Abstract

How can we efficiently mitigate the overhead of gradient communications in distributed optimization? This problem is at the heart of training scalable machine learning models and has been mainly studied in the unconstrained setting. In this paper, we propose Quantized Frank-Wolfe (QFW), the first projection-free and communication-efficient algorithm for solving constrained optimization problems at scale. We consider both convex and non-convex objective functions, expressed as a finite-sum or more generally a stochastic optimization problem, and provide strong theoretical guarantees on the convergence rate of QFW. This is accomplished by proposing novel quantization schemes that efficiently compress gradients while controlling the noise variance introduced during this process. Finally, we empirically validate the efficiency of QFW in terms of communication and the quality of returned solution against natural baselines.

1. Introduction

The Frank-Wolfe (FW) method (Frank and Wolfe, 1956), also known as conditional gradient, has recently received considerable attention in the machine learning community, as a projection free algorithm for various constrained convex (Jaggi, 2013; Garber and Hazan, 2014; Lacoste-Julien and Jaggi, 2015; Garber and Hazan, 2015; Hazan and Luo, 2016; Mokhtari et al.,
2018b) and non-convex (Lacoste-Julien, 2016; Reddi et al., 2016) optimization problems. In order to apply the FW algorithm to large-scale problems (e.g., training deep neural networks (Ravi et al., 2018. Schramowski et al., 2018. Berrada et al., 2018), RBMs (Ping et al., 2016)) parallelization is unavoidable. To this end, distributed FW variants have been proposed for specific problems, e.g., online learning (Zhang et al., 2017), learning low-rank matrices (Zheng et al., 2018), and optimization under block-separable constraint sets (Wang et al., 2016). A significant performance bottleneck of distributed optimization methods is the cost of communicating gradients, typically handled by using a parameter-server framework. Intuitively, if each worker in the distributed system transmits the entire gradient, then at least $d$ floating-point numbers are communicated for each worker, where $d$ is the dimension of the problem. This communication cost can be a huge burden on the performance of parallel optimization algorithms (Chilimbi et al., 2014; Seide et al., 2014; Strom, 2015). To circumvent this drawback, communication-efficient parallel algorithms have received significant attention. One major approach is to quantize the gradients while maintaining sufficient information (De Sa et al., 2015; Abadi et al., 2016; Wen et al., 2017). For unconstrained optimization, when projection is not required for implementing Stochastic Gradient Descent (SGD), several communication-efficient distributed methods have been proposed, including QSGD (Alistarh et al., 2017), SIGN-SGD (Bernstein et al., 2018), and Sparsified-SGD (Stich et al., 2018).

In the constrained setting, and in particular for distributed FW algorithms, the communication-efficient versions were only studied for specific problems such as sparse learning (Bellet et al., 2015; Lafond et al., 2016). In this paper, however, we develop Quantized Frank-Wolfe (QFW), a general communication-efficient distributed FW for both convex and non-convex objective functions. We study the performance of QFW in in two widely recognized settings: 1) stochastic and 2) finite-sum optimization.

Let $K \subseteq \mathbb{R}^d$ be the constraint set. For constrained stochastic optimization the goal is to solve
\begin{equation}
\min_{x \in K} f(x) := \min_{x \in K} \mathbb{E}_{z \sim P} [\tilde{f}(x, z)],
\end{equation}
where $x \in \mathbb{R}^d$ is the optimization variable, $Z \in \mathbb{R}^q$ is a random variable drawn from a distribution $P$, which determines the choice of a stochastic function $\tilde{f} : \mathbb{R}^d \times \mathbb{R}^q \to \mathbb{R}$. For constrained finite-sum optimization we further assume that $P$ is a uniform distribution over $[N] = \{1, 2, \cdots, N\}$ and the goal is to solve a special case of Problem (1), namely,
\begin{equation}
\min_{x \in K} f(x) := \min_{x \in K} \frac{1}{N} \sum_{i=1}^{N} f_i(x).
\end{equation}
In parallel settings, we suppose that there is a master and $M$ workers, and each worker maintains a local copy of $x$. At every iteration of the stochastic case, each worker has access to independent stochastic gradients of $f$; whereas in the finite-sum case, we assume $N = Mn$, thus the objective function can be decomposed as $f(x) = \frac{1}{Mn} \sum_{m \in [M], i \in [n]} f_{m,i}(x)$, and each worker $m$ has access to the exact gradients of $n$ component functions $f_{m,i}(x)$ for all $i \in [n]$. This way the task of computing gradients is divided among the workers. The master node aggregates local gradients from the workers, and sends the aggregated gradients back to them so that each worker can update the model (i.e., their own iterate) locally. Thus, by transmitting quantized gradients, we can reduce the communication complexity (i.e., number
1st stage
\[ \Phi(g_1^1(x_t)) \]

\[ x_{t+1} \leftarrow FW(x_t, \tilde{g}_t) \]

Figure 1: Stages of our general Quantized Frank-Wolfe scheme at time \( t \). In the first stage, each worker \( m \) computes its local gradient estimation \( g_m^m(x_t) \) and sends the quantized version \( \Phi(g_m^m(x_t)) \) to the master node. In the second stage, master computes the average of decoded received signals \( \Phi'(g_m^m(x_t)) \), i.e., \( \tilde{g}_t \leftarrow \frac{1}{M} \sum_{m=1}^{M} \Phi'(g_m^m(x_t)) \) and then sends its quantized version \( \Phi(\tilde{g}_t) \) to the workers. In the third stage, workers use the decoded gradient average computed by all workers \( \Phi'(\tilde{g}_t) \) and their previous gradient estimation \( \bar{g}_{t-1} \) to update their new gradient estimation \( \bar{g}_t \) via a variance reduction (VR) scheme. Once the variance reduced gradient approximation \( \tilde{g}_t \) is evaluated, workers compute the new variable \( x_{t+1} \) by following the update of Frank-Wolfe (FW).

Our contributions: In this paper, we propose a novel distributed projection-free framework that handles quantization for constrained convex and non-convex optimization problems in stochastic and finite-sum cases. It is well-known that unlike projected gradient-based methods, FW methods may diverge when fed with stochastic gradient (Mokhtari et al., 2018b). Indeed, a similar issue arises in a distributed setting where nodes exchange quantized gradients which are noisy estimates of the gradients. By incorporating appropriate variance reduction techniques in different settings, we show that with quantized gradients, we can obtain a provably convergent method which preserves the convergence rates of the vanilla unquantized method in most cases. We believe our work presents the first quantized, distributed, and projection-free method, in contrast to all the previous works which
consider quantization in the unconstrained setting. Our theoretical results for Quantized Frank-Wolfe (QFW) are summarized in Table 1, where the SFO complexity is the required number of stochastic gradients in stochastic case, and the IFO complexity is the number of exact gradients for component functions in finite-sum case. To be more specific, we show that (i) QFW improves the IFO complexity $O(1/\epsilon^4)$ of the SVRF method (Hazan and Luo, 2016) to $O(n/\epsilon)$ for finite-sum convex case, by using the newly proposed SPIDER variance reduction technique; (ii) QFW preserves the SFO/IFO complexities of the SFW algorithm (Mokhtari et al. 2018b) for stochastic convex case, and the accelerated NFWU method (Shen et al., 2019) for finite-sum non-convex case; (iii) QFW has slightly worse SFO complexity $O(1/\epsilon^4)$ than that of SVRF-S (Reddi et al., 2016), $O(1/\epsilon^{10/3})$, for the stochastic non-convex case, while it uses quantized gradients.

### 2. Gradient Quantization Schemes

As mentioned earlier, the communication cost can be reduced effectively by sending quantized gradients. In this section, we introduce a quantization scheme called s-Partition Encoding Scheme. Consider the gradient vector $g \in \mathbb{R}^d$ and let $g_i$ be the $i$-th coordinate of the gradient. The s-Partition Encoding Scheme encodes $g_i$ into an element from the set \{±1, ±2/3, ..., ±1, 0\} in a random way. To do so, we first compute the ratio $|g_i|/\|g\|_\infty$ and find the indicator $l_i \in \{0, 1, \cdots, s - 1\}$ such that $|g_i|/\|g\|_\infty \in [l_i/s, (l_i + 1)/s]$. Then we define the random variable $b_i$ as

$$b_i = \begin{cases} 
    l_i/s, & \text{w.p. } 1 - \frac{|g_i|}{\|g\|_\infty} s + l_i, \\
    (l_i + 1)/s, & \text{w.p. } \frac{|g_i|}{\|g\|_\infty} s - l_i.
\end{cases}$$

Finally, instead of transmitting $g_i$, we send $\text{sgn}(g_i) \cdot b_i$, alongside the norm $\|g\|_\infty$. It can be verified that $\mathbb{E}[b_i|g_i] = |g_i|/\|g\|_\infty$. So we define the corresponding decoding scheme as $\phi'(g_i) = \text{sgn}(g_i) b_i \|g\|_\infty$ to ensure that $\phi'(g_i)$ is an unbiased estimator of $g_i$. We note that this quantization scheme is similar to the Stochastic Quantization method in (Alistarh et al., 2017), except that we use $\ell_\infty$-norm while they adopt the $\ell_2$-norm. In the s-Partition Encoding Scheme, for each coordinate $i$, we need 1 bit to transmit $\text{sgn}(g_i)$. Moreover, since $b_i \in \{0, 1/s, \ldots, (s - 1)/s, 1\}$, we need $z = \log_2(s + 1)$ bits to send $b_i$. Finally, we need 32 bits to transmit $\|g\|_\infty$. Hence, the total number of communicated bits is $32 + d(z + 1)$. Here, by “bits” we mean the number of 0’s and 1’s transmitted.
One major advantage of the s-Partition Encoding Scheme is that by tuning the partition parameter $s$ or the corresponding assigned bits $z$, we can smoothly control the trade-off between gradient quantization and information loss, which helps distributed algorithms to attain their best performance. We proceed to characterize the variance of the s-Partition Encoding Scheme.

**Lemma 1** The variance of s-Partition Encoding Scheme $\phi$ for any $g \in \mathbb{R}^d$ is bounded by

$$\text{Var}[\phi'(g)|g] \leq \frac{d}{s^2} \|g\|_\infty^2.$$  \hspace{1cm} (4)

If we set $s = 1$, we obtain the Sign Encoding Scheme, which requires communicating the encoded scalars $\text{sgn}(g_i) b_i \in \{\pm 1, 0\}$ and the norm $\|g\|_\infty$. Since $z = \log_2(s + 1) = 1$, the overall communicated bits for each worker are $32 + 2d$ per round. We characterize its variance in Lemma 2.

**Lemma 2** The variance of Sign Encoding Scheme is given by

$$\text{Var}[\phi'(g)|g] = \|g\|_1\|g\|_\infty - \|g\|_2^2.$$  \hspace{1cm} (5)

**Remark 1** For the probability distribution of the random variable $b_i$, instead of $\|g\|_\infty$, we can use other norms $\|g\|_p$ (where $p \geq 1$). But it can be verified that the $\ell_\infty$-norm leads to the smallest variance for Sign Encoding Scheme. That is also the reason why we do not use $\ell_2$-norm as in (Alistarh et al., 2017).

### 3. Stochastic Optimization

In this section, we aim to solve the constrained stochastic optimization problem defined in (1) in a distributed fashion. In particular, we are interested in projection-free (Frank-Wolfe type) methods and execute quantization to reduce the communication cost between the workers and the master. Recall that we assume at each round $t$, each worker $m \in [M]$ has access to an unbiased estimator of the objective function gradient $\nabla f(x_t)$, which is denoted by $g^m_t(x_t)$, i.e., $\nabla f(x_t) = \mathbb{E}[g^m_t(x_t)|x_t]$. We further assume that the stochastic gradients are independent of each other.

In our proposed Stochastic Quantized Frank-Wolfe (S-QFW) method, at iteration $t$, each worker $m$ first computes its local stochastic gradient $g^m_t(x_t)$. Then, it encodes $g^m_t(x_t)$ as $\Phi(g^m_t(x_t))$ – which is quantized and can be transmitted at a low communication cost – to the master. Once the master receives all the coded stochastic gradients $\{\Phi(g^m_t(x_t))\}_{m=1}^M$, it uses a proper decoding scheme to evaluate $\{\Phi'(g^m_t(x_t))\}_{m=1}^M$, which are the decoded versions of the received signals $\{\Phi(g^m_t(x_t))\}_{m=1}^M$. Indeed, by design, each of the decoded signals $\Phi'(g^m_t(x_t))$ is an unbiased estimator of the objective function gradient $\nabla f(x_t)$. Then, the master evaluates the average of the decoded signals denoted by $\tilde{g}_t$, i.e., $\tilde{g}_t = (1/M) \sum_{m=1}^M \Phi'(g^m_t(x_t))$. After using a proper quantization scheme, the master broadcasts the coded signal $\Phi(\tilde{g}_t)$ to all the workers. The workers decode the received signals and use the resulted $\Phi'(\tilde{g}_t)$ vector to improve their gradient approximation.

Note that even in the unquantized setting, if we use the stochastic gradient $g^m_t(x_t)$, instead of $\nabla f(x_t)$, Frank-Wolfe may still diverge Mokhtari et al. (2018b). As a result, we
need to further reduce the variance. To do so, each worker $m$ uses a momentum local vector $\tilde{g}_t$ to update the iterates, which is defined by

$$\tilde{g}_t \leftarrow (1 - \rho_t)\tilde{g}_{t-1} + \rho_t\Phi'\tilde{(g)}_t.$$  \hfill (6)

As the update of $\tilde{g}_t$ in (6) computes a weighted average of the previous stochastic gradient approximation $\tilde{g}_{t-1}$ and the updated network average stochastic gradient $\Phi'(\tilde{g}_t)$, it has a lower variance comparing to the vector $\Phi'(\tilde{g})$. The key fact that allows us to prove convergence is that the estimation error of $\tilde{g}_t$ approaches zero as time passes (check Lemma 3 in Appendix C). After computing the gradient estimation $\tilde{g}_t$ based on (6), workers update their variables by following the FW scheme, i.e., $x_{t+1} = x_t + \eta_t(v_t - x_t)$, where $v_t = \arg\min_{v \in K} \langle v, \tilde{g}_t \rangle$. S-QFW is outlined in Algorithm 1. Finally, note that we can use different quantization schemes $\Phi$ in S-QFW, which leads to different convergence rates and communication costs.

Now we proceed to analyze S-QFW and first focus on convex settings.

**Assumption 1** The constraint set $K$ is convex and compact, with diameter $D = \sup_{x,y \in K} \|x - y\|$.

**Assumption 2** The function $f$ is convex, bounded, i.e., $\sup_{x \in K} |f(x)| \leq M_0$, and $L$-smooth over $K$.

**Assumption 3** For each worker $m$ and iteration $t$, the stochastic gradient $g_t^m$ is unbiased and has a uniformly bounded variance, i.e., for all $m \in [M]$ and $t \in [T]$,

$$\mathbb{E}[g_t^m(x_t)|x_t] = \nabla f(x_t), \quad \text{Var}[g_t^m(x_t)|x_t] \leq \sigma_1^2.$$

**Assumption 4** For any $x_t \in K$, and vectors $g_t^m(x_t)$ and $\tilde{g}_t$ generated by Stochastic Quantized Frank-Wolfe, the quantization scheme $\Phi$ satisfies

$$\mathbb{E}[\Phi'(g_t^m(x_t))|g_t^m(x_t)] = g_t^m(x_t), \quad \mathbb{E}[\Phi'(\tilde{g}_t)|\tilde{g}_t] = \tilde{g}_t,$$

$$\mathbb{E}[\|\Phi'(g_t^m(x_t)) - g_t^m(x_t)\|^2] \leq \sigma_2^2, \quad \mathbb{E}[\|\Phi'(\tilde{g}_t) - \tilde{g}_t\|^2] \leq \sigma_3^2.$$
**Theorem 2 (Convex)** Under Assumptions 1 to 4, if we set $\eta_t = 2/(t + 3), \rho_t = 2/(t + 3)^{2/3}$ in Algorithm 1, then after $T$ iterations, the output $x_{T+1} \in K$ satisfies
\[
\mathbb{E}[f(x_{T+1})] - f(x^*) \leq \frac{Q_0}{(T + 4)^{1/3}},
\]
where $Q_0 = \max\{4M_0, 2D(Q^{1/2} + LD)\}, Q = \max\{3\|\nabla f(x_1)\|^2, 4(\sigma_1^2 + \sigma_2^2)/M + 4\sigma_3^2 + 8L^2D^2\}$, and $x^*$ is a global minimizer of $f$ on $K$.

Theorem 2 shows that the suboptimality gap of S-QFW converges to zero at a sublinear rate of $O(1/T^{1/3})$. Hence, after running at most $O(\epsilon^{-3})$ iterations, we can find a solution that is $\epsilon$ close to the optimum. We also characterize the exact complexity bound for S-QFW when the Sign Encoding Scheme is used for quantization and show that it obtains an $\epsilon$-accurate solution after $O(\epsilon^{-3})$ rounds for communication. This result is presented in Appendix E due to space limit. Note that as each communication round in Sign Encoding Scheme requires $(M + 1)(32 + 2d)$ bits, the overall communication cost to find an $\epsilon$-suboptimal solution is of $O(Md\epsilon^{-3})$.

With slightly different parameters, S-QFW can be applied to non-convex settings as well. In unconstrained non-convex optimization problems, the gradient norm $\|\nabla f\|$ is usually a good measure of convergence as $\|\nabla f\| \to 0$ implies convergence to a stationary point. However, in the constrained setting we study the Frank-Wolfe Gap (Jaggi, 2013; Lacoste-Julien, 2016) defined as
\[
\mathcal{G}(x) = \max_{v \in K} \langle v - x, -\nabla f(x) \rangle. \tag{7}
\]
For constrained optimization problem (1), if a point $x$ satisfies $\mathcal{G}(x) = 0$, then it is a first-order stationary point. Also, by definition, we have $\mathcal{G}(x) \geq 0$, for all $x \in K$. We analyze the convergence rate of Algorithm 1 under the following assumption on the objective function $f$.

**Assumption 5** The function $f$ is bounded, i.e., $\sup_{x \in K}|f(x)| \leq M_0$, and $L$-smooth over $K$.

**Theorem 3 (Non-convex)** Under Assumptions 1 and 3 to 5, and given the iteration horizon $T$, if we set $\eta_t = 1/(T + 3)^{3/4}, \rho_t = 2/(t + 3)^{1/2}$ in Algorithm 1, then
\[
\mathbb{E}[\mathcal{G}(x_0)] \leq \frac{8M_0 + 20DQ^{1/2}/3}{(T + 3)^{1/4}} + \frac{LD^2}{2(T + 3)^{3/4}},
\]
where $Q = \max\{2\|\nabla f(x_1)\|^2, 4(\sigma_1^2 + \sigma_2^2)/M + 4\sigma_3^2 + 2L^2D^2\}$.

Theorem 3 indicates that in the non-convex setting, S-QFW finds an $\epsilon$-first order stationary point after at most $O(\epsilon^{-4})$ iterations. By using Sign Encoding Scheme, each round of communication requires $(M + 1)(32 + 2d)$ bits. Therefore, to find an $\epsilon$-first order stationary point, we need $O(\epsilon^{-4})$ rounds with the overall communication cost of $O(Md\epsilon^{-4})$.

4. Finite-Sum Optimization

In this section, we analyze the finite-sum problem defined in (2). Recall that we assume that there are $N$ functions and $M$ workers in total, and each worker $m$ has access to $n = N/M$
functions $f_{m,i}$ for $i \in [n]$. The major difference with the stochastic setting is that we can use a more aggressive variance reduction for communicating quantized gradients. Nguyen et al. (2017a,b, 2019) developed the StochAstic Recursive grAdient algoritHm (SARAH), a stochastic recursive gradient update framework. Recently, Fang et al. (2018) proposed Stochastic Path-Integrated Differential Estimator (SPIDER) technique, a variant of SARAH, for unconstrained optimization in centralized settings. In this paper, we generalize SPIDER to the constrained and distributed settings.

We first consider the case where no quantization is performed. Let $p \in \mathbb{N}^+$ be a period parameter. At the beginning of each period, namely, mod($t, p$) = 1, each worker $m_i$ computes the average of all its local gradients and sends it to the master. Then, master calculates the average of the $M$ received signals and broadcasts it to all workers. Then, workers update their gradient estimation $\bar{g}_t$ as

$$\bar{g}_t = \frac{1}{Mn} \sum_{m=1}^{M} \sum_{i=1}^{n} \nabla f_{m,i}(x_t).$$

Note $\bar{g}_t$ is identical for all the workers. In the rest of that period, i.e., mod($t, p$) $\neq 1$, each worker $m_i$ samples a set of local component functions, denoted as $S^m_t$, of size $S$ uniformly at random, computes the average of these gradients and sends it to master. Then, master calculates the average of the $M$ signals and broadcasts it to all the workers. The workers update their gradient estimation $\bar{g}_t$ as

$$\bar{g}_t = \bar{g}_{t-1} + \frac{1}{MS} \sum_{m=1}^{M} \sum_{i \in S^m_t} [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})].$$

(8)

So $\bar{g}_t$ is still identical for all the workers. In order to incorporate quantization, each worker simply pushes the quantized version of the average gradients. Then the master decodes the quantizations, encodes the average of decoded signals in a quantized fashion, and broadcasts the quantization. Finally, each worker decodes the quantized signal and updates $x_t$ locally. The full description of our proposed Finite-Sum Quantized Frank-Wolfe (F-QFW) algorithm is outlined in Algorithm 2.

To analyze the convex case, we first make an assumption on the component functions.

**Assumption 6** The functions $f_{m,i}$ are convex, $L$-smooth on $\mathcal{K}$, and uniformly bounded, i.e., $\sup_{x \in \mathcal{K}} |f_{m,i}(x)| \leq M_0$. We also assume that $\sup_{x \in \mathcal{K}} \|\nabla f_{m,i}(x)\|_{\infty} \leq G_{\infty}$, for all $m \in [M], i \in [n]$.

**Theorem 4 (Convex)** Consider F-QFW outlined in Algorithm 2. Recall that $n$ indicates the number of local functions at each node, and $S$ indicates the size of mini-batch used in (8). Under Assumptions 1 and 6, if we set $p = \sqrt{n}$, $S = \sqrt{n}$, and $\eta_t = 2/(p\lceil \frac{\xi}{p} \rceil)$, and use the $s_{1,t} = (pd^{1/2}S^{1/2}M^{-1/2}\lceil \frac{\xi}{p} \rceil)$-Partition Encoding Scheme, and $s_{2,t} = (pd^{1/2}S^{1/2}\lceil \frac{\xi}{p} \rceil)$-Partition Encoding Scheme as $\Phi_{1,t}$ and $\Phi_{2,t}$ in Algorithm 2, then the output $x_{T+1} \in \mathcal{K}$ satisfies

$$\mathbb{E}[f(x_{T+1})] - f(x^*) \leq Q_0/T,$$

where $Q_0 = \max\{6pM_0, 3Q\}$, $Q = 4D(\sqrt{L^2D^2 + 2G_{\infty}^2} + LD)$, and $x^*$ is a minimizer of $f$ on $\mathcal{K}$.
Algorithm 2 Finite-Sum Quantized Frank-Wolfe (F-QFW)

1: Input: $\mathcal{K}$, $T$, No. of workers $M$, initial point $x_1 \in \mathcal{K}$, period parameter $p$, sample size $S$

3: for $t = 1$ to $T$ do
4:   if mod$(t, p) = 1$ then
5:     Each worker $m$ computes its local gradient $g^m_t(x_t) = \frac{1}{n} \sum_{i=1}^{n} \nabla f_{m,i}(x_t)$
6:     Each worker $m$ encodes $g^m_t(x_t)$ as $\Phi_{1,t}(g^m_t(x_t))$ and pushes it to the master
7:     Master decodes $\Phi_{1,t}(g^m_t(x_t))$ as $\Phi'_{1,t}(g^m_t(x_t))$
8:     Master computes the average gradient $\bar{g}_t \leftarrow \frac{1}{M} \sum_{m=1}^{M} \Phi'_{1,t}(g^m_t(x_t))$
9:     Master encodes $\bar{g}_t$ as $\Phi_{2,t}(\bar{g}_t)$, and broadcasts it to all workers
10:    Workers decode $\Phi_{2,t}(\bar{g}_t)$ as $\Phi'_{2,t}(\bar{g}_t)$ and update $\bar{g}_t \leftarrow \Phi'_{2,t}(\bar{g}_t)$
11:   else
12:    Each worker $m$ at time $t$ samples $S$ component functions uniformly at random called $\mathcal{S}_t^m$
13:    Each worker $m$ computes exact gradients $\nabla f_{m,i}(x_t), \nabla f_{m,i}(x_{t-1})$ for all $i \in \mathcal{S}_t^m$
14:    Each worker $m$ encodes $\Phi_{1,t}(\frac{1}{S} \sum_{i \in \mathcal{S}_t^m} [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})])$ and pushes to master
15:    Master decodes the signals $\Phi_{1,t}(\frac{1}{S} \sum_{i \in \mathcal{S}_t^m} [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})])$
16:    Master computes $\tilde{g}_t \leftarrow \frac{1}{M} \sum_{m=1}^{M} \Phi'_{1,t}(\frac{1}{S} \sum_{i \in \mathcal{S}_t^m} [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})])$
17:    Master encodes $\tilde{g}_t$ as $\Phi_{2,t}(\tilde{g}_t)$, and broadcasts all workers
18:    Workers decode $\Phi_{2,t}(\tilde{g}_t)$ as $\Phi'_{2,t}(\tilde{g}_t)$ and update $\tilde{g}_t \leftarrow \Phi'_{2,t}(\tilde{g}_t) + \tilde{g}_{t-1}$
19:   end if
20: Each worker updates $x_{t+1}$ locally by $x_{t+1} \leftarrow x_t + \eta_t(v_t - x_t)$ where $v_t \leftarrow \text{argmin}_{v \in \mathcal{K}} \langle v, \tilde{g}_t \rangle$
21: end for

Theorem 4 indicates that in convex setting, if we use the recommended quantization schemes, then the output of Finite-Sum Quantized Frank-Wolfe is $\epsilon$-suboptimal with at most $Q_0/e$ rounds. As $p = \sqrt{n}$, the Linear-optimization Oracle (LO) complexity is $O(\sqrt{n}/\epsilon)$. Also, the total Incremental First-order Oracle (IFO) complexity is $[MN + 2(p - 1)MS] \times (T/p) = O(n/\epsilon)$. By considering the quantization schemes with $s_{1,t}$ and $s_{2,t}$ quantization levels, the average communication bits per round are at most $d(M[\log_2(\sqrt{n}dT^2/M)^{1/2} + 1]) + \log_2((\sqrt{n}dT^{1/2} + 1)]) + (M + 1)(d + 32)$.

Algorithm 2 can also be applied to the non-convex setting with a slight change in parameters. We first make a standard assumption on the component functions.

Assumption 7 The component functions $f_{m,i}$ are $L$-smooth on $\mathcal{K}$ and uniformly bounded, i.e., $\sup_{x \in \mathcal{K}} |f_{m,i}(x)| \leq M_0$. We also assume that $\sup_{x \in \mathcal{K}} \|\nabla f_{m,i}(x)\|_\infty \leq G_\infty$, for all $m \in [M], i \in [n]$.

Theorem 5 (Non-convex) Under Assumptions 1 and 7, if we set $p = \sqrt{n}$, $S = \sqrt{n}$, and $\eta_t = T^{-1/2}$, and use the $s_{1,t} = ((4\sqrt{ndT}/M)^{1/2})$-Partition Encoding Scheme, and $s_{2,t} = ((4\sqrt{ndT})^{1/2})$-Partition Encoding Scheme as $\Phi_{1,t}$ and $\Phi_{2,t}$ in Algorithm 2, then the
output $x_0 \in \mathcal{K}$ satisfies
\[
\mathbb{E}[\mathcal{G}(x_0)] \leq \frac{2M_0 + D\sqrt{L^2D^2 + 2G_\infty^2} + LD^2}{\sqrt{T}}.
\]

Theorem 5 shows that for non-convex minimization, if we adopt the recommended quantization schemes, then Algorithm 2 finds an $\epsilon$-first order stationary point with at most $\mathcal{O}(1/\epsilon^2)$ rounds. Also, the total IFO complexity is $[Mn + 2(p-1)MS] \cdot \frac{T}{p} = \mathcal{O}$(√$n$/ε²), and the average communication bits per round are $d(M[\log_2(\sqrt{8d}T/M)^{1/2} + 1]) + \log_2([4\sqrt{n}dT]^{1/2} + 1)) + (M + 1)(d + 32)$.

5. Experiments

We evaluate the performance of algorithms by visualizing their optimality gap $f(x_t) - f(x^*)$ (for convex settings), their loss $f(x_t)$ (for non-convex settings) as well as their testing accuracy vs. the number of transmitted bits. The experiments were performed on 20 Intel Xeon E5-2660 cores and thus the number of workers is 20. For each curve in the figures below, we ran at least 50 repeated experiments, and the height of shaded regions represents two standard deviations.

In our first setup, we consider a multinomial logistic regression problem. Consider the dataset $\{(x_i, y_i)\}_{i=1}^N \subseteq \mathbb{R}^d \times \{1, \ldots, C\}$ with $N$ samples that have $C$ different labels. We aim to find a model $w$ to classify these sample points under the condition that the solution has a small $\ell_1$-norm. Therefore, we aim to solve the following convex problem

\[
\min_w f(w) := -\sum_{i=1}^N \sum_{c=1}^C 1\{y_i = c\} \log \frac{\exp(w_c^\top x_i)}{\sum_{j=1}^C \exp(w_j^\top x_i)}, \quad \text{s.t. } \|w\|_1 \leq 1. \quad (9)
\]

In our experiments, we use the MNIST and CIFAR-10 datasets. For the MNIST dataset, we assume that each worker stores 3000 images, and, therefore, the overall number of samples in the training set is $N = 60000$. The result on CIFAR-10 is similar and deferred to Appendix J.

In our second setup, our goal is to minimize the loss of a three-layer neural network under some conditions on the norm of the solution. Before stating the problem precisely, let us define the log-loss function as $h(y, p) \triangleq -\sum_{c=1}^C 1\{y = c\} \log p_c$ for $y \in \{1, \ldots, C\}$ and a $C$-dimensional probability vector $p := (p_1, \ldots, p_C)$. We aim to solve the following non-convex problem

\[
\min_{w_1, w_2} f(W_1, W_2, b_1, b_2) := \sum_{i=1}^N h(y_i, \phi(W_2\sigma(W_1x_i+b)+b_2)), \quad \text{s.t. } \|W_i\|_1 \leq a_1, \|b_i\|_1 \leq a_2, \quad (10)
\]

where $\sigma(x) \triangleq (1 + e^{-x})^{-1}$ is the sigmoid function and $\phi$ is the softmax function. The imposed $\ell_1$ constraint on the weights leads to a sparse network. We further remark that Frank-Wolfe methods are suitable for training a neural network subject to an $\ell_1$ constraint as they are equivalent to a dropout regularization (Ravi et al., 2018). We use the MNIST and CIFAR-10 datasets. For the MNIST dataset, we assume that each worker stores 3000 images. The size of matrices $W_1$ and $W_2$ are 784 × 10 and 10 × 10, respectively, and the constraints parameters are $a_1 = a_2 = 10$. We obtain a similar result on CIFAR-10 and discuss it in Appendix J.
In our third setup, we study a multi-task least square regression problem (Zheng et al., 2018). Its setting and result are discussed in Appendix J.

For all of the considered settings, we vary the quantization level and use the $s$-partition encoding scheme ($s = uq$ indicates FW without quantization). We also propose $\text{SignFW}$, an effective heuristic based on QFW, where the norm of the gradient is discarded and only the sign of each coordinate is transmitted. Even though this method may not enjoy the strong theoretical guarantees of QFW (and may even diverge) we observed in our experiments that it performs on par with QFW in practice. Let us emphasize that the proposed $\text{SignFW}$ algorithm is similar to QFW with $\text{Sign Encoding Scheme}$ except that $\|g\|_\infty$ is not transmitted and only $\text{sgn}(g_i)b_i$ is transmitted (see Section 2).

Figure 2: Comparison in terms of optimality gap (left) and test accuracy (right) versus number of transmitted bits for a multinomial logistic regression problem. The best performance belongs to QFW with $\text{Sign Encoding Scheme}$ ($s = 1$), and FW without quantization has the worst performance.

Figure 3: Comparison of algorithms in terms of loss function (left) and test accuracy (right) versus number of transmitted bits for a three-layer neural network. FW without quantization ($s = uq$) significantly underperforms the quantized FW methods.
In Figure 2, we observe the performance of SignFW, FW without quantization, and different variants of QFW for solving the multinomial logistic regression problem in (9). We observe that QFW with Sign Encoding Scheme \((s = 1)\) has the best performance and all quantized variants of FW outperform the FW method without quantization both in terms of training error and test accuracy. Specifically, QFW with Sign Encoding Scheme \((s = 1)\) requires \(8 \times 10^6\) transmitted bits to hit the lowest optimality gap in Fig. 2a, while QFW with \(s = 3\) and \(s = 7\) require \(10^7\) and \(1.5 \times 10^7\) bits, respectively, for achieving the same error. Furthermore, FW without quantization requires more than \(2 \times 10^8\) bits to reach the same error, i.e., quantization reduces communication load by at least an order of magnitude.

Figure 3 demonstrates the performance of SignFW, FW without quantization, and different variants of QFW for solving the three-layer neural network in (10). The relative behavior of the considered methods in Figure 3 is similar to the one in Figure 2. QFW with Sign Encoding Scheme obtains a loss less than 2 after transmitting \(2 \times 10^6\) bits, while to attain the same loss level, it takes \(5 \times 10^6\) bits if one uses SignFW or QFW with \(s = 3\). The number of required bits becomes approximately \(1.5 \times 10^7\) for \(s = 7\). Also, if no quantization is applied, then the number of required bits is at least \(3 \times 10^8\) (i.e., quantization reduces communication load by at least two orders of magnitude). To achieve a testing accuracy greater than 0.8, QFW with \(s = 1\) requires \(3 \times 10^6\) bits transmission, while the second most communication-efficient method QFW with \(s = 3\) needs \(10^7\) bits.

6. Conclusion

In this paper, we developed Quantized Frank-Wolfe (QFW), the first general-purpose projection-free and communication-efficient framework for constrained optimization. Along with proposing various quantization schemes, QFW can address both convex and non-convex optimization settings in stochastic and finite-sum cases. We provided theoretical guarantees on the convergence rate of QFW and validated its efficiency empirically on training multinomial logistic regression and neural networks. Our theoretical results highlighted the importance of variance reduction techniques to stabilize Frank Wolfe and achieve a sweet trade-off between the communication complexity and convergence rate in distributed settings.
References

Appendix A. Proof of Lemma 1

Proof For any given vector \( g \in \mathbb{R}^d \), the ratio \( \frac{|g_i|}{\|g\|_\infty} \) lies in an interval of the form \([l_i/s, (l_i + 1)/s]\) where \( l_i \in \{0, 1, \ldots, s - 1\} \). Hence, for that specific \( l_i \), the following inequalities

\[
\frac{l_i}{s} \leq \frac{|g_i|}{\|g\|_\infty} \leq \frac{l_i + 1}{s}
\]  

(11)

are satisfied. Moreover, based on the probability distribution of \( b_i \) we know that

\[
\frac{l_i}{s} \leq b_i \leq \frac{l_i + 1}{s}.
\]

(12)

Therefore, based on the inequalities in (11) and (12) we can write

\[
-\frac{1}{s} \leq \frac{|g_i|}{\|g\|_\infty} - b_i \leq \frac{1}{s}
\]

(13)

Hence, we can show that the variance of s-Partition Encoding Scheme is upper bounded by

\[
\text{Var}[\phi'(g) | g] = \mathbb{E}[\|\phi'(g) - g\|^2 | g]
\]

\[
= \sum_{i=1}^{d} \mathbb{E}[(g_i - \text{sgn}(g_i)b_i\|g\|_\infty)^2 | g]
\]

\[
= \sum_{i=1}^{d} \mathbb{E}[(|g_i| - b_i\|g\|_\infty)^2 | g]
\]

\[
= \sum_{i=1}^{d} \|g\|_\infty^2 \mathbb{E} \left[ \left( \frac{|g_i|}{\|g\|_\infty} - b_i \right)^2 | g \right]
\]

\[
\leq \frac{d}{s} \|g\|_\infty^2,
\]

(14)

where the inequality holds due to (13).

Appendix B. Proof of Lemma 2

Proof For any \( g \), as we know that \( \mathbb{E}[\phi'(g) | g] = g \), the variance of \( \phi'(g) \) can be written as

\[
\text{Var}[\phi'(g) | g] = \mathbb{E}[\|\phi'(g) - g\|^2 | g]
\]

\[
= \sum_{i=1}^{d} \mathbb{E}[(g_i - \text{sgn}(g_i)b_i\|g\|_\infty)^2 | g]
\]

\[
= \sum_{i=1}^{d} g_i^2 + \|g\|_\infty^2 \mathbb{E} [b_i^2 | g] - 2g_i \text{sgn}(g_i)|g_i|
\]

\[
= \sum_{i=1}^{d} \|g\|_\infty^2 \mathbb{E} [b_i^2 | g] - g_i^2,
\]

(15)
where the third equality follows from \( E[b_i|g] = |g_i|/\|g\|_\infty \) and \( \text{sgn}(g_i)^2 = 1 \). Note that based on the probability distribution of \( b_i \), we can simplify the expression \( E[b_i^2|g] \) as \( |g_i|/\|g\|_\infty \) and write

\[
\text{Var}[\phi'(g)|g] = \sum_{i=1}^{d} ||g||_\infty |g_i - g_i^2| = ||g||_1 ||g||_\infty - ||g||_2^2,
\]

which shows that the claim in (5) holds. \( \square \)

Appendix C. Bounding \( \|\nabla f(x_t) - \bar{g}_t\| \) in Stochastic Case

In order to upper bound \( \|\nabla f(x_t) - \bar{g}_t\| \), we need a lemma for variance reduction, which is a generalization of Lemma 2 in (Mokhtari et al., 2018a).

**Lemma 3** Let \( \{a_t\}_{t=0}^{T} \) be a sequence of points in \( \mathbb{R}^n \) such that \( \|a_t - a_{t-1}\| \leq G/(t+s)\alpha \) for all \( 1 \leq t \leq T \), where constants \( G \geq 0 \), \( \alpha \in (0, 1) \), \( s \geq 8\frac{1}{2\alpha} - 1 \). Let \( \{\hat{a}_t\}_{t=1}^{T} \) be a sequence of random variables such that \( E[\hat{a}_t|\mathcal{F}_{t-1}] = a_t \) and \( \mathbb{E}[\|\hat{a}_t - a_t\|^2|\mathcal{F}_{t-1}] \leq \sigma^2 \) for every \( t \geq 1 \), where \( \mathcal{F}_{t-1} \) is the \( \sigma \)-field generated by \( \{\hat{a}_i\}_{i=1}^{t-1} \) and \( \mathcal{F}_0 = \emptyset \). Let \( \{d_t\}_{t=0}^{T} \) be a sequence of random variables where \( d_0 \) is fixed and subsequent \( d_t \) are obtained by the recurrence

\[
d_t = (1 - \rho_t)d_{t-1} + \rho_t\hat{a}_t
\]

with \( \rho_t = \frac{2}{(t+s)2\alpha^3} \). Then we have

\[
\mathbb{E}[\|a_t - d_t\|^2] \leq \frac{Q}{(t+s+1)^{2\alpha/3}}
\]

where \( Q \triangleq \max\{\|a_0 - d_0\|^2(s + 1)^{2\alpha/3}, 4\sigma^2 + 2G^2\} \).

**Proof** First, for all \( t \geq 1 \), we have \( \rho_t \geq 0 \) and

\[
\rho_t \leq \frac{2}{(1+s)^{2\alpha/3}} \leq \frac{2}{(8\frac{1}{2\alpha})^{2\alpha/3}} = 1.
\]

Then we define \( \Delta_t = \|a_t - d_t\|^2 \), thus

\[
\mathbb{E}[\Delta_t|\mathcal{F}_{t-1}] = \mathbb{E}[\|\rho_t(a_t - \hat{a}_t) + (1 - \rho_t)(a_t - a_{t-1}) + (1 - \rho_t)(a_{t-1} - d_{t-1})\|^2|\mathcal{F}_{t-1}]
\]

\[
\leq \rho_t^2\sigma^2 + (1 - \rho_t)^2 \frac{G^2}{(t+s)^{2\alpha}} + (1 - \rho_t)^2 \Delta_{t-1}
\]

\[
+ 2(1 - \rho_t)^2\mathbb{E}[(a_t - a_{t-1}, a_{t-1} - d_{t-1})|\mathcal{F}_{t-1}].
\]

By Law of Total Expectation, \( \mathbb{E}[\Delta_t] = \mathbb{E}[\mathbb{E}[\Delta_t|\mathcal{F}_{t-1}]] \)

\[
\leq \rho_t^2\sigma^2 + (1 - \rho_t)^2 \frac{G^2}{(t+s)^{2\alpha}} + (1 - \rho_t)^2\mathbb{E}[\Delta_{t-1}] + 2(1 - \rho_t)^2\mathbb{E}[(a_t - a_{t-1}, a_{t-1} - d_{t-1})].
\]
Apply Young’s inequality, we have

\[2\langle a_t - a_{t-1}, a_{t-1} - d_{t-1}\rangle \leq \beta_t \|a_{t-1} - d_{t-1}\|^2 + \frac{\|a_t - a_{t-1}\|^2}{\beta_t} \leq \beta_t \|a_{t-1} - d_{t-1}\|^2 + \frac{G^2}{\beta_t(t + s)^{2\alpha}}.\]

So if we let \( z_t = E[\Delta_t] \) and set \( \beta_t = \rho_t/2 \), we have

\[z_t \leq \rho_t^2 \sigma^2 + (1 - \rho_t)^2 \frac{G^2}{(t + s)^{2\alpha}} + (1 - \rho_t^2) z_{t-1} + (1 - \rho_t)^2 (\beta_t z_{t-1} + \frac{G^2}{\beta_t(t + s)^{2\alpha}})\]
\[\leq \rho_t^2 \sigma^2 + (1 - \rho_t)^2 (1 + 1/\beta_t) \frac{G^2}{(t + s)^{2\alpha}} + (1 - \rho_t)^2 (1 + \beta_t) z_{t-1}\]
\[= \rho_t^2 \sigma^2 + (1 - \rho_t)^2 (1 + 2/\rho_t) \frac{G^2}{(t + s)^{2\alpha}} + (1 - \rho_t)^2 (1 + \rho_t/2) z_{t-1}\]
\[\leq \rho_t^2 \sigma^2 + (1 + 2/\rho_t) \frac{G^2}{(t + s)^{2\alpha}} + (1 - \rho_t) z_{t-1}.\]

The last inequality holds since \( \rho_t \in [0, 1] \) implies \( (1 - \rho_t)^2 \leq 1 \) and \( (1 - \rho_t)(1 + \rho_t/2) \leq 1 \). Now we can further simplify \( z_t \)

\[z_t \leq (1 - \frac{2}{(t + s)^{2\alpha/3}}) z_{t-1} + \frac{4\sigma^2}{(t + s)^{4\alpha/3}} + \frac{G^2}{(t + s)^{2\alpha}} + \frac{G^2}{(t + s)^{4\alpha/3}}\]
\[\leq (1 - \frac{2}{(t + s)^{2\alpha/3}}) z_{t-1} + \frac{4\sigma^2 + 2G^2}{(t + s)^{4\alpha/3}}\]
\[\leq (1 - \frac{2}{(t + s)^{2\alpha/3}}) z_{t-1} + \frac{Q}{(t + s)^{4\alpha/3}}.\]

Now we claim that \( z_t \leq \frac{Q}{(t + s)^{2\alpha/3}} \) for all \( t \in \{0, 1, \cdots, T\} \). We show it by induction.

The statement holds for \( t = 0 \) because of the definition of \( Q \). If the statement holds for some \( t = k - 1 \), where \( k \in [T] \), then

\[z_k \leq (1 - \frac{2}{(k + s)^{2\alpha/3}}) z_{k-1} + \frac{Q}{(k + s)^{4\alpha/3}}\]
\[\leq (1 - \frac{2}{(k + s)^{2\alpha/3}}) \frac{Q}{(k + s)^{2\alpha/3}} + \frac{Q}{(k + s)^{4\alpha/3}}\]
\[= \frac{(k + s)^{2\alpha/3} - 1}{(k + s)^{4\alpha/3}} Q.\]

So we only need to prove that

\[\frac{(k + s)^{2\alpha/3} - 1}{(k + s)^{4\alpha/3}} \leq \frac{1}{(k + s + 1)^{2\alpha/3}}\]

or equivalently,

\[\frac{(k + s)^{2\alpha/3} - 1}{(k + s + 1)^{2\alpha/3}} \leq (k + s)^{2\alpha/3}.\]

It suffices to show that

\[(k + s + 1)^{2\alpha/3} \leq (k + s)^{2\alpha/3} + 1.\]
Appendix D. Proof of Theorem 2

Proof First, since \( x_{t+1} = (1 - \eta_t)x_t + \eta_t v_t \) is a convex combination of \( x_t, v_t \), and \( x_1 \in \mathcal{K}, v_t \in \mathcal{K} \) for all \( t \), we can prove \( x_t \in \mathcal{K} \) for all \( t \) by induction. So \( x_{T+1} \in \mathcal{K} \).

Then we observe that for any iteration \( t \), we have

\[
\begin{align*}
    f(x_{t+1}) - f(x^*) &= f(x_t + \eta_t(v_t - x_t)) - f(x^*) \\
    &\leq f(x_t) + \eta_t \langle v_t - x_t, \nabla f(x_t) \rangle + \frac{L}{2} \eta_t^2 \| v_t - x_t \|^2 - f(x^*) \\
    &= f(x_t) - f(x^*) + \eta_t \langle v_t - x_t, \tilde{g}_t \rangle + \frac{L}{2} \eta_t^2 \| v_t - x_t \|^2 \\
    &\leq f(x_t) - f(x^*) + \eta_t \langle v_t - x_t, \nabla f(x_t) \rangle + \frac{L}{2} \eta_t^2 \| v_t - x_t \|^2 \\
    &= f(x_t) - f(x^*) + \eta_t \langle v_t - x_t, \nabla f(x_t) \rangle + \frac{L}{2} \eta_t^2 \| v_t - x_t \|^2 \\
    &\leq (1 - \eta_t)(f(x_t) - f(x^*)) + \eta_t \| v_t - x_t, \tilde{g}_t \| - \nabla f(x_t) - \tilde{g}_t \| + \frac{L}{2} \eta_t^2 \| v_t - x_t \|^2 \\
    &\leq (1 - \eta_t)(f(x_t) - f(x^*)) + \eta_t D \| \nabla f(x_t) - \tilde{g}_t \| + \frac{L}{2} \eta_t^2 \| v_t - x_t \|^2 \\
\end{align*}
\]

(16)

where Inequality \((a)\) holds because of the \( L \)-smoothness. In \((b)\) we used the optimality of \( v_t \). Inequality \((c)\) is due to the convexity of \( f \), and we applied the Cauchy-Schwarz inequality in \((d)\).

Now we want to apply Lemma 3 to bound \( \| \nabla f(x_t) - \tilde{g}_t \| \). By the smoothness of \( f \) and \( \eta_t = \frac{2}{t+3} \), we have

\[
\| \nabla f(x_t) - \nabla f(x_{t-1}) \| \leq \eta_{t-1} \| v_{t-1} - x_{t-1} \| L \leq \frac{2LD}{t+2}.
\]

Let \( \mathcal{F}_{t-1} \) be the \( \sigma \)-field generated by \( \{ \Phi'(\tilde{g}_i) \}_{i=1}^{t-1} \) and \( \mathcal{F}_0 = \emptyset \), by the unbiasedness of the random encoding scheme \( \Phi \) and the stochastic gradient \( g_t^m \), we have for all \( t \geq 1 \)

\[
\mathbb{E}[\Phi'(\tilde{g}_t) | \mathcal{F}_{t-1}] = \mathbb{E}[\tilde{g}_t | \mathcal{F}_{t-1}] = \mathbb{E}[\frac{\sum_{m=1}^{M} \Phi'(g^m_t(x_t))}{M} | \mathcal{F}_{t-1}] = \mathbb{E}[\frac{\sum_{m=1}^{M} g^m_t(x_t)}{M} | \mathcal{F}_{t-1}] = \nabla f(x_t)
\]
and
\[
\mathbb{E}[\|\Phi'(\tilde{g}_t) - \nabla f(x_t)\|^2 | \mathcal{F}_{t-1}] \\
= \mathbb{E}[\|\Phi'(\tilde{g}_t) - \tilde{g}_t + \tilde{g}_t - g_t - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} + \frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\|^2 | \mathcal{F}_{t-1}] \\
= \mathbb{E}[\|\Phi'(\tilde{g}_t) - \tilde{g}_t + \frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\|^2 | \mathcal{F}_{t-1}] \\
= \mathbb{E}[\frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} \|2 | \mathcal{F}_{t-1}] + \mathbb{E}[\|\frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\|^2 | \mathcal{F}_{t-1}] \\
+ 2\mathbb{E}[\langle \Phi'(\tilde{g}_t) - \tilde{g}_t, \frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} \rangle | \mathcal{F}_{t-1}] \\
+ 2\mathbb{E}[\|\frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\| | \mathcal{F}_{t-1}] \\
\]
By Assumptions 3 and 4, we have
\[
\mathbb{E}[\|\frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} \|2 | \mathcal{F}_{t-1}] = \frac{\sum_{m=1}^M \mathbb{E}[\|\Phi'(g_t^m(x_t)) - g_t^m(x_t)\|^2 | \mathcal{F}_{t-1}]}{M^2} \leq \frac{\sigma_2^2}{M}, \\
\mathbb{E}[\|\frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\|^2 | \mathcal{F}_{t-1}] = \frac{\sum_{m=1}^M \text{Var}[g_t^m(x_t) | \mathcal{F}_{t-1}]}{M^2} \leq \frac{\sigma_1^2}{M}, \\
\mathbb{E}[\|\Phi'(\tilde{g}_t) - \tilde{g}_t\|^2 | \mathcal{F}_{t-1}] \leq \sigma_3^2, \\
\]
and
\[
\mathbb{E}[\langle \Phi'(\tilde{g}_t) - \tilde{g}_t, \frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} \rangle | \mathcal{F}_{t-1}] = 0, \\
\mathbb{E}[\langle \Phi'(\tilde{g}_t) - \tilde{g}_t, \frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\rangle | \mathcal{F}_{t-1}] = 0, \\
\mathbb{E}[\|\frac{\sum_{m=1}^M \Phi'(g_t^m(x_t))}{M} - \frac{\sum_{m=1}^M g_t^m(x_t)}{M} - \nabla f(x_t)\| | \mathcal{F}_{t-1}] = 0. \\
\]
Therefore,
\[
\mathbb{E}[\|\Phi'(\tilde{g}_t) - \nabla f(x_t)\|^2 | \mathcal{F}_{t-1}] \leq \frac{\sigma_2^2}{M} + \frac{\sigma_1^2}{M} + \frac{\sigma_3^2}{M} = \frac{\sigma_1^2 + \sigma_2^2 + \sigma_3^2}{M}. \tag{17}
\]
Now apply Lemma 3 with \(\alpha = 1, G = 2LD, s = 2 > 2\sqrt{2} - 1 = 8^{1/3} - 1, \sigma^2 = \frac{s_1^2 + s_2^2 + s_3^2}{M}, d_t = \tilde{g}_t, \) for all \(t \geq 0, a_t = \nabla f(x_t), \tilde{a}_t = \Phi'(\tilde{g}_t), \) for all \(t \geq 1, a_0 = a_1 = \nabla f(x_1), \) we have
\[
\mathbb{E}[\|\nabla f(x_t) - \tilde{g}_t\|^2] \leq \frac{Q}{(t + 3)^{2/3}},
\]
where \(Q = \max\{3^{2/3}\|\nabla f(x_1)\|^2, \frac{4(s_1^2 + s_2^2)}{M} + 4s_3^2 + 8L^2D^2\}.\)
By Jensen’s Inequality,
\[
\mathbb{E}[\|\nabla f(x_t) - \tilde{g}_t\|] \leq \sqrt{\mathbb{E}[\|\nabla f(x_t) - \tilde{g}_t\|^2]} \leq \frac{Q^{1/2}}{(t + 3)^{1/3}}. \tag{18}
\]
Combine Eqs. (16) and (18) and recall $\eta_t = \frac{2}{t+3}$, we have
\[
E[f(x_{t+1})] - f(x^*) \leq (1 - \eta_t)(E[f(x_t)] - f(x^*)) + \eta_t \frac{DQ^{1/2}}{(t+3)^{1/3}} + L \frac{2\eta_t^2 D^2}{(t+3)^{2/3}}.
\]
(19)

Now we claim that for all $t \in [T+1]$
\[
E[f(x_t)] - f(x^*) \leq \frac{Q_0}{(t+3)^{1/3}}
\]
where $Q_0 = \max\{4^{1/3} \cdot 2M_0, 2D(Q^{1/2} + LD)\}$.

We prove it by induction. When $t = 1$, we have
\[
\frac{Q_0}{(t+3)^{1/3}} \geq \frac{4^{1/3} \cdot 2M_0}{4^{1/3}} = 2M_0 \geq E[f(x_1)] - f(x^*).
\]
Now suppose that for some $t \in [T]$, we have $E[f(x_t)] - f(x^*) \leq \frac{Q_0}{(t+3)^{1/3}}$, then by Eq. (19), we have
\[
E[f(x_{t+1})] - f(x^*) \leq \left(1 - \frac{2}{t+3}\right) \frac{Q_0}{(t+3)^{1/3}} + \frac{Q_0}{(t+3)^{4/3}} \leq \frac{Q_0}{(t+3)^{1/3}} - \frac{Q_0}{(t+3)^{4/3}}
\]
where the last inequality holds since $(t+2)^3(t+4) \leq (t+3)^4$, for all $t \geq 1$. Therefore, we have
\[
E[f(x_t)] - f(x^*) \leq \frac{Q_0}{(t+3)^{1/3}}, \text{ for all } t \in [T+1].
\]
Specifically, we have
\[
E[f(x_{T+1})] - f(x^*) \leq \frac{Q_0}{(T+4)^{1/3}}.
\]

Appendix E. Proof of Theorem 1 with Sign Encoding Scheme

Next, we incorporate the Sign Encoding Scheme into S-QFW as quantization scheme. We first make the following assumption on the stochastic gradients.

Assumption 8 The stochastic gradients $g^m_t$ have uniformly bounded $\ell_1$ and $\ell_\infty$ norms, i.e., $\|g^m_t\|_1 \leq G_1, \|g^m_t\|_\infty \leq G_\infty$, for all $m \in [M], t \in [T]$.

Corollary 6 Under Assumptions 1 to 3 and 8, if we set $\eta_t = 2/(t+3), \rho_t = 2/(t+3)^{2/3}$ and apply Sign Encoding Scheme in S-QFW, then $E[f(x_{T+1})] - f(x^*) \leq \frac{Q_0}{(T+4)^{1/3}},$ where $Q_0 = \max\{4M_0, 2D(Q^{1/2}+LD)\}$, and $Q = \max\{3\|\nabla f(x_1)\|^2, 4(\sigma^2_1 + G_1G_\infty)/M + 4G_1G_\infty + 8L^2D^2\}$. 

21
Appendix F. Proof of Theorem 3

Proof Since \( \text{sgn}(g) \circ b \) requires 2d bits and \( \|g\|_{\infty} \) requires 32 bits, so for each \( \phi(g) \), we need 2d + 32 bits of communication. At Step 4 of Stochastic Quantized Frank-Wolfe, each worker \( m \) should push \( \phi(g_t^m) \) to the master, and at Step 6, the master should broadcast \( \phi(\tilde{g}_t) \) to all the \( M \) workers, so we need \((2d + 32) \cdot M + 2d + 32 = (M + 1)(2d + 32)\) bits per round.

In order to apply Theorem 2, we only need to prove that \( \phi \) has similar properties to Assumption 4. We have shown that the Sign Encoding Scheme \( \phi \) is unbiased. Then by Lemma 2, we have

\[
\mathbb{E}[\|\phi'(g_t^m) - g_t^m\|^2] = \mathbb{E}[\mathbb{E}[\|\phi'(g_t^m) - g_t^m\|^2|g_t^m]] = \mathbb{E}[\|g_t^m\|_1\|g_t^m\|_{\infty} - \|g_t^m\|_2^2] \leq G_1G_{\infty}.
\]

Since

\[
\mathbb{E}[\|\phi'(\tilde{g}_t) - \tilde{g}_t\|^2] = \mathbb{E}[\mathbb{E}[\|\phi'(\tilde{g}_t) - \tilde{g}_t\|^2|\tilde{g}_t]] = \mathbb{E}[\|\tilde{g}_t\|_1\|\tilde{g}_t\|_{\infty} - \|\tilde{g}_t\|_2^2] \leq G_{\infty}\mathbb{E}[\|\tilde{g}_t\|_1]
\]

and

\[
\mathbb{E}[\|\tilde{g}_t\|_1|g_t^m] = \mathbb{E}[\|\sum_{m=1}^{M} \phi'(g_t^m)|\|1|g_t^m] \leq \sum_{m=1}^{M} \frac{\mathbb{E}[\|\phi'(g_t^m)|\|1|g_t^m]}{M} = \sum_{m=1}^{M} \frac{\mathbb{E}[\sum_{i=1}^{d} \phi'(g_t^m)\|g_t^m]}{M} \leq \sum_{m=1}^{M} \frac{\|g_t^m\|_1}{M} = G_1,
\]

where \( \phi'_i(g_t^m) \) is the \( i \)th element of \( \phi'(g_t^m) \), \( \tilde{g}_{t,i} \) is the \( i \)th element of \( g_t^m \). So we have

\[
\mathbb{E}[\|\tilde{g}_t\|_1] = \mathbb{E}[\mathbb{E}[\|\tilde{g}_t\|_1|g_t^m]] \leq G_1,
\]

and

\[
\mathbb{E}[\|\phi'(\tilde{g}_t) - \tilde{g}_t\|^2] \leq G_1G_{\infty}.
\]

we can apply Theorem 2 with \( \sigma_2^2 = G_1G_{\infty}, \sigma_3^2 = G_1G_{\infty} \), then we have

\[
\mathbb{E}[f(x_{T+1})] - f(x^*) \leq \frac{Q_0}{(T + 4)^{1/3}}
\]

where \( Q_0 = \max\{4^{1/3} \cdot 2M_0, 2D(Q^{1/2} + LD)\}, \) and \( Q = \max\{3^{2/3}\|\nabla f(x_1)\|^2, \frac{4(\sigma_2^2 + G_1G_{\infty})}{M} + 4G_1G_{\infty} + 8L^2D^2\} \).

Appendix F. Proof of Theorem 3

Proof First, since \( x_{t+1} = (1 - \eta_t) x_t + \eta_t v_t \) is a convex combination of \( x_t, v_t \), and \( x_1 \in \mathcal{K}, v_t \in \mathcal{K} \), for all \( t \), we can prove \( x_t \in \mathcal{K} \), for all \( t \) by induction. So the output \( x_o \in \mathcal{K} \).

Note that if we define \( v'_t = \text{argmin}_{v \in \mathcal{K}} \langle v, \nabla f(x_t) \rangle \), then \( g(x_t) = \langle v'_t - x_t, -\nabla f(x_t) \rangle = -\langle v'_t - x_t, \nabla f(x_t) \rangle \). So we have
\[ f(x_{t+1}) \leq f(x_t) + \langle \nabla f(x_t), x_{t+1} - x_t \rangle + \frac{L}{2} \| x_{t+1} - x_t \|^2 \]

\[ = f(x_t) + \langle \nabla f(x_t), \eta_t(v_t - x_t) \rangle + \frac{L}{2} \| \eta_t(v_t - x_t) \|^2 \]

\[ \leq f(x_t) + \eta_t \| \nabla f(x_t) \| v_t - x_t \| + \frac{L \eta_t^2 D^2}{2} \]

where we used the assumption that \( f \) has \( L \)-Lipschitz continuous gradient in inequality (a).\n
Inequalities (b), (e) hold because of Assumption 1. Inequality (c) is due to the optimality of \( v_t \), and in (d), we applied the Cauchy-Schwarz inequality.

Rearrange the inequality above, we have

\[ \eta_t \mathcal{G}(x_t) \leq f(x_t) - f(x_{t+1}) + \eta_t D \| \nabla f(x_t) \| v_t - x_t \| + \frac{L \eta_t^2 D^2}{2}. \] (20)

Apply Eq. (20) recursively for \( t = 1, 2, \cdots, T \), and take expectations, we attain the following inequality:

\[ \sum_{t=1}^{T} \eta_t \mathbb{E}[\mathcal{G}(x_t)] \leq f(x_1) - f(x_{T+1}) + D \sum_{t=1}^{T} \eta_t \mathbb{E}[\| \nabla f(x_t) \| v_t - x_t \|] + \frac{LD^2}{2} \sum_{t=1}^{T} \eta_t^2. \] (21)

Since \( f \) has \( L \)-Lipschitz continuous gradient, and \( \eta_t = (T + 3)^{-3/4} \), we have

\[ \| \nabla f(x_t) - \nabla f(x_{t-1}) \| \leq \| \eta_{t-1}(v_{t-1} - x_{t-1}) \| = \eta_{t-1} \| v_{t-1} - x_{t-1} \| L \]

\[ \leq \frac{LD}{(T + 3)^{3/4}} \leq \frac{LD}{(t + 3)^{3/4}}. \]

Combine the inequality above with Eq. (17), and apply Lemma 3 with \( \alpha = 3/4, G = LD, s = 3 = 8^{3/4} - 1 = 8.40 - 1 = \frac{\sigma^2 + \sigma^2 + t L}{\sqrt{M}} \), \( d_t = \tilde{g}_t \), for all \( t \geq 0, a_t = \nabla f(x_t), \tilde{a}_t = \Phi'(\tilde{g}_t), \) for all \( t \geq 1, a_0 = a_1 = \nabla f(x_1) \), we have

\[ \mathbb{E}[\| \nabla f(x_t) - \tilde{g}_t \|^2] \leq \frac{Q}{(t + 4)^{1/2}} \]
where \( Q = \max \{2\|\nabla f(x_1)\|^2, \frac{4(\sigma_1^2 + \sigma_2^2)}{M} + 4\sigma_3^2 + 2L^2D^2\} \).

By Jensen’s Inequality,

\[
\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|] \leq \sqrt{\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2]} \leq \frac{Q^{1/2}}{(t + 4)^{1/4}}.
\]

Since

\[
\sum_{t=1}^{T} \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|] \leq \sum_{t=1}^{T} \frac{Q^{1/2}}{(t + 4)^{1/4}} \leq \int_{0}^{T} \frac{Q^{1/2}}{(t + 4)^{1/4}} dt = \frac{4Q^{1/2}}{3} [(T + 4)^{3/4} - 4^{3/4}] \leq \frac{4Q^{1/2}}{3} (T + 4)^{3/4},
\]

by Eq. (21), we have

\[
\sum_{t=1}^{T} \mathbb{E}[G(x_t)] \leq \frac{f(x_1) - f(x_{T+1})}{(T + 3)^{3/4}} + D \sum_{t=1}^{T} \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|] + \frac{LD^2}{2} \frac{T}{(T + 3)^{3/4}} (T + 3)^{-3/4}
\]

\[
\leq [f(x_1) - f(x_{T+1})][T + 3]^{3/4} + \frac{4DQ^{1/2}}{3} (T + 4)^{3/4} + \frac{LD^2}{2} T (T + 3)^{-3/4}.
\]

So we have

\[
\mathbb{E}[G(x_0)] = \frac{\sum_{t=1}^{T} \mathbb{E}[G(x_t)]}{T} \leq \frac{[f(x_1) - f(x_{T+1})]}{(T + 3)^{3/4}} \frac{T}{T} + \frac{4DQ^{1/2}}{3} \frac{(T + 4)^{3/4}}{(T + 4)^{3/4}} + \frac{LD^2}{2} (T + 3)^{-3/4}
\]

\[
\leq 2M_0 \frac{(T + 3)^{3/4}}{(T + 3)^{3/4}} + \frac{4DQ^{1/2}}{3} \frac{(T + 4)^{3/4}}{(T + 4)^{3/4}} + \frac{LD^2}{2} (T + 3)^{-3/4}
\]

\[
\leq 8M_0 + 20DQ^{1/2}/3 \frac{(T + 3)^{1/4}}{(T + 3)^{3/4}} + \frac{LD^2}{2(T + 3)^{3/4}}.
\]

\[
\square
\]

Appendix G. Bounding \( \|\nabla f(x_t) - \bar{g}_t\| \) in Finite-Sum Case

We now address the bound of \( \|\nabla f(x_t) - \bar{g}_t\| \), which is resolved in the following lemma.

**Lemma 4** Under Assumption 1, if we further assume that each \( f_{m,i} \) is bounded and has \( L \)-Lipschitz continuous gradient, and \( \|\nabla f_{m,i}(x)\|_{\infty} \leq G_{\infty} \), for all \( x \in K, m \in [M], i \in [n], \) where \( G_{\infty} \) is a positive constant, by setting \( p = \sqrt{n}, S = \sqrt{n} \) and applying the \( s_{1,t} = (2^{2i,t} - 1) \)-Partition Encoding Scheme \( \phi_{1,t} \), the \( s_{2,t} = (2^{2i,t} - 1) \)-Partition Encoding Scheme \( \phi_{2,t} \) as \( \Phi_{1,t}, \Phi_{2,t} \), we have

\[
\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq (L^2D^2 + 2G_{\infty}^2) \frac{\sum_{i=0}^{s-1} \frac{1}{p^i} \frac{1}{p+1} \leq (\frac{1}{p^i} + 1)p \eta^2}{\sqrt{n}},
\]

\[
\text{where } s = 2^{2i,t} - 1.
\]
where

\[ z_{1,t} = \left\lfloor \log_2 \left( \frac{4dpS}{M \sum_{l=\lfloor \frac{1}{p} \rfloor p+1}^{\lceil \frac{1}{p} \rceil +1} \eta_l^2} \right)^{1/2} + 1 \right\rfloor \tag{22} \]

\[ z_{2,t} = \left\lfloor \log_2 \left( \frac{4dpS}{\sum_{l=\lfloor \frac{1}{p} \rfloor p+1}^{\lceil \frac{1}{p} \rceil +1} \eta_l^2} \right)^{1/2} + 1 \right\rfloor. \tag{23} \]

This lemma looks a bit complicated because of the summation of \( \eta_l^2 \). The range of the summation is just the subset which contains \( l \) and can be expressed as \( \{kp+1, kp+2, \ldots, (k+1)p\} \), where \( k \in \mathbb{N} \). This is easy to understand, since intuitively, the variance is only related to the factors within the same period \( \{kp+1, kp+2, \ldots, (k+1)p\} \). In practical applications, we usually have concrete values for \( \eta_l \), which will make the sum and thus the expressions look much simpler.

**Proof** We first define an auxiliary variable \( g_t \), which is \( \nabla f(x_t) \) if \( \text{mod}(t, p) = 1 \), and is set to \( \frac{1}{M^2} \sum_{m=1}^{M} \sum_{i \in S^m} [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})] + g_{t-1} \) otherwise.

We also define \( \mathcal{F}_{t-1} \) to be the \( \sigma \)-field generated by all the randomness before round \( t \). We note that given \( \mathcal{F}_{t-1} \), \( x_t \) is actually determined, and we can verify that \( \mathbb{E}[g_t | \mathcal{F}_{t-1}] = \nabla f(x_t) \), and \( \mathbb{E}[\bar{g}_t | \mathcal{F}_{t-1}, g_t] = g_t \) for all \( t \in [T] \). Here, with abuse of notation, \( \mathbb{E}[\cdot | g_t] \) is the conditional expectation given not only the value of \( g_t \), but also the gradients \( \nabla f_{m,i}(x_t), \nabla f_{m,i}(x_{t-1}) \) for all \( i \in S^m, m \in [M] \).

Then by law of total expectation, we have

\[
\mathbb{E}[\|\nabla f(x_t) - g_t\|^2] = \mathbb{E}[\mathbb{E}[\|\nabla f(x_t) - g_t\|^2 | \mathcal{F}_{t-1}]]
\]

\[
= \mathbb{E}[\mathbb{E}[\|\nabla f(x_t) - g_t + g_t - \bar{g}_t\|^2 | \mathcal{F}_{t-1}]]
\]

\[
= \mathbb{E}[\mathbb{E}[\|\nabla f(x_t) - g_t\|^2 | \mathcal{F}_{t-1}]] + \mathbb{E}[\mathbb{E}[\|g_t - \bar{g}_t\|^2 | \mathcal{F}_{t-1}]]
\]

\[
+ 2\mathbb{E}[\mathbb{E}[\langle \nabla f(x_t) - g_t, g_t - \bar{g}_t \rangle | \mathcal{F}_{t-1}]]
\]

\[
= \mathbb{E}[\|\nabla f(x_t) - g_t\|^2] + \mathbb{E}[\|g_t - \bar{g}_t\|^2],
\]

where the last equation holds since

\[
\mathbb{E}[\langle \nabla f(x_t) - g_t, g_t - \bar{g}_t \rangle | \mathcal{F}_{t-1}] = \mathbb{E}[\mathbb{E}[\langle \nabla f(x_t) - g_t, g_t - \bar{g}_t \rangle | \mathcal{F}_{t-1}, g_t] | \mathcal{F}_{t-1}] = \mathbb{E}[\langle \nabla f(x_t) - g_t, \mathbb{E}[g_t - \bar{g}_t | \mathcal{F}_{t-1}, g_t] \rangle | \mathcal{F}_{t-1}] = 0.
\]

Moreover, for \( \text{mod}(t, p) \neq 1 \),

\[
\mathbb{E}[\|\nabla f(x_t) - g_t\|^2] = \mathbb{E}[\|\nabla f(x_t) - \nabla f(x_{t-1}) + \nabla f(x_{t-1}) - g_t\|^2]
\]

\[-\frac{1}{M^2} \sum_{m=1}^{M} \sum_{i \in S^m} [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})] [\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})] | \mathcal{F}_{t-1}].
\]

With abuse of notation, we have \( \mathbb{E}[\sum_{m=1}^{M} \nabla f_{m,i}(x_t) / M | \mathcal{F}_{t-1}] = \nabla f(x_t) \), and

\[
\mathbb{E}[\sum_{m=1}^{M} \nabla f_{m,i}(x_{t-1}) / M | \mathcal{F}_{t-1}] = \nabla f(x_{t-1}).
\]
where $i$ actually depends on $m$, and is sampled from $S_t^m$ at random. Thus
\[
\mathbb{E}\left[ \frac{1}{MS} \sum_{m=1}^{M} \sum_{i \in S_t^m} (\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1})) | F_{t-1} \right] = \nabla f(x_t) - \nabla f(x_{t-1}),
\]
and
\[
\mathbb{E}[\nabla f(x_t) - \nabla f(x_{t-1}) - \frac{1}{MS} \sum_{m=1}^{M} \sum_{i \in S_t^m} (\nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1}), \nabla f(x_{t-1}) - g_{t-1}) | F_{t-1}] = 0.
\]
So we have
\[
\mathbb{E}[\| \nabla f(x_t) - g_t \|^2] = \mathbb{E}[\mathbb{E}[\| \nabla f(x_t) - g_t \|^2 | F_{t-1}]]
\]
\[
= \mathbb{E}[\mathbb{E}[\| \nabla f(x_t) - g_t \|^2 | F_{t-1}]] + \mathbb{E}[\| \nabla f(x_t) - g_t \|^2]
\]
\[
= \frac{1}{S} \mathbb{E}[\mathbb{E} \sum_{m=1}^{M} \frac{\| \nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1}) \|^2}{M} | F_{t-1}] + \mathbb{E}[\| \nabla f(x_t) - g_t \|^2]
\]
\[
\leq \frac{1}{S} \mathbb{E}[\mathbb{E} \sum_{m=1}^{M} \frac{\| \nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1}) \|^2}{M} | F_{t-1}] + \mathbb{E}[\| \nabla f(x_t) - g_t \|^2]
\]
\[
\leq \frac{1}{S} \mathbb{E}[\mathbb{E} \sum_{m=1}^{M} \| \nabla f_{m,i}(x_t) - \nabla f_{m,i}(x_{t-1}) \|^2 | F_{t-1}] + \mathbb{E}[\| \nabla f(x_t) - g_t \|^2]
\]
\[
\leq \frac{1}{S} (LD\eta_t)^2 + \mathbb{E}[\| \nabla f(x_t) - g_t \|^2] = \frac{L^2D^2\eta_t^2}{S} + \mathbb{E}[\| \nabla f(x_t) - g_t \|^2].
\]
Note for any $t$ such that $\text{mod}(t, p) = 1$, we have $g_t = \nabla f(x_t)$. Therefore
\[
\mathbb{E}[\| \nabla f(x_t) - g_t \|^2] \leq \frac{L^2D^2}{S} \sum_{\lfloor \frac{t+1}{p} \rfloor j+1 \leq t \leq \lfloor \frac{t+1}{p} \rfloor + p} \eta_t^2.
\]
(25)
Now we turn to bound $\mathbb{E}[\| g_t - \bar{g}_t \|^2]$. For $\text{mod}(t, p) \neq 1$, We have
\[
\mathbb{E}[\| g_t - \bar{g}_t \|^2] = \mathbb{E}[\mathbb{E}[\| g_t - \bar{g}_t \|^2 | F_{t-1}]]
\]
\[
= \mathbb{E}[\mathbb{E}[\| g_t - \bar{g}_t \|^2 | F_{t-1}]] + \mathbb{E}[\| g_t - \bar{g}_t \|^2]
\]
\[
= \mathbb{E}[\mathbb{E}[\| g_t - \bar{g}_t \|^2 | F_{t-1}]] + \mathbb{E}[\| g_t - \bar{g}_t \|^2]
\]
\[
+ \mathbb{E}[\mathbb{E}[\| g_t - \bar{g}_t \|^2 | F_{t-1}]] + \mathbb{E}[\| g_t - \bar{g}_t \|^2]
\]
\[
+ \mathbb{E}[\mathbb{E}[\| g_t - \bar{g}_t \|^2 | F_{t-1}]] + \mathbb{E}[\| g_t - \bar{g}_t \|^2].
\]
26
Moreover
\[
\mathbb{E}[\phi_2, t(\tilde{g}_t) | \mathcal{F}_{t-1}, g_t] = \mathbb{E}[\tilde{g}_t | \mathcal{F}_{t-1}, g_t]
\]
\[
= \mathbb{E} \left[ \sum_{m=1}^{M} \phi_{1, t}^{i} \left( \sum_{i \in S_{m}} \nabla f_{m, i}(x_t) - \nabla f_{m, i}(x_{t-1}) \right) / M | \mathcal{F}_{t-1}, g_t \right]
\]
\[
= \frac{1}{MS} \sum_{i \in S_t} \sum_{m=1}^{M} \left[ \nabla f_{m, i}(x_t) - \nabla f_{m, i}(x_{t-1}) \right],
\]
and
\[
\mathbb{E}[\mathbb{E} \left[ \frac{1}{MS} \sum_{m=1}^{M} \sum_{i \in S_{m}} \left[ \nabla f_{m, i}(x_t) - \nabla f_{m, i}(x_{t-1}) \right] - \phi_{2, t}(\tilde{g}_t) \right] | \mathcal{F}_{t-1}, g_t]
\]
\[
= \mathbb{E}[\mathbb{E} \left[ \frac{1}{MS} \sum_{m=1}^{M} \sum_{i \in S_{m}} \left[ \nabla f_{m, i}(x_t) - \nabla f_{m, i}(x_{t-1}) \right] \right] - \tilde{g}_t \right] | \mathcal{F}_{t-1}, g_t]
\]
\[
\leq \frac{1}{M} \frac{d}{s_{1, t}^2} (2G_{\infty})^2 + \frac{d}{s_{2, t}^2} (2G_{\infty})^2 = \frac{4dG_{\infty}^2}{Ms_{1, t}^2} + \frac{4dG_{\infty}^2}{s_{2, t}^2},
\]
where in the inequality, we apply Lemma 1 with \( \| \sum_{i \in S_{m}} \nabla f_{m, i}(x_t) - \nabla f_{m, i}(x_{t-1}) \|_{\infty} \leq 2G_{\infty} \) and
\( \| \tilde{g}_t \|_{\infty} = \| \sum_{m=1}^{M} \phi_{1, t}^{i} \left( \sum_{i \in S_{m}} \nabla f_{m, i}(x_t) - \nabla f_{m, i}(x_{t-1}) \right) / M \|_{\infty} \leq 2G_{\infty} \).

Now we have for \( \text{mod}(t, p) \neq 1 \),
\[
\mathbb{E}[\| g_t - \tilde{g}_t \|^{2}] \leq \frac{4dG_{\infty}^2}{Ms_{1, t}^2} + \frac{4dG_{\infty}^2}{s_{2, t}^2} + \mathbb{E}[\| g_t - \tilde{g}_t - 1 \|^{2}].
\]

If \( \text{mod}(t, p) = 1 \), we have
\[
\mathbb{E}[\| g_t - \tilde{g}_t \|^{2}] = \mathbb{E}[\| \nabla f(x_t) - \tilde{g}_t - \tilde{g}_t - \phi_{2, t}(\tilde{g}_t) \|^{2}]
\]
\[
= \mathbb{E} \left[ \| \nabla f(x_t) - \sum_{m=1}^{M} \phi_{1, t}^{i} \left( \sum_{i \in S_{m}} \nabla f_{m, i}(x_t) / n \right) \|^{2} | \mathcal{F}_{t-1}, g_t \right]
\]
\[
+ \mathbb{E}[\| \tilde{g}_t - \phi_{2, t}(\tilde{g}_t) \|^{2} | \mathcal{F}_{t-1}, g_t]
\]
\[
\leq \frac{1}{M} \mathbb{E}[\left( \sum_{i=1}^{n} \nabla f_{m, i}(x_t) / n - \phi_{1, t}^{i} \left( \sum_{i \in S_{m}} \nabla f_{m, i}(x_t) / n \right) \right)^{2} | \mathcal{F}_{t-1}, g_t] + \frac{d}{s_{2, t}^2} (2G_{\infty})^2
\]
\[
\leq \frac{dG_{\infty}^2}{Ms_{1, t}^2} + \frac{dG_{\infty}^2}{s_{2, t}^2},
\]
27
where in the inequality, we apply Lemma 1 with $\|\sum_{i=1}^n \nabla f_{m,i}(x_t)/n\|_{\infty} \leq G_\infty$ and $\|\bar{g}_t\| = \|\sum_{m=1}^M \phi_i(x_t)/(n/n)\|_{\infty} \leq G_\infty$. Since for any $t_1, t_2$ such that $\lfloor \frac{t_1}{p} \rfloor = \lfloor \frac{t_2}{p} \rfloor$, we have $s_1 \triangleq s_{1,t_1} = s_{1,t_2}, s_2 \triangleq s_{2,t_1} = s_{2,t_2}$, thus

$$E[\|g_t - \bar{g}_t\|^2] \leq \frac{4dG_\infty^2}{Ms_1^2} + \frac{4dG_\infty^2}{s_2^2}(p - 1) + \frac{dG_\infty^2}{M} + \frac{dG_\infty^2}{s_2^2} \leq \frac{4dpG_\infty^2}{Ms_1^2} + \frac{4dpG_\infty^2}{s_2^2}. \quad (26)$$

Now combine Eqs. (24) to (26), we have

$$E[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq \frac{L^2D^2}{S} \sum_{\lfloor \frac{t_1}{p} \rfloor + \lfloor \frac{t_2}{p} \rfloor \leq (\lfloor \frac{t_1}{p} \rfloor + 1)p} \eta_t^2 + \frac{4dpG_\infty^2}{Ms_1^2} + \frac{4dpG_\infty^2}{s_2^2}.$$

Since we set $p = \sqrt{n}, S = \sqrt{n}, s_1 = 2^{z_2} - 1 \geq (M \sum_{\lfloor \frac{t_1}{p} \rfloor + \lfloor \frac{t_2}{p} \rfloor \leq \lfloor \frac{t_1}{p} \rfloor + 1)p} \eta_t^2, s_2 = 2^{z_2} - 1 \geq (\sum_{\lfloor \frac{t_1}{p} \rfloor + \lfloor \frac{t_2}{p} \rfloor \leq \lfloor \frac{t_1}{p} \rfloor + 1)p} \eta_t^2)$, we have

$$E[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq \left( \frac{L^2D^2}{2} + 2G_\infty^2 \right) \frac{\sum_{\lfloor \frac{t_1}{p} \rfloor + \lfloor \frac{t_2}{p} \rfloor \leq \lfloor \frac{t_1}{p} \rfloor + 1)p} \eta_t^2}{\sqrt{n}}.$$

Appendix H. Proof of Theorem 4

Proof First, since $x_{t+1} = (1 - \eta_t)x_t + \eta_t v_t$ is a convex combination of $x_t, v_t$, and $v_1 \in \mathcal{K}, v_t \in \mathcal{K}$, for all $t$, we can prove $x_t \in \mathcal{K}$, for all $t$ by induction. So $x_{T+1} \in \mathcal{K}$.

Since for the $s$-Sign Encoding Scheme, the required number of bits is $z = \log_2(s + 1)$. So for $\Phi_{1,t}, \Phi_{2,t}$, the corresponding assigned bits are $z_{1,t} = \log_2(s_{1,t} + 1), z_{2,t} = \log_2(s_{2,t} + 1)$. To make them integers, we can set $z_{1,t} = \lceil \log_2([pd^{1/2} S^{1/2}]/[p^{1/2} + 1]) \rceil, z_{2,t} = \lceil \log_2(pd^{1/2} S^{1/2}/[p^{1/2} + 1]) \rceil$.

Then with $\eta_t = 2/(p^{1/2} + 1)$, the conditions Eqs. (22) and (23) in Lemma 4 are satisfied. So by Lemma 4, we have

$$E[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq \frac{4(L^2D^2 + 2G_\infty^2)}{2^p \left[ \frac{t_1}{p} \right]^2}.$$ 

So

$$E[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq \sqrt{E[\|\nabla f(x_t) - \bar{g}_t\|^2]} \leq \frac{2\sqrt{L^2D^2 + 2G_\infty^2}}{p^{1/2} \left[ \frac{t_1}{p} \right]^2}.$$ 

On the other hand, by Assumption 6 $f = \sum_{m=1}^M f_{m,i}[n_i/n]$ is a bounded $L$-smooth convex function on $\mathcal{K}$, with $\sup_{x \in \mathcal{K}} |f(x)| \leq M_0$. So Eq. (16) still holds. Taking expectation on both sides, we have

$$E[f(x_{t+1})] - f(x^*) \leq (1 - \eta_t)(E[f(x_t)] - f(x^*)) + \eta_t D E[\|\nabla f(x_t) - \bar{g}_t\|] + L \eta_t^2 D^2 \leq (1 - \frac{2}{p^{1/2} \left[ \frac{t_1}{p} \right]})E[f(x_t)] - f(x^*) + \frac{2D(2\sqrt{L^2D^2 + 2G_\infty^2} + LD)}{p^{1/2} \left[ \frac{t_1}{p} \right]^2}.$$ 

28
Let $t = kp, Q = 2D(2\sqrt{L^2D^2 + 2G^2} + LD)$ where $k \in \mathbb{N}^+$, and apply the inequality recursively for $p$ times, we have

$$\mathbb{E}[f(x_{kp+1})] - f(x^*) \leq (1 - \frac{2}{pk})^p(\mathbb{E}[f(x_{(k-1)p+1})] - f(x^*)) + \frac{Q}{pk^2}.$$ 

Now we claim that $(1 - \frac{2}{pk})^p \leq 1 - \frac{2}{k} + \frac{2(p-1)}{pk^2}$. The inequality holds trivially for $p = 1$ and $p = 2$. For $p \geq 3$, we have $\frac{2}{pk} < 1$. Define function $h(x) = (1 - x)^p - 1 + px - \frac{p(p-1)}{2}x^2$. Then for $x \in [0, 1]$, we have $h'(x) = p[1 - (p-1)x - (1-x)p^{-1}], h''(x) = p(p-1)((1-x)^{p-2} - 1) \leq 0$, then $h'(x) \leq h'(0) = 0$, which implies 

Thus $h(x) \leq h(0) = 0$, i.e., $(1-x)^p \leq 1 - px + \frac{p(p-1)}{2}x^2$. Let $x = \frac{2}{pk}$, then we have $(1 - \frac{2}{pk})^p \leq 1 - \frac{2}{k} + \frac{2(p-1)}{2}x^2 = 1 - \frac{2}{k} + \frac{2(p-1)}{pk^2}$. Consider $k \geq 3$, then

$$(1 - \frac{2}{pk})^p \leq 1 - \frac{2}{k} + \frac{2(p-1)}{3pk} \leq 1 - \frac{2}{k} + \frac{2}{3k} = 1 - \frac{4}{3k},$$

and thus

$$\mathbb{E}[f(x_{kp+1})] - f(x^*) \leq (1 - \frac{4}{3k})(\mathbb{E}[f(x_{(k-1)p+1})] - f(x^*)) + \frac{Q}{pk^2}.$$ 

Define $Q_0 = \max\{6pM_0, 3Q\}$. Then we claim $\mathbb{E}[f(x_{kp+1})] - f(x^*) \leq \frac{Q_0}{(k+1)p}$, for all $k \in \mathbb{N}$. We prove this inequality by induction. For $k = 0, 1, 2$, we have $\mathbb{E}[f(x_{kp+1})] - f(x^*) \leq 2M_0 \leq \frac{Q_0}{(k+1)p} \leq \frac{Q_0}{(k+1)p}$. Now suppose that for some $k \geq 3$, we have $\mathbb{E}[f(x_{(k-1)p+1})] - f(x^*) \leq \frac{Q_0}{(k+1)p}$, then

$$\mathbb{E}[f(x_{kp+1})] - f(x^*) \leq (1 - \frac{4}{3k})\frac{Q_0}{kp} + \frac{Q_0}{3pk^2} = \frac{k - 1}{kp^2}Q_0 \leq \frac{Q_0}{(k+1)p},$$

where the last inequality holds since $(k-1)(k+1) \leq k^2$.

So we have $\mathbb{E}[f(x_{kp+1})] - f(x^*) \leq \frac{Q_0}{(k+1)p}$, for all non-negative integer $k \leq T/p$. Let $T = Kp$, then

$$\mathbb{E}[f(x_{T+1})] - f(x^*) = \mathbb{E}[f(x_{Kp+1})] - f(x^*) \leq \frac{Q_0}{(K+1)p} \leq \frac{Q_0}{T}.$$ 

For any $\epsilon > 0$, set $T = \frac{Q_0}{\epsilon}$, then we have $\mathbb{E}[f(x_{T+1})] - f(x^*) \leq \epsilon$. So the LO complexity is $O(1/\epsilon)$. Also note in each period, the total number of gradient call is $Mn+(p-1)M_2 = M_0 + 2MS(p-1) = T/p$, so the average cost is $[Mn + 2MS(p-1)]/p = M[3\sqrt{n}/2]$. Thus the total IFO complexity is $M[3\sqrt{n}/2]Q_0/\epsilon = O(\sqrt{n} \max\{6M_0\sqrt{n}, 3Q\}/\epsilon)$. The communication bits per round are at most $M(d(z_1,T+1) + 32) + d(z_2,T+1) + 32 = d(Mz_1,T + z_2,T) + (M+1)(d+32) \approx d(M[\log_2(\sqrt{d}T^2/M^{1/2}) + 1] + [\log_2((\sqrt{d}T^2)^{1/2} + 1)] + (M+1)(d+32).$
Appendix I. Proof of Theorem 5

Lemma 5 Under Assumptions 1 and 7, with \( \eta_t = T^{-1/2} \) and fixed \( T \) in Algorithm 2, if we further assume that

\[
\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq \frac{c^2}{T},
\]

where \( c \) is a positive constant, then we have \( x_o \in \mathcal{K} \) and

\[
\mathbb{E}[\mathcal{G}(x_o)] \leq \frac{2M_0 + cD + \frac{LD^2}{2}}{\sqrt{T}}.
\]

Since here we already assume that \( \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2] \) has an upper bound. The convergence rate can be proved by solving a recursive inequality directly. Moreover, since finite-sum optimization is a special case of stochastic gradient optimization, we can use the analysis in the proof of Theorem 3 to get the inequality.

Proof First, since \( x_{t+1} = (1 - \eta_t)x_t + \eta_tv_t \) is a convex combination of \( x_t, v_t \), and \( x_t \in \mathcal{K}, v_t \in \mathcal{K} \), for all \( t \), we can prove \( x_t \in \mathcal{K} \), for all \( t \) by induction. So \( x_o \in \mathcal{K} \).

By Assumption 7, \( f \) is also a bounded (potentially) non-convex function on \( \mathcal{K} \) with \( L \)-Lipschitz continuous gradient. Specifically, we have \( \sup_{x \in \mathcal{K}} |f(x)| \leq M_0 \). So Eq. (21) still holds, i.e.,

\[
\sum_{t=1}^{T} \eta_t \mathbb{E}[\mathcal{G}(x_t)] \leq f(x_1) - f(x_{T+1}) + D \sum_{t=1}^{T} \eta_t \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|] + \frac{LD^2}{2} \sum_{t=1}^{T} \eta_t^2.
\]

Since we assume that \( \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq \frac{c^2}{T} \), we have

\[
\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|] \leq \sqrt{\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2]} \leq \frac{c}{\sqrt{T}}.
\]

With \( \eta_t = T^{-1/2} \), we then have

\[
\sum_{t=1}^{T} \mathbb{E}[\mathcal{G}(x_t)] \leq \sqrt{T}[f(x_1) - f(x_{T+1})] + D \sum_{t=1}^{T} \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|] + \sqrt{T} \frac{LD^2}{2} T(T^{-1/2})^2
\]

\[
\leq 2M_0 \sqrt{T} + DT \frac{c}{\sqrt{T}} + \frac{LD^2}{2} \sqrt{T} = (2M_0 + cD + \frac{LD^2}{2}) \sqrt{T}.
\]

So

\[
\mathbb{E}[\mathcal{G}(x_o)] = \frac{\sum_{t=1}^{T} \mathbb{E}[\mathcal{G}(x_t)]}{T} \leq \frac{2M_0 + cD + \frac{LD^2}{2}}{\sqrt{T}}.
\]

Now we can prove Theorem 5

Proof By Lemma 5, we only need to bound \( \mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2] \), which can be achieved by applying Lemma 4

Since for the \textit{s-Sign Encoding Scheme}, the required number of bits is \( z = \log_2(s + 1) \). So for \( \Phi_{1,t}, \Phi_{2,t} \), the corresponding assigned bits are \( z_{1,t} = \log_2(s_{1,t} + 1), z_{2,t} = \log_2(s_{2,t} + 1) \).
Figure 4: Comparison in terms of the optimality gap versus the number of transmitted bits for the multinomial logistic regression problem (left) and training a three-layer neural network (right) on the CIFAR-10 dataset. The best performance belongs to QFW with Sign Encoding Scheme ($s = 1$), and FW without quantization ($s = uq$) has the worst performance.

1). To make them integers, we can set $z_{1,t} = z_1 = \lceil \log_2((4\sqrt{n}dT/M)^{1/2} + 1) \rceil, z_{2,t} = z_2 = \lceil \log_2((4\sqrt{n}dT)^{1/2} + 1) \rceil$.

Then with $\eta_t = T^{-1/2}$, the conditions Eqs. (22) and (23) in Lemma 4 are satisfied. So by Lemma 4, we have

$$\mathbb{E}[\|\nabla f(x_t) - \bar{g}_t\|^2] \leq (L^2D^2 + 2G_\infty^2) \frac{\sum_{t=1}^{\lfloor T/p \rfloor} \eta_{t+1}^2}{\sqrt{n}} = \frac{L^2D^2 + 2G_\infty^2}{T}.$$ 

By Lemma 5,

$$\mathbb{E}[\mathcal{G}(x_o)] \leq \frac{2M_0 + D \sqrt{L^2D^2 + 2G_\infty^2} + LD^2/2}{\sqrt{T}}.$$ 

The average communication bits per round are $M(d(z_1 + 1) + 32) + d(z_2 + 1) + 32 = d(Mz_1 + z_2) + (M + 1)(d + 32)$.

For any $\epsilon > 0$, set $T = (2M_0 + D \sqrt{L^2D^2 + 2G_\infty^2} + LD^2)^2/\epsilon^2$, then we have $\mathbb{E}[\mathcal{G}(x_o)] \leq \epsilon$. So the LO complexity is $O(1/\epsilon^2)$. Also note in each period, the total number of gradient call is $Mn + (p - 1) \cdot M \cdot S \cdot 2 = Mn + 2MS(p - 1)$, so the average cost is $[Mn + 2MS(p - 1)]/p = M[3\sqrt{n} - 2]$. Thus the total IFO complexity is $M[3\sqrt{n} - 2](2M_0 + D \sqrt{L^2D^2 + 2G_\infty^2} + LD^2)^2/\epsilon^2 = O(\sqrt{n}/\epsilon^2)$.

Appendix J. Additional Experiment Results

We conduct additional experiments on the CIFAR-10 dataset. The total number of images in the training set of CIFAR-10 is $N = 50000$. We assume that each worker stores 2500 images. We consider the loss function of multinomial logistic regression (9) and the log loss of a three-layer neural network (10). In both (9) and (10), the number of classes is
Figure 5: Optimality gap vs. bits transmitted for the task of multi-task least square regression. The Frank-Wolfe algorithm without quantization is denoted by \( s = uq \).

\( C = 10 \). In (10), the size of matrices \( W_1 \) and \( W_2 \) are \( 3072 \times 10 \) and \( 10 \times 10 \), respectively. The constraints parameters are \( a_1 = a_2 = 10 \). As are presented in Fig. 4, the results are similar to those of the experiments on the MNIST dataset. For both objective functions, QFW with \textbf{Sign Encoding Scheme} \((s = 1)\) achieves the best performance and the Frank-Wolfe without quantization has the worst performance.

Our third setup studies a multi-task least square regression problem (Zheng et al., 2018). We aim to minimize the following objective

\[
\min_W f(W) = \frac{1}{2} \|XW - Y\|_F = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{m} (x_i^T w_j - y_{ij})^2 \quad \text{s.t.} \quad \|W\|_1 \leq 1, \quad (27)
\]

where \( X \in \mathbb{R}^{N \times d} \) is termed the feature matrix, \( Y \in \mathbb{R}^{N \times m} \) is the response matrix, \( W \in \mathbb{R}^{d \times m} \) is the weight matrix that we aim to optimize, and \( \| \cdot \|_F \) denotes the Frobenius norm. In this setup, we use the synthetic data. We set \( N = 50000 \) and \( m = d = 300 \). Every component of \( X \) is sampled from the standard normal distribution and the true value of \( W^* \) is \( \frac{W'}{\|W'\|_1} \), where every entry of \( W' \) is sampled from the standard normal distribution. Then we form \( Y = XW^* \). We use 20 workers, each storing 2500 rows of the matrices \( X \) and \( Y \). We present the optimality gap versus the number of transmitted bits in Fig. 5. It can be observed that the Frank-Wolfe algorithm without quantization is the least communication-efficient. Although \textbf{SignFW} achieves the smallest optimality gap at the initial stage, QFW with \( s = 3 \) and \( s = 7 \) outperform other algorithms eventually.
