On the Limits of a Generalized Harmonic Progression

Jose Risomar Sousa

May 28, 2019

Abstract

This is the fourth paper I’m releasing on the topic of harmonic progressions. In here we will address a more complicated and difficult problem, namely, the determination of the limiting function of a generalized harmonic progression.

It will provide strong evidence of the utility of the general formula we derived for $\sum_{j=1}^{n} \frac{1}{(a_j + b)^k}$ in my third paper, ”Complex Harmonic Progression”, in contrast to formulae based on the digamma function, $\psi$. It will also demonstrate the utility of some of the results presented in my first paper, ”Generalized Harmonic Numbers Revisited”.

Our goal is to create a generating function for $\sum_{k=2}^{\infty} \sum_{j=1}^{\infty} x^k/(a_j + b)^k$, with $a, b, x \in \mathbb{C}$, which will allow us to know the limit of most harmonic progressions of order 2 and higher. Lastly, I want to attest that I’ve tested all the results achieved here on Mathematica, as was the case with all my previous work. This should give it more credibility, since not all papers featured on arXiv are refereed.

Summary

1 Introduction
2 Direct Calculation of the Real Part
3 Generating Function
   3.1 Imaginary Part
   3.2 Real Part
4 Conclusion

1 Introduction

When I wrote my second paper, Generalized Harmonic Progression[3] I mentioned in passing that I would not try to obtain the limit of that expression, as I imagined that it would be nearly impossible to achieve. It turns out that I really had no idea how take that formula and come up with an approach that would allow me to figure out those limits. But after I wrote
the third paper, *Complex Harmonic Progression*, with an even more general formula for the harmonic progression, the insight on how to use it to figure out the limit of the expression came almost instantly.

This is one of those problems that given the proper tools they become possible to solve with a little creativity, unlike others that no matter how hard one tries they never give in. Not that it was very easy to figure out all the steps here, but it was much easier than I had thought. This solution will also provide another proof that the complex harmonic progression diverges for $k = 1$.

First let’s recall the general formula from the previous paper. For simplicity, let’s assume that $a$ and $b$ are real, so we know which part of the formula is real and which part is complex. Let $\phi$ be the Hurwitz-Lerch transcendent function. Then, if $ib/a \notin \mathbb{Z}$:

$$
\sum_{j=1}^{n} \frac{1}{(aij + b)^k} = -\frac{1}{2b^k} + \frac{1}{2(a^2n + b)^k} + \frac{e^{-2\pi b/a}}{(2\pi/a)^k} \int_{0}^{1} \sum_{j=1}^{k} \phi\left(\frac{e^{-2\pi b/a}}{a}, -j + 1, 0\right) \frac{(1 - u)^{k-j}}{(j-1)!(k-j)!} e^{\pi(i+2b/a)u} \sin \pi nu \cot \pi u \, du
$$

This formula can be rewritten in various different forms. For example, by using Euler’s formula for the exponential of a complex argument, and by replacing $\cos \pi nu \sin \pi nu$ and $\sin^2 \pi nu$ with simpler expressions we get:

$$
\sum_{j=1}^{n} \frac{1}{(aij + b)^k} = -\frac{1}{2b^k} + \frac{1}{2(a^2n + b)^k} + \frac{e^{-2\pi b/a}}{(2\pi/a)^k} \int_{0}^{1} \sum_{j=1}^{k} \phi\left(\frac{e^{-2\pi b/a}}{a}, -j + 1, 0\right) \frac{(1 - u)^{k-j}}{(j-1)!(k-j)!} e^{\pi(2b/a)u/2} + \frac{i}{2} \frac{1 - \cos 2\pi nu}{2} \cot \pi u \, du
$$

2 Direct Calculation of the Real Part

Now, let’s recall a result that appeared in my first paper, whose complete proof actually depends on formulæ that feature in Abramowitz and Stegun (though to be fair I’d provided independent proofs for cases $k = 0$ and $k = 1$):

**Theorem 1** \(\lim_{n \to \infty} \int_{0}^{1} u^k \sin 2\pi nu(1 - u) \cot \pi(1 - u) \, du = \begin{cases} 1, & \text{if } k = 0 \\ \frac{1}{2}, & \text{if } k > 0 \end{cases} \)

Given the above theorem, it becomes convenient to rewrite the previous formula once again:

$$
\sum_{j=1}^{n} \frac{1}{(aij + b)^k} = -\frac{1}{2b^k} + \frac{1}{2(a^2n + b)^k} + \frac{1}{2} \left(\frac{2\pi}{a}\right)^k \int_{0}^{1} \sum_{j=1}^{k} \phi\left(\frac{e^{-2\pi b/a}}{a}, -j + 1, 0\right) \frac{(1 - u)^{k-j}}{(j-1)!(k-j)!} e^{-2\pi b/a} \sin 2\pi nu(1 - u) + i(1 - \cos 2\pi nu(1 - u)) \cot \pi(1 - u) \, du
$$
The above is splitting the sum within the integral into a polynomial in \( u \) and an independent term. And since \( e^{-2\pi bu/a} \) is a polynomial in \( u \) itself, when they are multiplied together we get a sum such that in only one of the four possible cases the limit as \( n \) approaches infinity is 1, all others being 1/2:

\[
\lim_{n \to \infty} \int_0^1 \left[ \phi \left( \frac{e^{-2\pi bu/a}}{u} \right) \frac{1}{(k-1)!} + \sum_{j=1}^{k-1} \phi \left( \frac{e^{-2\pi bu/a}}{u} \right) \frac{u^{j-k}}{(j-1)!(k-j)!} \right] \left( 1 + \sum_{i=1}^{\infty} \frac{(-2\pi bu/a)^i}{i!} \right) \sin 2\pi n(1-u) \cot \pi(1-u) \, du
\]

Therefore, in light of theorem 1, we can draw our first conclusion:

\[
\mathfrak{R} \left( \sum_{j=1}^{\infty} \frac{1}{(a\bar{z} + b)^k} \sum_{i=1}^{j} \phi \left( e^{-2\pi x/a}, -j+1, 0 \right) \frac{(2\pi x/a)^i}{i!} (2\pi(1-u)/a)^{k-j} \frac{e^{2\pi bu/a}}{(k-j)!} \right) = -\frac{1}{2} \sum_{k=1}^{\infty} \int_0^1 \sum_{j=1}^{k} \frac{e^{-2\pi bu/a}}{u} \phi \left( e^{-2\pi bu/a}, -j+1, 0 \right) \frac{(2\pi x/a)^i}{i!} (2\pi(1-u)/a)^{k-j} \frac{e^{2\pi bu/a}}{(k-j)!} \sin 2\pi n(1-u) \cot \pi(1-u) \, du
\]

Unfortunately, doing the same for the imaginary part is not as easy, and hence we need to resort to the generating function of the harmonic complex progression.

### 3 Generating Function

In this section we will try to come up with a generating function for the complex harmonic progression, that is, we'll try to produce a formula for the below sum:

\[
f(x) = \sum_{k=1}^{\infty} \sum_{j=1}^{n} \frac{x^k}{(a\bar{z} + b)^k} = \sum_{k=1}^{\infty} -\frac{x^k}{2b^k} + \frac{x^k}{2(a\imath n + b)^k} + \frac{1}{2} \sum_{k=1}^{\infty} \sum_{j=1}^{k} \frac{e^{-2\pi bu/a}}{u} \phi \left( e^{-2\pi bu/a}, -j+1, 0 \right) \frac{(2\pi x/a)^i}{i!} (2\pi(1-u)/a)^{k-j} \frac{e^{2\pi bu/a}}{(k-j)!} \sin 2\pi n(1-u) \cot \pi(1-u) \, du
\]

But, the sum within the integral is the sum of the product of the general terms of two functions that we know how to obtain separately, hence, all together the above is the power series of the product of these two functions:

\[
p(x) = \frac{-2\pi x}{a \left( e^{2\pi x/a} - e^{2\pi bu/a} \right)} \cdot e^{2\pi x(1-u)/a}
\]

Therefore, we can rewrite the formula as:

\[
\sum_{k=1}^{\infty} \sum_{j=1}^{n} \frac{x^k}{(a\bar{z} + b)^k} = \sum_{k=1}^{\infty} -\frac{x^k}{2b^k} + \frac{x^k}{2(a\imath n + b)^k} + \frac{\pi x}{a \left( e^{2\pi x/a} - e^{2\pi bu/a} \right)} \int_0^1 e^{2\pi x(1-u)/a} e^{2\pi bu/a} \sin 2\pi n(1-u) \cot \pi(1-u) \, du
\]

Now we want to take the limit of that expression when \( n \) goes to infinity, hence we need to
subtract the harmonic numbers, which diverge (our method will show us why down the line). Thus we have:

\[
\sum_{k=2}^{\infty} \sum_{j=1}^{n} \frac{x^k}{(aij + b)^k} = \sum_{k=2}^{\infty} \frac{x^k}{2b^k} \left( k \sum_{j=1}^{\infty} \frac{x^j}{j} \right) + \frac{x^k}{2(ai + b)^k} + \frac{1}{e^{2\pi b/a} - 1} \int_0^1 \left( \frac{1}{e^{2\pi x/a} - 1} + \frac{e^{2\pi x(1-u)/a}}{e^{2\pi x/a} - e^{2\pi b/a}} \right) e^{2\pi bu/a} [\sin 2\pi nu + i(1 - \cos 2\pi nu)] \cot \pi u \, du
\]

3.1 Imaginary Part

Let’s tackle the limit of the imaginary part first. We can obviously discard the two terms outside of the integral, as one is real and the other one goes to zero as \( n \) goes to infinity, leaving us with:

\[
\Im \left( \sum_{k=2}^{\infty} \sum_{j=1}^{\infty} \frac{x^k}{(aij + b)^k} \right) = \lim_{n \to \infty} -\frac{\pi x}{a} \int_0^1 \left( \frac{1}{e^{2\pi b/a} - 1} + \frac{e^{2\pi x(1-u)/a}}{e^{2\pi x/a} - e^{2\pi b/a}} \right) e^{2\pi bu/a} (1 - \cos 2\pi nu) \cot \pi u \, du
\]

Here it becomes clear that in order to figure out the above limits, we need to solve the below problem. To solve the two limits at once, let’s use \( c = c(x) \) as the coefficient of \( u \):

\[
\lim_{n \to \infty} \int_0^1 e^{-cu} (1 - \cos 2\pi nu) \cot \pi u \, du
\]

Now we need to go back to one of the results from the first paper. They deal with an equivalence between certain integrals and generalized harmonic numbers, more specifically we’ve seen that:

\[
\int_0^1 u^{2k+1} [1 - \cos 2\pi n(1 - u)] \cot \pi(1 - u) \, du = \frac{2(-1)^k(2k + 1)!}{(2\pi)^{2k+1}} \left[ \sum_{j=0}^{k} \frac{(-1)^{k-j}(2\pi)^{2k-2j}}{(2k + 1 - 2j)!} H_{2j+1}(n) - \frac{1}{2n^{2k+1}} \sum_{j=0}^{k} \frac{(-1)^j(2\pi n)^{2j}}{(2j + 1)!} \right]
\]

\[
\int_0^1 u^{2k+2} [1 - \cos 2\pi n(1 - u)] \cot \pi(1 - u) \, du = \frac{2(-1)^k(2k + 2)!}{(2\pi)^{2k+1}} \left[ \sum_{j=0}^{k} \frac{(-1)^{k-j}(2\pi)^{2k-2j}}{(2k + 2 - 2j)!} H_{2j+1}(n) - \frac{1}{2n^{2k+1}} \sum_{j=0}^{k} \frac{(-1)^j(2\pi n)^{2j}}{(2j + 2)!} \right]
\]

Let’s consider their limit as \( n \) approaches infinity. If \( n \) is sufficiently large:

\[
\int_0^1 u^{2k+1} [1 - \cos 2\pi n(1 - u)] \cot \pi(1 - u) \, du \sim \frac{2(-1)^k(2k + 1)!}{(2\pi)^{2k+1}} \left[ (-1)^k(2\pi)^{2k} (\gamma + \log n) + \sum_{j=1}^{k} \frac{(-1)^{k-j}(2\pi)^{2k-2j}}{(2k + 1 - 2j)!} \zeta(2j + 1) \right]
\]

\[
\int_0^1 u^{2k+2} [1 - \cos 2\pi n(1 - u)] \cot \pi(1 - u) \, du \sim \frac{2(-1)^k(2k + 2)!}{(2\pi)^{2k+1}} \left[ (-1)^k(2\pi)^{2k} (\gamma + \log n) + \sum_{j=1}^{k} \frac{(-1)^{k-j}(2\pi)^{2k-2j}}{(2k + 2 - 2j)!} \zeta(2j + 1) \right]
\]

Just to be sure we’re not missing anything, let’s make our initial formula more in sync with the above by changing \( u \) for \( 1 - u \):

\[
\Im \left( \sum_{k=2}^{\infty} \sum_{j=1}^{n} \frac{x^k}{(aij + b)^k} \right) = \lim_{n \to \infty} -\frac{\pi x e^{2\pi b/a}}{a} \int_0^1 \left( \frac{e^{-2\pi bu/a}}{e^{2\pi b/a} - 1} + \frac{e^{2\pi (x-b)u/a}}{e^{2\pi x/a} - e^{2\pi b/a}} \right) [1 - \cos 2\pi n(1 - u)] \cot \pi(1 - u) \, du
\]
Also, let’s introduce a variable \( y \) in the integral we need to evaluate, to help us with the power series manipulations that we need to perform. In the end we just need to remember to set \( y \to 1 \) (and \( c \to 2\pi b/a \) or \( 2\pi (b-x)/a \)):

\[
\int_0^1 e^{-cy}(1 - \cos 2\pi n(1-u)) \cot \pi(1-u) \, du \Rightarrow
\]

\[
\int_0^1 \sum_{k=0}^{\infty} \left( \frac{(-cy)^{2k+1}}{(2k+1)!} u^{2k+1} + \frac{(-cy)^{2k+2}}{(2k+2)!} u^{2k+2} \right) [1 - \cos 2\pi n(1-u)] \cot \pi(1-u) \, du
\]

Therefore, after we plug the integrals approximation formulae into the sum, part of the above expression simplifies to:

\[
\frac{\gamma + \log n}{\pi} \sum_{k=0}^{\infty} \frac{c^{2k+1}}{(2k+1)!} + \frac{c^{2k+2}}{(2k+2)!} = \frac{\gamma + \log n}{\pi} (-\sinh c - 1 + \cosh c)
\]

This is the part that explodes to infinity. Fortunately, as expected, these infinities cancel out when we add up the terms that have \( c = 2\pi b/a \) and \( c = 2\pi (b-x)/a \) in our initial formula. Now, let’s see the part that doesn’t explode:

\[
\frac{1}{\pi} \sum_{k=0}^{\infty} \frac{(-1)^k (2\pi)^{2j+1}}{(2k+1-2j)!} \zeta(2j+1) + \frac{c^{2k+2}}{(2k+2-2j)!} \sum_{j=1}^{\infty} \frac{(-1)^j (2\pi)^{-2j}}{(2k+2-2j)!} \zeta(2j+1)
\]

It’s not a very simple sum, and it’s not very easy to know how to proceed from here. But, let’s recall the integral representation we derived for \( \zeta(2j+1) \) in the first paper; only here it’s been slightly modified:

\[
\zeta(2j+1) = \frac{(-1)^j (2\pi)^{2j+1}}{2} \int_0^1 \sum_{p=0}^{j} \frac{B_{2p} (2 - 2^{2p}) u^{2j-2p+1}}{(2p)! (2j-2p+1)!} \cot \pi u \, du
\]

Now, let’s solve the first part of the previous sum:

\[
-\frac{1}{\pi} \sum_{k=0}^{\infty} \frac{(-1)^k (2\pi)^{2j+1}}{(2k+1-2j)!} \int_0^1 \sum_{p=0}^{j} \frac{B_{2p} (2 - 2^{2p}) u^{2j-2p+1}}{(2p)! (2j-2p+1)!} \cot \pi u \, du
\]

\[
\sum_{k=0}^{\infty} \frac{(-1)^k (2\pi)^{2j+1}}{(2k+1-2j)!} \int_0^1 \sum_{p=0}^{j} \frac{B_{2p} (2 - 2^{2p}) u^{2j-2p+1}}{(2p)! (2j-2p+1)!} \cot \pi u \, du
\]

\[
\frac{1}{cy} \int_0^1 \sum_{k=0}^{\infty} \frac{(-1)^k c^{2k+1}}{(2k+1-2j)!} \zeta(2j+1) + \frac{c^{2k+2}}{(2k+2-2j)!} \sum_{j=1}^{\infty} \frac{(-1)^j c^{2j-2p+1}}{(2k+2-2j)!} \cot \pi u \, du
\]

Again, the above power series is the product of two kind of familiar functions. One of them
is obviously $\sinh cy$, and the other one (which appeared in my first paper[2] in non-hyperbolic form) is:

$$\sum_{j=0}^{\infty} (cy)^{2j+1} \sum_{p=0}^{j} \frac{B_{2p} (2 - 2^{2p}) u^{2j-2p+1}}{(2p)!(2j - 2p + 1)!} = cy \cosh cy \sinh cuy$$

Therefore, the final conclusion is:

$$-\frac{1}{\pi} \sum_{k=0}^{\infty} (cy)^{2k+1} \sum_{j=1}^{k} \frac{(-1)^j (2\pi)^{-2j}}{(2k + 1 - 2j)!} \zeta(2j + 1) = \sinh cy \int_{0}^{1} (\cosh cy \sinh cuy - u) \cot \pi u \, du$$

And since the second part follows an analogous thought process, its development is omitted, but the end result is below:

$$\frac{1}{\pi} \sum_{k=0}^{\infty} (cy)^{2k+2} \sum_{j=1}^{k} \frac{(-1)^j (2\pi)^{-2j}}{(2k + 2 - 2j)!} \zeta(2j + 1) = (1 - \cosh cy) \int_{0}^{1} (\cosh cy \sinh cuy - u) \cot \pi u \, du$$

Now, we can sum it all up by making $y = 1$:

$$\frac{1}{\pi} \sum_{k=0}^{\infty} -c^{2k+1} \sum_{j=1}^{k} \frac{(-1)^j (2\pi)^{-2j}}{(2k + 1 - 2j)!} \zeta(2j + 1) + c^{2k+2} \sum_{j=1}^{k} \frac{(-1)^j (2\pi)^{-2j}}{(2k + 2 - 2j)!} \zeta(2j + 1) =$$

$$- (e^{-c} - 1) \int_{0}^{1} (\cosh c \sinh cu - u) \cot \pi u \, du$$

Now, to wrap it up, we just need to evaluate the initial expression with the above identity, and when we do so we find that:

$$\Im \left( \sum_{k=2}^{\infty} \sum_{j=1}^{\infty} \frac{x^k}{(aij + b)^k} \right) = \frac{\pi x}{a} \int_{0}^{1} \left[ \csc \frac{2\pi(b-x)}{a} \sinh \frac{2\pi(b-x)u}{a} - \csc \frac{2\pi b}{a} \sinh \frac{2\pi bu}{a} \right] \cot \pi u \, du$$

### 3.2 Real Part

Now, just as we found out the imaginary part of the limiting function, we need to find out the real part. By following the same process that’s been laid out in section [2], the real part is given by:

$$\Re \left( \sum_{k=2}^{\infty} \sum_{j=1}^{\infty} \frac{x^k}{(aij + b)^k} \right) = -\frac{x^2}{2b(b-x)} + \frac{\pi x(e^{2\pi x/a} - 1)}{a(e^{-2\pi b/a} - 1)(e^{2\pi x/a} - e^{2\pi b/a})}$$

### 4 Conclusion

If we don’t assume that $a$ and $b$ are real then, provided that $ib/a \notin \mathbb{Z}$ (and provided that the right-hand side doesn’t contain singularities, such as $\sinh 2\pi(b-x)/a = 0$), we can simply
say that, for $a, b, x \in \mathbb{C}$, when the limit exists it’s given by:

$$f(x) = \sum_{k=2}^{\infty} \sum_{j=1}^{\infty} \frac{x^k}{(aij + b)^k} = -\frac{x^2}{2b(b-x)} + \frac{\pi x(e^{2\pi x/a} - 1)}{a(e^{-2\pi b/a} - 1)(e^{2\pi x/a} - e^{2\pi b/a})} + \frac{i\pi x}{a} \int_{0}^{1} \left[ \frac{2\pi(b-x)}{a} \sin \frac{2\pi(b-x)u}{a} - \csc \frac{2\pi bu}{a} \sin \frac{2\pi bu}{a} \right] \cot \pi u \, du$$

However, when the left-hand side diverges, the expression on the right can still converge, if it doesn’t have singularities, meaning that it’s probably an analytic continuation of the left-hand side.

The above can be turned into a much better looking equation, which in principle holds if $a \neq 0$, $b \neq 0$, $b \neq x$ and $2b/a$ and $2(b - x)/a$ are not integers:

$$h(x) = \sum_{k=2}^{\infty} \sum_{j=1}^{\infty} \frac{x^k}{(aj + b)^k} = -\frac{x^2}{2b(b-x)} + \frac{\pi x}{2a} \csc \frac{\pi b}{a} \csc \frac{\pi(b-x)}{a} \sin \frac{\pi x}{a}$$

$$-\frac{\pi x}{a} \int_{0}^{1} \left( \frac{2\pi(b-x)}{a} \sin \frac{2\pi(b-x)u}{a} - \csc \frac{2\pi bu}{a} \sin \frac{2\pi bu}{a} \right) \cot \pi u \, du$$

Notice that $x = 2b$ causes the integral to vanish, which hints at a possible set of solutions for the zeros of this equation, if they exist, though we won’t pursue it.

And finally, if we want to know the limit of the complex harmonic progression of order $k \geq 2$:

$$\sum_{j=1}^{\infty} \frac{1}{(aj + b)^k} = \frac{h^{(k)}(0)}{k!}$$
