τ-tilting finiteness of two-point algebras I

Qi Wang

Abstract. In this paper, we give criteria on τ-tilting finiteness for two kinds of two-point algebras. Moreover, we show the τ-tilting finiteness of some algebras, such as the (infinite-)tame block algebras of Hecke algebras of classical type over an algebraically closed field of characteristic not equal to 2, and the algebras from Table T and Table W introduced by Han [19].

1. Introduction

In this paper, we always assume that Λ is a finite dimensional basic algebra over an algebraically closed field K.

τ-tilting theory is introduced by Adachi, Iyama and Reiten [3]. They constructed a class of Λ-modules named support τ-tilting modules (see Definition 2.1) as a generalization of classical tilting modules from the viewpoint of mutation, i.e., the authors showed that mutation (see Definition 2.4) at any indecomposable direct summand of support τ-tilting modules is always possible. Besides, this wider class of modules bijectively corresponds to two-term silting complexes [3], functorially finite torsion classes [3], left finite semibricks [10], left finite wide subcategories [23] and so on.

It is important to classify support τ-tilting modules and many scholars worked on this, recently. For example, Adachi [1] classified τ-tilting modules for Nakayama algebras, Adachi [2] and Zhang [27] studied τ-rigid modules for algebras with radical square zero and Mizuno [24] classified support τ-tilting modules for preprojective algebras of Dynkin type and so on. In this context, it is natural to consider algebras with only finitely many support τ-tilting modules, which are called τ-tilting finite algebras (see Definition 2.3) and studied by Demonet, Iyama and Jasso [15].

Any idempotent truncation of a τ-tilting finite algebra is again τ-tilting finite ([2, Corollary 2.4], [23, Corollary 2.4]). In order to consider τ-tilting finiteness of general algebras, it is necessary to consider τ-tilting finiteness of two-point algebras, that is, algebras with exactly two simple modules.

Let Q(i, j, m, n) (i, j, m, n ∈ N) be a quiver consisting of two vertices 1, 2, i loops on vertex 1, j loops on vertex 2, m arrows from 1 to 2 and n arrows from 2 to 1. It is well-known that if m ≥ 2 or n ≥ 2, then KQ(i, j, m, n)/I is τ-tilting infinite for any admissible ideal I. Thus, it suffices to consider the cases m ≤ 1 and n ≤ 1.

We point out that Aihara and Kase [5] and Kase [22] have got some interesting results for two-point algebras. In particular, Kase [22, Theorem 6.1] showed that for any t ≥ 4, there exists a τ-tilting finite two-point algebra such that the Hasse quiver of the set of support τ-tilting modules is isomorphic to an t-gon.

But so far, there is no complete classification of τ-tilting finite two-point algebras, even in some simple cases. In this paper, we determine the τ-tilting finiteness for two kinds of two-point algebras, which play a fundamental role in the complete classification of τ-tilting finite two-point algebras.
Theorem 1.1. Let $\Lambda$ be a two-point algebra with quiver $Q_{\Lambda} = Q(i, j, m, n)$ and $\Lambda^{op}$ its opposite algebra. Assume that $m + n = 1$ and $\Gamma_i$ comes from the Table $\Gamma$ below.

1. If $i + j = 1$, then $\Lambda$ is $\tau$-tilting infinite if and only if it has $\Gamma_3$ or $\Gamma_3^{op}$ as a factor algebra.

2. If $i = j = 1$, then $\Lambda$ is $\tau$-tilting infinite if and only if it has one of $\Gamma_3, \Gamma_4, \Gamma_5, \Gamma_6$ and their opposite algebras as a factor algebra.

Therefore, we have classified $\tau$-tilting finite two-point algebras if there is no multiple loops on the two vertices. This is the first step toward the complete classification of $\tau$-tilting finite two-point algebras.

Similar to the notion of minimal wild algebra, we call $\Lambda$ minimal $\tau$-tilting infinite if $\Lambda$ is $\tau$-tilting infinite, but any proper factor algebra of $\Lambda$ is $\tau$-tilting finite.

Theorem 1.2. Let $\Gamma_i$ be an algebra from the Table $\Gamma$ below.

1. For $i = 1, 3, 4, 5, 6, 7$, $\Gamma_i$ is minimal $\tau$-tilting infinite.

2. For the remaining $i = 2, 8, 9, \ldots, 20$, $\Gamma_i$ is $\tau$-tilting finite. Moreover,

where $\#\text{st-tilt } \Gamma_i$ is the number of support $\tau$-tilting $\Gamma_i$-modules and the type of $\mathcal{H}(\text{st-tilt } \Gamma_i)$ is defined by Definition 2.9.

The following criterion is useful to determine $\tau$-tilting finiteness of general algebras through idempotent truncation.

Corollary 1.3. Let $\Lambda$ be a finite dimensional algebra. If $\Lambda$ contains one of $\Gamma_1, \Gamma_3, \Gamma_4$, $\Gamma_5, \Gamma_6, \Gamma_7$ and their opposite algebras as a factor algebra, then $\Lambda$ is $\tau$-tilting infinite.

The representation type of two-point algebras is determined by various authors, such as Bongartz and Gabriel [12], Hoshino and Miyachi [20], Brustle and Han [13] and so on. In particular, Han [19, Theorem 1] (see also Proposition 4.1) showed that representation type of two-point algebras is determined by degeneration to quotient of algebras in Table $T$ and quotient to algebras in Table $W$. As an application of Theorem 1.1 and Theorem 1.2 we determine the $\tau$-tilting finiteness for algebras from Table $T$ and Table $W$ (see the end of this paper).

Theorem 1.4. Let $T_i$ and $W_i$ be algebras from Table $T$ and Table $W$, respectively.

1. $T_1, T_3, T_7, W_1, W_2, W_3$ and $W_5$ are $\tau$-tilting infinite.

2. Others are $\tau$-tilting finite. Moreover, $\#\text{st-tilt } T_i$, $\#\text{st-tilt } W_i$, the type of $\mathcal{H}(\text{st-tilt } T_i)$ and the type of $\mathcal{H}(\text{st-tilt } W_i)$ are as follows.

Remark: For an algebra \( \Gamma_i \), we mean the bound quiver algebra with an admissible ideal generated by relation (i). Besides, we assume that \( m,n,r \in \mathbb{N} \).
This paper is organized as follows. In Section 2, we review some basic concepts of \( \tau \)-tilting theory and silting theory. Besides, we list some reduction theorems that we will use and carry out several explicit computation. In Section 3 and 4, we prove our main results, while Theorem 1.2 and 1.4 are computational results, Theorem 1.1 gives an important criterion for \( \tau \)-tilting infiniteness. In the last section, we apply our results to two classes of algebras, the two-point symmetric special biserial algebras and the tame block algebras of Hecke algebras of classical type over an algebraically closed field of characteristic not equal to 2.

Acknowledgements. I am grateful to my supervisor Prof. Susumu Ariki for suggesting this project and for his kind help during the writing of this paper. I am also grateful to Dr. Kengo Miyamoto for teaching me numerous knowledge on \( \tau \)-this project and for his kind help during the writing of this paper. On this occasion, I would also like to mention my sincere gratitude to Prof. Toshiaki Shoji. Without his recommendation, I did not imagine of studying abroad.

2. Preliminaries

For background materials on representation theory of finite dimensional algebras and basic knowledge on quiver representations, we refer to \([11]\).

Let \( \text{mod } \Lambda \) be the category of finitely generated right \( \Lambda \)-modules and \( \text{proj } \Lambda \) the full subcategory of \( \text{mod } \Lambda \) consisting of projective \( \Lambda \)-modules. For any \( M \in \text{mod } \Lambda \), we denote by \( \text{add}(M) \) (respectively, \( \text{Fac}(M) \)) the full subcategory of \( \text{mod } \Lambda \) whose objects are direct summands (respectively, factor modules) of finite direct sums of copies of \( M \). Moreover, we often describe \( \Lambda \)-modules via their composition series. For example, each simple module \( S_i \) is written as \( i \), and then \( \frac{1}{2} \) is an indecomposable \( \Lambda \)-module \( M \) with a unique simple submodule \( S_2 \) such that \( M/S_2 = S_1 \).

Let \( C(\Lambda) \) be the center of \( \Lambda \) and \( \Lambda^{\text{op}} \) the opposite algebra of \( \Lambda \). We denote by \( |M| \) the number of isomorphism classes of indecomposable direct summands of \( M \).

We denote by \( \mathcal{C}^b(\text{proj } \Lambda) \) the category of bounded complexes of projective \( \Lambda \)-modules and by \( \mathbb{K}^b(\text{proj } \Lambda) \) the corresponding homotopy category, which is triangulated. Let \( \tau \) be the Auslander-Reiten translate on the module category. Note that it is not functorial.

**Definition 2.1.** (\([3\), Definition 0.1]) Let \( M \in \text{mod } \Lambda \).

1. \( M \) is called \( \tau \)-rigid if \( \text{Hom}_{\Lambda}(M, \tau M) = 0 \).
2. \( M \) is called \( \tau \)-tilting if \( M \) is \( \tau \)-rigid and \( |M| = |\Lambda| \).
3. \( M \) is called support \( \tau \)-tilting if there exists an idempotent \( e \) of \( \Lambda \) such that \( M \) is a \( \tau \)-tilting \((\Lambda/\langle e \rangle)\)-module. Equivalently, we may consider a pair of \( \Lambda \)-modules \((M, P)\) called a support \( \tau \)-tilting pair where \( M \) is \( \tau \)-rigid, \( P \) is projective, \( \text{Hom}_{\Lambda}(P, M) = 0 \), and \( |M| + |P| = |\Lambda| \).

Note that a faithful \( \tau \)-tilting \( \Lambda \)-module is a tilting \( \Lambda \)-module (\([3\), Proposition 2.2]) and \( M \) is a \( \tau \)-tilting \((\Lambda/\langle e \rangle)\)-module if and only if \((M, P)\) is a support \( \tau \)-tilting pair with \( P = e\Lambda \). We denote by \( \tau \)-rigid \( \Lambda \) (respectively, \( \tau \)-tilt \( \Lambda \)) the set of isomorphism classes of indecomposable \( \tau \)-rigid (respectively, support \( \tau \)-tilting) \( \Lambda \)-modules.

**Definition 2.2.** (\([3\), Definition 2.1]) A complex \( T \) in \( \mathbb{K}^b(\text{proj } \Lambda) \) is called silting if \( \text{thick } T = \mathbb{K}^b(\text{proj } \Lambda) \) and \( \text{Hom}_{\mathbb{K}^b(\text{proj } \Lambda)}(T, T[i]) = 0 \) for any \( i > 0 \), where \( \text{thick } T \) is the smallest full subcategory of \( \mathbb{K}^b(\text{proj } \Lambda) \) containing \( T \) and is closed under cones, \([\pm 1]\), direct summands and isomorphisms.
Recall that a complex $T$ in $K^b(\text{proj } \Lambda)$ is called two-term if it is a complex concentrated in degree 0 and $-1$. We denote by $2\text{-silt } \Lambda$ the set of isomorphism classes of basic two-term silting complexes in $K^b(\text{proj } \Lambda)$.

Let $K_0(K^b(\text{proj } \Lambda))$ be the split Grothendieck group generated by isomorphism classes of indecomposable complexes $[P_1], [P_2], \ldots, [P_n]$ concentrated in degree 0. For any $T \in K^b(\text{proj } \Lambda)$, we define its $g$-vector as an integer vector $g^T = (g_1, g_2, \ldots, g_n)$ such that $T = \sum_{i=1}^n g_i [P_i]$. Then, \cite{3} Theorem 5.5 implies that a basic two-term silting complex is uniquely determined by its $g$-vector.

**Definition-Proposition 2.3.** (\cite{15} Corollary 2.9) Each of the following conditions is equivalent to $\Lambda$ being $\tau$-tilting finite.

1. There are only finitely many isomorphism classes of indecomposable $\tau$-rigid $\Lambda$-modules.
2. One of (equivalently, any of) $\tau$-tilt $\Lambda$ and $2\text{-silt } \Lambda$ is finite.

Let $C$ be an additive category and $X, Y$ objects of $C$. A morphism $f : X \rightarrow Z$ with $Z \in \text{add}(Y)$ is called a minimal left $\text{add}(Y)$-approximation of $X$ if it satisfies:

- every $h \in \text{Hom}_C(Z, Z)$ that satisfies $h \circ f = f$ is an automorphism.
- $\text{Hom}_C(f, Z') : \text{Hom}_C(Z, Z') \rightarrow \text{Hom}_C(X, Z')$ is surjective for any $Z' \in \text{add}(Y)$, where $\text{add}(Y)$ denotes the category of all direct summands of finite direct sums of copies of $Y$.

Next, we introduce the concept of mutation, which is the core of $\tau$-tilting theory.

**Definition-Proposition 2.4.** (\cite{3} Definition 2.19, Theorem 2.30) Let $T = M \oplus N$ be a basic $\tau$-tilting $\Lambda$-module with an indecomposable summand $M$ satisfying $M \notin \text{Fac}(N)$. We take an exact sequence with a minimal left $\text{add}(N)$-approximation $\pi$,

$$M \xrightarrow{\pi} N' \rightarrow U \rightarrow 0,$$

then we call $\mu_M^T(T) := U \oplus N$ the left mutation of $T$ with respect to $M$. Moreover, $\mu_M^T(T)$ is $\tau$-tilting if $U \neq 0$ and $\mu_M^T(T)$ is support $\tau$-tilting if $U = 0$.

**Remark 2.5.** In the above definition, Zhang \cite{28} Theorem 1.2 showed that $U$ is either zero or indecomposable ($\notin \text{add}(T)$).

We define the support $\tau$-tilting quiver $Q(\tau\text{-silt } \Lambda)$ of $\Lambda$ as follows.

- The set of vertices is $\tau\text{-silt } \Lambda$.
- We draw an arrow from $M$ to $N$ if $N$ is a left mutation of $M$.

Similarly, we define irreducible left silting mutation (\cite{4} Definition 2.30) of silting complexes. Let $T = X \oplus Y$ be a basic silting complex in $K^b(\text{proj } \Lambda)$ with an indecomposable summand $X$. We take a minimal left $\text{add}(Y)$-approximation $\pi$ and a triangle

$$X \xrightarrow{\pi} Z \rightarrow \text{cone}(\pi) \rightarrow X[1].$$

Then $\text{cone}(\pi)$ is indecomposable and $\mu_X(T) := \text{cone}(\pi) \oplus Y$ is a basic silting complex (\cite{4} Theorem 2.31) in $K^b(\text{proj } \Lambda)$. We call $\mu_X(T)$ the irreducible left mutation of $T$ with respect to $X$. The two-term silting quiver $Q(2\text{-silt } \Lambda)$ of $\Lambda$ is defined as follows.

- The set of vertices is $2\text{-silt } \Lambda$.
- We draw an arrow from $T$ to $S$ if $S$ is an irreducible left mutation of $T$.

### 2.1. Poset structures on $\tau$-silt $\Lambda$ and $2$-silt $\Lambda$.

There exists a natural partial order on $\tau$-silt $\Lambda$ defined as follows.
Definition 2.6. ([3] Lemma 2.25]) For $M, N \in \text{s}r$-tilt $\Lambda$, let $(M, P)$ and $(N, Q)$ be their corresponding support $\tau$-tilting pairs respectively. We say $M \geq N$ if $\text{Fac}(N) \subseteq \text{Fac}(M)$ or, equivalently, $\text{Hom}_\Lambda(N, \tau M) = 0$ and $\text{add}(P) \subseteq \text{add}(Q)$.

We denote the Hasse quiver of $\text{s}r$-tilt $\Lambda$ by $\mathcal{H}(\text{s}r$-tilt $\Lambda)$.

Proposition 2.7. ([3] Theorem 2.33, Corollary 2.34]) The support $\tau$-tilting quiver $Q(\text{s}r$-tilt $\Lambda)$ and the Hasse quiver $\mathcal{H}(\text{s}r$-tilt $\Lambda)$ coincide.

There is a partial order on 2-silt $\Lambda$ introduced in [3] Theorem 2.11]. For any $T, S$ in 2-silt $\Lambda$, we say $T \geq S$ if $\text{Hom}_{\mathcal{K}^b(\text{proj} \Lambda)}(T, S[i]) = 0$ for any $i > 0$. We denote by $\mathcal{H}(2$-silt $\Lambda)$ the Hasse quiver of 2-silt $\Lambda$, which is compatible with mutation.

Proposition 2.8. ([3] Theorem 3.2]) There exists a poset isomorphism between $\text{s}r$-tilt $\Lambda$ and 2-silt $\Lambda$.

Note that $\text{s}r$-tilt $\Lambda$ has the unique maximal element $\Lambda$ and the unique minimal element 0. Then we can define the type of $\mathcal{H}(\text{s}r$-tilt $\Lambda)$ (equivalently, $\mathcal{H}(2$-silt $\Lambda)$).

Definition 2.9. Let $\Lambda$ be a $\tau$-tilting finite algebra. We say that the Hasse quiver $\mathcal{H}(\text{s}r$-tilt $\Lambda)$ is of type $\mathcal{H}_{m,n}$ if it is of the form

\[
\Lambda \leftarrow \triangle_1 \rightarrow \triangle_2 \rightarrow \ldots \rightarrow \triangle_m \rightarrow 0.
\]

Note that $\mathcal{H}_{m,n} \simeq \mathcal{H}_{n,m}$.

2.2. Reduction. There are some reduction theorems. First, we recall the brick-$\tau$-tilting correspondence introduced by Demonet, Iyama and Jasso [15]. Recall that $M \in \text{mod} \Lambda$ is called a brick if $\text{End}_\Lambda(M) = K$. We denote the set of isomorphism classes of bricks in $\text{mod} \Lambda$ by $\text{brick} \Lambda$.

Lemma 2.10. ([15] Theorem 1.4]) An algebra $\Lambda$ is $\tau$-tilting finite if and only if there are only finitely many isomorphism classes of bricks in $\text{mod} \Lambda$.

Let $\Lambda_1, \Lambda_2$ be two algebras over $K$, we call $\Lambda_2$ a factor algebra of $\Lambda_1$ if there exists a surjective $K$-algebra homomorphism $\phi: \Lambda_1 \rightarrow \Lambda_2$.

Corollary 2.11. Assume that $\Lambda_2$ is a factor algebra of $\Lambda_1$. If $\Lambda_2$ is $\tau$-tilting infinite, then so is $\Lambda_1$.

Proof. Note that there exists a $K$-linear fully-faithful functor $T: \text{mod} \Lambda_2 \rightarrow \text{mod} \Lambda_1$. Thus it is clear that $\text{brick} \Lambda_2 \subseteq \text{brick} \Lambda_1$. \hfill \Box

Lemma 2.12. ([3] Theorem 2.14]) There exists a poset isomorphism between $\text{s}r$-tilt $\Lambda$ and $\text{s}r$-tilt $\Lambda^{\text{op}}$.

Lemma 2.13. ([17] Theorem 1]) For an ideal $I$ which is generated by central elements and contained in the Jacobson radical of $\Lambda$, there exists a poset isomorphism between $\text{s}r$-tilt $\Lambda$ and $\text{s}r$-tilt $(\Lambda/I)$.

Lemma 2.14. ([26] Theorem 1.1]) A gentle algebra is $\tau$-tilting finite if and only if it is representation-finite.

Lemma 2.15. Let $\mathcal{K}^b(\text{proj} \Lambda)$ be the homotopy category of $\Lambda$. If $Y \neq 0$ and

\[
T_1 := ( 0 \rightarrow X \xrightarrow{(f)} X \oplus Y \xrightarrow{(-g,f,g)} Z \rightarrow 0 ) \in \mathcal{K}^b(\text{proj} \Lambda),
\]

We denote the Hasse quiver of $\text{s}r$-tilt $\Lambda$ by $\mathcal{H}(\text{s}r$-tilt $\Lambda)$.
Lemma 3.1. In Table \( \Gamma \), algebras \( \Gamma_2 \) and \( \Gamma_{11} \) are \( \tau \)-tilting finite.

3. Main Results

3.1. Some lemmas. We divide the proof of Theorem 1.2 into some lemmas.

Lemma 3.1. In Table \( \Gamma \), algebras \( \Gamma_2 \) and \( \Gamma_{11} \) are \( \tau \)-tilting finite.
Proof. We show that \( \mathcal{H}(2\text{-silt } \Gamma_2) \) and \( \mathcal{H}(2\text{-silt } \Gamma_{11}) \) are finite sets by direct calculation, then the result follows from Proposition 2.8.

(1) The indecomposable projective modules of \( \Gamma_2 \) are \( P_1 := e_1 \Gamma_2 = \frac{e_1}{\mu \beta^2} \) and \( P_2 := e_2 \Gamma_2 = \frac{e_2}{\beta} \), we show that \( \mathcal{H}(2\text{-silt } \Gamma_2) \) is as follows. (We often omit the direct sum symbol \( \oplus \))

\[
\begin{array}{c|c}
0 \rightarrow P_1 & 0 \rightarrow P_2 \\
\mu \beta^2 & \\
\mu \beta^2 & \mu \beta^2
\end{array}
\]

where \( f_1 = \left( \begin{smallmatrix} \mu & 0 \\ \mu \beta \\ \mu \beta^2 \end{smallmatrix} \right) \), \( f_2 = \left( \begin{smallmatrix} \mu \\ 0 \\ 0 \\ \mu \beta \end{smallmatrix} \right) \), \( f_3 = \left( \begin{smallmatrix} \mu & 0 \\ 0 & 0 \\ 0 & \mu \beta \end{smallmatrix} \right) \).

Since \( \text{Hom}_{\mathcal{T}_2}(P_2, P_1) \simeq e_1 \Gamma_2 e_2 = K \mu \perp K \mu \beta \perp K \mu \beta^2 \) and \( \text{Hom}_{\mathcal{T}_2}(P_1, P_2) = 0 \), one can easily compute the mutation at \( P_1 \) and the mutation at \( P_2 \). We only show details for the rest.

(i) Let \( T_2 = X \oplus Y := (0 \rightarrow P_1) \oplus (P_2 \xrightarrow{f_1} P_1^{\oplus 3}) \), then \( \mu^{-1}_X(T_2) \) does not belong to \( 2\text{-silt } \Gamma_2 \) and we ignore this mutation. To compute \( \mu^{-1}_X(T_2) \), we take a triangle \( X \xrightarrow{\pi} Y' \xrightarrow{\text{cone}(\pi)} X[1] \), where \( \pi \) is a minimal left \( \text{add}(Y) \)-approximation. Then \( Y' = Y \) and \( \pi = \left( \begin{smallmatrix} 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right) \).

In fact, if we compose \( \pi \) with the endomorphism

\[
\begin{array}{c|c|c}
Y : & P_2 & P_1^{\oplus 3} \\
\left( k_1 k_2 k_3 \right) & \xrightarrow{\left( \begin{smallmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right)} & \left( \begin{smallmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right) \\
Y : & P_2 & P_1^{\oplus 3}
\end{array}
\]

then all elements of \( \text{Hom}_{\mathcal{T}_2}(X, Y) \) are obtained. If \( \left( \begin{smallmatrix} k_1 k_2 k_3 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right) \), then \( k_1 = 1 \) and \( k_2 = k_3 = 0 \). Thus we get \( Y' = Y \) and \( \pi = \left( \begin{smallmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right) \) as required. By Lemma 2.15

\[
\text{cone}(\pi) = \left( P_1 \oplus P_2 \xrightarrow{\left( \begin{smallmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right)} P_1^{\oplus 3} \right) \sim (P_2 \xrightarrow{f_3} P_1^{\oplus 2}),
\]

thus \( \mu_X^{-1}(T_2) = (P_2 \xrightarrow{f_2} P_1^{\oplus 2}) \oplus (P_2 \xrightarrow{f_1} P_1^{\oplus 3}) \).

(ii) Let \( T_{21} = X \oplus Y := (P_2 \xrightarrow{f_2} P_1^{\oplus 2}) \oplus (P_2 \xrightarrow{f_1} P_1^{\oplus 3}) \), then \( \mu_X^{-1}(T_{21}) \notin 2\text{-silt } \Gamma_2 \). To compute \( \mu_X^{-1}(T_{21}) \), we take a triangle \( Y' \xrightarrow{\pi} X' \xrightarrow{\text{cone}(\pi)} Y'[1] \), and show that \( X' = X^{\oplus 3} \) and \( \pi = \left( \begin{smallmatrix} \beta \\ \beta \end{smallmatrix} \right) \left( \begin{smallmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{smallmatrix} \right) \) is a minimal left \( \text{add}(X) \)-approximation. In fact, we have \( \text{End}_{\mathcal{T}_2}(X^{\oplus 3}) \simeq \text{Mat}(3, 3, K) \) since \( \text{End}_{\mathcal{T}_2}(P_1) = K \), and \( \lambda \circ \pi = \pi \) for any \( \lambda \in \text{End}_{\mathcal{T}_2}(X^{\oplus 3}) \) implies that \( \lambda \) is the identity. By applying Lemma 2.15 twice,
\(\tau\)-tilting finiteness of two-point algebras I

\[
\text{cone}(\pi) = \begin{pmatrix} -\mu & 0 & 0 \\ -\mu \beta & 0 & 0 \\ -e_2 \beta & 0 & \rho \end{pmatrix} \begin{pmatrix} \pi \oplus P_{2}^{\oplus 3} \oplus P_{1}^{\oplus 6} \end{pmatrix} \sim_{h} (P_{2}^{\oplus 2} \to_{\mu} P_{1}^{\oplus 3}),
\]

thus \(\mu_{Y}(T_{211}) = (P_{2} \xrightarrow{f_{2}} P_{1}^{\oplus 2}) \oplus (P_{2}^{\oplus 2} \to_{\mu} P_{1}^{\oplus 3}).\)

(iii) Let \(T_{212} = X \oplus Y := (P \xrightarrow{f_{2}} P_{1}^{\oplus 2}) \oplus (P_{2}^{\oplus 2} \to_{\mu} P_{1}^{\oplus 3}),\) then \(\mu_{Y}(T_{212}) \notin 2\text{-silt } \Gamma_{2}\).

To compute \(\mu_{X}(T_{212}),\) we take a triangle \(X \xrightarrow{\pi} Y \xrightarrow{\tau} \text{cone}(\pi) \xrightarrow{} X[1],\) and show that \(Y' = Y\) and \(\pi = \left( \begin{array}{c} 0 \\ e_2 \end{array} \right), \left( \begin{array}{c} 0 \\ 0 \end{array} \right) \right)\) is a minimal left \(\text{add}(Y)\)-approximation. In fact, if we compose \(\pi\) with the endomorphism

\[
Y : \begin{cases} P_{2}^{\oplus 2} \xrightarrow{f_{3}} P_{1}^{\oplus 3} \\ (k_{1} e_2 - k_{2} \beta e_2, -k_{2} \beta e_2, k_{1} e_2) \end{cases}, \text{where } k_{1}, k_{2} \in K.
\]

then all elements of \(\text{Hom}_{K^{\text{proj}}^{\oplus 2}}(X, Y)\) are obtained. And if \(k_{1} e_2 - k_{2} \beta e_2, -k_{2} \beta e_2, k_{1} e_2) = \left( \begin{array}{c} 0 \\ 1 \end{array} \right), \left( \begin{array}{c} 0 \end{array} \right) \right)\), then \(k_{1} = 1\) and \(k_{2} = 0.\) By Lemma 2.11, we have

\[
\text{cone}(\pi) = \begin{pmatrix} -\mu & 0 & 0 \\ 0 & \rho & 0 \\ -e_2 \beta & 0 & 0 \end{pmatrix} \begin{pmatrix} \pi \oplus P_{2}^{\oplus 3} \oplus P_{1}^{\oplus 3} \end{pmatrix} \sim_{h} (P_{2}^{\oplus 2} \to_{\mu} P_{1}^{\oplus 3}),
\]

thus \(\mu_{X}(T_{212}) = (P_{2} \xrightarrow{f_{2}} P_{1}) \oplus (P_{2}^{\oplus 2} \to_{\mu} P_{1}^{\oplus 3}).\)

(iv) Let \(T_{2121} = X \oplus Y := (P \xrightarrow{f_{2}} P_{1}^{\oplus 2}) \oplus (P_{2}^{\oplus 2} \to_{\mu} P_{1}^{\oplus 3}),\) then \(\mu_{X}(T_{2121}) \notin 2\text{-silt } \Gamma_{2}.\)

To compute \(\mu_{Y}(T_{2121}),\) we take a triangle \(Y \xrightarrow{\pi} X \xrightarrow{\tau} \text{cone}(\pi) \xrightarrow{} Y'[1],\) where \(\pi\) is a minimal left \(\text{add}(X)\)-approximation. Then \(X' = X^{\oplus 3}\) and \(\pi = \left( \begin{array}{c} e_2 \beta \\ 0 \end{array} \right), \left( \begin{array}{c} 1 \end{array} \right) \right)\) since \(\text{End}_{K^{\text{proj}}^{\oplus 2}}(X) = K.\) By Lemma 2.11 we get

\[
\text{cone}(\pi) = \begin{pmatrix} -\mu & 0 & 0 \\ 0 & \rho & 0 \\ -e_2 \beta & 0 & 0 \end{pmatrix} \begin{pmatrix} \pi \oplus P_{2}^{\oplus 3} \oplus P_{1}^{\oplus 3} \end{pmatrix} \sim_{h} (P_{2} \to_{\mu} 0),
\]

thus \(\mu_{Y}(T_{2121}) = (P_{2} \xrightarrow{f_{2}} P_{1}) \oplus (P_{2} \to_{\mu} 0).\)

(v) Let \(T_{21212} = X \oplus Y := (P \xrightarrow{f_{2}} P_{1}^{\oplus 2}) \oplus (P_{2}^{\oplus 2} \to_{\mu} 0),\) then it is clear that \(\mu_{Y}(T_{21212})\) does not belong to 2-silt \(\Gamma_{2}\) and \(\mu_{X}(T_{21212}) = (P_{2} \to_{\mu} 0) \oplus (P_{2} \to_{\mu} 0).\)

(2) Since \(\alpha^{3}, \nu_{\mu}, \nu_{\alpha \mu}, \nu_{\alpha^{2} \mu} \in C(\Gamma_{11}),\) it is enough to consider \(\hat{\Gamma}_{11}\) by Lemma 2.13 where \(\hat{\Gamma}_{11} := \Gamma_{11}/\{\alpha^{3} = \nu_{\mu} = \nu_{\alpha \mu} = \nu_{\alpha^{2} \mu} = 0\}.\) The indecomposable projective modules of \(\hat{\Gamma}_{11}\) are

\[
P_{1} := e_{1} \hat{\Gamma}_{11} = \left( \begin{array}{c} \alpha^{2} \\ \alpha^{3} \end{array} \right) \mu = \left( \begin{array}{c} 1 \\ 2 \end{array} \right) \text{ and } P_{2} := e_{2} \hat{\Gamma}_{11} = \left( \begin{array}{c} \alpha^{3} \nu_{\alpha} \\ \nu_{\alpha^{2}} \end{array} \right) \sim \left( \begin{array}{c} 2 \\ 1 \end{array} \right),
\]

then \(H(2\text{-silt } \hat{\Gamma}_{11})\) is as follows.
we show that there exists the following sequence in Lemma 3.3. Aihara for pointing out this argument. We will show that is similar to case (1) and the mutation at $P_1$ gives a new matrix $M$. To get the $\Gamma$-tilting infinite if $\ell = 2, 3$. This implies that $M^\tau$ is not $-1 \times \text{identity matrix for any } r > 0$ unless $\ell = 2, 3$. Hence $\Lambda$ is $\tau$-tilting infinite if $\ell \geq 4$. The author is grateful to Prof. Aihara for pointing out this argument.

Remark 3.2. (i) In case (1) in the proof of Lemma 3.1 we have obtained the $g$-vectors of $\Gamma_2$ as below.

\[
\begin{array}{cccccc}
(1,0) & \oplus & (1,0) & \oplus & (1,0) & \oplus \\
(0,1) & \oplus & (2,-1) & \oplus & (2,-1) & \oplus \\
(3,-1) & \oplus & (3,-1) & \oplus & (3,-2) & \oplus \\
& \oplus & (1,-1) & \oplus & (1,-1) & \oplus \\
& & (0,-1) & \oplus & (0,-1) & \\
\end{array}
\]

Note that we may also compute the $g$-vectors of $\Gamma_2$ by using the two steps $(3, -1) = 3 \cdot (1, 0) - (0, 1)$ which gives $(\frac{1}{3}, \frac{1}{3})$ and $(2, -1) = -(1, 0) + (3, -1)$ which gives $(-\frac{1}{3}, \frac{1}{3})$. Namely, $(\frac{1}{3}, \frac{1}{3}) \circ (\frac{1}{3}, \frac{1}{3}) = (\frac{2}{3}, -\frac{1}{3})$, $(\frac{1}{3}, \frac{1}{3}) \circ (\frac{1}{3}, -\frac{1}{3}) = (\frac{2}{3}, -\frac{1}{3})$, $(\frac{1}{3}, -\frac{1}{3}) \circ (\frac{1}{3}, -\frac{1}{3}) = (\frac{2}{3}, -\frac{1}{3})$, and $(\frac{1}{3}, -\frac{1}{3}) = (\frac{2}{3}, -\frac{1}{3})$.

(ii) The computation is valid for $\Lambda = KQ/\{\beta^\ell = 0\}$, where $Q := \bullet \xrightarrow{\mu} \bullet \xrightarrow{\beta}$. To get the $g$-vector $(-1,0)\oplus(0,-1)$ for $\Lambda$, we need to repeat the mutation. As in the case $\ell = 3$ above, we may yield the $g$-vector $(\ell-1,-1)\oplus(\ell,-1)$ for $\Lambda$ and we denote it by the matrix $M := \left(\ell^{-1},-1\right)$. When we apply the mutation twice, one calculates $M^2$, which gives a new $g$-vector. Note that the characteristic polynomial of $M$ is cyclotomic if and only if $\ell = 2, 3$. This implies that $M^\tau$ is not $-1 \times \text{identity matrix for any } r > 0$ unless $\ell = 2, 3$. Hence $\Lambda$ is $\tau$-tilting infinite if $\ell \geq 4$. The author is grateful to Prof. Aihara for pointing out this argument.

Lemma 3.3. In Table $\Gamma$, algebras $\Gamma_5$, $\Gamma_6$ and $\Gamma_7$ are $\tau$-tilting infinite.

Proof. We will show that $\mathcal{H}(2\text{-silt } \Gamma_5)$, $\mathcal{H}(2\text{-silt } \Gamma_6)$ and $\mathcal{H}(2\text{-silt } \Gamma_7)$ are infinite sets.

(1) The indecomposable projective modules of $\Gamma_5$ are $P_1 = \frac{e_1}{\alpha \mu \beta}$ and $P_2 = \frac{\beta^2}{\beta}$, we show that there exists the following sequence in $\mathcal{H}(2\text{-silt } \Gamma_5)$.
By Lemma 2.15,

\[ \cdots \]

where \( \mu \) is a matrix

\[ \text{Hom}(\pi, H) \]

Hence,

\[ \text{Note that the map} \ (\pi, \mu) \text{ thus implies there is no nonzero null homotopic endomorphism.} \]

\[ n \rightarrow \lambda \]

\[ \Gamma = \sum\n\]

\[ \tau \rightarrow \mu \]

\[ \cdots \]

Let \( T = X \oplus Y := (P_2^{\oplus n} \xrightarrow{f_n} P_1^{\oplus n+1}) \oplus (P_2^{\oplus n-1} \xrightarrow{f_{n-1}} P_1^{\oplus n}), \) then we show that \( \mu_\tau(T) = S. \) To compute \( \mu_\tau(T), \) we consider \( T \xrightarrow{\pi} X' \xrightarrow{\text{cone}(\pi)} Y[1], \) where \( \pi \) is a minimal left \( \text{add}(X) \)-approximation. Let \( \pi = (\pi_1, \pi_2) \in \text{Hom}_{K^e(\text{proj } \Gamma_5)}(Y, X), \)

\[ Y : \]

\[ \begin{array}{ccc}
\pi_1 & f_{n-1} & P_2^{\oplus n-1} \\
\pi_2 & f_n & P_2^{\oplus n} \end{array} \]

\[ X : \]

\[ \begin{array}{ccc}
P_2^{\oplus n} & f_n & P_2^{\oplus n+1} \\
P_2^{\oplus n} & f_{n-1} & P_2^{\oplus n-1} \end{array} \]

Note that the map \( (p, q, r, s) \in K^4 \mapsto \alpha + (q + s)\alpha \mu \beta \in \Gamma_5 \) is injective and \( \text{Hom}_{K^e \text{proj } \Gamma_5}(P_1, P_2) = 0 \) implies there is no nonzero null homotopic endomorphism. Hence, \( \pi_2 \) is uniquely determined by \( \pi_2 \circ f_{n-1} = f_n \circ \pi_1 \) from the commutativity of maps between two complexes, and it is enough to determine \( \pi_1. \) So is \( \lambda = (\lambda_1, \lambda_2) \in \text{End}_{K^e(\text{proj } \Gamma_5)}(X), \) where \( \lambda_1 \) is in degree \(-1\) and \( \lambda_2 \) is in degree \(0.\)

We have \( \lambda_1 \in \text{span} \{ I_n, \beta E_{n,n}, \beta^2 E_{n,n} \} \) so that \( X \) is indecomposable and

\[ \pi_1 \in \text{span} \left\{ (I_{n-1})_{n\times(n-1)} : (I_n)_{n\times(n-1)} : \beta E_{n,n-1}, \beta^2 E_{n,n-1} \right\}, \]

where \( O \) is a zero matrix with suitable size, \( I_n \) is the \( n \times n \) identity matrix and \( E_{m,n} \) is a matrix \( (a_{i,j})_{m \times n} \) such that \( a_{k,\ell} = 1 \) and \( a_{i,j} = 0 \) for any \( i \neq k, j \neq \ell. \) Then \( X' = X^{\oplus 2} \) and \( \pi = \left( \begin{array}{c} I_{n-1} \\ I_n \end{array} \right), \left( \begin{array}{c} I_{n-1} \\ I_n \end{array} \right) \right) \) since we may obtain all elements of \( \text{Hom}_{K^e \text{proj } \Gamma_5}(Y, X) \) by

\[ \beta E_{n,n} : (I_{n-1})_{n\times(n-1)} = \beta E_{n,n-1} \text{ and } \beta^2 E_{n,n} : (I_{n-1})_{n\times(n-1)} = \beta^2 E_{n,n-1}. \]

By Lemma 2.15,

\[ \text{cone}(\pi) = \cdots \]

\[ \cdots \]

thus \( \mu_\tau(T) = (P_2^{\oplus n} \xrightarrow{f_n} P_1^{\oplus n+1}) \oplus (P_2^{\oplus n+1} \xrightarrow{f_{n+1}} P_1^{\oplus n+2}) = S. \)

(2) The indecomposable projective modules of \( \Gamma_5 \) are
there exists the following sequence in $\mathcal{H}(2\text{-}silt \Gamma_7)$ and the calculation is similar to case (1).

$$
\begin{array}{c}
\begin{pmatrix} 0 \rightarrow P_1 \\ 0 \rightarrow P_2 \end{pmatrix} \\
\oplus
\begin{pmatrix} 0 \rightarrow P_1 \\ 0 \rightarrow P_2 \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} p_{12}^{0,2} f_2, p_{13}^{0,5} \\ p_{21}^{0,1}, p_{13}^{0,3} \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} \cdots \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} p_{2n}^{2n} f_n, p_{2n+1}^{2n+1} \\ p_{2n-1}^{2n} f_{n-1}, p_{2n-1}^{2n-1} \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} \cdots \end{pmatrix}
\end{array}
$$

where $f_1 \begin{pmatrix} \mu \\ \mu \beta \end{pmatrix}$, $f_2 \begin{pmatrix} \mu \\ \mu \beta \\ \mu \beta \end{pmatrix}$, \ldots, $f_{n-1} \begin{pmatrix} \mu \\ \mu \beta \\ \mu \beta \end{pmatrix}$, $f_n \begin{pmatrix} \mu \\ \mu \beta \\ \mu \beta \end{pmatrix}$.

\vspace{0.5cm}

(3) The indecomposable projective modules of $\Gamma_7$ are

$$
P_1 = \begin{pmatrix} \alpha \\ \alpha \beta \end{pmatrix}, \quad P_2 = \begin{pmatrix} \beta \\ \beta \end{pmatrix},
$$

we show that there exists the following sequence in $\mathcal{H}(2\text{-}silt \Gamma_7)$,

$$
\begin{array}{c}
\begin{pmatrix} 0 \rightarrow P_1 \\ 0 \rightarrow P_2 \end{pmatrix} \\
\oplus
\begin{pmatrix} 0 \rightarrow P_1 \\ 0 \rightarrow P_2 \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} p_{12}^{0,2} f_2, p_{13}^{0,5} \\ p_{21}^{0,1}, p_{13}^{0,3} \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} \cdots \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} p_{2n}^{2n} f_n, p_{2n+1}^{2n+1} \\ p_{2n-1}^{2n} f_{n-1}, p_{2n-1}^{2n-1} \end{pmatrix}
\end{array}
\begin{array}{c}
\begin{pmatrix} \cdots \end{pmatrix}
\end{array}
$$

$$
T := \begin{pmatrix} p_{2n}^{2n} f_n, p_{2n+1}^{2n+1} \\ p_{2n-1}^{2n} f_{n-1}, p_{2n-1}^{2n-1} \end{pmatrix} \\
S := \begin{pmatrix} p_{2n+1}^{2n+1} f_{n+1}, p_{2n+1}^{2n+3} \end{pmatrix}
$$

where $f_1 \begin{pmatrix} \mu \\ \mu \beta \end{pmatrix}$, $f_2 \begin{pmatrix} \mu \\ \mu \beta \\ \mu \beta \end{pmatrix}$, \ldots, $f_{n-1} \begin{pmatrix} \mu \\ \mu \beta \\ \mu \beta \end{pmatrix}$, $f_n \begin{pmatrix} \mu \\ \mu \beta \\ \mu \beta \end{pmatrix}$.

Let $T = X \oplus Y := (P_1^{2n} f_n) \oplus (P_1^{2n} f_n)$, then $\mu_\gamma(T) = S$. To compute $\mu_\gamma(T)$, we take a triangle $Y \xrightarrow{\pi} X' \xrightarrow{\pi} \text{cone}(\pi) \rightarrow Y[1]$, where $\pi$ is a minimal left add($X$)-approximation.

For $\pi = (\pi_1, \pi_2) \in \text{Hom}_{\mathcal{A}(\text{proj} \Gamma_7)}(Y, X)$ and $\lambda = (\lambda_1, \lambda_2) \in \text{End}_{\mathcal{A}(\text{proj} \Gamma_7)}(X)$, we have $\lambda_1 \in \text{span} \left\{ I_n, \beta_1 E_{n,n}, \beta_2 E_{n,n}, \beta_2 E_{n,n} \right\}$ and $\lambda_2 \in \text{span} \left\{ I_n, \beta_1 E_{n,n}, \beta_2 E_{n,n}, \beta_2 E_{n,n} \right\}$

\vspace{0.5cm}

Then $X' = X^{\oplus 2}$ and $\pi = \begin{pmatrix} (I_n, \beta_1) \\ (I_n, \beta_1) \end{pmatrix}$ since $\beta_1 F_{n,n} \cdot (I_n, \beta_1) = \beta_1 F_{n,n}$.

\vspace{0.5cm}

By using Lemma 2.15

$$
\text{cone}(\pi) = \begin{pmatrix} \begin{pmatrix} f_{n-1} \\ I_{n-1} \\ I_{n-1} \end{pmatrix} \\ f_n \end{pmatrix} \oplus \begin{pmatrix} (I_{2n-1}, f_n) \end{pmatrix} \oplus \begin{pmatrix} (I_{2n-1}, f_n) \end{pmatrix}.
$$
thus \( \mu_\gamma(T) = (P_2^{\oplus n} \xrightarrow{f_n} P_1^{\oplus 2n+1}) \oplus (P_2^{\oplus n+1} \xrightarrow{f_{n+1}} P_1^{\oplus 2n+3}) = S \).

In case (1) and case (3), \( S \) is obtained by \((n + 1)\) irreducible left mutations. It follows from Proposition 2.7 that \( T > S \) and \( S \) cannot be homotopy equivalent to an already computed complex. Thus the sequences in (1) and (3) are infinite. \( \square \)

3.2. Proof of Theorem 1.2. We prove the result case by case.

(1) \( \Gamma_1 \) is just the Kronecker algebra and it is minimal \( \tau \)-tilting infinite, obviously.

(2) It is clear that \( \mathcal{H}(s\tau\text{-}\text{tilt } \Gamma_2) \) is of type \( \mathcal{H}_{1,5} \) by Proposition 2.3 and Lemma 3.1.

(3) By the similar computation as case (1) in the proof of Lemma 3.1 we find that there is a sequence \( T_* : T_2 \rightarrow T_{21} \rightarrow T_{212} \rightarrow T_{2121} \rightarrow T_{21212} \rightarrow T_{212121} \rightarrow \ldots \) in \( \mathcal{H}(2\text{-}\text{silt } \Gamma_3) \) such that

\[
\begin{align*}
\text{End}_{k^0}(\Gamma_3)(T_21) &\approx \text{End}_{k^0}(\Gamma_3)(T_{2121}) \approx \ldots \approx \text{End}_{k^0}(\Gamma_3)(T_{21212121}) \approx \Gamma_3. \\
\text{End}_{k^0}(\Gamma_3)(T_2) &\approx \text{End}_{k^0}(\Gamma_3)(T_{212}) \approx \ldots \approx \text{End}_{k^0}(\Gamma_3)(T_{21212121}) \approx \Gamma_3^{op}.
\end{align*}
\]

We have the following sequence of \( g \)-vectors for \( \Gamma_3 \) (similar to Remark 3.2).

The \( g \)-vector \( v_n \) is computed by \((\frac{3}{2} - 1)^n\) and it is of the form \((a_n, 1 - n) \oplus (b_n, 3 - 2n)\). Then \( v_{2n+1} = (a_n, 1 - n) \oplus (4a_n - b_n, 1 - 2n) \). This means that \( T_* \) is an infinite sequence by [15] Theorem 6.5, thus \( \Gamma_3 \) is \( \tau \)-tilting infinite. For the minimality, it is enough to consider \( \hat{\Gamma}_3 := \mathcal{H}_3/\{\mu \beta^3 = 0\} \) since \( \text{Soc}(P_1) = K\mu \beta^3 \) and \( \text{Soc}(P_2) = K\beta^3 \). Note that \( \mathcal{H}(s\tau\text{-}\text{tilt } \hat{\Gamma}_3) \approx \mathcal{H}(s\tau\text{-}\text{tilt } \Gamma_2) \), thus \( \Gamma_3 \) is minimal \( \tau \)-tilting infinite.

(4) \( \Gamma_4 \) is a gentle algebra and it is representation-tame by Hoshino and Miyachi’s result [20] Theorem A, thus \( \Gamma_4 \) is \( \tau \)-tilting infinite by Lemma 2.14. For the minimality, we consider \( \hat{\Gamma}_4 := \Gamma_4/\{\alpha \mu = 0\} \) since \( \text{Soc}(P_1) = K\alpha \mu \beta \) and \( \text{Soc}(P_2) = K\beta \). Denote the projective modules of \( \hat{\Gamma}_4 \) by \( \hat{P}_1 \) and \( \hat{P}_2 \), then \( \hat{P}_1 = \frac{1}{2} \oplus \frac{2}{1} \), \( \hat{P}_2 = \frac{2}{1} \) and \( \mathcal{H}(s\tau\text{-}\text{tilt } \hat{\Gamma}_4) \) is finite as follows.

\[
\begin{array}{cccccccc}
1 & 2 & 2 & 2 \\
\frac{1}{2} & \frac{2}{1} & \frac{2}{1} & 1 \\
\end{array}
\]

\[
\begin{array}{cccccccc}
1 & 2 & 2 & 2 & 2 \\
\frac{1}{2} & \frac{2}{1} & \frac{2}{1} & 1 & 0 \\
\end{array}
\]

\[
\mathcal{H}(s\tau\text{-}\text{tilt } \hat{\Gamma}_4)
\]

\[
\begin{array}{cccccccc}
1 & 2 & 2 & 2 & 2 & 2 \\
\frac{1}{2} & \frac{2}{1} & \frac{2}{1} & 1 & 0 \\
\end{array}
\]

\[
\mathcal{H}(s\tau\text{-}\text{tilt } \Gamma_5)
\]

(5) For the minimality of \( \Gamma_5 \), we consider \( \Gamma_5 := \Gamma_5/\{\alpha \mu = 0\} \) since \( \text{Soc}(P_1) = K\alpha \mu \beta \) and \( \text{Soc}(P_2) = K\beta \). Note that \( s\tau\text{-}\text{tilt } \hat{\Gamma}_5 \approx s\tau\text{-}\text{tilt } \hat{\Gamma}_4 \), thus \( \Gamma_5 \) is minimal \( \tau \)-tilting infinite.

(6) For the minimality of \( \Gamma_6 \), we consider \( \Gamma_6 := \Gamma_6/\{\beta^3 = 0\} \) since \( \text{Soc}(P_1) = K\alpha \mu \beta = K\mu \beta^3 \), \( \text{Soc}(P_2) = K\beta^3 \) and \( \beta^3 \in C(\Gamma_6/\{\mu \beta^3 = 0\}) \). The indecomposable projective modules of \( \hat{\Gamma}_6 \) are

\[
\hat{P}_1 = \frac{\alpha}{\alpha \mu} \frac{e_1}{\mu \beta \beta^2} \text{ and } \hat{P}_2 = \frac{e_2}{\beta^2},
\]

it is clear that \( \hat{\Gamma}_6 \) is \( \tau \)-tilting finite and \( \mathcal{H}(s\tau\text{-}\text{tilt } \hat{\Gamma}_6) \) is isomorphic to \( \mathcal{H}_{1,5} \).

(7) For the minimality of \( \Gamma_7 \), it is enough to consider \( \Gamma_7 := \Gamma_7/\{\mu \beta_1 = 0\} \). One can easily check that \( \Gamma_7 \) is \( \tau \)-tilting finite and \( \mathcal{H}(s\tau\text{-}\text{tilt } \Gamma_7) \) is of type \( \mathcal{H}_{1,3} \).

(8) In this case, \( P_1 = \frac{1}{2} \), \( P_2 = \frac{2}{1} \), then \( \mathcal{H}(s\tau\text{-}\text{tilt } \Gamma_8) \) is shown as above.
(9) In this case, \( P_1 = \frac{1}{2}, P_2 = \frac{3}{2} \), then by the similar (but easier) computation as \( \Gamma_2 \), one can find that \( \mathcal{H}(s\tau\text{-tilt } \Gamma_9) \simeq \mathcal{H}(2\text{-silt } \Gamma_9) \) is as follows.

\[
\begin{array}{cccccc}
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\end{array}
\]

\( \mathcal{H}(s\tau\text{-tilt } \Gamma_9) \)

\[
\begin{array}{cccccc}
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\end{array}
\]

\( \mathcal{H}(s\tau\text{-tilt } \Gamma_{10}) \)

(10) In this case, \( P_1 = \frac{1}{2}, P_2 = \frac{1}{2} \), then \( \mathcal{H}(s\tau\text{-tilt } \Gamma_{10}) \) is as shown above.

In the following cases, we apply Lemma 2.13 without further notice. We compute the center of an algebra by using GAP, see [29].

(11) \( \mathcal{H}(s\tau\text{-tilt } \Gamma_{11}) \) is of type \( H_{5,5} \) by case (2) in the proof of Lemma 3.1.

(12) Since \( \alpha^3, \nu \mu + \nu \mu \in C(\Gamma_{12}) \), then

\( s\tau\text{-tilt } \Gamma_{12} \simeq s\tau\text{-tilt } (\Gamma_{13}/\{\alpha^3 = \nu \mu + \nu \mu \}) \simeq s\tau\text{-tilt } \Gamma_9. \)

(13) Since \( \alpha^2, \nu \mu, \alpha \nu \mu + \nu \mu \alpha + \nu \mu \in C(\Gamma_{13}) \) and \( \alpha \nu \mu \in C(\hat{\Gamma}_{13}) \), where \( \hat{\Gamma}_{13} := \Gamma_{13}/\{\alpha^2 = \nu \mu \alpha \nu \mu + \nu \mu \alpha = 0 \} \), then \( \nu \mu \in C(\hat{\Gamma}_{13}/\{\alpha \nu \mu = 0 \}) \), thus

\( s\tau\text{-tilt } \Gamma_{13} \simeq s\tau\text{-tilt } (\Gamma_{13}/\{\alpha^2 = \nu \mu = \nu \mu + \nu \mu \alpha = 0 \}) \simeq s\tau\text{-tilt } \Gamma_{10}. \)

(14) Since \( \alpha^2 + \nu \mu, \alpha^3 + \nu \mu \alpha \in C(\Gamma_{14}) \), then

\( s\tau\text{-tilt } \Gamma_{14} \simeq s\tau\text{-tilt } (\Gamma_{14}/\{\alpha^2 = \nu \mu = \nu \mu \alpha = 0 \}) \simeq s\tau\text{-tilt } \Gamma_{10}. \)

(15) Since \( \alpha^3 + \nu \mu, \alpha \nu \mu + \nu \mu \alpha + \alpha \nu \mu \alpha \in C(\Gamma_{15}) \), then

\( s\tau\text{-tilt } \Gamma_{15} \simeq s\tau\text{-tilt } (\Gamma_{15}/\{\alpha^3 = \nu \mu = \nu \mu \alpha + \alpha \nu \mu \alpha = 0 \}) \simeq s\tau\text{-tilt } \hat{\Gamma}_{11}. \)

where \( \hat{\Gamma}_{11} \) is from the proof of Lemma 3.1.

(16) Since \( \alpha^3, \nu \mu, \nu \alpha \mu, \nu \alpha^2 \mu \in C(\Gamma_{16}) \), then

\( s\tau\text{-tilt } \Gamma_{16} \simeq s\tau\text{-tilt } (\Gamma_{16}/\{\alpha^3 = \nu \mu = \nu \alpha \mu + \nu \alpha^2 \mu = 0 \}) \simeq s\tau\text{-tilt } \hat{\Gamma}_{11}. \)

(17) Since \( \alpha^2, \beta, \alpha \nu \mu + \nu \mu \alpha + \nu \mu \alpha \in C(\Gamma_{17}) \) and \( \alpha \nu \mu \in C(\hat{\Gamma}_{17}) \), where \( \hat{\Gamma}_{17} := \Gamma_{17}/\{\alpha^2 = \beta = \nu \mu \alpha \nu \mu + \nu \mu \alpha = 0 \} \), then \( \nu \mu \in C(\hat{\Gamma}_{17}/\{\alpha \nu \mu = 0 \}) \), thus

\( s\tau\text{-tilt } \Gamma_{17} \simeq s\tau\text{-tilt } (\Gamma_{17}/\{\alpha^2 = \beta = \nu \mu = \nu \mu \alpha = 0 \}) \simeq s\tau\text{-tilt } \Gamma_{10}. \)

(18) Since \( \alpha^2, \beta^2, \alpha \nu \mu \in C(\Gamma_{18}) \) and \( \nu \mu \in C(\hat{\Gamma}_{18}/\{\alpha^2 = \beta^2 = \alpha \nu \mu = 0 \}) \), then we have \( s\tau\text{-tilt } \Gamma_{18} \simeq s\tau\text{-tilt } \hat{\Gamma}_{18}, \) where \( \hat{\Gamma}_{18} := \Gamma_{18}/\{\alpha^2 = \beta^2 = \nu \mu = 0 \} \). Then \( \mathcal{H}(s\tau\text{-tilt } \hat{\Gamma}_{18}) \) is as follows.

\[
\begin{array}{cccccc}
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\end{array}
\]

\( \mathcal{H}(s\tau\text{-tilt } \hat{\Gamma}_{18}) \)

\[
\begin{array}{cccccc}
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\frac{1}{2} & \frac{1}{2} & \frac{2}{1} & \frac{2}{1} & \frac{2}{1} & \frac{1}{1} \\hline
\end{array}
\]

\( \mathcal{H}(s\tau\text{-tilt } \hat{\Gamma}_{20}) \)

(19) Since \( \alpha^2 + \beta^2, \nu \alpha \mu, \mu \beta \nu \in C(\Gamma_{19}) \), then \( s\tau\text{-tilt } \Gamma_{19} \simeq s\tau\text{-tilt } \hat{\Gamma}_{19}, \) where

\( \hat{\Gamma}_{19} := \Gamma_{19}/\{\alpha^2 = \beta^2 = \nu \alpha \mu = \mu \beta \nu = 0 \}. \)

Then \( \mathcal{H}(s\tau\text{-tilt } \hat{\Gamma}_{19}) \) is as follows.
Proof of Theorem 1.1. (1) We only show the case $Q_{\Lambda} = Q(0,1,1,0)$. If $\Lambda$ has $\Gamma_3$ as a factor algebra, then it is $\tau$-tilting infinite by Corollary 2.11. If $\Lambda$ does not have $\Gamma_3$ as a factor algebra, we show that either $\Lambda$ is a factor algebra of $\Gamma_2$ or $\beta^3$ is a central element and $\Lambda/\langle \beta^3 = 0 \rangle$ is a factor algebra of $\Gamma_2$.

Let $r = \min \{ i \in \mathbb{N} \mid \beta = 0 \}$. The indecomposable projective modules of $\Lambda$ are

$$ P_1 = \mu_{\beta^r}^{e_1} \quad \text{and} \quad P_2 = \mu_{\beta^r}^{e_2}. $$

If $2 \leq r \leq 3$, then $\beta^3 = 0$ and $\Lambda$ is a factor algebra of $\Gamma_2$. Suppose that $r \geq 4$. If $\mu \beta^3 \neq 0$, then $\Gamma_3$ is a factor algebra of $\Lambda$, so that $\mu \beta^3 = 0$. Then $\beta^3$ is a central element and $\Lambda/\langle \beta^3 = 0 \rangle$ is a factor algebra of $\Gamma_2$. Thus $\Lambda$ is $\tau$-tilting finite if it does not have $\Gamma_3$ as a factor algebra.

(2) We only show the case $Q_{\Lambda} = Q(1,1,1,0)$. Let $I$ be an admissible ideal such that $\Lambda = KQ_{\Lambda}/I$ is finite dimensional. We divide the proof into the following cases.

Case A: $\alpha \mu \in I$ or $\mu \beta \in I$. If $\alpha \mu \in I$, then $\tau$-tilt $\Lambda \simeq \tau$-tilt $\Lambda/\langle \alpha \rangle$ since $\alpha \in C(\Lambda)$. Similarly, $\tau$-tilt $\Lambda \simeq \tau$-tilt $\Lambda/\langle \beta \rangle$ if $\mu \beta \in I$. Both of them are reduced to (1), i.e., the case $Q(0,1,1,0)$ or $Q(1,0,1,0)$.

Case B: $\alpha \mu, \mu \beta \notin I$ and $\alpha \mu$ or $\mu \beta$ appears in the relations. Note that if

$$ \alpha - \sum_{i \geq 1, j \geq 2} k_{ij} \alpha^i \mu^j \in I $$

with $k_{ij} \in K$, then $\alpha \mu = 0$ by recursive operations of replacing $\alpha \mu$ with $\sum k_{ij} \alpha^i \mu^j$ and this is a contradiction. Hence,

$$ \alpha - \sum_{i \geq 1, j \geq 2} k_{ij} \alpha^i \mu^j \notin I $$

for any choice of $k_{ij}$. Similarly, for any choice of $k_{ij}$, we have

$$ \mu \beta - \sum_{j \geq 1, j \geq 2} k_{ij} \alpha^i \mu^j \notin I. $$

Thus we only consider (B.1) and (B.2) below, both of them are reduced to (1).

(B.1) If $\alpha - \sum_{i \geq 0} k_i \mu \beta^i \in I$ with $k_{0} \neq 0$, then $\tau$-tilt $\Lambda \simeq \tau$-tilt $\Lambda/\langle \alpha, \beta^{0} \rangle$ since

$$ \alpha + \sum_{i \geq 0} k_i \beta^i \in C(\Lambda). $$

(B.2) If $\mu \beta - \sum_{j \geq 0} k_j \alpha \beta^j \in I$ with $k_{0} \neq 0$, then $\tau$-tilt $\Lambda \simeq \tau$-tilt $\Lambda/\langle \alpha^{0}, \beta \rangle$ since

$$ \beta + \sum_{j \geq 0} k_j \alpha \beta^j \in C(\Lambda). $$

Case C: $\alpha \mu, \mu \beta \notin I$, except (B.1) and (B.2).

(C.1) $\alpha \mu, \beta \in I$. Let $p = \min \{ i \in \mathbb{N} \mid \alpha^i = 0 \}$ and $q = \min \{ j \in \mathbb{N} \mid \beta^j = 0 \}$. Note that $p \geq 2$ and $q \geq 2$. The indecomposable projective modules of $\Lambda$ are
where there may exist linear dependence in $P_1$. We show that $\Lambda$ is $\tau$-tilting finite if it does not have $\Gamma_3$ or $\Gamma_3^{op}$ as a factor algebra.

Recall $\hat{\Gamma}_4$ and $\hat{\Gamma}_6$ from the proof of Theorem [1,2]. If $(p, q) = (2, 2)$, then $\Lambda \simeq \hat{\Gamma}_4$ and $\mathcal{H}(\text{sr-tilt } \Lambda)$ is of type $\mathcal{H}_{1,4}$. If $(p, q) = (2, 3)$ or $(3, 2)$, then $\Lambda$ is a factor algebra of $\hat{\Gamma}_6$ or $\hat{\Gamma}_6^{op}$. Thus $\Lambda$ is $\tau$-tilting finite.

Suppose that $p \geq 3, q \geq 3$ and $\Lambda$ does not have $\Gamma_3$ or $\Gamma_3^{op}$ as a factor algebra. If $\mu \beta^3 \neq 0$, then we have either $\Gamma_3$ is a factor algebra of $\Lambda$ or

$$a \mu \beta^2 + b \mu \beta^3 = \sum_{i \geq 2} k_i \alpha_i \mu,$$

for some $k_i \in K$ and $(0, 0) \neq (a, b) \in K^2$. In the latter case, we have

$$\text{sr-tilt } \Lambda \simeq \text{sr-tilt } (\Lambda/\{a \mu \beta^2 + b \mu \beta^3 = 0\}),$$

so that we may assume $\mu \beta^3 = 0$. Similarly, we may assume that $\alpha^3 \mu = 0$ holds. Then $\alpha^3$ and $\beta^3$ are central elements of $\Lambda$. Thus it is enough to consider

$$\Lambda' = KQ(1, 1, 1, 0)/\{\alpha^3 = \beta^3 = \alpha \mu \beta = 0\}.$$

One can check that $\Lambda'$ is $\tau$-tilting finite and $\mathcal{H}(\text{sr-tilt } \Lambda')$ is of type $\mathcal{H}_{1,5}$ by the similar computation with Lemma [3] thus we omit the details.

(C.2) $\alpha \mu \beta \notin I$. In this case, let $p = \min\{i \in \mathbb{N} \mid \alpha^i = 0\}$, $r = \min\{i \in \mathbb{N} \mid \alpha^i \mu = 0\}$, $q = \min\{j \in \mathbb{N} \mid \beta^j = 0\}$ and $t = \min\{j \in \mathbb{N} \mid \mu \beta^j = 0\}$. Note that $p \geq r \geq 2$ and $q \geq t \geq 2$. The indecomposable projective modules of $\Lambda$ are

$$P_1 = \begin{array}{cccccc}
\alpha^3 & \alpha^2 & \alpha \mu & \mu \beta & e_1 \\
\alpha^2 & \alpha \mu & \mu \beta & e_2 \\
\alpha & e_3 \\
\alpha^r & \alpha^r \mu & \alpha^r \mu \beta & \mu \beta^r & e_1 \\
\alpha^r & \alpha^r \mu & \alpha^r \mu \beta & e_2 \\
\alpha & e_3 \\
\alpha^p & \alpha^p \mu & \alpha^p \mu \beta & \mu \beta^p & e_1 \\
\alpha^p & \alpha^p \mu & \alpha^p \mu \beta & e_2 \\
\alpha & e_3 \\
\alpha^t & \alpha^t \mu & \alpha^t \mu \beta & \mu \beta^t & e_1 \\
\alpha^t & \alpha^t \mu & \alpha^t \mu \beta & e_2 \\
\alpha & e_3 \\
\alpha^q & \alpha^q \mu & \alpha^q \mu \beta & \mu \beta^q & e_1 \\
\alpha^q & \alpha^q \mu & \alpha^q \mu \beta & e_2 \\
\alpha & e_3 \\
\alpha^q & \alpha^q \mu & \alpha^q \mu \beta & \mu \beta^q & e_1 \\
\alpha^q & \alpha^q \mu & \alpha^q \mu \beta & e_2 \\
\alpha & e_3 \\
\end{array}$$

and $P_2 = \begin{array}{cccccc}
\beta^3 & e_2 \\
\beta^2 & e_2 \\
\beta^1 & e_2 \\
\beta^r & \beta^r \beta^t & e_2 \\
\beta^r & \beta^r \beta^t & e_2 \\
\beta & e_3 \\
\beta^p & \beta^p \beta^t & e_2 \\
\beta^p & \beta^p \beta^t & e_2 \\
\beta & e_3 \\
\beta^q & \beta^q \beta^t & e_2 \\
\beta^q & \beta^q \beta^t & e_2 \\
\beta & e_3 \\
\beta^t & \beta^t \beta^t & e_2 \\
\beta^t & \beta^t \beta^t & e_2 \\
\beta & e_3 \\
\beta^q & \beta^q \beta^t & e_2 \\
\beta^q & \beta^q \beta^t & e_2 \\
\beta & e_3 \\
\beta^t & \beta^t \beta^t & e_2 \\
\beta^t & \beta^t \beta^t & e_2 \\
\beta & e_3 \\
\end{array}$

where some of $\alpha^i \mu \beta^j$ may be zero and there may exist linear dependence in $P_1$. We show that $\Lambda$ is $\tau$-tilting infinite.

If $(p, q) = (2, 2)$, then $\Lambda = \Gamma_4$. Suppose that $(p, q) \neq (2, 2)$. If there is no linear dependence between $\alpha \mu \beta$ and $\{\alpha^i \mu \beta^j, \alpha^i \mu \beta^j \}_{1 \leq i, s < r, 1 \leq j, d < t}$, then $\Lambda$ is $\tau$-tilting infinite since $\Lambda$ has $\Gamma_4$ as a factor algebra.

If there is a linear dependence between $\alpha \mu \beta$ and $\{\alpha^i \mu \beta^j, \alpha^i \mu \beta^j \}_{1 \leq i, s < r, 1 \leq j, d < t}$, then we show that it is enough to consider (C.2.1), (C.2.2) and (C.2.3) below. First, one can easily check that

$$\alpha \mu \beta - \sum_{1 \leq i < r, 1 \leq j < t, (i, j) \neq (1, 1)} k_{ij} \alpha^i \mu \beta^j \notin I$$

for any $k_{ij} \in K$.

(i) Assume that

$$\alpha \mu \beta - \sum_{s \geq 1} k_{is} \alpha^i \mu - \sum_{1 \leq i < r, 1 \leq j < t, (i, j) \neq (1, 1)} k_{ij} \alpha^i \mu \beta^j \in I$$
with $2 \leq i_s < r$, $0 \neq k_{i_s} \in K$ and $k_{ij} \in K$. Rewriting procedure changes $(i, j)$ to $(i', j - 1)$ with $i' \geq i + 1$ or $(i', j')$ with $i' \geq i$, $j' \geq j$ and $(i', j') \neq (i, j)$. Then it reduces to the following case.

(C.2.1)  
\[ \alpha \mu \beta - \sum_{s \geq 1} k_{i_s} \alpha^s \mu \in I \]

with $2 \leq i_s < r$ and $0 \neq k_{i_s} \in K$. Then $\min \{i_s\}_{s \geq 1}$ depends on relations of the form (C.2.1) and let $i_0$ be the minimum.

- If $i_0 = 2$, then $e_1, e_2, \alpha, \mu, \beta, \alpha^2, \alpha \mu, \mu \beta, \alpha \mu \beta$ are linearly independent and $\Lambda$ has $\Gamma_5^{\text{op}}$ as a factor algebra. More precisely, $\Lambda/\{\alpha^3 = \beta^2 = 0\} \simeq \Gamma_5^{\text{op}}$.
- If $i_0 = 3$, then $\Lambda$ has $\Gamma_6^{\text{op}}$ as a factor algebra, i.e., $\Lambda/\{\alpha^4 = \beta^3 = 0\} \simeq \Gamma_6^{\text{op}}$ since $\mu \beta^2$ and $\mu \beta^3$ are linearly independent by the definition of $i_0$. Note that even though $\alpha^3 \mu$ appears in the basis of $\Lambda$, $\Lambda$ does not have $\Gamma_3^{\text{op}}$ as a factor algebra. Because there exists a linear dependence $\alpha \mu \beta - k_3 \alpha^3 \mu - \ldots \in I$ so that we cannot construct a $K$-algebra homomorphism from $\Lambda$ to $\Gamma_3^{\text{op}}$.
- If $i_0 \geq 4$, then $\Lambda$ has $\Gamma_3^{\text{op}}$ as a factor algebra, i.e., $\Lambda/\{\alpha^4 = 0\} \simeq \Gamma_3^{\text{op}}$.

Hence $\Lambda$ is $\tau$-tilting infinite.

(ii) Assume that

\[ \alpha \mu \beta - \sum_{d \geq 1} k_{jd} \mu \beta^{jd} - \sum_{1 \leq i < r, 1 \leq j < t, [(i, j) \neq (1, 1)]} k_{ij} \alpha^i \mu \beta^j \in I \]

with $2 \leq j_d < t$, $0 \neq k_{jd} \in K$ and $k_{ij} \in K$. Rewriting procedure changes $(i, j)$ to $(i - 1, j')$ with $j' \geq j + 1$ or $(i', j')$ with $i' \geq i$, $j' \geq j$ and $(i', j') \neq (i, j)$. Then it reduces to the following case.

(C.2.2)  
\[ \alpha \mu \beta - \sum_{d \geq 1} k_{jd} \mu \beta^{jd} \in I \]

with $2 \leq j_d < t$ and $0 \neq k_{jd} \in K$. Then $\min \{j_d\}_{d \geq 1}$ depends on relations of the form (C.2.2) and let $j_0$ be the minimum.

- If $j_0 = 2$, then $\Lambda$ has $\Gamma_5$ as a factor algebra, i.e., $\Lambda/\{\alpha^2 = 0\} \simeq \Gamma_5$.
- If $j_0 = 3$, then $\Lambda$ has $\Gamma_6$ as a factor algebra, i.e., $\Lambda/\{\alpha^4 = 0\} \simeq \Gamma_6$.
- If $j_0 \geq 4$, then $\Lambda$ has $\Gamma_3$ as a factor algebra, i.e., $\Lambda/\{\alpha = 0\} \simeq \Gamma_3$.

Hence $\Lambda$ is $\tau$-tilting infinite.

(iii) Assume that

\[ \alpha \mu \beta - \sum_{s > 1} k_{i_s} \alpha^s \mu - \sum_{d \geq 1} k_{jd} \mu \beta^{jd} - \sum_{1 \leq i < r, 1 \leq j < t, [(i, j) \neq (1, 1)]} k_{ij} \alpha^i \mu \beta^j \in I \]

with $2 \leq i_s < r$, $2 \leq j_d < t$, $0 \neq k_{i_s} \in K, 0 \neq k_{jd} \in K$ and $k_{ij} \in K$. Rewriting procedure changes $(i, j)$ to $(i', j - 1)$ with $i' \geq i + 1$ or $(i', j')$ with $j' \geq j + 1$ or $(i', j')$ with $i' \geq i$, $j' \geq j$ and $(i', j') \neq (i, j)$. Then it reduces to the following case.

(C.2.3)  
\[ \alpha \mu \beta - \sum_{s > 1} k_{i_s} \alpha^s \mu - \sum_{d \geq 1} k_{jd} \mu \beta^{jd} \in I \]

with $2 \leq i_s < r$, $2 \leq j_d < t$, $0 \neq k_{i_s} \in K$ and $0 \neq k_{jd} \in K$. Similarly, $\min \{i_s\}_{s \geq 1}$ and $\min \{j_d\}_{d \geq 1}$ depend on relations of the form (C.2.3). Let $i_0$ and $j_0$ be their minimums respectively.

- If $(i_0, j_0) = (2, 2)$, then $\Lambda$ has $\Gamma_5$ and $\Gamma_5^{\text{op}}$ as factor algebras.
- If $(i_0, j_0) = (3, 3)$, then $\Lambda$ has $\Gamma_6$ and $\Gamma_6^{\text{op}}$ as factor algebras.
• If \((i_0, j_0) = (2, 3)\) or \((3, 2)\), then \(\Lambda\) has \(\Gamma_3^\text{op}\) and \(\Gamma_6\) or \(\Gamma_5\) and \(\Gamma_5^\text{op}\) as factor algebras.
• If \((i_0, j_0) = (2, 4)\) or \((4, 2)\), then \(\Lambda\) has \(\Gamma_3\) and \(\Gamma_3^\text{op}\) or \(\Gamma_3^\text{op}\) and \(\Gamma_5\) as factor algebras.
• If \((i_0, j_0) = (3, 4)\) or \((4, 3)\), then \(\Lambda\) has \(\Gamma_3\) and \(\Gamma_6^\text{op}\) or \(\Gamma_3^\text{op}\) and \(\Gamma_6\) as factor algebras.
• If \(i_0 \geq 4\) and \(j_0 \geq 4\), then \(\Lambda\) has \(\Gamma_3\) and \(\Gamma_6^\text{op}\) as factor algebras.

Hence \(\Lambda\) is \(\tau\)-tilting infinite.

Conversely, if \(\Lambda\) does not have one of \(\Gamma_3, \Gamma_4, \Gamma_5, \Gamma_6\) and their opposite algebras as a factor algebra, we must have \(\alpha\mu\beta \in I\). Then \(\Lambda\) is \(\tau\)-tilting finite by (C.1).

**Corollary 3.4.** Let \(\Lambda\) be a two-point algebra without loops, \(\Lambda\) is \(\tau\)-tilting finite if and only if it is representation-finite.

**Proof.** It is well-known that \(\Lambda\) is \(\tau\)-tilting finite if and only if its Gabriel quiver satisfying \(Q(0,0,m,n), m \leq 1\) and \(n \leq 1\). In fact, any finite dimensional algebra with quiver \(Q(0,0,1,1)\) or \(Q(0,0,1,0) \simeq Q(0,0,0,1)\) is representation-finite from Bongartz and Gabriel \[12\]. \(\square\)

4. Application 1

We recall the main result in \[19\] as follows. See the end of this paper for Table T and Table W.

**Proposition 4.1.** (\[19\] Theorem 1) Let \(A\) be a two-point algebra. Up to isomorphism and duality, \(A\) is representation-tame if and only if \(A\) degenerates to a factor algebra of a tame algebra from Table T, and \(A\) is representation-wild if and only if \(A\) has a wild algebra from Table W as a factor algebra.

4.1. **Proof of Theorem \[13\]** First, one can easily check that

• \(T_1, W_1, W_2, W_3\) and \(W_3\) have \(\Gamma_1\) as a factor, \(\Gamma_3\) and \(T_{17}\) have \(\Gamma_4\) as a factor.
• \(T_2, W_6\) and \(W_7\) do not have \(\Gamma_3\) or \(\Gamma_3^\text{op}\) as a factor algebra.
• \(T_3 \sim T_8\) and \(W_5 \sim W_{13}\) do not have one of \(\Gamma_3, \Gamma_4, \Gamma_5, \Gamma_6\) and their opposite algebras as a factor algebra.
• \(#s\tau\)-tilt \(T_{20} = 7\) and \(#s\tau\)-tilt \(T_{21} = 6\) (by the following computation).
• \(T_5\) is a factor algebra of \(\Gamma_{13}\); \(T_{10}, W_{14}, W_{15}, W_{16}, W_{17}, W_{18}\) and \(W_{19}\) are factor algebras of \(\Gamma_{11}\); \(T_{11}, T_{15}, T_{16}\) and \(W_{24}\) are factor algebras of \(\Gamma_{15}\); \(T_{12}\) is a factor algebra of \(\Gamma_{16}\); \(T_{13}, W_{20}, W_{21}\) and \(W_{22}\) are factor algebras of \(\Gamma_{12}\) when \(n \geq 2\); \(T_{14}\) and \(W_{23}\) are factor algebras of \(\Gamma_{14}\); \(T_{18}\) and \(W_{25}\) are factor algebras of \(\Gamma_{17}\); \(T_{19}, W_{31}, W_{32}, W_{33}\) and \(W_{34}\) are factor algebras of \(\Gamma_{20}\); \(W_4\) is a factor algebra of \(\Gamma_7\); \(W_{25}\) is a factor algebra of \(\Gamma_{18}\); \(W_{27}, W_{28}, W_{29}\) and \(W_{30}\) are factor algebras of \(\Gamma_{19}\).

Therefore, we can determine \(\tau\)-tilting finiteness of Table T (except \(T_{20}\) and \(T_{21}\)) and Table W by Table \(\Gamma\) and Theorem \[1.1\].

Next, we apply Lemma \[2.13\] to construct a two-sided ideal \(I\) generated by elements which are contained in the center and the radical of \(T_{i}\) (respectively, \(W_{i}\)) such that \(s\tau\)-tilt \(\Lambda \simeq s\tau\)-tilt \((T_{i}/I)\) (respectively, \(s\tau\)-tilt \((W_{i}/I)\)). Then, we can determine the number of support \(\tau\)-tilting modules as follows.
We show Theorem 1.4 for the remaining cases by direct calculation.

Case $(T_5)$. Since $\alpha^2 \in C(T_5)$, then $\text{sr-tilt } T_5 \simeq \text{sr-tilt } (T_2/\{\alpha^2 = 0\})$.

Case $(T_9)$. Since $\alpha, \beta \in C(T_9)$, then $\text{sr-tilt } T_9 \simeq \text{sr-tilt } (T_5/\{\alpha = \beta = 0\})$.

The corresponding Hasse quivers are as follows.

\[
\begin{array}{c}
\begin{array}{c}
\frac{1}{2} \oplus 2 \\
\frac{1}{2} \oplus \frac{1}{2} \rightarrow \frac{1}{2} \oplus \frac{1}{2} \rightarrow \frac{1}{2} \rightarrow 0 \\
\end{array}
\rightarrow \begin{array}{c}
\frac{1}{2} \oplus 2 \\
\frac{1}{2} \oplus 1 \rightarrow 1 \rightarrow 0 \\
\end{array}
\end{array}
\]

\(\mathcal{H}(\text{sr-tilt } (T_2/\{\alpha^2 = 0\}))\)

\(\mathcal{H}(\text{sr-tilt } (T_5/\{\alpha = \beta = 0\}))\)

Case $(T_9)$. Since $\nu \mu, \alpha \nu \mu + \mu \alpha \nu + \nu \alpha \mu \in C(T_9)$ and $\alpha \nu \mu \in C(T_9)$, where $\tilde{T_9} := T_9/\{\nu \mu = \alpha \nu \mu = \alpha \mu \nu + \mu \nu \alpha = 0\}$. Then $\nu \mu \in C(T_9/\{\alpha \mu \nu = 0\})$, thus

\(\text{sr-tilt } T_9 \simeq \text{sr-tilt } (T_9/\{\nu \mu = \alpha \nu \mu = \alpha \mu \nu + \mu \nu \alpha = 0\}) \simeq \text{sr-tilt } \tilde{T_9} \Gamma_{10}\).

Case $(T_{20})$. If $k = 1$, then $\mu \nu + \nu \mu \in C(T_{20})$. If $k \geq 2$, then $\nu \mu, \nu \mu \in C(T_{20})$. Thus $\text{sr-tilt } T_{20} \simeq \text{sr-tilt } (T_{20}/\{\nu \mu = \nu \mu = 0\})$.

\[
\begin{array}{c}
\begin{array}{c}
\frac{1}{2} \oplus \frac{2}{1} \\
\frac{1}{2} \oplus \frac{1}{2} \rightarrow \frac{1}{2} \oplus \frac{1}{2} \rightarrow \frac{1}{2} \rightarrow 0 \\
\end{array}
\rightarrow \begin{array}{c}
\frac{1}{2} \oplus \frac{2}{1} \\
\frac{1}{2} \oplus 1 \rightarrow 1 \rightarrow 0 \\
\end{array}
\end{array}
\]

\(\mathcal{H}(\text{sr-tilt } (T_{20}/\{\nu \mu = \nu \mu = 0\}))\)

\(\mathcal{H}(\text{sr-tilt } (T_{21}/\{\nu \mu = \nu \mu = 0\}))\)

Case $(T_{21})$. If $(k_1, k_2) = (m, 1)$, then $\text{sr-tilt } T_{21} \simeq \text{sr-tilt } (T_{21}/\{\alpha = \beta = 0\}) \simeq \text{sr-tilt } \tilde{T_{21}}$ since $\alpha + \beta \in C(T_{21})$. If $(k_1, k_2) = (1, n)$, then $\nu \mu + \nu \mu \in C(T_{20})$. If $(k_1, k_2) = (m, n)$ with $m, n \geq 2$, then $\nu \mu, \nu \mu \in C(T_{20})$. Thus $\text{sr-tilt } T_{21} \simeq \text{sr-tilt } (T_{21}/\{\nu \mu = \nu \mu = 0\})$.

The corresponding Hasse quiver is shown above.

Case $(W_4)$ and $(W_{28})$. Note that $\nu \mu \in C(W_{28})$, we have
Case $(W_{14})$. Note that $\nu \alpha \mu \in C(W_{14})$ and the indecomposable projective modules of $W_{14}/\{\nu \alpha \mu = 0\}$ are

$$P_1 = \alpha^2 \alpha \alpha^1 \mu$$
and

$$P_2 = \nu \nu^1 \nu^2,$$

then one can check that the Hasse quiver $H(s\tau\text{-tilt}(W_{14}/\{\nu \alpha \mu = 0\}))$ is of type $H_{3,5}$.

**Corollary 4.2.** The number of bricks in $\text{mod } W_i$ is as follows.

**Proof.** This is an immediate consequence of Theorem **1.4** and the fact

$$\#\text{brick } \Lambda = \#s\tau\text{-tilt } \Lambda - 2$$

for a given $\tau$-tilting finite algebra $\Lambda$. □

Note that the proof of Theorem 2 in [19] depends on $\#\text{brick } W_i$, thus we can check that proof by Corollary **4.2**. Unfortunately, there are two missing in the proof of Theorem 2 of [19], but Theorem 2 still holds. We got Prof. Han’s permission to make up for these missing as follows.

**Remark 4.3.** Let $A$ be an algebra from the proof of Theorem 2 in [19].

1. In case $A = W(14)$, there are 8 bricks in $\text{mod } A$ and $\text{Ext}_A^1(B_8, B_8) = 0$, where

$$B_8 := \left(k^3, k^2; \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, 0; \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}\right).$$

2. In case $A = W(23)$, there are 6 bricks in $\text{mod } A$, $\text{Ext}_A^1(B_4, B_4) = 0$ and $\text{Ext}_A^1(B_6, B_6) = 0$, where

$$B_4 := (k^2, k; (0, 0), (0, 1), 0)$$
and

$$B_6 := (k^2, k; (0, 0), (0, 1), 0).$$

**5. Application 2**

**5.1. Two-point symmetric special biserial algebras.** For basic concepts and properties of symmetric special biserial algebras, or equivalently, Brauer graph algebras, we refer to [25].

In [9], the authors classified two-point symmetric special biserial algebras up to Morita equivalence, so that we can determine their $\tau$-tilting finiteness. First, we recall the classification from [9].
Proposition 5.1. ([9] Theorem 7.1) Let $\Lambda$ be a two-point symmetric special biserial algebra, then $\Lambda$ is Morita equivalent to one of the bound quiver algebras below.

$\mu$  
$\nu$  

$B_1 : (\mu\nu)^n\mu = (\nu\mu)^n\nu = 0, n \geq 1.$

$\mu_1, \mu_2$  
$\nu_1, \nu_2$  

$B_2 : \mu_1\nu_2 = \nu_2\mu_1 = \mu_2\nu_1 = \nu_1\mu_2 = 0,$
\[ (\mu_1\nu_1)^m = (\mu_2\nu_2)^n, (\nu_1\mu_1)^m = (\nu_2\mu_2)^n, m, n \geq 1. \]

$B_3 : \mu_1\nu_2 = \nu_1\mu_1 = \mu_2\nu_1 = \nu_1\mu_2 = 0,$
\[ (\mu_1\nu_1\mu_2\nu_2)^n = (\mu_2\nu_2\mu_1\nu_1)^n, (\nu_1\nu_2\mu_1\mu_2)^n = (\nu_2\mu_1\nu_1\mu_2)^n, n \geq 1. \]

$\alpha$  
$\mu$  
$\nu$  

$B_4 : \alpha\mu = \nu\alpha = 0, \alpha^m = (\mu\nu)^n, m \geq 2, n \geq 1.$

$B_5 : \alpha^2 = \nu\mu = 0, (\alpha\mu\nu)^n = (\mu\nu\alpha)^n, n \geq 1.$

$\alpha$  
$\mu$  
$\nu$  

$B_6 : \alpha\mu = \mu\beta = \beta\nu = \nu\alpha = 0, \alpha^m = (\mu\nu)^n, \beta^r = (\nu\mu)^n, m, r \geq 2, n \geq 1.$

$B_7 : \alpha^2 = \nu\mu = \mu\beta = \beta\nu = 0, (\alpha\mu\nu)^n = (\mu\nu\alpha)^n, n \geq 2, n \geq 1.$

$B_8 : \alpha^2 = \beta^2 = \mu\nu = \nu\mu = 0, (\nu\alpha\mu\beta)^n = (\beta\nu\alpha\mu)^n, (\alpha\mu\beta\nu)^n = (\beta\nu\alpha\mu)^n, n \geq 1.$

In the above, we assume that $m, n, r \in \mathbb{N}$.

Then, we have the following result.

Theorem 5.2. Let $B_i$ be an algebra from the above list, then $B_i$ is $s\tau$-tilting finite if $i = 1, 4, 5, 6, 7$, $s\tau$-tilting infinite if $i = 2, 3, 8$. Moreover, we have

<table>
<thead>
<tr>
<th>$B_i$</th>
<th>$B_1$</th>
<th>$B_4$</th>
<th>$B_5$</th>
<th>$B_6$</th>
<th>$B_7$</th>
</tr>
</thead>
<tbody>
<tr>
<td>#s$\tau$-tilt $B_i$</td>
<td>6</td>
<td>8</td>
<td>6</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>type</td>
<td>$\mathcal{H}_{3,2}$</td>
<td>$\mathcal{H}_{3,3}$</td>
<td>$\mathcal{H}_{3,2}$</td>
<td>$\mathcal{H}_{3,3}$</td>
<td></td>
</tr>
</tbody>
</table>

Proof. First, one can easily check that $B_2$ and $B_3$ contain $\Gamma_1$ as a factor, and $B_8$ contains $\Gamma_1$ as a factor. Therefore, they are $s\tau$-tilting infinite by Corollary 5.11.

Then, we show the remaining as follows.

1. Case $(B_1)$. If $n = 1$, then $\mu\nu, \nu\mu \in C(B_1)$. If $n \geq 2$, then $\mu\nu + \nu\mu \in C(B_1)$.
Both of them are satisfying
\[ s\tau\text{-tilt } B_1 \simeq s\tau\text{-tilt } (B_1/\{\mu\nu = \nu\mu = 0\}) \simeq s\tau\text{-tilt } \hat{\Gamma}_{20}. \]

2. Case $(B_4)$. If $n = 1$, then $\alpha, \nu\mu \in C(B_4)$. If $n \geq 2$, then $\alpha, \mu\nu + \nu\mu \in C(B_4)$.
We have $s\tau\text{-tilt } B_4 \simeq s\tau\text{-tilt } (B_4/\{\alpha = \mu\nu = \nu\mu = 0\}) \simeq s\tau\text{-tilt } \hat{\Gamma}_{20}.

3. Case $(B_5)$. If $n = 1$, then $\mu\nu, \nu\alpha\mu \in C(B_5)$. If $n \geq 2$, then $\alpha\mu\nu + \mu\alpha\nu \in C(B_5)$ and $\alpha\mu\nu \in C(B_5)$ such that $\mu\nu \in C(B_5/\{\alpha\mu\nu = 0\})$, where
\[ B_5 \colonequals B_5/\{\nu\alpha\mu = \alpha\mu\nu + \mu\alpha\nu = 0\}. \]
Thus,
\[ s\tau\text{-tilt } B_5 \simeq s\tau\text{-tilt } (B_5/\{\mu\nu = \nu\alpha\mu = 0\}) \simeq s\tau\text{-tilt } \hat{\Gamma}_{10}. \]

4. Case $(B_6)$. If $n = 1$, then $\alpha, \beta \in C(B_6)$. If $n \geq 2$, then $\alpha, \beta, \mu\nu + \nu\mu \in C(B_6)$.
We have $s\tau\text{-tilt } B_6 \simeq s\tau\text{-tilt } (B_6/\{\alpha = \beta = \mu\nu = \nu\mu = 0\}) \simeq s\tau\text{-tilt } \hat{\Gamma}_{20}. \]
(5) Case \((B_7)\). If \(n = 1\), then \(\beta, \mu \nu \in C(B_7)\). If \(n \geq 2\), then \(\beta, \alpha \mu \nu + \mu \alpha \nu \in C(B_7)\) and \(\alpha \mu \nu \in C(B_7)\) such that \(\mu \nu \in C(B_7/\{\alpha \mu \nu = 0\})\), where 
\[\hat{B}_7 := B_7/\{\beta = \nu \alpha \mu = \alpha \mu \nu + \mu \alpha = 0\}.\]
Thus, 
\[s\tau\text{-tilt} B_7 \simeq s\tau\text{-tilt} (B_7/\{\beta = \mu \nu = \nu \alpha \mu = 0\}) \simeq s\tau\text{-tilt} \Gamma_{10}.\]

\[\square\]

5.2. Tame blocks of Hecke algebras. In this subsection, let \(K\) be an algebraically closed field of characteristic not equal to 2. Recall that any finite dimensional algebra over an algebraically closed field has exactly one representation type: representation-finite, (infinite-)tame or wild.

We consider the block algebras of Hecke algebras of classical type over \(K\), which are studied by Prof. Ariki [7] and [8].

**Proposition 5.3.** ([7, Theorem C], [8, Theorem 2]) Let \(\Lambda\) be a block algebra of Hecke algebras of classical type over \(K\).

1. If \(\Lambda\) is representation-finite, then it is a Brauer tree algebra \(\Lambda_n := KQ/I\) with the following quiver and relations.

\[Q : 1 \xrightarrow{\alpha_1} 2 \xrightarrow{\alpha_2} \cdots \xrightarrow{\alpha_{n-2}} n \xleftarrow{\alpha_{n-1}} n\]

\[I : \alpha_i \alpha_{i+1} = \beta_i, \beta_i = \beta_{i-1} = \alpha_{i+1} \beta_{i+1} = 0, 1 \leq i \leq n - 2.\]

2. If \(\Lambda\) is representation-infinite and tame, then it is Morita equivalent to one of the bound quiver algebras below.

- **D1**: \(\alpha^2 = \beta^2 = 0, \alpha \beta = \beta \alpha.\)

- **D2**: \(\alpha \mu = \nu \alpha = 0, \alpha^2 = (\mu \nu)^2.\)

- **D3**: \(\alpha \mu = \mu \beta = \beta \nu = \nu \alpha = 0, \alpha^2 = \mu \nu, \beta^2 = \nu \mu.\)

- **D4**: \(\alpha \mu = \mu \beta = \beta \nu = \nu \alpha = 0, \alpha^2 = (\mu \nu)^2, \beta^2 = (\nu \mu)^2.\)

It is obvious that representation-finite block algebras are \(\tau\)-tilting finite. In addition, Aoki [6] showed the number of support \(\tau\)-tilting modules for such a Brauer tree algebra.

**Proposition 5.4.** ([6, Theorem 3.5]) Let \(\Lambda_n\) be a Brauer tree algebra defined above, then \(\#s\tau\text{-tilt} \Lambda_n = \binom{2n}{n}\).

As the final application of this paper, we show that all (infinite-)tame block algebras are \(\tau\)-tilting finite.

**Theorem 5.5.** Let \(\Lambda\) be a (infinite-)tame block algebra of Hecke algebras of classical type over \(K\), then \(\Lambda\) is \(\tau\)-tilting finite. Moreover, we have
We prove the result case by case.

1. Obviously, \( D_1 \) has only two support \( \tau \)-tilting modules: \( D_1 \) and 0.
2. Since \( \alpha, \mu + \nu \mu \in C(D_2) \), then we have
   \[ \text{\( \text{\( \sigma \)-tilt} \) } D_2 \simeq \text{\( \text{\( \sigma \)-tilt} \) } (D_2/\{\alpha = \mu + \nu \mu = 0\}) \simeq \text{\( \text{\( \sigma \)-tilt} \) } \hat{\Gamma}_{20}. \]
3. Since \( \alpha, \beta \in C(D_3) \), then
   \[ \text{\( \text{\( \sigma \)-tilt} \) } D_3 \simeq \text{\( \text{\( \sigma \)-tilt} \) } (D_3/\{\alpha = \beta = 0\}) \simeq \text{\( \text{\( \sigma \)-tilt} \) } \hat{\Gamma}_{20}. \]
4. Since \( \alpha, \beta, \mu + \nu \mu \in C(D_4) \), then
   \[ \text{\( \text{\( \sigma \)-tilt} \) } D_4 \simeq \text{\( \text{\( \sigma \)-tilt} \) } (D_4/\{\alpha = \beta = \mu + \nu \mu = 0\}) \simeq \text{\( \text{\( \sigma \)-tilt} \) } \hat{\Gamma}_{20}. \]

\[ \square \]

**Table T**

(1) \( \ell_1 \mu_1 = \nu_2 \mu_2 = (\ell_1 \mu_1 + \ell_2 \mu_2)(k_1 \nu_1 + k_2 \nu_2) = (\ell_3 \mu_1 + \ell_4 \mu_2)(k_3 \nu_1 + k_4 \nu_2) = 0 \), where \( k_1, k_2, k_3, k_4, \ell_1, \ell_2, \ell_3, \ell_4 \in K \) and \( k_1 k_4 \neq k_2 k_3, \ell_1 \ell_4 \neq \ell_2 \ell_3 \).
Table W
