \times [-b + 2m_{R,f}, -b + 2M_{R,f}]. \]
where \( b \) displaces \( \Phi_{R,j}^{-1}(0,b) \) from itself whenever \( b \notin [-b + 2m_{R,f}, -b + 2M_{R,f}] \), equivalently, \( b \notin [m_{R,f}, M_{R,f}] \).

As a consequence, \( \psi \) displaces \( \Phi_{R,j}^{-1}(a,b) \) from itself whenever \( (a, b) \notin \{0\} \times [m_{R,f}, M_{R,f}] \).

We set

\[ \mathbb{N} = \inf \{ \| f \|_{L^\infty} \mid \Phi_{1,f} \text{ has only one non-displaceable fiber} \}. \]

By Corollary 5.1 and Theorem 5.2, \( 1/4 \leq \mathbb{N} \leq 1 \). It is an interesting problem to determine the exact value of \( \mathbb{N} \).

### 5.2. Proof of Theorem 1.10

We set \( M = (S^2 \setminus \{ N, S \})^2 \subset S^2 \times S^2 \) where \( N = (0, 0, 1) \) and \( S = (0, 0, -1) \). The Hamiltonian circle action generated by the function \( J_1: S^2 \times S^2 \to \mathbb{R} \) is free on the regular level set \((J_1|_M)^{-1}(0) \) (recall [1] for the definition of \( J_1 \)). Then, the quotient manifold \((J_1|_M)^{-1}(0)/S^1 \) carries a symplectic form \( \sigma \) such that \( \tau^* \sigma = \iota^* \omega_1 \), where

\[ \tau: (J_1|_M)^{-1}(0) \to (J_1|_M)^{-1}(0)/S^1 \quad \text{and} \quad \iota: (J_1|_M)^{-1}(0) \to S^2 \times S^2 \]

are the projection and the inclusion, respectively (see [20] for details, see also [23] Section 1.7).

Let \((z, \theta)\) denote the coordinates of the annulus \((-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}\) and set \( \sigma = (4\pi)^{-1} d\zeta \wedge d\theta \). Eliashberg and Polterovich [6] implicitly constructed a symplectomorphism \( \phi: ((J_1|_M)^{-1}(0)/S^1, \sigma) \to ((-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}, \sigma) \) such that

\[ \tau(x_1, y_1, z, x_2, y_2, -z) = (z, \theta), \]

for each \((x_1, y_1, z, x_2, y_2, -z) \in (J_1|_M)^{-1}(0) \subset S^2 \times S^2 \), where \( \tau = \phi \circ \tau \) and \( \theta \) is the angle between \((x_1, y_1)\) and \((x_2, y_2)\) in \( \mathbb{R}^2 \).

Let \( s, b \in \mathbb{R} \) be real numbers satisfying \( 0 \leq s \leq 1 \) and \( -s < b \leq 0 \). We set

\[ \alpha(s, b) = \left\{ (z, \theta) \in (-1, 1) \times \mathbb{R}/2\pi\mathbb{Z} \mid z^2 = \frac{\cos \theta - b}{\cos \theta + s} \right\}. \]

Then \( \alpha(s, b) \) is a contractible simple closed curve in the annulus \((-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}\). Moreover,

\[ (\Phi_{1,j}^s)^{-1}(0, b) = \iota \left( \tau^{-1}(\alpha(s, b)) \right), \]

where \( \Phi_{1,j}^s = (J_1, H^s): S^2 \times S^2 \to \mathbb{R}^2 \) (recall [3] for the definition of \( H^s \)).

Let \( D(s, b) \) denote the open disk bounded by \( \alpha(s, b) \). Then, the area of \( D(s, b) \) with respect to \( \sigma \) is given by

\[ \text{Area}_{\sigma}(D(s, b)) = \frac{1}{\pi} \int_0^{\arccos b} \sqrt{\frac{\cos \theta - b \cos \theta + s}{\cos \theta + s}} d\theta, \]

where \( \arccos b \in [0, \pi] \).

We consider the case \( b = -s \) where \( 0 \leq s \leq 1 \). We define subsets of \((-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}\) by

\[ \mathcal{A}_s = (-1, 1) \times q\left( \{ \pm \arccos(-s) \} \right), \]
\[ \mathcal{D}_s = (-1, 1) \times q\left( [-\arccos(-s), \arccos(-s)] \right), \]

where \( q: \mathbb{R} \to \mathbb{R}/2\pi\mathbb{Z} \) is the natural quotient map. We note that

\[ \mathcal{A}_s = \tau \left( (\Phi_{1,j}^s)^{-1}(0, -s) \cap M \right). \]

For convenience, we set \( \alpha(s, -s) = \mathcal{A}_s \) and \( D(s, -s) = \mathcal{D}_s \) (see Figure 3). Since we have

\[ \text{Area}_{\sigma}(D(s, -s)) = \frac{1}{4\pi} \int_{-\arccos(-s)}^{\arccos(-s)} \left( \int_{-1}^1 dz \right) d\theta = \frac{1}{\pi} \arccos(-s), \]
Thus, the contractible simple closed curve fixing $s \in [0, 1]$, the function $\text{Area}_\sigma(D(s, b))$ on $b \in [-s, 0]$ is continuous and strictly monotone decreasing.

\[ \theta = \text{Arccos}(-s) \]

\[ \theta = \pm \pi \]

\[ \theta = -\text{Arccos}(-s) \]

\[ z = 1 \]

\[ z = -1 \]

\[ D(s, -s) \]

\[ \text{Figure 3.} \text{ The case } s = 1/2. \text{ The subset } \alpha(s, -s) \text{ is the union of the two thick lines and } D(s, -s) \text{ is the blue-colored area.} \]

We have the following result on the partial symplectic quasi-states $\zeta_c$, $c \in [-1, -1/2]$, on $(S^2 \times S^2, \omega_1)$ introduced in Section 1.2.

**Theorem 5.5.** For any $c \in [-1, -1/2]$ the fiber $(\Phi^c_1)^{-1}(0, -s_c)$ is $\zeta_c$-superheavy for any $d \in [-1, c]$, and is not $\zeta_c$-superheavy for any $d \in (c, -1/2]$, where $s_c = -\cos(\pi \text{Area}_\sigma(D(1, c)))$.

To prove Theorem 5.5, we use the following proposition.

**Proposition 5.6 (see, for example, the proof of [3, Lemma 3.1]).** Let $X$ be a subset of $(-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}$ and $\psi \in \text{Ham}((-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}, \sigma)$. Then, there exists $\bar{\psi} \in \text{Ham}(S^2 \times S^2, \omega_1)$ such that $\text{supp} \bar{\psi} \subset M$ and $\bar{\psi} \left(\iota(\tau^{-1}(\psi(X))) \right) = \iota(\tau^{-1}(\psi(X)))$.

**Proof of Theorem 5.5.** Let $c \in [-1, -1/2]$. Since the function $b \mapsto \text{Area}_\sigma(D(1, b))$ is strictly monotone decreasing,

\[ \frac{1}{2} = \text{Area}_\sigma(D(1, -1/2)) \leq \text{Area}_\sigma(D(1, c)) \leq \text{Area}_\sigma(D(1, 1)) = 1. \]

Therefore, $0 \leq s_c \leq 1$. Moreover,

\[ \text{Area}_\sigma(D(s_c, -s_c)) = \frac{1}{\pi} \text{Arccos}(-s_c) = \text{Area}_\sigma(D(1, c)). \]

Let $d \in [-1, c]$. If $b \in (-s_c, 0]$, then

\[ \text{Area}_\sigma(D(s_c, b)) < \text{Area}_\sigma(D(s_c, -s_c)) = \text{Area}_\sigma(D(1, c)) \leq \text{Area}_\sigma(D(1, d)). \]

Thus, the contractible simple closed curve $\alpha(s_c, b)$ is displaceable from $\alpha(1, d)$ in the annulus $(-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}$. Namely, we can choose a Hamiltonian diffeomorphism $\psi$ of $((-1, 1) \times \mathbb{R}/2\pi\mathbb{Z}, \sigma)$ such that

\[ \psi(\alpha(s_c, b)) \cap \alpha(1, d) = \emptyset. \]

Then, applying Proposition 5.6 for $\alpha(s_c, b)$ yields that there exists a Hamiltonian diffeomorphism $\bar{\psi}$ of $(S^2 \times S^2, \omega_1)$ such that $\text{supp} \bar{\psi} \subset M$ and

\[ \bar{\psi} \left(\iota(\tau^{-1}(\alpha(s_c, b))) \right) = \iota(\tau^{-1}(\psi(\alpha(s_c, b)))) . \]
By \([5]\), \((\Phi^c_1)^{-1}(0, b) = \iota \left( \tau^{-1}(\alpha(s_c, b)) \right) \subset M\). Note that \(\iota \left( \tau^{-1}(\alpha(1, d)) \right) = L_d \cap M\). Since \(\text{supp} \psi \subset M\), using \([6]\) and \([7]\),
\[
\tilde{\psi} \left( ((\Phi^c_1)^{-1} (0, b) \cap L_d = \tilde{\psi} \left( (\Phi^c_1)^{-1}(0, b) \cap M \right) \cap L_d \\
= \tilde{\psi} \left( (\Phi^c_1)^{-1}(0, b) \cap (L_d \cap M) \right) \cap L_d \\
= \tilde{\psi} \left( \iota \left( \tau^{-1}(\alpha(s_c, b)) \right) \right) \cap \iota \left( \tau^{-1}(\alpha(1, d)) \right) \\
= \iota \left( \tau^{-1}(\psi(\alpha(s_c, b))) \right) \cap \iota \left( \tau^{-1}(\alpha(1, d)) \right) \\
= \iota \left( \tau^{-1}(\psi(\alpha(s_c, b)) \cap \alpha(1, d)) \right) \\
= 0.
\]

Therefore, \((\Phi^c_1)^{-1}(0, b)\) is displaceable from \(L_d\) in \((S^2 \times S^2, \omega_1)\). Since \(L_d\) is \(\zeta_d\)-superheavy, Proposition \([6,6]\) implies that \((\Phi^c_1)^{-1}(0, b)\) is not \(\zeta_d\)-pseudoheavy. Moreover, by Example \([5,4]\), \((\Phi^c_1)^{-1}(a, b)\) is displaceable from itself whenever \((a, b) \notin \{0\} \times [-s_c, 0]\). Therefore, the fiber \((\Phi^c_1)^{-1}(0, -s_c)\) is a \(\zeta_d\)-NPH-stem, and hence, is \(\zeta_d\)-superheavy by Theorem \([2,6]\).

Let \(d \in [-c, \frac{1}{2}]\). Since the function \(b \mapsto \text{Area}_\sigma(D(s_c, b))\) is continuous and strictly monotone decreasing, there uniquely exists \(b_d \in (-s_c, 0)\) such that
\[
\text{Area}_\sigma(D(s_c, b_d)) = \text{Area}_\sigma(D(1, d)).
\]

Then,
\[
\text{Area}_\sigma(D(s_c, -s_c)) > \text{Area}_\sigma(D(s_c, b_d)) = \text{Area}_\sigma(D(1, d)).
\]

Hence the subset \(\alpha(s_c, -s_c)\) is displaceable from \(\alpha(1, d)\) in the annulus \((-1, 1) \times \mathbb{R}/2\pi \mathbb{Z}\). By \([5]\), \(L_d = \iota \left( \tau^{-1}(\alpha(1, d)) \right) \subset M\). We note that \(\iota \left( \tau^{-1}(\alpha(s_c, -s_c)) \right) = (\Phi^c_1)^{-1}(0, -s_c) \cap M\). Therefore, applying Proposition \([5,6]\) as above, we can prove that \((\Phi^c_1)^{-1}(0, -s_c)\) is displaceable from \(L_d\) in \(S^2 \times S^2\). Since \(L_d\) is \(\zeta_d\)-superheavy, Theorem \([1,3]\) implies that the fiber \((\Phi^c_1)^{-1}(0, -s_c)\) is not \(\zeta_d\)-superheavy. This completes the proof of Theorem \([5,5]\).

Now we prove Theorem \([1,10]\) stated in Section \([1.2]\).

**Proof of Theorem \([1,10]\)**. Let \(c \in [-1, \frac{1}{2}]\). We set
\[
Z_c = (\Phi^c_1)^{-1}(0, -s_c) = \iota \left( \tau^{-1}(\alpha(s_c, -s_c)) \right) \cup \{(N, S), (S, N)\},
\]
where \(s_c = -\cos \left( \pi \text{Area}_\sigma(D(1, c)) \right)\). If \(c \neq -1\), then \(Z_c\) is homeomorphic to the doubly pinched torus \(Z\) (Note that the points \((N, S), (S, N)\) correspond to the pinched points).

By Theorem \([5,5]\), the subset \(Z_c\) of \(S^2 \times S^2\) is \(\zeta_d\)-superheavy for any \(d \in [-1, c]\). In particular, Theorem \([1,3]\) implies that \(Z_c\) is non-displaceable from the \(\zeta_{-1}\)-superheavy subset \(Z_c\) for any \(c' \in [-1, \frac{1}{2}]\) and from the \(\zeta_d\)-superheavy subset \(L_d\) for any \(d \in [-1, c]\). Moreover, we have shown that \(Z_c\) is displaceable from \(L_d\) for any \(d \in (c, \frac{1}{2})\) in the proof of Theorem \([5,5]\).}

**Acknowledgments**

The authors would like to thank Professors Michael Entov, Kaoru Ono, and Leonid Polterovich for some comments. Especially, they thank Michael and Kaoru for suggesting Proposition \([1,8]\) and Corollary \([1,9]\) and for giving some advice on notions, respectively. They also thank Renato Vianna for recommending the first author to read papers on semi-toric geometry.
