MORE FINITE SETS COMING FROM NON-COMMUTATIVE COUNTING

GEORGE DIMITROV AND LUDMIL KATZARKOV

Abstract. In our previous papers we introduced categorical invariants, which are, roughly speaking, sets of triangulated subcategories in a given triangulated category and their quotients. Here is extended the list of examples, where these sets are finite. Using results by Geigle, Lenzning, Meltzer, Hübner for weighted projective lines we show that for any two affine acyclic quivers $Q, Q'$ (i.e. quivers of extended Dynkin type) there are only finitely many full triangulated subcategories in $D^b(\text{Rep}_K(Q))$, which are equivalent to $D^b(\text{Rep}_K(Q'))$, where $K$ is an algebraically closed field. Some of the numbers counting the elements in these finite sets are explicitly determined.

1. Introduction

In [6] we introduced some categorical invariants via counting of fully faithful functors. In [7] we focused on examples and extended our studies beyond counting.

The idea of non-commutative counting from [6] is unfolded here in Section 3. Namely, for a triangulated category $\mathcal{T}$, a subgroup $\Gamma \subset \text{Aut}(\mathcal{T})$ of exact equivalences, and a choice of some restrictions $P$ on fully faithful functors we define the set of subcategories of $\mathcal{T}$, which are equivalent to another chosen triangulated category $\mathcal{A}$ via an equivalence which satisfy $P$, and modulo $\Gamma$. The resulting set of equivalence classes of subcategories in $\mathcal{T}$ we denote by $C^\Gamma_{A,P}(\mathcal{T})$. When the categories $\mathcal{T}, \mathcal{A}$ are $K$-linear for some field $K$, then choosing the property $P$ imposed on the functors to be $K$-linear, and restricting $\Gamma$ to be subgroup of the group of $K$-linear auto-equivalences $\text{Aut}_K(\mathcal{T})$ results in the set $C^\Gamma_{A,K}(\mathcal{T})$, which we denote by $C^\Gamma_{A,K}(\mathcal{T})$ (see Section 3).

Following Kontsevich-Rosenberg [14] we denote $D^b(\text{Rep}_K(K(l+1)))$ by $N^p_l$ for $l \geq -1$, where $K(l+1)$ is the Kroncker quiver as explained in Section 2. For a $K$-linear category $\mathcal{T}$ and any $l \geq -1$ we denote $C^\Gamma_{N^p,K}(\mathcal{T})$ by $C^\Gamma_{l}(\mathcal{T})$ and refer to this set as the set of non-commutative curves, sometimes nc curves for short, of non-commutative genus $l$ in $\mathcal{T}$ modulo $\Gamma$. Note that $N^p_{-1}$ has...
homological dimension 0 and one should think of the “curves” of non-commutative genus −1 as a kind of degenerate curves.

In [7] we enriched our invariants with structures: the inclusion of subcategories makes them partially ordered sets, and on the other hand considering semi-orthogonal pairs of subcategories as edges amounts to directed graphs. In addition to computing the non-commutative curve-counting invariants in $D^b(Q)$ for the affine quivers shown in (1), for $A_n$, and for $D_4$ the paper [7] contains deriving of formulas for counting of the subcategories of type $D^b(A_k)$ in $D^b(A_n)$, whereas for the two affine quivers and for $D_4$ we determined and counted all generated by an exceptional collection subcategories in $D^b(Q)$. It turns out that the problem for counting $D^b(A_k)$ in $D^b(A_n)$ has a geometric combinatorial parallel - counting of maps between polygons. Estimating the numbers counting non-commutative curves in $D^b(\mathbb{P}^2)$ modulo the group of auto-equivalences we proved finiteness and that the exact determining of these numbers leads to solution of Markov problem. Via homological mirror symmetry this gives a new approach to this problem. Regarding the structure of a partially ordered set mentioned above we initiated in [7] intersection theory of non-commutative curves focusing on the case of non-commutative genus zero. In the last section of [7] we built an analogue of the classical curve complex, introduced by Harvey and Harer and used in a spectacular way in Teichmueller theory and Thurston theory by Farb, Minsky, Mazur and many others. The above-mentioned structure of a directed graph (and related simplicial complex) is a categorical analogue of the curve complex. The paper [7] contains pictures of the graphs in many examples and presents also an approach to Markov conjecture via counting of subgraphs in a graph associated with $D^b(\mathbb{P}^2)$.

Some of the examples, studied in [7], are as follows: Let $Q_1, Q_2$ be the quivers:

\[
Q_1 = \begin{array}{ccc}
1 & \rightarrow & 2 \\
\rightarrow & & \rightarrow \\
2 & \rightarrow & 3
\end{array}
\quad Q_2 = \begin{array}{ccc}
1 & \rightarrow & 3 \\
\rightarrow & & \rightarrow \\
4 & \rightarrow & 1
\end{array}
\]

then for any other affine quiver $Q'$ and for $i = 1, 2$ we have $\left| C_{D^b(Q')}^{(\text{Id})}(D^b(Q_i)) \right| < \infty$, all the non-zero cardinalities are computed in [7].

In this note we extend the result about finiteness, $\left| C_{D^b(Q')}^{(\text{Id})}(D^b(Q_i)) \right| < \infty$, to the case when $Q_i$ is any affine acyclic quiver. In addition to that, for any two affine quivers $Q, Q'$ we determine whether $C_{D^b(Q')}^{(\text{Id})}(D^b(Q))$ is empty or not. The main result is Theorem 4.25.

After that in Section 5 we prove that $\left| C_{1}^{\text{Aut}(D^b(Q))}(D^b(Q)) \right| = 1$ for any acyclic affine connected quiver $Q$ (Corollary 5.4). In Corollary 5.6 we deduce the number $\left| C_{D^b(Q')}^{(\text{Id})}(D^b(Q)) \right|$ for any acyclic affine connected quiver $Q$.

Important role for the proof of Theorem 4.25 Corollary 5.4 and Corollary 5.6 play results by Geigle, Lenzning, Meltzer, Hübner for weighted projective lines in the papers [9], [10], [16], [18], [13], [12], [17]. The proofs here rely often upon [19] Corollary 1.9] and on [15] as well.

In the final Section 6 we make some comments and conjectures. We expect that with the help of the cited here works of Geigle, Lenzning, Meltzer, Hübner finiteness of other sets of the type $C_{D^b(\text{coh}(X'))}^{(\text{Id})}(D^b(\text{coh}(X)))$ can be proved, where $X, X'$ are weighted projective lines. In Section 6 we note also that whereas there are infinitely many non-commutative curves in $D^b(\mathbb{P}^2)$ and infinitely many smooth projective curves in $\mathbb{P}^2$ we have $C_{D^b(\mathbb{P}^2)}^{(\text{Id})}(D^b(\mathbb{P}^2)) = \emptyset$ for any smooth projective curve.
S (see Lemma 6.1 and the discussion before it). The final conjecture 6.2 discusses some threefolds $X$ and some smooth projective curves $S$ for which $C_{D^b(S)}^{(B)}(D^b(X)) \neq \emptyset$.

2. Notations

We fix a universe and assume that the set of objects and the set of morphisms of any category we consider are elements of this universe.

The shift functor in a triangulated category $\mathcal{T}$ is designated sometimes by $[1]$. We write $\langle S \rangle \subset \mathcal{T}$ for the triangulated subcategory of $\mathcal{T}$ generated by $S$, when $S \subset \text{Ob}(\mathcal{T})$. We write $\text{Hom}^i(X,Y)$ for $\text{Hom}(X,Y[i])$. In this paper $\mathbb{K}$ denotes an algebraically closed field. If $\mathcal{T}$ is $\mathbb{K}$-linear triangulated category we write $\text{hom}^i(X,Y)$ for $\text{dim}_\mathbb{K}(\text{Hom}(X,Y[i]))$, where $X,Y \in \mathcal{T}$.

A $\mathbb{K}$-linear triangulated category $\mathcal{T}$ is called proper if $\sum_{i \in \mathbb{Z}} \text{hom}^i(X,Y) < +\infty$ for any two objects $X,Y$ in $\mathcal{T}$.

An exceptional object in a $\mathbb{K}$-linear triangulated category is an object $E \in \mathcal{T}$ satisfying $\text{Hom}^i(E,E) = 0$ for $i \neq 0$ and $\text{Hom}(E,E) = \mathbb{K}$. We denote by $\mathcal{T}_{\text{exc}}$ the set of all exceptional objects in $\mathcal{T}$.

An exceptional collection is a sequence $\mathcal{E} = (E_0, E_1, \ldots, E_n) \subset \mathcal{T}_{\text{exc}}$ satisfying $\text{hom}^i(E_i,E_j) = 0$ for $i > j$. If in addition we have $\langle \mathcal{E} \rangle = \mathcal{T}$, then $\mathcal{E}$ will be called a full exceptional collection.

If an exceptional collection $\mathcal{E} = (E_0, E_1, \ldots, E_n) \subset \mathcal{T}_{\text{exc}}$ satisfies $\text{hom}^k(E_i,E_j) = 0$ for any $i,j$ and for $k \neq 0$, then it is said to be strong exceptional collection.

An abelian category $\mathcal{A}$ is said to be hereditary, if $\text{Ext}^i(X,Y) = 0$ for any $X,Y \in \mathcal{A}$ and $i \geq 2$, it is said to be of finite length, if it is Artinian and Noetherian.

By $Q$ we denote an acyclic quiver and by $D^b(\text{Rep}_\mathbb{K}(Q))$, or just $D^b(Q)$, - the derived category of the category of $\mathbb{K}$-representations of $Q$, this is a $\mathbb{K}$-linear triangulated category.

For an integer $l \geq 0$ the $l$-Kronecker quiver (the quiver with two vertices and $l$ parallel arrows) will be denoted by $K(l)$.

The number of elements of a finite set $X$ we denote by $|X|$. If $X$ is infinite, we write $|X| = \infty$.

Definition 2.1. If $\mathcal{T}$ is a triangulated category, $\mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n$ are triangulated subcategories in it satisfying the equalities $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ and $\text{Hom}(\mathcal{T}_j, \mathcal{T}_i) = 0$ for $j > i$, then we say that $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ is a semi-orthogonal decomposition. For short we write SOD instead of semi-orthogonal decomposition.

3. The sets $C^F_{\mathcal{A},\mathbb{K}}(\mathcal{T}), C^F_l(\mathcal{T})$

For $\mathbb{K}$-linear triangulated categories $\mathcal{A}$, $\mathcal{T}$ and a subgroup $\Gamma \subset \text{Aut}_\mathbb{K}(\mathcal{T})$ of the group of $\mathbb{K}$-linear auto-equivalences we defined in [21] Definition 4.2 a set $C^F_{\mathcal{A},\mathbb{K}}(\mathcal{T})$. For short we write $C^F_l(\mathcal{T})$ instead of $C^F_{\mathcal{A},\mathbb{K}}(\mathcal{T})$. In this note we consider only $\mathbb{K}$-linear categories and we will omit writing $\mathbb{K}$ in the notations $C^F_{\mathcal{A},\mathbb{K}}(\mathcal{T})$. In particular, here we need only the following:
Lemma 3.1. [7, Lemma 4.5] Let $\mathcal{A}, \mathcal{T}$ be $\mathbb{K}$-linear triangulated categories. Let $\Gamma \subset \text{Aut}_\mathbb{K}(\mathcal{T})$ be a subgroup of the group of $\mathbb{K}$-linear auto-equivalences. There is a bijection:

$$C^\Gamma_{\text{A}_{\mathbb{K}}}(\mathcal{T}) \to \left\{ \mathcal{B} \subset \mathcal{T} : \begin{array}{c} \mathcal{B} \text{ is a full tr. subcategory s.t.} \\
\text{there exists a } \mathbb{K}\text{-linear exact equivalence } \mathcal{A} \longrightarrow \mathcal{B}
\end{array} \right\} / \Gamma$$

the quotient by $\Gamma$ on the right hand side means that this is set of equivalence classes of subcategories, where two subcategories $\mathcal{B}_1, \mathcal{B}_2$ are in the same class iff there exists $[\beta] \in \Gamma$, s.t. $\beta(\mathcal{B}_1) = \mathcal{B}_2$. The meaning of $\text{Im}(F)$ and $\beta(\mathcal{B}_1)$ is explained in [7, Lemma 3.6].

Proposition 3.2. [7, Proposition 5.5.] Let $\mathcal{T}$ be a triangulated category linear over $\mathbb{K}$. Let $\mathcal{T}$ admits an enhancement. Then the bijection from Lemma 3.1 can be described as follows:

$$C^\{\text{Id}\}_{D^b(\mathcal{T})} \to \left\{ \mathcal{A} \subset \mathcal{T} : \begin{array}{c} \mathcal{A} \text{ is a full tr. subcategory s.t. } \mathcal{A} = (E_1, E_2) \\
\text{s.t. } \text{hom}(E_1, E_2) = l + 1
\end{array} \right\} .$$

4. Finiteness of $\left| C^\{\text{Id}\}_{D^b(\mathbb{Q})} \right|$ for affine acyclic quivers $\mathbb{Q}, \mathbb{Q}'$

Definition 4.1. By $\mathbf{p}$ we will denote a sequence $\mathbf{p} = (p_1, p_2, \ldots, p_t)$, $t \geq 1$ of integers such that $p_i \geq 1$ for $1 \leq i \leq t$.

Following [10, p. 319] the sequences $\mathbf{p} = (p_1, p_2, 1)$, $p_1 \geq 1, p_2 \geq 1$, $\mathbf{p} = (2, 2, p)$ with $p \geq 2$, $\mathbf{p} = (2, 3, 3)$, $\mathbf{p} = (2, 3, 4)$, $\mathbf{p} = (2, 3, 5)$ will be said to be of Dynkin type.

For a sequence of Dynkin type $\mathbf{p}$ we denote by $\mathcal{T}(\mathbf{p})$ a triangulated category which is a derived category of a corresponding extended Dynkin quiver. More precisely, for $p \geq 1, q \geq 1$ we will denote by $\mathcal{T}(p, q, 1)$ the derived category of representations of a quiver, whose graph is an extended Dynkin diagram of type $\mathcal{A}$ with $p + q$ vertices and orientation determined by the pair $p, q$ as shown in [15, Figure 6]. In [15, p. 363] is explained that for any acyclic quiver whose underlying graph is an extended Dynkin diagram of type $\mathcal{A}$ we have $D^b(Q) \cong \mathcal{T}(p, q, 1)$ for some $p \geq 1, q \geq 1$.

When writing $D^b \left( \tilde{D}_n \right)$ ($n \geq 4$), $D^b \left( \tilde{E}_6 \right)$, $D^b \left( \tilde{E}_7 \right)$, $D^b \left( \tilde{E}_8 \right)$ we mean derived categories of representations of quivers whose underlying graphs are corresponding extended Dynkin diagrams and with any choice of orientation (changing the orientation gives equivalent categories [15, Section 5]). With this stipulation we denote

$$\mathcal{T}(2, 2, p) = D^b \left( \tilde{D}_{p+2} \right), \quad \mathcal{T}(2, 3, 3) = D^b \left( \tilde{E}_6 \right),$$

$$\mathcal{T}(2, 3, 4) = D^b \left( \tilde{E}_7 \right), \quad \mathcal{T}(2, 3, 5) = D^b \left( \tilde{E}_8 \right).$$

Definition 4.2. Let $\mathbf{p}, \mathbf{p}'$ be two sequences of length 3. We write $\mathbf{p}' \preceq \mathbf{p}$ iff there exists a permutation $\sigma$ of $\{1, 2, 3\}$ such that $p'_{\sigma(i)} \leq p_i$ for $i = 1, 2, 3$.

Remark 4.3. In the beginning of [10, Section 9] is explained how to view a sequence of natural numbers and a normalized sequence of points in $\mathbb{P}^1$ (i.e. the latter has the same length as the first sequence and starts with $\infty$, 0, 1) as a weight function $\mathbf{w} : \mathbb{P}^1 \to \mathbb{N}$. For the case of a sequence of length three $\mathbf{p} = (p_1, p_2, p_3)$ the weight function $\mathbf{w}_p$ has values $\mathbf{w}_p(\infty) = p_1$, $\mathbf{w}_p(0) = p_2$, $\mathbf{w}_p(1) = p_2$ and 1 elsewhere. On [10, p. 321] is defined what is meant by saying that a weight function $\mathbf{w}$ dominates another weight function $\mathbf{v}$. It can be shown that for two sequences $\mathbf{p}, \mathbf{p}'$ of
length 3 we have \( p' \preceq p \), as defined in Definition 4.2, iff the weight function \( w_p \) corresponding to \( p \) dominates the weight function \( w_{p'} \) corresponding to \( p' \).

Remark 4.4. In [6] was shown that (see [6] (7) and (8)):

\[
\text{If } l \geq 2 \text{ and } Q \text{ is affine acyclic quiver } \Rightarrow \left| C_1^{\text{Id}}(D^b(Q)) \right| = 0.
\]

\[
\text{If } l \geq 1 \text{ and } Q \text{ is Dynkin quiver } \Rightarrow \left| C_1^{\text{Id}}(D^b(Q)) \right| = 0.
\]

We will use later the following

Lemma 4.5. Let \( p \) be of Dynkin type. From Remark 4.4 we get \( \left| C_1^{\text{Id}}(\mathcal{T}(p)) \right| = 0 \) for \( l \geq 2 \). We claim that furthermore, \( \left| C_1^{\text{Id}}(\mathcal{T}(p)) \right| \neq 0 \).

Proof. Lemma 3.38 ensures an exceptional pair \( (E_1, E_2) \in \mathcal{T}(p) \), such that \( \text{hom}(E_1, E_2) = 2 \) and \( \text{hom}^i(E_1, E_2) = 0 \) for \( i < 0 \). From Lemma 2.3.4 it follows that also \( \text{hom}^i(E_1, E_2) = 0 \) for \( i > 0 \). Now using Proposition 3.2 we deduce \( (E_1, E_2) \in C_1^{\text{Id}}(\mathcal{T}(p)) \).

Lemma 4.6. Let \( Q \) be an acyclic connected quiver, which is neither Dynkin nor extended Dynkin. Then \( \left| C_1^{\text{Id}}(D^b(Q)) \right| \neq 0 \) for some \( l \geq 2 \).

Proof. We use Proposition 3.34 to get an exceptional pair \( (E_1, E_2) \in D^b(Q) \), s.t. \( \text{Hom}(E_1, E_2) \geq 3 \) and then the same arguments as in Lemma 4.5 compete the proof.

Corollary 4.7. For any acyclic connected quiver \( Q \), which is not Dynkin, there exist infinitely many pairwise non-equivalent exceptional objects in \( \text{Rep}_K(Q) \).

Proof. Lemmas 1.6, 4.5 ensure that there exists a triangulated subcategory \( \mathcal{T} \subset D^b(Q) \) equivalent to \( D^b(K(l)) \) for some \( l \geq 2 \). Since in \( D^b(K(l)) \) there exists a sequence of exceptional objects \( \{s_i\}_{i \in \mathbb{Z}} \) such that \( s_i \not\sim s_j[k] \) for any \( i \neq j \) and any \( k \in \mathbb{Z} \) (see [5] Section 5), such sequence exists in \( D^b(Q) \) as well. Now the lemma follows since after shift each \( s_i \) becomes an exceptional representation in \( \text{Rep}_K(Q) \).

4.1. Domestic weighted projective lines. For any sequence of \( p = (p_1, p_2, \ldots, p_t) \), \( t \geq 1 \) of integers and \( p_i \geq 1 \) in [9] were introduced hom-finite hereditary abelian categories (called the category of coherent sheaves on weighted projective lines of weight \( p \)). In our considerations we will have \( t = 3 \) and in this case the sequence \( p \) determines by the method in [9] a unique up to equivalence hereditary abelian category, which we will denote by \( \text{coh}(\mathbb{X}(p)) \), as in [9] we refer to the objects of \( \text{coh}(\mathbb{X}(p)) \) as to sheaves on the weighted projective line \( \mathbb{X}(p) \). The full subcategory in \( \text{coh}(\mathbb{X}(p)) \) whose objects are sheaves of finite length, is denoted by \( \text{coh}_0(\mathbb{X}(p)) \). There is another full subcategory, whose elements are referred to as vector bundles on \( \mathbb{X}(p) \) and this subcategory will be denoted by \( \text{vect}(\mathbb{X}(p)) \). We list some facts for \( \text{coh}(\mathbb{X}(p)) \), which we need later:

Fact 4.8. ([9] Proposition 2.4.) Each object \( X \in \text{coh}(\mathbb{X}(p)) \) is a direct sum of an object in \( \text{coh}_0(\mathbb{X}(p)) \) and an object in \( \text{vect}(\mathbb{X}(p)) \).

1to show this in one direction one uses that \( PSL(2, \mathbb{K}) \) acts 3-transitively on \( \mathbb{P}^1 \) (\( \mathbb{K} \) is algebraically closed field).
Fact 4.9. ([18] see p. 25) There are only finitely many objects in $\text{coh}_0(\mathbb{X}(p))$ up to isomorphism, which are exceptional (since $\text{coh}(\mathbb{X}(p))$ is hereditary, an exceptional object in $\text{coh}(\mathbb{X}(p))$ is the same as an object $A \in \text{coh}(\mathbb{X}(p))$, s. t. $\text{Hom}(X, X) = \mathbb{K}$, $\text{Ext}^1(X, X) = 0$).

The rank one abelian group $L(p)$ on generators $x_1, x_2, \ldots, x_t$ and relations $p_i x_i = p_j x_j$ for $1 \leq i < j \leq t$ acts on $\text{coh}(\mathbb{X}(p))$ by exact auto-equivalences. For $x \in L(p)$ and $X \in \text{coh}(\mathbb{X}(p))$ the action of $x$ on $X$ is denoted by $X(x)$. The element $p_1 x_1 = \cdots = p_t x_t$ in $L(p)$ is denoted by $c$.

One can define rank of the objects in $\text{coh}(\mathbb{X}(p))$, which is zero for the objects in $\text{coh}_0(\mathbb{X}(p))$ and positive integer on the objects in $\text{vect}(\mathbb{X}(p))$ ([9, see subsection 5.4.1]).

Fact 4.10. ([9] Proposition 2.1.|) There is a specific rank one vector bundle, denoted by $O \in \text{vect}(\mathbb{X}(p))$, such that the function $L(p) \ni x \mapsto O(x)$ is a bijection between $L(p)$ and all rank one vector bundles in $\text{vect}(\mathbb{X}(p))$.

Fact 4.11. (follows from [9] Corollary 1.8.1, Proposition. 4.1; see also [18] p. 37, Lemma 2.3.4) For any weight sequence $p = (p_1, p_2, \ldots, p_t)$ the sequence:

$$(7) \quad (O, O(x_1), \ldots, O((p_1 - 1)x_1), O(x_2), \ldots, O((p_2 - 1)x_2), \ldots, O(x_t), \ldots, O((p_t - 1)x_t), O(c))$$

is a full strong exceptional collection on $D^b(\text{coh}(\mathbb{X}(p)))$.

Fact 4.12. (see [18] Lemmas 3.1.2, 3.1.3) Each exceptional collection in $D^b(\text{coh}(\mathbb{X}(p)))$ of length equal to $\text{rank}(K_0(D^b(\text{coh}(\mathbb{X}(p))))))$ is full. Each exceptional collection in $D^b(\text{coh}(\mathbb{X}(p)))$ can be extended to a full exceptional collection.

Fact 4.13. (see [18] Lemma 3.1.4) Let $E_1, \ldots, E_n, D_1, \ldots, D_n$ be two exceptional collections in $\text{coh}(\mathbb{X}(p))$ of length equal to $\text{rank}(K_0(D^b(\text{coh}(\mathbb{X}(p))))))$. If $E_i \cong D_i$ for $i \neq j$, then also $E_j \cong D_j$.

Fact 4.14. Let $E$ be the direct sum of the elements of sequence (7). Then the finite dimensional $\mathbb{K}$-algebra $\text{Hom}(E, E)$ is the same as the so called canonical algebra of weight $p$ introduced in [21] and denoted by $\Lambda(p)$. The algebra $\Lambda(p)$ is obtained via quiver with relations as explained in [9] Section 4| or [18] p. 19,20.

Fact 4.15. ([9] see subsection 5.4.1) For any weight sequence $p$ we have a $\mathbb{K}$-linear equivalence $D^b(\text{coh}(\mathbb{X}(p))) \cong D^b(\text{mod} - \Lambda(p))$. Furthermore, if $p$ is of Dynkin type, in which case $\mathbb{X}(p)$ is said to be of domestic type, we have also $\mathbb{K}$-linear equivalence $\mathcal{I}(p) \cong D^b(\text{mod} - \Lambda(p))$ ($\mathcal{I}(p)$ is explained in Definition 4.7).

Fact 4.16. From [19] Proposition 9.1 and Remark 4.3 it follows that if $p_1$ and $p_2$ are two weight sequences of length 3 related by a permutation, then $\text{coh}(\mathbb{X}(p_1))$ is equivalent to $\text{coh}(\mathbb{X}(p_2))$.

Using Facts 4.10 and 4.15 one shows that:

Corollary 4.17. Let $p, p'$ be two sequences with length 3. Let $p$ be of Dynkin type. If $p' \preceq p$ (as defined in Definition 4.3), then up to permutation $p'$ is of Dynkin type and assuming that $q$ is the permuted sequence, which is of Dynkin type, we have $D^b(\text{coh}(\mathbb{X}(p'))) \cong \mathcal{I}(q)$.

\footnote{Note that for an acyclic affine quiver of type $A$ the category of its representations is equivalent to the category of representations of the dual quiver, so we have these equivalences although we work with covariant representations of quivers in Definition 4.3.}
Fact 4.18. [10] PROPOSITION 1.1, here we use also that \( \text{coh}(\mathbb{X}(p)) \) is hereditary. Let \( E \) be an exceptional sheaf on a weighted projective line \( \mathbb{X}(p) \). Then the full subcategory:

\[
\{E\}^\perp = \{X \in \text{coh}(\mathbb{X}(p)) : \text{Ext}^i(E, X) = 0 \forall i\}
\]

is closed under kernels, co-kernels and extensions, in particular it is an abelian subcategory in \( \text{coh}(\mathbb{X}(p)) \) and \( \text{Ext}^1_{\{E\}^\perp}(A, B) = \text{Ext}^1_{\text{coh}(\mathbb{X}(p))}(A, B) \), \( \text{Hom}_{\{E\}^\perp}(A, B) = \text{Hom}_{\text{coh}(\mathbb{X}(p))}(A, B) \) for any \( A, B \in \{E\}^\perp \) (see the arguments in [16, p. 5]).

Remark 4.19. Let \( A \) be an abelian category. Let \( A_1, A_2 \) be two full subcategories, such that each object in \( A \) is a direct sum of an object in \( A_1 \) and an object in \( A_2 \). Let \( \text{Hom}(X, Y) = \text{Hom}(Y, X) = 0 \) for any \( X \in A_1 \), and any \( Y \in A_2 \). It follows that also \( \text{Ext}^1(X, Y) = \text{Ext}^1(Y, X) = 0 \) for any \( X \in A_1 \), and any \( Y \in A_2 \). Furthermore, it follows that \( A_1, A_2 \) are Serre subcategories in \( A \) and \( \text{Ext}^1_{A_1}(A, B) = \text{Ext}^1_{A_2}(A, B) \), \( \text{Hom}_{A_1}(A, B) = \text{Hom}_{A_2}(A, B) \) for any \( A, B \in A_i \) and any \( i = 1, 2 \).

Corollary 4.20. Let \( E \) be an exceptional sheaf in \( \text{coh}_0(\mathbb{X}(p)) \). Then the subcategory \( \{E\}^\perp \) in \( \text{coh}(\mathbb{X}(p)) \) is coproduct of two subcategories \( A_1, A_2 \), such that \( A_1 \) is equivalent to the category of representations of some quiver \( Q \), whose components are Dynkin quivers (i.e. of finite representation type), and \( A_2 \) is equivalent to \( \text{coh}(\mathbb{X}(p')) \) for some sequence \( p' < p \) (strictly smaller for the defined in Definition 4.2 partial order). Furthermore \( A_1 \subset \text{coh}_0(\mathbb{X}(p)) \).

Proof. From [17, page 2550] (see also [10, THEOREM 10.1 and the remark that follows]) we get that the subcategory: \( \{E\}^\perp \) from (8) in \( \text{coh}(\mathbb{X}(p)) \) is coproduct of two subcategories \( A_1, A_2 \), such that \( A_1 \) is equivalent to \( \text{mod}(H) \) for some hereditary finite dimensional \( \mathbb{K} \)-algebra, and \( A_2 \) is equivalent to \( \text{coh}(\mathbb{X}(p')) \) for some sequence \( p' < p \) (strictly smaller for the defined in Definition 4.2 partial order). Furthermore \( A_1 \subset \text{coh}_0(\mathbb{X}(p)) \).

It remains to show that the category \( \text{mod}(H) \) is equivalent to the category of representations of some quiver \( Q \) as specified. Since \( H \) is finite dimensional hereditary it follows that \( \text{mod}(H) \) is equivalent to the category of representations of some acyclic quiver \( Q \) (see e.g. [21, p. 80]). From Remark 4.19 and Fact 4.18 we see that any exceptional object in \( A_1 \) is an exceptional object in \( \text{coh}(\mathbb{X}(p)) \) and since \( A_1 \) is a full subcategory in \( \text{coh}(\mathbb{X}(p)) \) pairwise inequivalent exceptional objects in \( A_1 \) are pairwise inequivalent in \( \text{coh}(\mathbb{X}(p)) \). Now from Fact 4.9 and \( A_1 \subset \text{coh}_0(\mathbb{X}(p)) \) it follows that there are finitely many exceptional objects in \( \text{Rep}_\mathbb{K}(Q) \). Now the corollary follows from Corollary 4.17.

Corollary 4.21. Let \( E \) be an exceptional sheaf in \( \text{coh}_0(\mathbb{X}(p)) \). Then we have a SOD \( D^b(\text{coh}(\mathbb{X}(p))) = (\tau_1, \tau_2, (E)) \), where \( \tau_1 \cong D^b(Q) \) for some acyclic quiver \( Q \) with components Dynkin quivers and \( \tau_2 \cong D^b(\text{coh}(\mathbb{X}(p'))) \) for some \( p' < p \). Furthermore \( \text{Hom}(\tau_1, \tau_2) = \text{Hom}(\tau_2, \tau_1) = 0 \).

If \( p \) is of Dynkin type, then \( p' \) can be chosen to be of Dynkin type.

Proof. Provided that everything else is proved, the last sentence follows from Corollary 4.17 and Fact 4.15.

Let \( A_1, A_2 \) be the subcategories in \( \text{coh}(\mathbb{X}(p)) \) from Corollary 4.20. Using Remark 4.19 and Fact 4.18 we see that exceptional collections in \( A_1 \) give rise to exceptional collections in \( D^b(\text{coh}(\mathbb{X}(p))) \) right orthogonal to \( (E) \). Furthermore from the same statements it follows that for any object \( X \) in \( A_1 \) and any object \( Y \) in \( A_2 \) the pair \( (X, Y) \) is orthogonal in \( D^b(\text{coh}(\mathbb{X}(p))) \).

Let \( A_1, \ldots, A_n \) be the full exceptional sequence in \( D^b(A_1) \) consisting of the projective representations in \( \text{Rep}_\mathbb{K}(Q) \), this is a strong exceptional collection. Let \( B_1, B_2, \ldots, B_m \) be the full exceptional
collection in $D^b(A_2)$ coming from the equivalence of $A_2$ to $\text{coh}(\mathcal{X}(p'))$ and from Fact 4.11. We claim that $A_1, \ldots, A_n, B_1, \ldots, B_m, E$ is a full exceptional collection in $D^b(\text{coh}(\mathcal{X}(p)))$. We already explained that $E = (A_1, \ldots, A_n, B_1, \ldots, B_m, E)$ is an exceptional collection in $D^b(\text{coh}(\mathcal{X}(p)))$ such that $(A_i, B_j)$ are orthogonal pairs for any $i, j$. If $E$ is not full then from Fact 4.12 there exists an exceptional object $X \in \langle E \rangle^\perp$. Since $X$ is indecomposable we can assume that $X \in \text{coh}(\mathcal{X}(p))$ and then from Corollary 4.21 we have $X \in A_i$ for $i = 1$ or $i = 2$. We assume $i = 1$ (otherwise the arguments are the same). However using again Remark 4.19, Fact 4.18 and $X \in \langle E \rangle^\perp$ we deduce that Ext$^1_{A_i}(A_i, X) = 0$ for all $l$ and all $j$, which contradicts the fact that $(A_1, A_2, \ldots, A_n)$ is a full exceptional collection in $D^b(A_1)$. So we proved that $E$ is a full exceptional collection. Let us denote $\mathcal{T}_1 = \langle A_1, \ldots, A_n \rangle$, $\mathcal{T}_2 = \langle B_1, \ldots, B_m \rangle$, then from the already explained we see that $D^b(\text{coh}(\mathcal{X}(p))) = \langle \mathcal{T}_1, \mathcal{T}_2, E \rangle$ is a SOD and $\text{Hom}(\mathcal{T}_1, \mathcal{T}_2) = \text{Hom}(\mathcal{T}_2, \mathcal{T}_1) = 0$. Now both $(A_1, \ldots, A_n)$, $(B_1, \ldots, B_m)$ are full strong exceptional collections in $\mathcal{T}_1$, $\mathcal{T}_2$, respectively. Since $A_1$ is equivalent to $\text{Rep}_E(Q)$ we have a full strong exceptional collection $(A_1', \ldots, A_n')$ in $D^b(Q)$ such that the endomorphism algebra of $A_1' \oplus \cdots \oplus A_n'$ is isomorphic to the endomorphism algebra of $A_1 \oplus \cdots \oplus A_n$, from [19 Corollary 1.9] it follows that $\mathcal{T}_1$ is equivalent to $D^b(Q)$. By similar arguments and from the way we constructed the strong exceptional collection $B_1, \ldots, B_m$ it follows that $\mathcal{T}_2$ is equivalent to $D^b(\text{coh}(\mathcal{X}(p')))$. We take into account Facts 4.14, 4.15.

We pass to studying the right orthogonal $\langle E \rangle^\perp$ in $D^b(\text{coh}(\mathcal{X}(p)))$ for an exceptional vector bundle $E$ on $\mathcal{X}(p)$.

**Corollary 4.22.** Let $p$ be of Dynkin type. Let $E$ be an exceptional vector bundle on $\mathcal{X}(p)$. Then the subcategory $\langle E \rangle^\perp$ in $D^b(\text{coh}(\mathcal{X}(p)))$ is equivalent to $D^b(Q)$ for some acyclic quiver $Q$ with $n - 1$ vertices, where $n = \text{rank}(K_0(\text{coh}(\mathcal{X}(p))))$, with components Dynkin quivers. Furthermore, if $E$ is a line bundle, then $Q$ is Dynkin of type $A$, $D$, $E$, when $p$ is of type $A$, $D$, $E$, respectively (see Definition 4.7).

**Proof.** In this case the subcategory $\text{coh}(\mathcal{X}(p)))$ is equivalent to mod($H$) for some finite dimensional hereditary $\mathbb{K}$-algebra with $n - 1$ simple objects [18 Theorem 2.4.3] (see also the beginning of [18 Section 2], where is specified that by an algebra they always mean a finite dimensional algebra). [18 Theorem 2.4.3] is taken from [13], it is stated in [12] as well.

Since $H$ is finite dimensional hereditary it follows that mod($H$) is equivalent to the category of representations of some acyclic quiver $Q$ (see e.g. [21 p. 80]). From Fact 4.18 we see that any exceptional collection in $\langle E \rangle^\perp$ gives rise to an exceptional collection in $\langle E \rangle^\perp \subset D^b(\text{coh}(\mathcal{X}(p)))$. Let $(E_1, E_2, \ldots, E_{n-1})$ be the exceptional collection of $\langle E \rangle^\perp$ coming from the projective representations in $\text{Rep}_E(Q)$, then by the already explained $(E_1, E_2, \ldots, E_{n-1}, E)$ is an exceptional collection in $D^b(\text{coh}(\mathcal{X}(p)))$ and from Fact 4.12 it is full, hence $\langle E \rangle^\perp = \langle E_1, E_2, \ldots, E_{n-1} \rangle$. Now as in the proof of the equivalence $\mathcal{T}_1 \cong D^b(Q)$ in Corollary 4.21 on proves that $\langle E \rangle^\perp \cong D^b(Q)$. Applying the explanation after [18 Theorem 2.4.3] to each of the possible $p$ one sees that if $E$ is a line bundle, then the quiver $Q$ is connected Dynkin of the corresponding type.

Consider exceptional vector bundle $E$, which is not line bundle. Assume that some component of $Q$ is not Dynkin. From Lemmas 4.3, 4.6, $C_l(\langle E \rangle^\perp) \neq \emptyset$ for some $l \geq 1$. Let $\langle E_1, E_2 \rangle \in C_l(\langle E \rangle^\perp)$, where $(E_1, E_2)$ is a strong exceptional pair with $\hom(E_1, E_2) = l + 1 \geq 2$ due to Proposition 4.2. After shifting we obtain an exceptional pair $(X, Y)$ in $\langle E \rangle^\perp \subset \text{coh}(\mathcal{X}(p))$ with either $\hom(X, Y) = l + 1$ or $\hom^1(X, Y) = l + 1$. Using again Fact 4.12 we obtain a complete exceptional collection $(X, Y, E_1, E_2, \ldots, E_{n-3}, E)$ in $\text{coh}(\mathcal{X}(p))$ (by complete here we mean of length $n$). From [17] Theorem
2.] and since \(E\) is a vector bundle, the smallest exact (by exact subcategory we mean closed under kernels, co-kernels and finite direct sums) and extension-closed subcategory in \(\text{coh}(X(p))\) containing \((X,Y)\) is equivalent to a module category over a finite dimensional hereditary algebra, hence it is equivalent to the category of representations of some acyclic quiver \(Q\) (see e.g. \([21, \text{p. 80}]\)). Denote this subcategory by \(\mathcal{A}\). Since it is exact and extension-closed, we have for any \(A,B \in \mathcal{A}\):

\[
\begin{align*}
\text{Hom}_{\text{coh}(X(p))}(A, B) &= \text{Hom}_{\mathcal{A}}(A, B) \quad \text{Ext}^1_{\text{coh}(X(p))}(A, B) = \text{Ext}^1_{\mathcal{A}}(A, B) \\
\Rightarrow & \quad \text{Hom}_{\mathcal{A}}(X, Y) \geq 2 \quad \text{or} \quad \text{Ext}^1_{\mathcal{A}}(X, Y) \geq 2
\end{align*}
\]

From the arguments in \([17, \text{Proposition 4.2}]\) we see that \(\text{rank}(K_0(\mathcal{A})) = 2\) and hence \(\mathcal{A}\) is equivalent to \(\text{Rep}_K(K(r))\) for some \(r \geq 0\). Since all exceptional pairs in \(\text{Rep}_K(K(r))\) have \(r\)-dimensional \(\text{Hom}\) or \(\text{Ext}\) between their elements\(^3\) from \((10)\) it follows that \(r = l + 1 \geq 2\). However this contradicts \([17, \text{Proposition 4.3}]\).

\[\Box\]

**Fact 4.23.** (see \([10, \text{THEOREM 9.8}]\) and Remark \([4.3])\). Let \(p, p'\) be of Dynkin type and let \(p' \preceq p\). Then \(\text{coh}(X(p'))\) is equivalent to a full exact subcategory of \(\text{coh}(X(p))\), which is closed under extensions.

**Corollary 4.24.** Let \(p, p'\) be of Dynkin type and let \(p' \preceq p\). then \(\mathcal{C}_{T(p')}^{(\text{Id})}(T(p)) \neq \emptyset\).

**Proof.** Due to Fact \([4.15]\) it is enough to show that \(\mathcal{C}_{D^b(\text{coh}(X(p')))}(D^b(\text{coh}(X(p)))) \neq \emptyset\). Using Fact \([4.23]\) we get an exact and extension closed subcategory \(\mathcal{A} \subset \text{coh}(X(p))\), which is equivalent to \(\text{coh}(X(p'))\). Since \(\mathcal{A}\) is exact and extension-closed, we have \((9)\) for any \(A,B \in \mathcal{A}\) again. This in turn ensures that the exceptional sequence on \(\text{coh}(X(p'))\) explained in Fact \([4.11]\) gives rise to a strong exceptional sequence \((E_1, \ldots, E_n)\) in \(D^b(\text{coh}(X(p))))\), whose endomorphism algebra \(\text{Hom}(\oplus_{i=1}^n E_i, \oplus_{i=1}^n E_i)\) is \(\Lambda(p')\) (see Fact \([4.14]\) as well). Now \([19, \text{Corollary 1.9}]\] ensures that \((E_1, \ldots, E_n) \cong D^b(\text{mod} - \Lambda(p'))\). Looking again Fact \([4.15]\) we get \((E_1, \ldots, E_n) \cong D^b(\text{coh}(X(p'))\)) and the corollary follows from Lemma \([3.1]\). \[\Box\]

**Theorem 4.25.** Let \(p', p\) be any two weight sequences of Dynkin type as defined in Definition \([4.1]\). Then \(\mathcal{C}_{T(p')}^{(\text{Id})}(T(p)) \neq \emptyset\) iff \(p' \preceq p\) as defined in Definition \([4.2]\). Furthermore \(\mathcal{C}_{T(p')}^{(\text{Id})}(T(p)) \prec \infty\).

It follows that for any two affine acyclic quivers \(Q', Q\) (i.e. quivers of extended Dynkin type) holds \(\mathcal{C}_{D^b(Q')}^{(\text{Id})}(D^b(Q)) \prec \infty\).

**Proof.** The last sentence follows from Fact \([4.15]\) and the comments in Definition \([4.1]\). Taking into account Corollary \([4.24]\) it is enough to prove that

\[
\begin{align*}
\mathcal{C}_{T(p')}^{(\text{Id})}(T(p)) \neq \emptyset & \quad \text{implies} \quad p' \preceq p \quad \text{and} \quad \left| \mathcal{C}_{T(p')}^{(\text{Id})}(T(p)) \right| \prec \infty.
\end{align*}
\]

Due to Fact \([4.15]\) we can work with \(\mathcal{C}_{D^b(\text{coh}(X(p')))}(D^b(\text{coh}(X(p))))\) instead of \(\mathcal{C}_{T(p')}^{(\text{Id})}(T(p))\). We note that:

\[\text{\footnote{see for example \([21, \text{Figures 10,11,12}]\) or Remark \([5.1]\) below.}}\]
Both $D^b(\text{coh}(\mathbb{X}(p'))), D^b(\text{coh}(\mathbb{X}(p)))$ have full exceptional collections,

(12) each exceptional collection of maximal length is full, and each exceptional collection
can be extended to a full exceptional collection (Facts 4.11, 4.12).

Due to (12) each $A \in C^{|\text{id}|}_{D^b(\text{coh}(\mathbb{X}(p')))}(D^b(\text{coh}(\mathbb{X}(p))))$ is a subcategory
generated by an exceptional collection and [2] Theorem 3.2 says that
$A$ is admissible, which in turn implies that $A$ is closed under direct summands.

Let us denote $|p| = p_1 + p_2 + p_3$ for any sequence $p = (p_1, p_2, p_3)$. We will make induction on $|p|$. We note first that from the very Definitions 4.1, 4.2 we have

(13) $\text{rank}(\mathcal{T}(p)) = |p| - 1, \quad |p'| < |p| \Rightarrow |p'| < |p'|.$

Recalling Definition 4.1 we see that the minimal $|p|$ is 3 and there is a unique $p$ where this is attained, it is $p = (1, 1, 1)$.

If $p = (1, 1, 1)$ and $C^{|\text{id}|}_{\mathcal{T}(p)}(\mathcal{T}(p)) \neq \emptyset$, then (13), (12), (11) imply that $|p'| \leq |p| = 3$, and by the minimality of $|p|$ and the uniqueness of $p$ we have $p' = p$ and $|C^{|\text{id}|}_{\mathcal{T}(p')}(\mathcal{T}(p))| = 1$.

The induction step: Let for some $N \geq 3$ we have that for any $p$ of Dynkin type and with $|p| \leq N$ (13) holds. Assume also that $C^{|\text{id}|}_{\mathcal{T}(p})(\mathcal{T}(p)) \neq \emptyset$, and that $|p| = N + 1$. We will show that $p' \leq p$ and that $|C^{|\text{id}|}_{\mathcal{T}(p)}(\mathcal{T}(p))| = 1$.

If rank $(K_0(D^b(\text{coh}(\mathbb{X}(p)))))) = rank (K_0(D^b(\text{coh}(\mathbb{X}(p))))))$, then from (12) it follows

$D^b(\text{coh}(\mathbb{X}(p')))) = D^b(\text{coh}(\mathbb{X}(p))), \mathcal{T}(p) \cong \mathcal{T}(p')$ and from [11, p. 56] it follows that $p = p'$, hence

$|C^{|\text{id}|}_{\mathcal{T}(p)}(\mathcal{T}(p))| = 1$.

So, let rank $(K_0(D^b(\text{coh}(\mathbb{X}(p)))))) < rank (K_0(D^b(\text{coh}(\mathbb{X}(p))))))$. In this case (12) ensures that

for each $A \in C^{|\text{id}|}_{D^b(\text{coh}(\mathbb{X}(p')))}(D^b(\text{coh}(\mathbb{X}(p))))$ there exists an exceptional sheaf $E \in \text{coh}(\mathbb{X}(p))$, s.t.

$A \subset \langle E \rangle \subset$, however Corollary 4.22 shows that $E$ cannot be a vector bundle. Indeed if $E$ is a vector bundle, then from Corollary 4.22 and $A \subset \langle E \rangle \subset$ would follow that for some acyclic quiver $Q$ with components Dynkin quivers we have a subcategory $A \subset D^b(Q)$ which is equivalent to

$D^b(\text{coh}(\mathbb{X}(p')))) \cong \mathcal{T}(p')$, which is impossible, since in $D^b(Q)$ there are only finitely many exceptional objects up to shift, whereas in $\mathcal{T}(p')$, there are infinitely many indecomposable objects up to shift (we use (12) as well here). So far, we deduce that $A \subset \langle E \rangle \subset$ for some exceptional sheaf of finite length $E \in \text{coh}(\mathbb{X}(p))$, recall also Fact 4.8. From Fact 4.9 we know that the set of such objects, say $E$, is finite. For each $E \in E$ from Corollary 4.21 we have $\langle E \rangle \subset = \langle T_1^E, T_2^E \rangle$ with $\mathbb{K}$-linear equivalences $T_1^E \cong Q_E$ for some acyclic quiver $Q_E$ with components Dynkin quivers and $T_2^E \cong D^b(\text{coh}(\mathbb{X}(p_E))))$ for some $p_E'$ of Dynkin type with $p'_E < p$ and Hom($T_1^E, T_2^E$) = Hom($T_2^E, T_1^E$) = 0. Thus we see that for each $A \in C^{|\text{id}|}_{D^b(\text{coh}(\mathbb{X}(p')))}(D^b(\text{coh}(\mathbb{X}(p))))$ we have $A \subset \langle T_1^E, T_2^E \rangle$ for some $E \in E$ with the described properties of $\langle T_1^E, T_2^E \rangle$, furthermore we claim that $A \subset T_2^E \cong D^b(\text{coh}(\mathbb{X}(p_E))))$, in particular $A \subset C^{|\text{id}|}_{D^b(\text{coh}(\mathbb{X}(p')))}(T_2^E)$.
A_1, A_2, \ldots, A_n in \mathcal{A} such that for any 1 \leq j < n \langle A_1, \ldots, A_j \rangle is not orthogonal to \langle A_{j+1}, \ldots, A_n \rangle, and since (\mathcal{T}_1, \mathcal{T}_2) is an orthogonal decomposition we have either \{A_i\}_{i=1}^n \subset \mathcal{T}_1 or \{A_i\}_{i=1}^n \subset \mathcal{T}_2, hence either \mathcal{A} \subset \mathcal{T}_1 or \mathcal{A} \subset \mathcal{T}_2, finally since we have \mathbb{K}\text{-linear equivalence } \mathcal{T}_1 \cong \mathcal{D}(Q_E) \text{ for some acyclic quiver } Q_E \text{ with components Dynkin quivers, we can exclude the case } \mathcal{A} \subset \mathcal{T}_2 \text{ by the fact that there are infinitely many indecomposable objects in } \mathcal{A} \text{ up to shifts and using (13) again.}

In the case \text{rank} \left(K_0(\mathcal{D}(\text{coh}(X(p')))) \right) < \text{rank} \left(K_0(\mathcal{D}(\text{coh}(X(p))))\right) we deduce that there is a finite set of triangulated subcategories \{\mathcal{T}_E : E \in \mathcal{E}\} of \mathcal{D}(\text{coh}(X(p))) such that \mathcal{T}_2 \cong \mathcal{D}(\text{coh}(X(p'_E))) with p'_E \text{ of Dynkin type and } p'_E \prec p \text{ for each } E \in \mathcal{E} \text{ and such that}

\begin{equation}
C^{[\text{Id}]}_{\mathcal{D}(\text{coh}(X(p')))}(\mathcal{D}(\text{coh}(X(p)))) \subset \bigcup_{E \in \mathcal{E}} C^{[\text{Id}]}_{\mathcal{D}(\text{coh}(X(p')))}(\mathcal{T}_E).
\end{equation}

If \text{C}^{[\text{Id}]}_{\mathcal{D}(\text{coh}(X(p')))}(\mathcal{D}(\text{coh}(X(p)))) = \emptyset, then \text{C}^{[\text{Id}]}_{\mathcal{D}(\text{coh}(X(p')))}(\mathcal{D}(\text{coh}(X(p'_E)))) = \emptyset \text{ for some } E \in \mathcal{E} \text{ and by (14) and the induction assumption } p' \prec p'_E. \text{ Furthermore, again by the induction assumption } C^{[\text{Id}]}_{\mathcal{D}(\text{coh}(X(p')))}(\mathcal{T}_E) \text{ is finite for each } E \in \mathcal{E} \text{ and therefore by (15) } C^{[\text{Id}]}_{\mathcal{D}(\text{coh}(X(p')))}(\mathcal{D}(\text{coh}(X(p)))) \text{ is finite.}

5. Remarks on \textit{C}^{[\text{Id}]}_1(\mathcal{D}(\text{coh}(X(p))))

Combining results in [10] and [17] we will study further \textit{C}^{[\text{Id}]}_1(\mathcal{D}(\text{coh}(X(p)))) for the case when p' is the unique sequence of Dynkin type with \{p'\} = 3. This is the case p' = (1,1,1) and then \mathcal{T}(p') = \mathcal{D}(K(2)). With the terminology explained in the introduction the set \textit{C}^{[\text{Id}]}_{\mathcal{T}(p')}(\mathcal{T}(p)) is the set of nc curves in \mathcal{T}(p) of non-commutative genus 1, i.e. this is \textit{C}^{[\text{Id}]}_1(\mathcal{T}(p)). Due to Fact [14] it is enough to determine \textit{C}^{[\text{Id}]}_1(\mathcal{D}(\text{coh}(X(p))))

\textbf{Remark 5.1.} For any } \mathcal{B} \subset \mathcal{C}^{[\text{Id}]}_1(\mathcal{D}(\text{coh}(X(p)))) \text{ there exists an exact equivalence } \mathcal{D}(\text{coh}(\mathbb{P}^1)) \cong \mathcal{D}(K(2)) \cong \mathcal{B} \text{ and from [15] (25), (26), (27)] we see that there is a sequence } \{s_i\}_{i \in \mathbb{Z}} \text{ of exceptional objects in } \mathcal{B} \text{ such that}

\begin{align}
&\forall i \in \mathbb{Z} \quad \mathcal{B} = \langle s_i, s_{i+1} \rangle, \quad \text{hom}(s_i, s_{i+1}) = 2, \quad \text{hom}^k(s_i, s_{i+1}) = 0 \text{ for } k \neq 0, \\
&\text{complete lists of exceptional pairs and objects (up to shifts) are } \{(s_i, s_{i+1})\}_{i \in \mathbb{Z}} \text{ and } \{s_i\}_{i \in \mathbb{Z}}. \\
&\text{there is an exact triangle } s_{i-1} \rightarrow s_i \rightarrow s_{i+1} \rightarrow s_{i-1}[1] \text{ for any } i \in \mathbb{Z}.
\end{align}

In [17] for any exceptional pair } (A, B) \subset \text{coh}(X(p)) \text{ is studied the smallest exact extension-closed subcategory of } \text{coh}(X(p)) \text{ containing } A \text{ and } B. \text{ We will denote this subcategory by } Z(X,Y). \text{ We note first:

\textbf{Lemma 5.2.} Let } \mathcal{A} \subset \text{coh}(X(p)) \text{ be an exact and extension-closed subcategory such that there exists a } \mathbb{K}\text{-linear exact equivalence } \mathbb{P}^1 \rightarrow \mathcal{A}. \text{ Then:

(a) object } X/ (\text{pair of objects } X, Y) \text{ in } \mathcal{A} \text{ is exceptional object/(exceptional pair) with respect to } \mathcal{A} \text{ iff it is exceptional object/(exceptional pair) with respect to } \text{coh}(X(p)).

(b) For any exceptional pair } X, Y \in \mathcal{A} \text{ we have } \text{hom}(X, Y) = 2, \text{hom}^k(X, Y) = 0 \text{ for } k \neq 0, \text{ and } Z(X, Y) = \mathcal{A}.

(c) There is a sequence } \{s_i\}_{i \in \mathbb{Z}} \text{ of exceptional objects contained in } \mathcal{A}, \text{ such that each exceptional object in } \mathcal{A} \text{ is isomorphic to } s_i \text{ for some } i \in \mathbb{Z} \text{ and each exceptional pair } (X, Y) \text{ in } \mathcal{A} \text{ is isomorphic}
to \((s_i, s_{i+1})\) for some \(i \in \mathbb{Z}\). Furthermore we have equality \(<\{s_i\}_{i \in \mathbb{Z}}\rangle = <s_j, s_{j+1}\rangle\) in \(D^b(\text{coh}(\mathbb{X}(p)))\) for any \(j \in \mathbb{Z}\).

(d) From (b), (c) follows that \(<\mathcal{A}_{\text{exc}}\rangle \subset C_1^{[1d]}(D^b(\text{coh}(\mathbb{X}(p))))\), where \(\mathcal{A}_{\text{exc}}\) is the set of exceptional objects in \(\mathcal{A}\).

Proof. Since \(\mathcal{A}\) is exact and extension-closed we have \([\mathcal{A}]\) and hence (a) follows.

(b) Let \(X, Y \in \mathcal{A}\) be an exceptional pair. Since \(\mathcal{A}\) is exact and extension-closed, \(\mathcal{Z}(X, Y) \subset \mathcal{A}\) by showing that for each \(A \in \text{vect}(\mathbb{P}^1)\) and each \(A \in \text{coh}(\mathbb{P}^1)\) holds \(F(A) \in \mathcal{Z}(X, Y)\) and using Fact 4.8.

All exceptional pairs in \(\text{coh}(\mathbb{P}^1)\) are of the form \((O(n), O(n+1))\) (see e.g. [17] the proof of Theorem 3]) hence we have \(X \cong F(O(n))\), \(Y \cong F(O(n+1))\) for some \(n \in \mathbb{Z}\), in particular \(F(O(n)), F(O(n+1)) \in \mathcal{Z}(X, Y)\) and \(\text{hom}(X, Y) = 2\), \(\text{hom}^k(X, Y) = 0\) for \(k \neq 0\). The sequence \(\{s_j : j \in \mathbb{Z}\}\) in \(D^b(\text{coh}(\mathbb{P}^1))\) from Remark 5.1 can be chosen to be \(\{O(j) : j \in \mathbb{Z}\}\) hence we have a short exact sequence \(0 \rightarrow O(i-1) \rightarrow O(i)^2 \rightarrow O(i+1) \rightarrow 0\) for each \(i\). Using these short exact sequences, the fact that the functor \(F\) is exact, and that \(\mathcal{Z}(X, Y)\) is exact an extension closed by induction one shows that \(F(O(j)) \in \mathcal{Z}(X, Y)\) for each \(j \in \mathbb{Z}\). From [9] Proposition 2.6] it follows that for each vector bundle \(A \in \text{vect}(\mathbb{P}^1)\) we have \(F(A) \in \mathcal{Z}(X, Y)\).

To show that for each \(A \in \text{coh}(\mathbb{P}^1)\) holds \(F(A) \in \mathcal{Z}(X, Y)\) it is enough to show that for each simple sheaf \(S_x \in \text{coh}(\mathbb{X}(p))\), \(x \in \mathbb{P}^1\) holds \(F(S_x) \in \mathcal{Z}(X, Y)\) because of [9] Proposition 2.5. Each simple sheaf \(S_x \in \text{coh}(\mathbb{X}(p))\) for each \(x \in \mathbb{P}^1\) arises as the co-kernel term of an exact sequence \(0 \rightarrow O \rightarrow O(1) \rightarrow S_x \rightarrow 0\) (see again in the [17] Theorem 3]). Therefore by the already proved part and the fact that the functor \(F\) is exact, and that \(\mathcal{Z}(X, Y)\) is exact an extension closed we get \(F(S_x) \in \mathcal{Z}(X, Y)\) for each \(x \in \mathbb{P}^1\). So we proved (b).

(c) The sequence \(\{s_i = F(O(i))\}_{i \in \mathbb{Z}}\) satisfies the desired properties, since \(F\) is equivalence and \(0 \rightarrow O \rightarrow O(1) \rightarrow S_x \rightarrow 0\) give rise to a distinguished triangle \(s_{i-1} \rightarrow s_i^2 \rightarrow s_{i+1} \rightarrow s_{i-1}[1]\) in \(D^b(\text{coh}(\mathbb{X}(p)))\) for each \(i \in \mathbb{Z}\) and it follows that \(<s_i, s_{i+1}\rangle = <s_{i-1}, s_i\rangle\) for each \(i\), therefore \(<\{s_i\}_{i \in \mathbb{Z}}\rangle = <s_j, s_{j+1}\rangle\) for any \(j \in \mathbb{Z}\).

Lemma 5.3. Let \(p\) be of Dynkin type. For any \(B \in C_1^{[1d]}(D^b(\text{coh}(\mathbb{X}(p))))\) there exists a unique exact and extension-closed subcategory \(\mathcal{A} \subset \text{coh}(\mathbb{X}(p))\), such that there exists a \(\mathbb{K}\)-linear exact equivalence \(\text{coh}(\mathbb{P}^1) \rightarrow \mathcal{A}\) and \(B = <\mathcal{A}_{\text{exc}}\rangle\), where \(\mathcal{A}_{\text{exc}}\) is the set of exceptional objects in \(\mathcal{A}\).

Proof. Let \(B \in C_1^{[1d]}(D^b(\text{coh}(\mathbb{X}(p))))\) and let \(\{s_i\}_{i \in \mathbb{Z}}\) be the sequence from Remark 5.1. Using that \(\text{coh}(\mathbb{X}(p))\) is hereditary we get integer \(k_i \in \mathbb{Z}\), s.t. \(s_i[k_i] \in \text{coh}(\mathbb{X}(p))\) for any \(i \in \mathbb{Z}\) and [10] shows that either \(k_i = k_{i+1}\) or \(k_i = k_{i+1} + 1\). We will show that must hold \(k_i = k_{i+1}\). Take any \(i \in \mathbb{Z}\) and denote for short \(A_1 = s_i[k_i], A_2 = s_{i+1}[k_{i+1}]\). Let \(\mathcal{Z}(A_1, A_2)\) be the smallest exact and extension-closed subcategory in \(\text{coh}(\mathbb{X}(p))\) containing \(A_1, A_2\). We claim that \(\mathcal{Z}(A_1, A_2)\) is equivalent to \(\text{coh}(\mathbb{P}^1)\) and that \(\text{hom}(A_1, A_2) = 2\), and then from [10] it follows that \(k_i = k_{i+1}\).

We show first that \(\mathcal{Z}(A_1, A_2)\) is not equivalent to a module category over a finite dimensional hereditary algebra. Indeed, if \(\mathcal{Z}(A_1, A_2)\) is equivalent to a module category over a finite dimensional hereditary algebra, from the arguments as those related to [9], [10] follows that \(\mathcal{Z}(A_1, A_2)\) is equivalent to \(\text{Rep}_{\mathbb{K}}(K(r))\) for some \(r \geq 0\). Since all exceptional pairs in \(\text{Rep}_{\mathbb{K}}(K(r))\) have \(r\)-dimensional Hom or Ext between their elements, using that \(\text{hom}^1(A_1, A_2) = 2\) or \(\text{hom}^1(A_1, A_2) = 2\) due to [10] we conclude that \(r = 2\), however this contradicts [17] Proposition 4.3].
Now, from [17 Theorem 2] we get that \( \mathcal{Z}(A_1, A_2) \) is equivalent to \( \text{coh}(\mathbb{P}^1) \), therefore \((A_1, A_2)\) corresponds to an exceptional pair in \( \text{coh}(\mathbb{P}^1) \), however all exceptional pairs in \( \text{coh}(\mathbb{P}^1) \) are of the form \((\mathcal{O}(n), \mathcal{O}(n + 1))\) (see e.g. [17, the proof of Theorem 3.1]), and therefore \(0 \neq \text{hom}(A_1, A_2) = 2\).

We see that \(k_i = k_{i+1}\) for each \(i \in \mathbb{Z}\) and it follows that we can ensure

\[
(19) \quad \forall i \in \mathbb{Z} \quad s_i \in \text{coh}(\mathbb{X}(p)).
\]

From (18), it follows that for any two integers \(i, j \in \mathbb{Z}\) we have

\[
(20) \quad \mathcal{Z}(s_i, s_{i+1}) = \mathcal{Z}(s_j, s_{j+1}).
\]

If we denote \( \mathcal{A} = \mathcal{Z}(s_i, s_{i+1}) \), then (20) implies that \(s_i \in \mathcal{A}\) for any \(i \in \mathbb{Z}\). Recalling that \((s_i, s_{i+1})\) is an exceptional pair for each \(i\), seeing the properties of the sequence from Lemma 5.2(c), and taking into account Fact 4.13 we see that in fact \(\{s_i\}_{i \in \mathbb{Z}}\) is a sequence as in (c) Lemma 5.2 hence the set of all exceptional objects in \(\mathcal{A}\) up to isomorphism is \(\{s_i\}_{i \in \mathbb{Z}}\) and \(\mathcal{B} = (\mathcal{A}_{\text{exc}}) = (s_i, s_{i+1})\).

Now we prove the uniqueness. Assume that \(\mathcal{B} \in C_{\text{fin}}^{[\text{id}]}(D^b(\text{coh}(\mathbb{X}(p))))\) and that \(\mathcal{B} = (\mathcal{A}_{\text{exc}}) = (A_{\text{exc}})\) where \(\mathcal{A}_i\) is an exact, extension closed subcategory \(\mathcal{A}_i \subset \text{coh}(\mathbb{X}(p))\), such that there exists a \(\mathbb{K}\)-linear exact equivalence \(\text{coh}(\mathbb{P}^1) \to \mathcal{A}_i\) for \(i = 1, 2\). From Lemma 5.2(c) we see that \(\mathcal{B} = \langle X_1, Y_1 \rangle = \langle X_2, Y_2 \rangle\), where \((X_i, Y_i)\) is an exceptional pair in \(\mathcal{A}_i\) for \(i = 1, 2\).

From Lemma 5.2(b) it follows that for \(i = 1, 2\) we have \(\mathcal{A}_i = \mathcal{Z}(X_i, Y_i)\). The pair \((X_1, Y_1)\) is exceptional in \(\mathcal{B}\), whose elements are in \(\text{coh}(\mathbb{X}(p))\), therefore (17) and (19) imply that it is isomorphic to a pair of the form \((s_i, s_{i+1})\) for some \(i \in \mathbb{Z}\), similarly \((X_2, Y_2)\) is isomorphic to a pair of the form \((s_j, s_{j+1})\) for some \(j \in \mathbb{Z}\). Now from (20) we get \(\mathcal{A}_1 = \mathcal{A}_2\). The lemma is proved.

**Corollary 5.4.** Let \(p = (p_1, p_2, p_3)\) be any weight sequences of Dynkin type as defined in Definition 4.4. Then \(\left| C_1^{\text{Aut}}(T(p)) \right| = 1 \).

It follows that for any affine connected acyclic quivers \(Q\) holds \(\left| C_1^{\text{Aut}}(D^b(Q)) \right| = 1 \).

**Proof.** The last sentence follows from Fact 4.15 and the comments in Definition 4.4.

Let \(\mathcal{B} \in C_{\text{fin}}^{[\text{id}]}(D^b(\text{coh}(\mathbb{X}(p))))\). To prove the corollary we will find \(\beta \in \text{Aut}(D^b(\text{coh}(\mathbb{X}(p))))\) such that \(\beta(\mathcal{B}) = (\mathcal{Z}(\mathcal{O}, \mathcal{O}(c)))_{\text{exc}}\), where \((\mathcal{O}, \mathcal{O}(c))\) is the corresponding subsequence of the sequence in Fact 4.11 From Lemma 5.3 we have \(\mathcal{B} = (\mathcal{A}_{\text{exc}})\) for some exact extension closed subcategory \(\mathcal{A}\) of \(\text{coh}(\mathbb{X}(p))\) which is equivalent to \(\text{coh}(\mathbb{P}^1)\). From Lemma 5.2(b) we deduce that \(\mathcal{A} = \mathcal{Z}(X,Y)\) for some exceptional pair \((X, Y)\). Since \(\mathcal{Z}(X,Y)\) is not equivalent to a module category (see also [17 Corollary 1]), from [17 Theorem 3] it follows that for some auto-equivalence \(\alpha \in \text{Aut}(\text{coh}(\mathbb{X}(p)))\) holds \(\alpha(\mathcal{Z}(X,Y)) = \mathcal{Z}(\mathcal{O}, \mathcal{O}(c))\), this auto-equivalence gives rise to an auto-equivalence \(\beta \in \text{Aut}(D^b(\text{coh}(\mathbb{X}(p))))\) s.t. \(\mathcal{Z}(\mathcal{O}, \mathcal{O}(c)))_{\text{exc}}\) is the isomorphism closure of the set \(\beta(\mathcal{A}_{\text{exc}})\), and it follows that \(\beta(\mathcal{B}) = (\mathcal{Z}(\mathcal{O}, \mathcal{O}(c)))_{\text{exc}}\).

In [10 COROLLARY 9.9] is written that “up to equivalence of functors there are exactly \(p_0 \cdots p_n\) exact embeddings \(\Phi_t, t = 0, \ldots, p_0 \cdots p_n\) from \(\text{coh}(\mathbb{P}^1)\) to \(\text{coh}(\mathbb{X}(p))\), whose image is closed under extensions.” We could not find in [10 COROLLARY 9.9] an explanation, what is the equivalence meant by saying “up to equivalence of functors”. In a previous version of our paper we presumed that
two exact embeddings $F,G$ from $\text{coh}(\mathbb{P}^1)$ to $\text{coh}(\mathbb{X}(p))$ should be considered equivalent

\[ \text{(21) COROLLARY 9.9} \quad \text{iff } F \circ \alpha \text{ is naturally isomorphic to } G \]

for some $\mathbb{K}$-linear auto-equivalence $\alpha$ of $\text{coh}(\mathbb{P}^1)$.

Professor Helmut Lenzing confirmed in a private communication that (21) is correct and now we can infer:

**Remark 5.5.** Let $p = (p_1, p_2, p_3)$ be of Dynkin type as defined in Definition 4.1. Since (21) holds then by similar arguments as in the proof of [7, Lemma 4.5] one can show that [10, COROLLARY 9.9] implies that the set of exact, extension-closed subcategories in $\text{coh}(\mathbb{X}(p))$, which are $\mathbb{K}$-equivalent to $\text{coh}(\mathbb{P}^1)$ contains $p_1p_2p_3$ elements.

**Corollary 5.6.** For any sequence $p = (p_1, p_2, p_3)$ of Dynkin type (as defined in Definition 4.1) holds

\[ \left| C_{\text{Id}}(\mathcal{T}(p)) \right| = p_1p_2p_3. \]

**Proof.** Follows from Lemmas 5.3 5.2 (d) and Remark 5.5

\[ \square \]

6. Final remarks and conjectures

We expect that with the help of the cited here works of Geigle, Lenzning, Meltzer, Hübner finiteness of other sets of the type $C_{\text{Id}}(\text{coh}(\mathbb{X}))$ can be proved, where $\mathbb{X}'$ and $\mathbb{X}$ are weighted projective lines.

Another example studied in [7] is $D_{\text{coh}(\mathbb{X}')}^b(\mathbb{P}^2)$, here we fix $\mathbb{K} = \mathbb{C}$. In particular it is shown that then

\[ C_{\text{Id}}(\mathcal{T}) = \emptyset, \quad \forall l \geq 0 \text{ the set } C_{l}(\mathcal{T}) \text{ is finite, and} \]

\[ (22) \quad \left\{ \left. t \geq 0 : C_{l}(\mathcal{T}) \neq \emptyset \right\} = \left\{ t \geq 0 : C_{l}(\mathcal{T}) \neq \emptyset \right\} = \{ 3m - 1 : m \text{ is a Markov number} \}. \]

Thus, there are infinitely many non-commutative curves in $D^b(\mathbb{P}^2)$. There are also infinitely many smooth projective curves in $\mathbb{P}^2$, in contrast to that we have:

**Lemma 6.1.** For any smooth projective curve $S$ we have $C_{\text{Id}}(\mathbb{P}^2) = \emptyset$.

**Proof.** We will omit writing the superscript {Id} in $C_{\text{Id}}(\mathbb{P}^2)$. From (22) it follows that $C_1(\mathbb{P}^2) = \emptyset$ and hence $C_{\text{Id}}(\mathbb{P}^2) = \emptyset$, since $D^b(\mathbb{P}^1) \cong D^b(K(2))$ by [2].

Let $S$ be a smooth projective curve of positive genus. We will show that there is no a full triangulated subcategory in $D^b(\mathbb{P}^2)$ equivalent to $D^b(S)$ and then from Lemma 3.1 it follows that $C_{\text{Id}}(\mathbb{P}^2) = \emptyset$. Due to the fact that $D^b(\mathbb{P}^2)$ is generated by an exceptional triple we have $K_0(D^b(\mathbb{P}^2)) \cong \mathbb{Z}^3$ and hence:

\[ (23) \quad \text{each subgroup of } K_0(D^b(\mathbb{P}^2)) \cong \mathbb{Z}^3 \text{ is free of rank at most } 3. \]

If there is a full triangulated subcategory $B \subset D^b(\mathbb{P}^2)$ which is equivalent to $D^b(S)$ then there is a SOD $\langle B^{-1} , B \rangle$ of $D^b(\mathbb{P}^2)$ (see [3, page 3]) and then we would have that $K_0(B) \cong K_0(D^b(S))$ is a subgroup of $K_0(D^b(\mathbb{P}^2))$. Therefore from (23) it follows that $K_0(D^b(S))$ is free of finite rank.

\[ \text{Recall that a Markov number } x \text{ is a number } x \in \mathbb{N}_{\geq 1} \text{ such that there exist integers } y,z \text{ with } x^2 + y^2 + z^2 = 3xyz. \]
However the Grothendieck group of a smooth projective curve $S$ is isomorphic to $\text{Pic}(S) \oplus \mathbb{Z}$ (see [20, Remark on page 34]) and $\text{Pic}(S)$ contains a subgroup, $\text{Pic}_0(S)$, isomorphic to the Jacobian variety of the curve $S$ (see e.g. [22, p. 168]) and for positive genus this is not a group of finite rank (it is even uncountable).

Finally we discuss cases of projective threefolds for which there are smooth curves $S$, such that $C_{D^b(S)}(D^b(X)) \neq \emptyset$.

**Conjecture 6.2.** From [1, Corollary 3.9, Remarks 3.8, 3.12] it follows that for a threefold $X$ satisfying certain properties, in particular its intermediate Jacobian splits in Jacobians of curves $J(X) = \bigoplus_{i=1}^{N} J(S_i)$, and for a smooth projective curve $S$ of positive genus there exists a fully faithful functor $D^b(S) \rightarrow D^b(X)$ iff $S \cong S_i$ for some $i \in \{1,\ldots,N\}$. Therefore for such threefold $X$ we have $C_{D^b(S)}(D^b(X)) \neq \emptyset$ iff $S \cong S_i$ for some $i \in \{1,\ldots,N\}$. Examples of $X$ for which this holds are (see [1, Remark 3.12]):

(a) Smooth quadric, or a $\mathbb{P}^1$-bundle over a rational surface, or a $\mathbb{P}^2$-bundle over $\mathbb{P}^1$, or a $V_5$, or a $V_2$ Fano threefold.

(b) $X$ is the complete intersection of two quadrics or a Fano threefold of type $V_{18}$, and $J(\Gamma) \cong J(X)$ with $\Gamma$ hyperelliptic.

(c) Rational conic bundle $X \rightarrow S$ over a minimal surface.

(d) Del Pezzo fibrations: $X \rightarrow \mathbb{P}^1$ is a quadric fibration with at most simple degenerations, in which case the hyperelliptic curve $\Gamma \rightarrow \mathbb{P}^1$ ramified along the degeneration appears naturally as the orthogonal complement of an exceptional sequence of $D^b(X)$. $X \rightarrow \mathbb{P}^1$ is a rational Del Pezzo fibration of degree four.

We conjecture that $\left| C_{D^b(S)}^{\text{Aut}(D^b(X))}(D^b(X)) \right| < \infty$ for such $X$ and any $i = 1,\ldots,N$.
