Irrationality Measure of Pi

N. A. Carella

Abstract: The first estimate of the upper bound \( \mu(\pi) \leq 42 \) of the irrationality measure of the number \( \pi \) was computed by Mahler in 1953, and more recently it was reduced to \( \mu(\pi) \leq 7.6063 \) by Salikhov in 2008. Here, it is shown that \( \pi \) has the same irrationality measure \( \mu(\pi) = \mu(\alpha) = 2 \) as almost every irrational number \( \alpha > 0 \).

1 Introduction

Let $\alpha \in \mathbb{R}$ be a real number. The irrationality measure $\mu(\alpha)$ of the real number $\alpha$ is the infimum of the subset of real numbers $\mu(\alpha) \geq 1$ for which the Diophantine inequality

$$|\alpha - \frac{p}{q}| \ll \frac{1}{q^{\mu(\alpha)}} \quad (1)$$

has finitely many rational solutions $p$ and $q$. The analysis of the irrationality measure $\mu(\pi) \geq 2$ was initiated by Mahler in 1953, who proved that

$$|\alpha - \frac{p}{q}| > \frac{1}{q^{42}} \quad (2)$$

for all rational solutions $p$ and $q$, see [17], et alii. This inequality for all rational approximations has an effective constant. Over the last seven decades, the efforts of several authors have improved this estimate significantly, see Table 1. More recently, it was reduced to $\mu(\pi) \leq 7.6063$, see [24]. This note has the followings result.

**Theorem 1.1.** For any number $\varepsilon > 0$, the Diophantine inequality

$$|\pi - \frac{p}{q}| \ll \frac{1}{q^{2+\varepsilon}} \quad (3)$$

has finitely many rational solutions $p$ and $q$. In particular, the irrationality measure $\mu(\pi) = 2$.

After some preliminary preparations, the proof of Theorem 1.1 is assembled in Section 6. Three distinct proofs from three different perspective are presented. Section 2 explores the relationship between the irrationality measure of $\pi = [a_0; a_1, a_2, \ldots]$ and the magnitude of the partial quotients $a_n$. In Section 7 there is an application to the convergence of the Flint Hills series. A second independent proof of the convergence of this series also appears in Section 8. Some numerical data for the ratio $\sin p_n/\sin 1/p_n$ is included in the last Section. These data match the theoretical result.
2 Bounded Partial Quotients

A result for the partial quotients based on the properties of the continued fractions and the asymptotic expansions of the sine function is derived below.

**Theorem 2.1.** Let \( p_n/q_n \) be the sequence of convergents of the irrational number \( \pi = [a_0; a_1, a_2, \ldots] \). Then, the \( n \)th partial quotient \( a_n \) has the upper bound

\[
a_n = O(1)
\]

for all sufficiently large \( n \geq 1 \).

**Proof.** The forward ratio has the upper bound

\[
\left| \frac{\sin (p_n)}{\sin (\frac{1}{p_n})} \right| = \frac{\sin (\lfloor p_n - \pi q_n \rfloor)}{\sin (\frac{1}{p_n})} = \frac{|p_n - \pi q_n| \left( 1 - \frac{1}{3!} |p_n - \pi q_n|^2 + \frac{1}{5!} |p_n - \pi q_n|^4 - \cdots \right)}{\frac{1}{p_n} \left( 1 - \frac{1}{3!} \frac{1}{p_n^2} + \frac{1}{5!} \frac{1}{p_n^4} - \cdots \right)} \leq p_n |p_n - \pi q_n|,
\]

see Lemma 2.2. Applying the inequality \(|p_n - \pi q_n| < 1/(a_{n+1}q_n)\), see Lemma 12.3 and \( p_n = \pi q_n + O(q_n^{-1}) \) yield

\[
\left| \frac{\sin (p_n)}{\sin (\frac{1}{p_n})} \right| \leq p_n |p_n - \pi q_n| \leq p_n \left( \frac{1}{a_{n+1}q_n} \right) \leq \frac{1}{a_{n+1}} \quad (5)
\]
as \( n \to \infty \). The reverse ratio has the upper bound

\[
\left| \frac{\sin (\frac{1}{p_n})}{\sin (p_n)} \right| = \frac{\sin (\frac{1}{p_n})}{\sin (\lfloor p_n - \pi q_n \rfloor)} = \frac{1}{p_n} \left( 1 - \frac{1}{3!} \frac{1}{p_n^2} + \frac{1}{5!} \frac{1}{p_n^4} - \cdots \right) \frac{|p_n - \pi q_n| \left( 1 - \frac{1}{3!} |p_n - \pi q_n|^2 + \frac{1}{5!} |p_n - \pi q_n|^4 - \cdots \right)}{\leq \frac{1}{p_n} |p_n - \pi q_n|},
\]

see Lemma 2.2. Applying the inequality \(|p_n - \pi q_n| > 1/(2q_{n+1})\), see Lemma 12.4 and the recursive relation \( q_{n+1} = a_{n+1}q_n + q_{n-1} \), yield

\[
\left| \frac{\sin (\frac{1}{p_n})}{\sin (p_n)} \right| \leq \frac{1}{p_n |p_n - \pi q_n|} \leq \frac{q_{n+1}}{p_n} \leq a_{n+1} \quad (6)
\]
Hence, both inequalities (5) and (6) yield
\[ a_{n+1} | \sin (p_n) | \ll \sin \left( \frac{1}{p_n} \right) \quad \text{and} \quad \sin \left( \frac{1}{p_n} \right) \ll a_{n+1} | \sin (p_n) |. \quad (7) \]

To complete the verification, let \( a_{n+1} = a_{n+1}(p_n) \approx p_n^v \), and let \( \sin (p_n) \approx \sin (p_n^{-\mu+1}) \), where \( v \geq 0 \) and \( \mu = \mu(\pi) \geq 2 \). Then, the symmetric inequality
\[ a_{n+1} | \sin (p_n) | \ll \sin \left( \frac{1}{p_n} \right) \ll a_{n+1} | \sin (p_n) |, \quad (8) \]
which is unique to the real number \( \pi \) or the symmetric limit inequality
\[ \lim_{p_n \to \infty} \left( \frac{a_{n+1} | \sin (p_n) |}{\sin \left( \frac{1}{p_n} \right)} \right) \ll 1 \ll \lim_{p_n \to \infty} \left( \frac{a_{n+1} | \sin (p_n) |}{\sin \left( \frac{1}{p_n} \right)} \right) \quad (9) \]
is true for all pairs of real numbers \( v = \mu - 2 \geq 0 \) and \( \mu = \mu(\pi) \geq 2 \). By definition the the irrationality measure is the least such real number \( \mu = \mu(\pi) \geq 2 \), see Definition [12.1] and Exercises [13.13] to [13.15]. Clearly, this implies that
\[ a_{n+1} \ll 1 \quad (10) \]
for all sufficiently large \( n \geq 1 \).

The current estimate \( \mu(\pi) \leq 7.6 \) in Table 1 corresponds to \( 0 \leq v \leq 5.6 \). Moreover, the symmetric inequality (5) remains consistent for any future improvement \( \hat{\mu} \) and \( \hat{v} \) in the range \( 2 = \mu(\pi) \leq \hat{\mu} \leq 7.6 \), and \( 0 = v \leq \hat{v} \leq 5.6 \).

**Lemma 2.1.** Let \( p_n/q_n \) be the sequence of convergents of the irrational number \( \pi = [a_0; a_1, a_2, \ldots] \). Then, the followings hold.

(i) \( \sin p_n = \sin (p_n - \pi q_n) \) for all \( p_n \) and \( q_n \).

(ii) \( \sin \left( \frac{1}{p_n} \right) = \frac{1}{p_n} \left( 1 - \frac{1}{3!} p_n^{-2} + \frac{1}{5!} p_n^{-4} - \cdots \right) \) as \( p_n \to \infty \).

**Lemma 2.2.** The power series ratios have the following upper bounds.

(i) \[ \frac{45}{53} \leq \frac{1 - \frac{1}{3!} |p_n - \pi q_n|^2 + \frac{1}{5!} |p_n - \pi q_n|^4 - \cdots}{1 - \frac{1}{3!} p_n^{-2} + \frac{1}{5!} p_n^{-4} - \cdots} \leq \frac{54}{53}. \]

(ii) \[ \frac{53}{45} \leq \frac{1 - \frac{1}{3!} p_n^{-2} + \frac{1}{5!} p_n^{-4} - \cdots}{1 - \frac{1}{3!} |p_n - \pi q_n|^2 + \frac{1}{5!} |p_n - \pi q_n|^4 - \cdots} \leq \frac{6}{5}. \]

**Proof.** (i) The convergent has \( p_1 = 3 \) and \( q_1 = 1 \), and for \( n \geq 2 \), the convergents have \( p_n \geq 22 \), \( q_n \geq 7 \) and \( |p_n - \pi q_n| < q_n^{-1} < 1 \). Thus, the numerator has the lower and upper bounds
\[ \frac{5}{6} \leq 1 - \frac{1}{3!} |p_n - \pi q_n|^2 + \frac{1}{5!} |p_n - \pi q_n|^4 - \cdots \leq 1 \quad (11) \]
are valid for all \( n \geq 1 \). Likewise, the denominator has the lower and upper bounds
\[ \frac{53}{54} \leq 1 - \frac{1}{3!} p_n^{-2} + \frac{1}{5!} p_n^{-4} - \cdots \leq 1. \quad (12) \]

(ii) The proof is similar. ■

Another approach to the result for the partial quotients based on the properties of the continued fractions and the sine function is derived below.
Theorem 2.2. Let \( \pi = [a_0; a_1, a_2, \ldots] \) be the continued fraction of the real number \( \pi \in \mathbb{R} \). Then, the quotients \( a_n \in \mathbb{N} \) are bounded. Specifically, \( a_n = O(1) \).

Proof. Let \( p_n/q_n \) be the sequence of convergents of the irrational number \( \pi = [a_0; a_1, a_2, \ldots] \), and let
\[
C = p_{n+1} - \pi q_{n+1} - \frac{1}{q_n} \quad \text{and} \quad D = \frac{1}{q_n}.
\]
For all sufficiently large integers \( n \geq 1 \), the Dirichlet approximation theorem and the addition formula \( \sin(C + D) = \cos C \sin D + \cos D \sin C \) lead to
\[
\frac{1}{q_n} \gg |p_{n+1} - \pi q_{n+1}|
\]
\[
\geq |\sin(p_{n+1} - \pi q_{n+1})|
\]
\[
= |\sin(p_{n+1} - \pi q_{n+1} - \frac{1}{q_n} + \frac{1}{q_n})|
\]
\[
= |\cos C \sin \left( \frac{1}{q_n} \right) + \cos \left( \frac{1}{q_n} \right) \sin C|.
\]
The sequence \( \{p_n : n \geq 1\} \) maximizes the cosine function and minimizes the sine function. Hence, using Lemma 5.1 and Lemma 5.3
\[
1 - \frac{2}{q_n^2} \leq 1 - \frac{C^2}{2} \leq \cos C \leq 1,
\]
and
\[
\frac{1}{2q_n} - \frac{1}{48q_n^3} \leq C - \frac{C^3}{6} \leq \sin C \leq \frac{1}{2q_n}.
\]
Substituting these estimates, and using the reverse triangle inequality \( |A + B| \geq ||A| - |B|| \), produce
\[
\frac{1}{q_{n+1}} \gg \left| \cos C \sin \left( \frac{1}{q_n} \right) + \cos \left( \frac{1}{q_n} \right) \sin C \right| \]
\[
\geq \left| (1) \left( \frac{1}{q_n} - \frac{1}{6q_n^3} \right) \right| - \left| (1) \left( \frac{1}{2q_n} - \frac{1}{48q_n^3} \right) \right| \]
\[
\geq \frac{c_0}{q_n},
\]
where \( c_0 > 0 \) is a constant. These show that
\[
\frac{1}{q_{n+1}} \gg \frac{1}{q_n}
\]
as \( n \to \infty \). Furthermore, \([15]\) implies that \( q_n \gg q_{n+1} = a_{n+1}q_n + q_{n-1} \) as claimed. \( \blacksquare \)

3 Asymptotic Expansions Of The Sine Function

Let \( f \geq 0 \) and \( g \geq 0 \) be real valued functions. The proportional symbol \( f \asymp g \) is defined by \( c_0g \leq f \leq c_1g \), where \( c_0, c_1 \in \mathbb{R} \) are constants. In addition, the symbol \( f \ll g \) is defined by \( |f| \leq cg \) for some constant \( c > 0 \).

Theorem 3.1. Let \( p_n/q_n \) be the sequence of convergents of the irrational number \( \pi = [a_0; a_1, a_2, \ldots] \). Then,
\[
\sin \left( \frac{1}{p_n} \right) \asymp \sin p_n
\]
as \( p_n \to \infty \).
Proof. Let \( p_n/q_n \) be the sequence of convergents of the irrational number \( \pi = [a_0; a_1, a_2, \ldots] \), and let

\[
A = p_n - \pi q_n - \frac{1}{q_n} \quad \text{and} \quad B = \frac{1}{q_n}.
\]  

The sequence \( \{p_n : n \geq 1\} \) maximizes the cosine function and minimizes the sine function. Hence, using Lemma 3.1 and Lemma 3.2:

\[
1 - \frac{2}{p_n^2} \leq 1 - \frac{A^2}{2} \leq \cos A \leq 1,
\]  

and

\[
\frac{1}{2p_n} - \frac{1}{48p_n^3} \leq A - \frac{A^3}{6} \leq \sin A \leq \frac{1}{2p_n}.
\]  

Replace these into the reverse triangle inequality \(|X + Y| \geq ||X| - |Y||\) for any real numbers \(X, Y \in \mathbb{R}\),

to show that

\[
|\sin p_n| = \left| \sin \left( p_n - \pi q_n - \frac{1}{p_n} + \frac{1}{p_n} \right) \right| 
\geq \left| \cos A \sin \left( \frac{1}{p_n} \right) + \cos \left( \frac{1}{p_n} \right) \sin A \right| 
\geq \left| \cos A \sin \left( \frac{1}{p_n} \right) - \cos \left( \frac{1}{p_n} \right) \sin A \right| 
\geq \left| (1) \left( \frac{1}{p_n} - \frac{1}{6p_n^3} \right) - (1) \left( \frac{1}{2p_n} - \frac{1}{48p_n^3} \right) \right| 
\geq \frac{1}{p_n} 
\geq \sin \left( \frac{1}{p_n} \right).
\]

On the other direction,

\[
\sin \left( \frac{1}{p_n} \right) \geq \frac{1}{p_n} 
\geq \frac{1}{q_n} 
\geq |p_n - \pi q_n| 
= |\sin (p_n - \pi q_n)| 
= |\sin (p_n)|.
\]

These prove that

\[
sin p_n \gg \sin \left( \frac{1}{p_n} \right) \quad \text{and} \quad \sin \left( \frac{1}{p_n} \right) \gg \sin p_n,
\]  

as \( n \to \infty \).

Lemma 3.1. Let \( z \in \mathbb{C} \) be complex number such that \(|z| < 1\). Then,

(i) \( 1 - \frac{|z|^2}{2} \leq \cos|z| \leq 1 \).

(ii) \( |z| - \frac{|z|^3}{6} \leq \sin|z| \leq |z| \).

Lemma 3.2. Let \( p_n/q_n \) be the sequence of convergents of the real number \( \pi = [a_0; a_1, a_2, \ldots] \). Then, as \( n \to \infty \),
Irrationality Measure of Pi

(i) \( \frac{1}{2q_n} \leq \left| p_n - \pi q_n - \frac{1}{q_n} \right| \leq \frac{2}{q_n} \)  

(ii) \( \frac{1}{2p_n} \leq \left| p_n - \pi q_n - \frac{1}{q_n} \right| \leq \frac{13}{p_n} \)

Proof. (i) Using the triangle inequality and Dirichlet approximation theorem yield the upper bound

\[
\left| p_n - \pi q_n - \frac{1}{q_n} \right| \leq \left| p_n - \pi q_n \right| + \frac{1}{q_n} \leq \frac{c_0}{q_n} + \frac{1}{q_n} \leq \frac{2}{q_n}
\]

where \( c_0 > 0 \) is a small constant. (ii) Use the Hurwitz approximation theorem

\[
\pi q_n - \frac{1}{\sqrt{5q_n^2}} \leq p_n \leq \pi q_n + \frac{1}{\sqrt{5q_n^2}}
\]

This completes the verification.

Lemma 3.3. Let \( p_n/q_n \) be the sequence of convergents of the real number \( \pi = [a_0; a_1, a_2, \ldots] \). Then, as \( n \to \infty \),

(i) \( \frac{1}{2q_n} \leq \left| p_{n+1} - \pi q_{n+1} - \frac{1}{q_n} \right| \leq \frac{2}{q_n} \)  

(ii) \( \frac{1}{2p_n} \leq \left| p_{n+1} - \pi q_{n+1} - \frac{1}{q_n} \right| \leq \frac{13}{p_n} \)

Proof. (i) Using the triangle inequality and Dirichlet approximation theorem yield the upper bound

\[
\left| p_{n+1} - \pi q_{n+1} - \frac{1}{q_n} \right| \leq \left| p_{n+1} - \pi q_{n+1} \right| + \frac{1}{q_n} \leq \frac{c_0}{q_{n+1}} + \frac{1}{q_n} \leq \frac{2}{q_n}
\]

since \( q_{n+1} = a_{n+1} q_n + q_{n-1} \). The lower bound

\[
\left| \frac{1}{q_n} - p_{n+1} - \pi q_{n+1} \right| \geq \frac{1}{q_n} - \left| p_{n+1} - \pi q_{n+1} \right| 
\]

\[
\geq \frac{1}{q_n} - \frac{c_1}{q_{n+1}} 
\]

\[
\geq \frac{1}{2q_n} 
\]

where \( c_0 > 0 \) and \( c_1 > 0 \) are small constants. (ii) Use the Hurwitz approximation theorem

\[
\pi q_n - \frac{1}{\sqrt{5q_n^2}} \leq p_n \leq \pi q_n + \frac{1}{\sqrt{5q_n^2}}
\]

This completes the verification.

\[
\pi q_n - \frac{1}{\sqrt{5q_n^2}} \leq p_n \leq \pi q_n + \frac{1}{\sqrt{5q_n^2}}
\]

as \( n \to \infty \) as claimed.
4 Statistics And Example

The result of Theorem 2.2 indicates that the real number \( \pi \) fits the profile of a random irrational number. The geometric mean value of the partial quotients of a random irrational number has the value

\[
K_0 = \lim_{n \to \infty} \left( \prod_{k \leq n} a_k \right)^{1/n} = 2.6854520010\ldots, \tag{31}
\]

which is known as the Khinchin constant. In addition, the Gauss-Kuzmin distribution specifies the frequency of each value by

\[
p(a_k = k) = -\log_2 \left( 1 - \frac{1}{(k+1)^2} \right). \tag{32}
\]

For a random irrational number, the proportion of partial quotients \( a_k = 1, 2 \) is about \( p(a_1) + p(a_2) \leq .5897 \). A large value \( a_k \geq 10^6 \) is very rare. In fact,

\[
p(a_k = 10^6) = -\log_2 \left( 1 - \frac{1}{(10^6 + 1)^2} \right) = 0.0000000000144, \tag{33}
\]

and the sum of probabilities is

\[
\sum_{k \geq 10^6} p(a_k = k) = \sum_{k \geq 10^6} -\log_2 \left( 1 - \frac{1}{(k+1)^2} \right) \leq 0.000001. \tag{34}
\]

Example 4.1. A short survey of the partial quotients \( \pi = [a_0; a_1, a_2, \ldots] \) is provided here to sample this phenomenon, most computer algebra systems can generate a few thousand terms within minutes. This limited numerical experiment established that \( a_n \leq 21000 \) for \( n \leq 10000 \), here \( a_{432} = 20776 \) is the only unusual partial quotient. This seems to be an instance of the Strong Law of Small Number.

\[
\pi = [3, 7, 15, 1, 292, 1, 1, 1, 2, 1, 1, 1, 2, 2, 2, 2, 1, 2, 2, 1, 5, 1, 1, 6, 2, 1, 84, 2, 1, 1, 15, 3, 13, 1, 4, 2, 6, 6, 99, 1, 2, 2, 6, 3, 5, 1, 1, 6, 8, 1, 7, 1, 2, 3, 7, 1, 2, 1, 1, 12, 1, 1, 1, 3, 1, 1, 8, 1, 1, \ldots]. \tag{35}
\]

5 Harmonic Summation Kernels

The harmonic summation kernels naturally arise in the partial sums of Fourier series and in the studies of convergences of continuous functions.

Definition 5.1. The Dirichlet kernel is defined by

\[
D_x(z) = \sum_{-x \leq n \leq x} e^{inz} = \frac{\sin((2x+1)z)}{\sin(z)}, \tag{36}
\]

where \( x, z \in \mathbb{C} - \pi \mathbb{Z} \) are complex numbers.

Definition 5.2. The Fejer kernel is defined by

\[
F_x(z) = \sum_{0 \leq n \leq x} \sum_{-n \leq k \leq n} e^{ikz} = \frac{\sin((x+1)z)^2}{2 \sin(z)^2}, \tag{37}
\]

where \( x, z \in \mathbb{C} - \pi \mathbb{Z} \) are complex numbers.

For \( z \neq k\pi \), the harmonic summation kernels have the upper bounds \( |K_x(z)| = |D_x(z)| \ll |x| \), and \( |K_x(z)| = |F_x(z)| \ll |x^2| \). An important property is that a proper choice of the parameter \( x \geq 1 \) can shift the sporadic large value of the reciprocal sine function \( 1/\sin z \) to \( K_x(z) \), and the term \( 1/\sin(2x+1)z \) remains bounded. The lacunary sequence \( \{p_n : n \geq 1\} \) maximize the reciprocal sine function \( 1/\sin z \), and is the main object of study here.

There are many different ways to prove an upper bound of the function \( 1/\sin z \) based on the harmonic summation kernels \( D_x(z) \) and or \( F_x(z) \). Two different approaches to a proof of an upper bound of the function \( 1/\sin z \) are provided below.
5.1 Continued Fraction Technique

**Theorem 5.1.** Let \( \varepsilon > 0 \) be an arbitrary small number, and let \( z \in \mathbb{C} - \pi \mathbb{Z} \) be a large real number. Then,
\[
\left| \frac{1}{\sin z} \right| \ll |z|^{1+\varepsilon}.
\]

**Proof.** Let \( |z| \neq k\pi \) be a large number, where \( k \in \mathbb{Z} \), and let \( \{u_m/v_m : m \geq 1\} \) be the sequence of convergents of the algebraic irrational number \( \sqrt{\alpha} \in \mathbb{R} \), such that \( \sqrt{\alpha} \leq 1/\pi \). Moreover, let \( v_m \gg |z| \) be a large integer, and let \( x = \alpha \pi v_m \) for which
\[
\varepsilon \ll \left| K_m \right| = \left| \varepsilon v_m - u_m \right|.
\]

To continue, observe that the irrationality measure \( \mu(\sqrt{\alpha}) = 2 \), and its partial quotients \( \sqrt{\alpha} = [b_0, b_1, \ldots] \) are bounded by \( b_m = O(v_m^\varepsilon) \), where \( \varepsilon > 0 \) is a small arbitrary number, see Lemma 12.5 and Example 12.4. Hence, the previous expression satisfies the inequality
\[
\frac{1}{v_m^\varepsilon} \ll \left| \sqrt{\alpha} v_m - u_m \right| v_m \ll 1,
\]
where \( v_m = u_m^2/v_m/2\pi \sim u_m^2 \). Next, use the principle of best rational approximations, see Lemma 12.5 to derive this estimate:
\[
\frac{1}{|\sin((2x+1)z)|} \ll \frac{1}{|\sqrt{\alpha} v_m - u_m| v_m} \ll v_m^\varepsilon.
\]

Lastly, putting them all together, yield
\[
\left| \frac{1}{\sin z} \right| = \left| \frac{K_x(z)}{\sin((2x+1)z)} \right| \ll \left| K_x(z) \right| \cdot \frac{1}{\sin((2x+1)z)} \ll 2\pi \sqrt{\alpha} v_m \cdot v_m^\varepsilon \ll |z|^{1+\varepsilon}.
\]

The last line uses the trivial estimate \( |K_x(z)| \ll |x| \gg v_m \gg |z| \). ■

**Lemma 5.1.** Let \( \{u_m/v_m : m \geq 1\} \) be the sequence of convergents of the algebraic irrational number \( \sqrt{\alpha} \in \mathbb{R} \), such that \( \sqrt{\alpha} \leq 1/\pi \). Then, as \( n \to \infty \),
\[
\varepsilon \ll \left| \alpha \nu_m^2 - u_m^2 + \frac{v_m}{2\pi} \right| < \frac{1}{2\pi}.
\]
Proof. It is sufficient to show that the error incurred in the approximation of the irrational number \( \alpha \) by the sequence \( \{ (u_m^2 - t_m)/v_m^2 : m \geq 1 \} \), where \( t_m^2 = u_m^2(1 - v_m/2\pi u_m^2) \approx u_m \), is bounded by a constant:

\[
\left| \alpha v_m^2 - u_m^2 + \frac{v_m}{2\pi} \right| = \left| \sqrt{\alpha}v_m - t_m \right| \left| \sqrt{\alpha}v_m + t_m \right| \tag{46}
\]

\[
\leq 2 \sqrt{\alpha} \left| \sqrt{\alpha}v_m - t_m \right| v_m
\]

\[
< 2 \sqrt{\alpha} < \frac{1}{2\pi},
\]

where \( t_m \sim u_m \), and \( 2 \sqrt{\alpha} \leq 1/2\pi \).

\[\blacksquare\]

A suitable choice to meet the condition in (45) is \( \sqrt{\alpha} = 1/2\sqrt{d} \), with \( 16\pi^4 < d \).

### 5.2 Sequence Technique

Theorem 5.2. Let \( z \in \mathbb{N} \) be a large integer. Then,

\[
\left| \frac{1}{\sin z} \right| \ll |z|. \tag{47}
\]

Proof. Let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents of the real number \( \pi \). Since the numerators sequence \( \{p_n : n \geq 1\} \) maximize the reciprocal sine function \( 1/\sin z \), it is sufficient to prove it for \( z = p_n \). Define the associated sequence

\[
\left\{ r_n = \left( \frac{2^{2+2v} + 1}{2^{2+2v}} \right) \pi p_n : n \geq 1 \right\}, \tag{48}
\]

where \( v_2 = v_2(p_n) = \max\{v : 2^v | p_n\} \) is the \( 2\)-adic valuation. Replacing the parameters \( x = r_n \) and \( z = p_n \) yield

\[
\sin(2x + 1)z = \sin((2r_n + 1)p_n) = \sin(2r_n + p_n) = \sin(2r_n p_n + p_n) = \sin(2r_n p_n) \cos(p_n) + \sin(p_n) \cos(2r_n p_n) = \sin \left( 2 \left( \frac{2^{2+2v} + 1}{2^{2+2v}} \right) \pi p_n^2 \right) \cos \left( \frac{2^{2+2v} + 1}{2^{2+2v}} \pi p_n^2 \right). \tag{49}
\]

One of the sine function expression has the value

\[
\sin \left( 2 \left( \frac{2^{2+2v} + 1}{2^{2+2v}} \right) \pi p_n^2 \right) = \sin \left( \frac{\pi}{2} w_n \right) = \pm 1 \tag{50}
\]

since

\[
w_n = \left( \frac{2^{2+2v} + 1}{2^{2v_2}} \right) p_n^2 \tag{51}
\]

is an odd integer. Similarly, one of the cosine function expression has the value

\[
\cos \left( 2 \left( \frac{2^{2+2v} + 1}{2^{2+2v}} \right) \pi p_n^2 \right) = \cos \left( \frac{\pi}{2} w_n \right) = 0. \tag{52}
\]

Substituting (50) and (52) into (49) return

\[
|\sin(2x + 1)z| = |\pm \cos(p_n)| \tag{53}
\]

\[
= |\pm \cos(p_n - \pi q_n)|
\]

\[
\ll 1
\]
since \(|p_n - \pi q_n| \to 0 \) as \(n \to \infty\). Lastly, putting them all together, yield
\[
\left| \frac{1}{\sin z} \right| = \frac{|K_n(z)|}{|\sin((2x+1)z)|} \leq |K_{r_n}(p_n)| \frac{1}{|\sin(2r_n+1)p_n)|} \leq |r_n| \cdot 1 \leq |z|
\]
since \(|z| \approx p_n \approx r_n\).

6 Main Result

The analysis of the irrationality measure \(\mu(\pi)\) of the number \(\pi\) provided here is completely independent of the prime number theorem, and it is not related to the earlier analysis used by many authors, based on the Laplace integral of a factorial like function
\[
\frac{1}{i2\pi} \int_C \left( \frac{n!}{z(z-1)(z-2)(z-3)\cdots(z-n)} \right)^{k+1} e^{-tz} dz,
\]
where \(C\) is a curve around the simple poles of the integrand, and \(k \geq 0\), see [17], [18], [8], [13], [24], and [6] for an introduction to the rational approximations of \(\pi\) and the various proofs.

6.1 First Proof

The first proof of the irrationality measure \(\mu(\pi)\) of the number \(\pi\) is based on the Diophantine inequality
\[
\left| \frac{1}{2q_{n+1}q_n} \right| \leq \left| \alpha - \frac{p_n}{q_n} \right| \leq \frac{1}{q_n^{\mu(\alpha)}}
\]
for irrational numbers \(\alpha \in \mathbb{R}\) of irrationality measure \(\mu(\alpha) \geq 2\), confer Lemma [12.1] and a result for the partial quotients in Theorem [2.1].

Proof. (Theorem [1.1]) Take the logarithm of the Diophantine inequality associated to the real number \(\pi\). Specifically,
\[
\frac{1}{2q_{n+1}q_n} \leq \left| \pi - \frac{p_n}{q_n} \right| \leq \frac{1}{q_n^{\mu(\pi)}}
\]
to reach
\[
\mu(\pi) \leq \frac{\log 2q_{n+1}q_n}{\log q_n} = 1 + \frac{\log 2q_{n+1}}{\log q_n}.
\]
By Theorem [2.1] there is a constant \(c > 0\) for which \(a_n \leq c\). Hence,
\[
q_{n+1} = a_{n+1}q_n + q_{n+1} \leq 2a_{n+1}q_n \leq 2c q_n.
\]
Substitute the last estimate [59] into [58] obtain
\[
\mu(\pi) \leq 1 + \frac{\log 4c q_n}{\log q_n} \leq 2 + \frac{\log 4c}{\log q_n}
\]
for all sufficiently large \(n \geq 1\). Taking the limit yields
\[
\mu(\pi) = \lim_{n \to \infty} \left( 2 + \frac{\log 4c}{\log q_n} \right) = 2.
\]
Quod erat demonstrandum.
6.2 Second Proof

The second proof of the irrationality measure \( \mu(\pi) \) of the number \( \pi \) is based on the asymptotic expansion of the sine function in Section 3. Related results based on the cosine and sine functions appears in \([1]\) and \([10]\).

Proof. (Theorem 1.1) Given a small number \( \varepsilon > 0 \), it will be shown that \( \psi(q) \leq q^{\mu(\pi)+\varepsilon} \leq q^{2+\varepsilon} \) is the irrationality measure of the real number \( \pi \).

Observe that in Theorem 3.1, the asymptotic expansion of the sine function satisfies

\[
|\sin(p_n)| \gg |\sin\left(\frac{1}{p_n}\right)|.
\]  

This inequality leads to the irrationality measures \( \psi(q) = q^{2+\varepsilon} \) for real number \( \pi \). Specifically,

\[
|p_n - \pi q_n| \gg |\sin\left(p_n - \pi q_n\right)| \\
= |\sin\left(p_n\right)| \\
\gg |\sin\left(p_n\right)| \\
\gg \frac{1}{p_n} \\
\gg \frac{1}{q_n} \\
\gg \frac{1}{q^{1+\varepsilon}}
\]

since \( p_n = \pi q_n + O(q_n^{-1}) \). Therefore,

\[
\psi(q) \leq q^{\mu(\pi)+\varepsilon} \leq q^{2+\varepsilon}.
\]  

Quod erat demontrandum.

6.3 Third Proof

The third proof of the irrationality measure \( \mu(\pi) \) of the number \( \pi \) is based on the shifting properties of the harmonic summation kernel

\[
K_x(z) = \sum_{-x \leq n \leq x} e^{2i\pi z} = \frac{\sin((2x+1)z)}{\sin(z)},
\]

where \( x \geq 1 \) is a large number, and \( z \neq k\pi \), see Section 5 for more details.

Proof. (Theorem 1.1) Let \( \varepsilon > 0 \) be an arbitrary small number, and let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents of the irrational number \( \pi \). By Theorem 5.1 (or Theorem 5.2), the reciprocal sine function has the upper bound

\[
\left|\frac{1}{\sin(p_n)}\right| \ll |p_n|^{1+\varepsilon}.
\]  

Therefore, it follows that

\[
\frac{1}{p_n^{1+\varepsilon}} \ll |\sin(p_n)| \\
\ll |\sin(p_n-\pi q_n)| \\
\ll |p_n-\pi q_n|
\]
for sufficiently large \( p_n \). Further, since \( \pi q_n = p_n + O( q_n^{-1}) \), it follows that

\[
\left| \pi - \frac{p}{q} \right| \gg \frac{1}{q^{b_1 (\pi) + \varepsilon}} = \frac{1}{q^{2 + \varepsilon}}.
\]

(68)

Clearly, this implies that the irrationality measure of the real number \( \pi \) is \( \mu(\pi) = 2 \), see Definition 12.1. Quod erat demonstrandum.

7 Convergence Of The Flint Hills Series I

The first analysis of the convergence of the Flint Hills series is based on the asymptotic relation

\[
\sin (p_n) \sim \sin \left( \frac{1}{p_n} \right),
\]

(69)

where \( p_n/q_n \in \mathbb{Q} \) is the sequence of convergents of the real number \( \pi \in \mathbb{R} \). In some way, the representation (69) removes any reference to the difficult problem of estimating the maximal value of the function \( 1/\sin n \) as \( n \to \infty \). Earlier study of the convergence the series (70) appears in [25, p. 583], [2], et alii.

**Theorem 7.1.** If the real numbers \( u > 0 \) and \( v > 0 \) satisfy the relation \( u - v > 0 \), then the Flint Hills series

\[
\sum_{n \geq 1} \frac{1}{n^u \sin^v n}
\]

(70)

is absolutely convergent.

**Proof.** Let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents of the real number \( \pi \). Since the numerators sequence \( \{p_n : n \geq 1\} \) maximize the reciprocal sine function \( 1/\sin z \). Hence, it is sufficient to consider the infinite series over the lacunary numerators sequence \( \{p_n : n \geq 1\} \).

Substituting the numerators sequence returns

\[
\sum_{n \geq 1} \frac{1}{n^u \sin^v n} \ll \sum_{n \geq 1} \frac{p_n^u}{n^u} \sin^v (\frac{1}{p_n})^v
\]

(71)

see Theorem 3.1. Substituting the Taylor series at infinity, see Lemma 2.1, return

\[
\sum_{n \geq 1} \frac{1}{n^u \sin^v n} \ll \sum_{n \geq 1} \frac{p_n^u}{n^u} \sin^v (\frac{1}{p_n})^v
\]

\[
\ll \sum_{n \geq 1} \frac{1}{p_n^v}.
\]

(72)

By the Binet formula, the sequence \( p_n = a_n p_{n-1} + p_{n-2}, a_n \geq 1 \), has exponential growth, namely,

\[
p_n \geq \frac{1}{\sqrt{5}} \left( \frac{1 + \sqrt{5}}{2} \right)^n
\]

(73)

for \( n \geq 2 \). Replacing (73) into (72) returns

\[
\sum_{n \geq 1} \frac{1}{p_n^v} \ll \sum_{n \geq 1} \left( \frac{2}{1 + \sqrt{5}} \right)^{(u-v)n} \ll 1.
\]

(74)

Hence, it immediately follows that the infinite series converges whenever \( u - v > 0 \). ■
Example 7.1. The infinite series
\[ \sum_{n \geq 1} \frac{1}{n^3 \sin^2 n} \tag{75} \]
has \( u - v = 3 - 2 = 1 > 0 \). Hence, by Theorem 7.1, it is convergent.

Example 7.2. Let \( \varepsilon > 0 \) be an arbitrary small number. The infinite series
\[ \sum_{n \geq 1} \frac{1}{n^{1+\varepsilon} \sin n} \tag{76} \]
has \( u - v = 1 + \varepsilon - 1 = \varepsilon > 0 \). Hence, by Theorem 7.1, it is absolutely convergent.

8 Convergence Of The Flint Hills Series II

The second analysis of the convergence of the Flint Hills series is based on the harmonic summation kernel
\[ K_x(z) = \sum_{-x \leq n \leq x} e^{i2nz} \frac{\sin((2x + 1)z)}{\sin(z)}. \tag{77} \]
Proper selection of the parameter \( x \geq 1 \) resolves the problem concerning the unpredictable maximal values of the function \( 1/\sin n \) as \( n \to \infty \).

Theorem 8.1. If the real numbers \( u > 0 \) and \( v > 0 \) satisfy the relation \( u - v(1 + \varepsilon) > 0 \), where \( \varepsilon > 0 \) is an arbitrary small number, then the Flint Hills series
\[ \sum_{n \geq 1} \frac{1}{n^u \sin^v n} \tag{78} \]
is absolutely convergent.

Proof. Let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents of the real number \( \pi \). Since the numerators sequence \( \{p_n : n \geq 1\} \) maximize the reciprocal sine function \( 1/\sin z \). Hence, it is sufficient to consider the infinite series over the lacunary numerators sequence \( \{p_n : n \geq 1\} \).

Substituting the numerators sequence returns
\[ \sum_{n \geq 1} \frac{1}{n^u \sin^v n} \ll \sum_{n \geq 1} \frac{1}{p_n^{1+\varepsilon}}. \tag{79} \]
By Theorem 5.1 (or Theorem 5.2), the reciprocal of the sine function is bounded
\[ \left| \frac{1}{\sin(p_n)} \right| \ll p_n^{1+\varepsilon}, \tag{80} \]
where \( \varepsilon > 0 \) is an arbitrary small number. Applying this bound yields
\[ \sum_{n \geq 1} \frac{1}{p_n^{1+\varepsilon}} \ll \sum_{n \geq 1} \frac{(p_n^{1+\varepsilon})^v}{p_n^v} \ll \sum_{n \geq 1} \frac{1}{p_n^u v(1+\varepsilon)}. \tag{81} \]
By the Binet formula, the sequence \( p_n = a_n p_{n-1} + p_{n-2}, a_n \geq 1 \), has exponential growth, namely,
\[ p_n \geq \frac{1}{\sqrt{5}} \left( \frac{1 + \sqrt{5}}{2} \right)^n. \tag{82} \]
for \( n \geq 2 \). Replacing (82) into (81) returns
\[ \sum_{n \geq 1} \frac{1}{p_n^{u-v(1+\varepsilon)}} \ll \sum_{n \geq 1} \left( \frac{2}{1 + \sqrt{5}} \right)^{(u-v(1+\varepsilon))n} \ll 1. \tag{83} \]
Hence, it immediately follows that the infinite series converges whenever \( u - v(1 + \varepsilon) > 0 \). ■
9 Convergence Of The Flat Hills Series

Let \( \{x\} \) be the fractional part function and let \( ||\alpha|| = \min\{|n - \alpha| : n \in \mathbb{Z}\} \) be the least distance to the nearest integer. Another classes of problems arise from the other properties of the number \( \pi \) and other irrational numbers. One of these problems is the convergence of the Flat Hills series.

**Definition 9.1.** Let \( a > 1 \) and \( b \neq 0 \) be a pair of real parameters. A Flat Hills series is defined by an infinite sum of the following forms.

(i) \[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} ||\pi n||}, \]

(ii) \[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} ||\pi 10^n||}, \]

(iii) \[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} \{\pi n\}}, \]

(iv) \[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} \{\pi 10^n\}}. \]

The known properties of some algebraic irrational numbers \( \alpha \in \mathbb{R} \) can be used to determine the convergence or divergence of the Flat Hills series

\[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} ||\alpha n||}, \]

see Exercise [15.29]. In the case \( \alpha = \pi \), the analytic properties of sequences such as \( \{||\pi n|| : n \geq 1\} \), and \( \{||\pi 10^n|| : n \geq 1\} \) are unknown. Accordingly, the convergence or divergence of the infinite series is unknown. Likewise, for the case \( \alpha = e \), the analytic properties of sequences such as \( \{||e^n|| : n \geq 1\} \), and \( \{||e 10^n|| : n \geq 1\} \) are unknown. Accordingly, the convergence or divergence of the infinite series is unknown, see Lemma [12.6] for some details.

10 Representations

The Flint Hills series and similar class of infinite series have representations in terms of other analytic functions. These reformulations could be useful in further analysis of these series.

10.1 Gamma Function Representation

The gamma function reflection formula produces a new reformulation as

\[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} n} = \sum_{n \geq 1} \frac{\Gamma(1 - n/\pi)^{a} \Gamma(n/\pi)^{b}}{n^{a}}, \]

see Lemma [11.1].

10.2 Zeta Function Representation

The zeta function reflection relation

\[ \zeta(s) = 2^s \pi^{1-s} \Gamma(1-s) \sin(\pi s/2) \zeta(1-s) \]

evaluated at \( s = 2n/\pi \) produces a new reformulation as

\[ \sum_{n \geq 1} \frac{1}{n^a \sin^{b} n} = \sum_{n \geq 1} \frac{(2^{2n/\pi} \pi^{1-2n/\pi}) \Gamma(1 - 2n/\pi) \zeta(1 - 2n/\pi)^{a}}{n^{a} \zeta(2n/\pi)^{b}}, \]
10.3 Harmonic Kernel Representation

The harmonic summation kernel is defined by

\[ K_x(z) = \sum_{-x \leq n \leq x} e^{i2nz} = \frac{\sin((2x+1)z)}{\sin(z)}, \tag{88} \]

where \( x, z \in \mathbb{C} \) are complex numbers. For \( z \neq k\pi \), the harmonic summation kernel has the upper bound \( |K_x(z)| \ll |x| \). Replacing it into the series produces a new reformulation as

\[ \sum_{n \geq 1} \frac{1}{n^\alpha \sin^n} = \sum_{n \geq 1} \frac{K_x(n)^\alpha}{n^\alpha \sin(2x+1)n}. \tag{89} \]

Here the choice of parameter \( x = \alpha n \), where \( \alpha > 0 \) is an algebraic irrational number, shifts the large value of the reciprocal sine function \( \frac{1}{\sin n} \) to \( K_x(z) \), and the \( \frac{1}{\sin(2\alpha n+1)n} \) remains bounded. Thus, it easier to prove the convergence of the series (89).

11 Beta and Gamma Functions

Certain properties of the beta function \( B(a, b) = \int_0^1 t^{a-1}(1-t)^{b-1}dt \), and gamma function \( \Gamma(z) = \int_0^\infty t^{z-1}e^{-t}dt \) are useful in the proof of the main result.

**Lemma 11.1.** Let \( B(a, b) \) and \( \Gamma(z) \) be the beta function and gamma function of the complex numbers \( a, b, z \in \mathbb{C} \setminus \{0, -1, -2, -3, \ldots \} \). Then,

(i) \( \Gamma(z+1) = z\Gamma(z) \), the functional equation.

(ii) \( B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} \), the multiplication formula.

(iii) \( \frac{B(1-z, z)}{\pi} = \frac{1}{\sin \pi z} \),

(iv) \( \frac{\Gamma(1-z)\Gamma(z)}{\pi} = \frac{1}{\sin \pi z} \), the reflection formula.

**Proof.** Standard analytic methods on the \( B(a, b) \), and gamma function \( \Gamma(z) \), see [11, Equation 5.12.1], [2, Chapter 1], et cetera.

The current result on the irrationality measure \( \mu(\pi) = 7.6063 \), see Table I of the number \( \pi \) implies that

\[ |\Gamma(z+1)\Gamma(z)| \ll |z|^{7.6063}. \tag{90} \]

A sharper upper bound is computed here.

**Lemma 11.2.** Let \( \Gamma(z) \) be the gamma function of a complex number \( z \in \mathbb{C} \), but not a negative integer \( z \neq 0, -1, -2, \ldots \). Then,

\[ |\Gamma(z+1)\Gamma(z)| \ll |z|. \tag{91} \]

**Proof.** Assume \( \Re(z) > 0 \). Then, the functional equation

\[ \Gamma(z+1) = z\Gamma(z), \tag{92} \]

see Lemma 11.1 or [11, Equation 5.5.1], provides an analytic continuation expression

\[ \frac{\Gamma(1-z)\Gamma(z)}{\pi} = \frac{1}{\sin \pi z}. \]

for any complex number \( z \in \mathbb{C} \) such that \( z \neq 0, -1, -2, -3, \ldots \). By Theorem 5.1

\[ \frac{1}{\sin |\pi z|} \asymp \frac{1}{\sin \left( \frac{1}{|\pi z|} \right)} \asymp |\pi z| \]

as \( |\pi z| \to \infty \).
12 Basic Diophantine Approximations Results

All the materials covered in this section are standard results in the literature, see [13, 16, 19, 22, 23, 29], et alii.

12.1 Rationals And Irrationals Numbers Criteria

A real number \( \alpha \in \mathbb{R} \) is called rational if \( \alpha = a/b \), where \( a, b \in \mathbb{Z} \) are integers. Otherwise, the number is irrational. The irrational numbers are further classified as algebraic if \( \alpha \) is the root of an irreducible polynomial \( f(x) \in \mathbb{Z}[x] \) of degree \( \deg(f) > 1 \), otherwise it is transcendental.

Lemma 12.1. If a real number \( \alpha \in \mathbb{R} \) is a rational number, then there exists a constant \( c = c(\alpha) \) such that

\[
\frac{c}{q} \leq \left| \frac{\alpha - p}{q} \right|
\]

holds for any rational fraction \( p/q \neq \alpha \). Specifically, \( c \geq 1/b \) if \( \alpha = a/b \).

This is a statement about the lack of effective or good approximations for any arbitrary rational number \( \alpha \in \mathbb{Q} \) by other rational numbers. On the other hand, irrational number \( \alpha \in \mathbb{R} - \mathbb{Q} \) have effective approximations by rational numbers. If the complementary inequality \( |\alpha - p/q| < c/q \) holds for infinitely many rational approximations \( p/q \), then it already shows that the real number \( \alpha \in \mathbb{R} \) is irrational, so it is sufficient to prove the irrationality of real numbers.

Lemma 12.2 (Dirichlet). Suppose \( \alpha \in \mathbb{R} \) is an irrational number. Then there exists an infinite sequence of rational numbers \( p_n/q_n \) satisfying

\[
0 < \left| \alpha - \frac{p_n}{q_n} \right| < \frac{1}{q_n^2}
\]

for all integers \( n \in \mathbb{N} \).

Lemma 12.3. Let \( \alpha = [a_0, a_1, a_2, \ldots] \) be the continued fraction of a real number, and let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents. Then

\[
0 < \left| \alpha - \frac{p_n}{q_n} \right| < \frac{1}{a_n+1q_n^2}
\]

for all integers \( n \in \mathbb{N} \).

This is standard in the literature, the proof appears in [13 Theorem 171], [23 Corollary 3.7], [15 Theorem 9], and similar references.

Lemma 12.4. Let \( \alpha = [a_0, a_1, a_2, \ldots] \) be the continued fraction of a real number, and let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents. Then

\[
(i) \quad \frac{1}{2q_{n+1}q_n} \leq \left| \alpha - \frac{p_n}{q_n} \right| \leq \frac{1}{q_n^2}, \quad (ii) \quad \frac{1}{2a_n+1q_n^2} \leq \left| \alpha - \frac{p_n}{q_n} \right| \leq \frac{1}{q_n^2},
\]

for all integers \( n \in \mathbb{N} \).

The recursive relation \( q_{n+1} = a_{n+1}q_n + q_{n-1} \) links the two inequalities. Confer [20 Theorem 3.8], [15 Theorems 9 and 13], et alia. The proof of the best rational approximation stated below, appears in [22 Theorem 2.1], and [23 Theorem 3.8].

Lemma 12.5. Let \( \alpha \in \mathbb{R} \) be an irrational real number, and let \( \{p_n/q_n : n \geq 1\} \) be the sequence of convergents. Then, for any rational number \( p/q \in \mathbb{Q}^\times \),

\[
\frac{1}{2q_{n+1}q_n} \leq \left| \alpha - \frac{p_n}{q_n} \right| \leq \frac{1}{q_n^2},
\]
(i) $|αq_n - p_n| \leq |αq - p|$,  
(ii) $|α - \frac{p_n}{q_n}| \leq |α - \frac{p}{q}|$,  
for all sufficiently large $n \in \mathbb{N}$ such that $q \leq q_n$.

### 12.2 Irrationalities Measures

The concept of measures of irrationality of real numbers is discussed in [26, p. 556], [5, Chapter 11], et alii. This concept can be approached from several points of views.

**Definition 12.1.** The irrationality measure $\mu(α)$ of a real number $α \in \mathbb{R}$ is the infimum of the subset of real numbers $\mu(α) \geq 1$ for which the Diophantine inequality

$$|α - \frac{p}{q}| \ll \frac{1}{q^{\mu(α)}}$$

has finitely many rational solutions $p$ and $q$. Equivalently, for any arbitrary small number $ε > 0$

$$|α - \frac{p}{q}| \gg \frac{1}{q^{\mu(α)+ε}}$$

for all large $q \geq 1$.

**Theorem 12.1.** ([7, Theorem 2]) The map $\mu : \mathbb{R} \to [2, \infty) \cup \{1\}$ is surjective function. Any number in the set $[2, \infty) \cup \{1\}$ is the irrationality measure of some irrational number.

**Example 12.1.** Some irrational numbers of various irrationality measures.

1. A rational number has an irrationality measure of $\mu(α) = 1$, see [14, Theorem 186].
2. An algebraic irrational number has an irrationality measure of $\mu(α) = 2$, an introduction to the earlier proofs of Roth Theorem appears in [22, p. 147].
3. Any irrational number has an irrationality measure of $\mu(α) \geq 2$.
4. A Champernowne number $κ_b = 0.123 \ldots b - 1 \cdot b \cdot b + 1 \cdot b + 2 \ldots$ in base $b \geq 2$, concatenation of the $b$-base integers, has an irrationality measure of $\mu(κ_b) = b$.
5. A Mahler number $ψ_b = \sum_{n \geq 1} b^{-[τ^n]}$ in base $b \geq 3$ has an irrationality measure of $\mu(ψ_b) = τ$, for any real number $τ \geq 2$, see [7, Theorem 2].
6. A Liouville number $ℓ_b = \sum_{n \geq 1} b^{-n!}$ parameterized by $b \geq 2$ has an irrationality measure of $\mu(ℓ_b) = \infty$, see [14, p. 208].

**Definition 12.2.** A measure of irrationality $\mu(α) \geq 2$ of an irrational real number $α \in \mathbb{R}^\times$ is a map $ψ : \mathbb{N} \to \mathbb{R}$ such that for any $p, q \in \mathbb{N}$ with $q \geq q_0$,

$$|α - \frac{p}{q}| \geq \frac{1}{ψ(q)}.$$  

Furthermore, any measure of irrationality of an irrational real number satisfies $ψ(q) \geq \sqrt{5}q^{\mu(α)} \geq \sqrt{5}q^2$. 

12.3 Normal Numbers

The earliest study was centered on the distribution of the digits in the decimal expansion of the number $\sqrt{2} = 1.414213562373\ldots$, which is known as the Borel conjecture.

Definition 12.3. An irrational number $\alpha \in \mathbb{R}$ is a normal number in base 10 if any sequence of $k$-digits in the decimal expansion occurs with probability $1/10^k$.

Lemma 12.6. (Wall) An irrational number $\alpha \in \mathbb{R}$ is a normal number in base 10 if and only if the sequence $\{\alpha 10^n : n \geq 1\}$ is uniformly distributed modulo 1.

13 Problems

13.1 Flint Hill Class Series

Exercise 13.1. The infinite series

$$S_1 = \sum_{n \geq 1} \frac{(-1)^{n+1}}{n} \quad \text{and} \quad S_2 = \sum_{n \geq 1} \frac{1}{n^2 \sin n}$$

have many asymptotic similarities. The first is conditionally convergent. Is the series $S_2$ conditionally convergent?

Exercise 13.2. Show that the infinite series

$$S_3 = \sum_{n \geq 1} \frac{\cos^v n}{n} \quad \text{and} \quad S_4 = \sum_{n \geq 1} \frac{\sin^v n}{n}$$

are conditionally convergent for odd $v \geq 1$. Are these series absolutely conditionally convergent for any $v > 0$?

Exercise 13.3. Explain the convergence of the infinite series

$$\frac{\pi}{\sin \pi z} = \frac{1}{z} + 2z \sum_{n \geq 1} \frac{(-1)^n}{z^2 - n^2}$$

at the real numbers $z = n/\pi$, where $n \geq 1$ is an integer. Is this series convergent?

Exercise 13.4. Explain the convergence of the infinite series

$$\pi \cot \pi z = \frac{1}{z} + 2z \sum_{n \geq 1} \frac{1}{z^2 - n^2}$$

at the real numbers $z = n/\pi$, where $n \geq 1$ is an integer. Is this series convergent? The derivation of this series appears in [9, p. 122].

Exercise 13.5. Explain the convergence of the infinite series

$$\frac{\pi}{\sin^2 \pi z} = \frac{1}{\pi^2} \sum_{-\infty < n < \infty} \frac{1}{(z - n)^2}$$

at the real numbers $z = n/\pi$, where $n \geq 1$ is an integer. Is this series convergent? The derivation of this series appears in [8, p. 122]; [12, p. 276].

Exercise 13.6. Explain the convergence of the infinite series

$$\frac{\sin z}{\sin \pi z} = \frac{2}{\pi} \sum_{n \geq 1} \frac{(-1)^n \sin n}{z^2 - n^2}$$

at the real numbers $z = n/\pi$, where $n \geq 1$ is an integer. This series has a different structure than the previous exercise, is this series is absolutely convergent? conditionally convergent? The derivation of this series appears in [12, p. 276].
\section{Complex Analysis}

\textbf{Exercise 13.7.} Assume that the infinite series is absolutely convergent. Use a Cauchy integral formula to evaluate the integral
\[ \frac{1}{i2\pi} \int_C \frac{1}{z^n \sin^n z} dz, \]
where \( C \) is a suitable curve.

\textbf{Exercise 13.8.} Determine whether or not there is a complex valued function \( f(z) \) for which the Cauchy integral evaluate to
\[ \frac{1}{i2\pi} \int_C f(z) dz = \sum_{n \geq 1} \frac{1}{n^\mu \sin^n n}, \]
where \( C \) is a suitable curve, and the infinite series is absolutely convergent.

\textbf{Exercise 13.9.} Let \( z \in \mathbb{C} \) be a large complex variable. Prove or disprove the asymptotic relation
\[ \frac{1}{\sin \pi z} \asymp \frac{1}{\sin \frac{\pi}{\pi z}} \asymp |\pi z|. \]

\textbf{Exercise 13.10.} Consider the product
\[ \sin \left( \frac{1}{z} \right) \times \sin z = 1 + O(1/z^2) \quad (99) \]
of a complex variable \( z \in \mathbb{C} \). Explain its properties in the unit disk \( \{ z \in \mathbb{C} : |z| < 1 \} \) and at infinity.

\textbf{Exercise 13.11.} Let \( z \in \mathbb{C} \) be a large complex variable. Use the properties of the gamma function to prove the asymptotic relation
\[ |\Gamma(1-z)\Gamma(z)| = O(|z|). \]

\textbf{Exercise 13.12.} Let \( x \in \mathbb{R} \) be a large real variable. Use the trigamma reflection formula
\[ \psi_1(1-x) + \psi_1(x) = \frac{\pi^2}{\sin^2(\pi x)} \]
to derive an asymptotic relation
\[ \frac{1}{\sin^2 \pi x} \asymp |\pi x|^2. \]
Explain any restrictions on the real variable \( x \in \mathbb{R} \).

\textbf{Exercise 13.13.} Let \( a_{n+1} = a_{n+1}(p_n) \ll p_n^\mu \). Show that the symmetric limit inequality
\[ \lim_{p_n \to \infty} \left( a_{n+1} \frac{|\sin (p_n)|}{\sin \left( \frac{1}{p_n} \right)} \right) \ll 1 < \lim_{p_n \to \infty} \left( a_{n+1} \frac{|\sin (p_n)|}{\sin \left( \frac{1}{p_n} \right)} \right) \]
is false for all pairs of real numbers \( v \geq 0 \) and \( \mu = \mu(\pi) \geq 2 \).

\textbf{Exercise 13.14.} Let \( a_{n+1} = a_{n+1}(p_n) \approx \log(p_n)^v \), and let \( \sin (p_n) \propto \sin \left( p_n^{-\mu+1} \right) \). Use the change of variable \( x = 1/p_n \) to show that the symmetric limit inequality
\[ \lim_{p_n \to \infty} \left( a_{n+1} \frac{|\sin (p_n)|}{\sin \left( \frac{1}{p_n} \right)} \right) \ll 1 < \lim_{p_n \to \infty} \left( a_{n+1} \frac{|\sin (p_n)|}{\sin \left( \frac{1}{p_n} \right)} \right) \]
is false for all pairs of real numbers \( v > 0 \) and \( \mu = \mu(\pi) \geq 2 \).

\textbf{Exercise 13.15.} Let \( a_{n+1} = a_{n+1}(p_n) \approx p_n^\mu \), and let \( \sin (p_n) \propto \sin \left( p_n^{-\mu+1} \right) \). Use the change of variable \( x = 1/p_n \) to show that the symmetric limit inequality
\[ \lim_{p_n \to \infty} \left( a_{n+1} \frac{|\sin (p_n)|}{\sin \left( \frac{1}{p_n} \right)} \right) \ll 1 < \lim_{p_n \to \infty} \left( a_{n+1} \frac{|\sin (p_n)|}{\sin \left( \frac{1}{p_n} \right)} \right) \]
is true for all pairs of real numbers \( v = \mu - 2 \) and \( \mu = \mu(\pi) \geq 2 \).
13.3 Irrationality Measures

Exercise 13.16. Do the irrationality measures of the numbers $\pi$ and $\pi^2$ satisfy $\mu(\pi) = \mu(\pi^2) = 2$? This is supported by the similarity of $\sin(n) = \sin(n - m\pi)$ and

$$\frac{\sin x}{x} = \prod_{m \geq 1} \left(1 - \frac{x^2}{\pi^2m^2}\right)$$

at $x = n$. More generally, $x = n^k\pi^{-k+1}$

Exercise 13.17. What is the relationship between the irrationality measures of the numbers $\pi$ and $\pi^k$, for example, do these measures satisfy $\mu(\pi) = \mu(\pi^k) = 2$ for $k \geq 2$?

13.4 Partial Quotients

Exercise 13.18. Determine an explicit bound $a_n \leq B$ for the continued fraction of the irrational number $\pi = [a_0; a_1, a_2, a_3, \ldots]$ for all partial quotients $a_n$ as $n \to \infty$.

Exercise 13.19. Does $\pi^2 = [a_0; a_1, a_2, a_3, \ldots]$ have bounded partial quotients $a_n$ as $n \to \infty$?

Exercise 13.20. Let $\alpha = [a_0; a_1, a_2, a_3, \ldots]$ and $\beta = [b_0; b_1, b_2, b_3, \ldots]$ be a pair of continued fractions. Is there an algorithm to determine whether or not $\alpha = \beta$ or $\alpha \neq \beta$ based on sequence of comparisons $a_0 = b_0, a_1 = b_1, a_2 = b_2, \ldots, a_N = b_N$ for some $N \geq 1$?

Exercise 13.21. Let $\epsilon = [a_0; a_1, a_2, a_3, \ldots]$, where $a_{3k} = a_{3k+2} = 1$, and $a_{3k+1} = 2k$, be the of continued fraction of the natural base $e$. Compute the geometric mean value of the partial quotients:

$$K_\epsilon \approx \lim_{n \to \infty} \left( \prod_{k \leq n} a_k \right)^{1/n} = \infty?$$

Exercise 13.22. Let $\pi = [a_0; a_1, a_2, a_3, \ldots]$ be the of continued fraction of the natural base. A short calculation gives

$$K_\pi \approx \lim_{n \leq 10} \left( \prod_{k \leq n} a_k \right)^{1/n} = 3.361 \ldots$$

Compute a numerical approximation for the geometric mean value of the partial quotients:

$$K_\pi \approx \lim_{n \leq 1000} \left( \prod_{k \leq n} a_k \right)^{1/n} = 2.628 \ldots$$

Exercise 13.23. Let $\alpha = [a_0; a_1, a_2, a_3, \ldots]$ be the of continued fraction of a real number. Assume it has a lacunary subsequence of unbounded partial quotients $a_n = O(\log \log n)$, such that $n_{i+1}/n_i > 1$, otherwise $a_n = O(1)$. Is the geometric mean value of the partial quotients unbounded

$$K_\alpha \approx \lim_{n \to \infty} \left( \prod_{k \leq n} a_k \right)^{1/n} = \infty?$$

13.5 Concatenated Sequences

Exercise 13.24. A Champernowne number $\kappa_b = 0.123 \cdots b - 1 \cdot b \cdot b + 1 \cdot b + 2 \cdots$ in base $b \geq 2$ is formed by concatenating

the sequence of consecutive integers in base $b$ is irrationality. Show that the number $0, F_0F_1F_2F_3 \ldots = 1/F_1$ formed by concatenating the sequence of Fibonacci numbers $F_{n+1} = F_n + F_{n-1}$ is rational.
Exercise 13.25. Let \( f(x) \in \mathbb{Z}[x] \) be a polynomial, and let \( D_n = |f(n)| \). Show that the number \( 0.D_0D_1D_2\ldots \) formed by concatenating the sequence of values is irrational.

Exercise 13.26. Let \( \{D_n \geq 0 : n \geq 0\} \) be an infinite sequence of integers, and let \( \alpha = 0.D_0D_1D_2\ldots \) formed by concatenating the sequence of integers. Determine a sufficient condition on the sequence of integers to have an irrational number \( \alpha > 0 \).

13.6 Exact Evaluations Of Power Series

Exercise 13.27. The exact evaluation of the first series below is quite simple, but the next series requires some work:

\[
L_1(1/2) = \sum_{n \geq 1} \frac{1}{2^n n} = \log 2 \quad \text{and} \quad L_2(1/2) = \sum_{n \geq 1} \frac{1}{2^n n^2} = \frac{\pi^2}{12} - \frac{1}{2} (\log 2)^2.
\]

Prove this, use the properties of the polylogarithm function \( L_k(z) = \sum_{n \geq 1} z^n / n^k \).

Exercise 13.28. Determine whether or not the series

\[
L_3(1/2) = \sum_{n \geq 1} \frac{1}{2^n n^3}
\]

has a closed form evaluation (exact).

13.7 Flat Hill Class Series

Exercise 13.29. Let \( \alpha = (1 + \sqrt{5})/2 \) be a Pisot number. Show that \( ||\alpha^n|| \to 0 \) as \( n \to \infty \). Explain the convergence of the first infinite series

\[
\sum_{n \geq 1} \sin||\alpha^n|| \quad \text{and} \quad \sum_{n \geq 1} \frac{1}{n^2 \sin||\alpha^n||}
\]

the divergence of the second infinite series.

Exercise 13.30. Assume that \( \pi \) is a normal number base 10. Show that \( ||\pi^{10^n}|| \) is uniformly distributed. Explain the convergence or divergence of the infinite series

\[
\sum_{n \geq 1} \frac{1}{n^2 \sin||\pi^{10^n}||}.
\]

Exercise 13.31. Assume that \( \pi \) is a normal number base 10. Determine the least parameters \( a > 1 \) and \( b > 0 \) for which the infinite series

\[
\sum_{n \geq 1} \frac{1}{n^a \sin^b||\pi^{10^n}||}
\]

converges. For example, is \( a - b > 0 \) sufficient?

Exercise 13.32. Assume that \( \pi \) is a normal number base 10. Determine the least parameters \( a > 1 \) and \( b > 0 \) for which the infinite series

\[
\sum_{n \geq 1} \frac{1}{n^a \sin^b||\pi^{10^n}||}
\]

converges. For example, is \( a - b > 0 \) sufficient?
Irrationality Measure of Pi

References

14 Numerical Data

The maxima of the function $1/\sin x$ occur at the numerators $x = p_n$ of the sequence of convergents $p_n/q_n \to \pi$. The first few terms of the sequence $p_n$, which is cataloged as A046947 in [21], are:

$$\mathcal{N}_\pi = \{1, 3, 22, 333, 355, 103993, 104348, 208341, 312689, 833719, 1146408, 4272943, 5419351, 80143857, 165707065, 245850922, 411557987, \ldots\}$$

14.1 The Sine Asymptotic Expansions

A few values were computed in Table 2 to illustrate the prediction in Theorem 3.1. Note that (69) is the restriction to convergents, so never vanishes, it is bounded below by $1/p_n$. The numerical data in Table 2 confirms this result.

14.2 The Sine Reflection Formula

Observe that the substitution $z \to p_n/\pi$ in $\Gamma(1-z)\Gamma(z)$ leads to

$$\frac{\Gamma(1-z)\Gamma(z)}{z} = \frac{\pi^2}{z \sin \pi z} = \frac{\pi^2}{p_n \sin p_n} = O(1).$$

A few values were computed to illustrate the prediction in Lemma 11.2. The ratio (101) is tabulated in the third column of Table 2.
