Abstract. The recently developed Wigner functional theory is used to formulate an evolution equation for arbitrary multi-photon states, propagating through a turbulent atmosphere under arbitrary conditions. The resulting evolution equation, which is obtained from an infinitesimal propagation approach, is in the form of a Fokker-Planck equation for the Wigner functional of the state and therefore incorporates functional derivatives. We briefly consider possible ways to find solutions for this equation.

Keywords: Free-space propagation, scintillation, multi-photon state, Wigner functional, Fokker-Planck equation

1. Introduction

The effect of a turbulent atmosphere on a photonic quantum state during propagation plays an important role in any free-space quantum information system (FS-QIS), such as free-space quantum communication [1, 2], quantum teleportation over free-space [3, 4, 5], and quantum protocols [6] for free-space time-transfer [7]. The random phase modulations induced by the fluctuating refractive index distort the spatial characteristics of the state, which in turn affects the photon-number distribution of the state.

Current implementations of such FS-QISs focus on either the spatiotemporal degrees of freedom of a few discrete photons [8, 9, 10, 11, 12, 13, 14, 15, 16], or the particle-number degrees of freedom (so-called continuous variables) for a few discrete spatial modes [17, 18, 19, 20, 21, 22, 23]. The implementations that are based on the spatial degrees of freedom often use orbital angular momentum (OAM) modes to encode the information [24, 25, 26, 27]. The polarization degree of freedom has been incorporated in both trends [24, 28, 29].

The natural culmination of these endeavors would be an approach that incorporates both the spatiotemporal degrees of freedom and the particle-number degrees of freedom to their full extent. For such an implementation, it would be necessary to understand the evolution during propagation through a turbulent atmosphere of a photonic state that
is arbitrary in terms of both its spatiotemporal degrees of freedom and particle-number degrees of freedom.

Such an analysis needs a special formalism in which neither the spatiotemporal degrees of freedom, nor the particle-number degrees of freedom, are treated as discrete variables — a few discrete photons or a few discrete modes. While the multi-photon nature of the states is represented by the particle-number degrees of freedom, the turbulent medium affects the spatial degrees of freedom of the state, scattering any input mode into an infinite dimensional modal space. This modal scattering process happens continuously, resulting in optical power being scattered back and forth among an infinite number of modes. A proper analysis of the evolution of multi-photon states, propagating through a turbulent atmosphere, therefore requires a formalism that incorporates both the particle-number degrees of freedom and the spatiotemporal degrees of freedom as continuous degrees of freedom.

Such a special formalism has recently been developed in the form of a Wigner functional formalism [30]. It is based on the spatiotemporal quadrature bases that are eigenstates of the momentum dependent quadrature operators [31]. This formalism is an extension of the Moyal formalism for quantum mechanics [32, 33, 34]. The Wigner functionals are defined in a phase space that represents a Hilbert space for all possible states in quantum optics. The operations are represented by a functional version of the star-products of the Moyal formalism.

The effect of turbulence on photonic quantum states has been studied extensively, but, as with the implementations, these studies invariably only focused on one of the two sets of continuous degrees of freedom. Those studies that focus on the spatial degrees of freedom [35, 36, 37, 38, 39, 40, 41], are mostly based on the single-phase screen approximation [37], which assumes weak scintillation [38]. However, we have also considered a multi-phase screen approach (based on infinitesimal propagation) to derive an evolution equation for the state [39, 40, 41, 42], which can address strong scintillation conditions [43]. Since the scintillation process directly affects the spatial degrees of freedom, the studies that focus on the particle-number degrees of freedom need a method to represent the affect of turbulence on the spatial degrees of freedom. They get around this problem by modeling the effect of turbulence simply as a loss mechanism, ignoring any other role that the spatial degrees of freedom may play in the process [44, 45].

In this paper, we’ll use the Wigner functional formalism for an infinitesimal propagation approach to derive an evolution equation for the Wigner functional of an arbitrary photonic state. The result is a functional differential equation in the form of a Fokker-Planck equation, which we call the infinitesimal propagation functional equation (IPFE). This is the main result of the paper.

The IPFE is difficult to solve. We discuss a few approaches for finding solutions. One of these approaches only provide a trivial solution, the vacuum state. An interesting observation emerges from considering the characteristic functional of the solution, namely that it obeys an identical functional differential equation as the Wigner functional
solution.

2. Infinitesimal propagation

2.1. Unitary evolution

Under general scintillation conditions, a photonic quantum state encounters two effects while propagating through the atmosphere. One is the free-space propagation process (without the effect of turbulence). The other is a continuous phase modulation caused by fluctuations in the refractive index of the medium. While the latter involves a modulation in the position domain, the former represents a modulation in the Fourier domain. The full dynamics, which incorporates both these effects, is captured in the classical context, by the equation of motion for paraxial propagation through a turbulent medium

$$\nabla^2_T g(x, z) - i2k\partial_z g(x, z) + 2k^2\tilde{n}(x, z)g(x, z) = 0.$$  \hspace{1cm} (1)

Here $g(x, z)$ is the classical scalar electromagnetic field, $k = 2\pi/\lambda$ is the wavenumber and $\tilde{n}(x, z)$ is the fluctuation in the refractive index of the atmosphere. The refractive index of the atmosphere can thus be represented as $n = 1 + \tilde{n}$. In the transverse Fourier domain, the equation becomes

$$\partial_z G(a, z) = \frac{i2\pi^2}{k}|a|^2G(a, z) - i k \int N(a - a', z)G(a', z) \, d^2a',$$  \hspace{1cm} (2)

where $a$ is the two-dimensional transverse spatial frequency vector, $G(a, z)$ is the transverse angular spectrum, which is also a function of the propagation distance $z$, and $N(a, z)$ is the transverse Fourier transform of the refractive index fluctuation. Moreover, $N^*(a, z) = N(-a, z)$, because the refractive index fluctuation is a real-valued function. Unless the field represented by the photonic state is strong enough to induce a nonlinear interaction with the atmosphere, the classical description of the propagation process, as given in (1), suffices to provide the basis for the development of the evolution of photonic states propagating through the atmosphere.

The approach that we’ll follow is to derive a dynamical equation from an infinitesimal propagation of the state, as proposed in [39, 41]. If $\hat{U}(z)$ represents that unitary evolution operator for the propagation of a state over a distance $z$ through the atmosphere and $\hat{\rho}$ is the density operator for the input state, then the output state is given by $\hat{\rho}(z) = \hat{U}(z)\hat{\rho}\hat{U}^\dagger(z)$. For an infinitesimal propagation, one expects to find that $\hat{U}(dz) = 1 + idz\hat{P}_\Delta$, where $\hat{P}_\Delta$ represents the infinitesimal propagation. It thus leads to an evolution equation of the form $\partial_z\hat{\rho}(z) = i[\hat{P}_\Delta, \hat{\rho}]$. The infinitesimal propagation operator $\hat{P}_\Delta$ assumes full knowledge of the medium that causes the scintillation process. Since we normally only know the statistical properties of the medium, we’ll eventually have to apply an ensemble averaging. However, we start by deriving an expression for the infinitesimal propagation operator. For this purpose we can use the classical equations, provided above.
To define quantum operators for the scintillation process, it is convenient to combine the two terms in (2), so that

$$\partial_z G(a, z) = i \int M(a, a', z) G(a', z) \, d^2 a' = i M(z) \circ G(z),$$

where the kernel is given by

$$M(a, a', z) \equiv \pi \lambda |a|^2 \delta(a - a') - k N(a - a', z),$$

and where we adopt the notation introduced in [30] to write the integral contraction as a binary operation denoted by $\circ$. Note that the kernel is Hermitian $M^*(a, a', z) = M(a', a, z)$. Represented as an infinitesimal propagation, the equation in (3) becomes

$$G(a, z + dz) = \int [\delta(a - a') + idz M(a, a', z)] G(a', z) \, d^2 a'.$$

The transverse angular spectrum is interpreted as a Fourier domain wave function $G(a, z) = \langle a | G(z) \rangle$. It allows us to define the single-photon states as

$$|G(z)\rangle = \int |a\rangle G(a, z) \, d^2 a.$$

The infinitesimal propagation for a single-photon state is $|G(z + dz)\rangle = \hat{P}_1(z, dz) |G(z)\rangle$, where $\hat{P}_1(z, dz) \equiv 1 + idz \hat{M}(z)$, with

$$1 \equiv \int |a\rangle \langle a| \, d^2 a,$$

being the projection operator for single-photon states, and

$$\hat{M}(z) \equiv \int |a\rangle M(a, a', z) \langle a'| \, d^2 a \, d^2 a',$$

representing the infinitesimal propagation process for single-photon states, which also incorporates a projection operation for single-photon states. Since $\hat{M}(z)$ is Hermitian, it follows that $\hat{P}_1^\dagger(z, dz) = 1 - idz \hat{M}(z)$.

While $\hat{P}_1$ implies a projection operation for single-photon states, the equivalent for $n$ photons, expressed as $\hat{P}_n \equiv \hat{P}_1^\otimes n$, would involve a projection operation for $n$-photon states. For general multi-photon states, one needs to sum over all such operators. Therefore, the unitary operator is given by

$$\hat{U}(z, dz) = \sum_n \frac{1}{n!} \left[ \hat{P}_1(z, dz) \right]^\otimes n = \exp_{\otimes} [\hat{P}_1(z, dz)]$$

$$= 1 + idz \hat{M}(z) \otimes 1 + O\{dz^2\},$$

where

$$1 = \sum_n \frac{1}{n!} = \exp_{\otimes} (1)$$

is the identity operator for the complete space, and $\exp_{\otimes}(\cdot)$ implies that all products in its expansion are tensor products and the first term in the expansion contains only the vacuum state $|\text{vac}\rangle \langle \text{vac}|$. The last line in (9) follows under infinitesimal propagation conditions due to the smallness of $dz$. The sub-leading order term serves as the
scintillation operator, $\hat{M}(z) \equiv \hat{M}(z) \otimes 1$. Although it does not involve any projection operations, only one photon is affected by the scintillation process.

For an arbitrary pure state, the infinitesimal propagation gives

$$|\psi(z + dz)⟩ = \hat{U}(z, dz) |\psi(z)⟩ = |\psi(z)⟩ + idz \hat{M}(z) |\psi(z)⟩.$$  \hspace{1cm} (11)

In the limit $dz \to 0$, it leads to the dynamical equations

$$\partial_z |\psi(z)⟩ = i \hat{M}(z) |\psi(z)⟩,$$
$$\partial_z ⟨\psi(z)| = -i ⟨\psi(z)| \hat{M}(z).$$  \hspace{1cm} (12)

An arbitrary (pure or mixed) state, expressed as a density operator $\hat{ρ}(z)$, would thus obey the dynamical equation

$$\partial_z \hat{ρ}(z) = i \left[ \hat{M}(z), \hat{ρ}(z) \right].$$  \hspace{1cm} (13)

We can now identify the scintillation operator $\hat{M}(z)$ with the infinitesimal propagation operator $\hat{P}_\Delta$, mentioned above. As such, it describes the unitary evolution of the state propagating through the turbulent atmosphere. However, the detail of the medium is only known in a statistical sense. To have a predictive ability, one needs to consider the ensemble average of the process. For that purpose, it is more convenient to consider the state in terms of its Wigner functional.

2.2. Wigner functional approach

To make the expression in (13) more analytically manageable, we define a generating function for the scintillation operator

$$\hat{R}(z; η) = \exp \left[ \int |a⟩ T(a, a', z; η) ⟨a'| \, da \, da' \right],$$  \hspace{1cm} (14)

where $η$ is an auxiliary variable, and

$$T(a, a', z; η) \equiv \exp \left( i π η |a|^2 \right) δ(a - a') - i η k N(a - a', z).$$  \hspace{1cm} (15)

The auxiliary variable $η$ carries the dimension of a distance and it effectively takes over the role of $dz$. The scintillation operator is recovered by

$$\partial_η \hat{R}(z; η) \bigg|_{η=0} = i \hat{M}(z).$$  \hspace{1cm} (16)

The dynamical equation can then be expressed as

$$\partial_z \hat{ρ}(z) = \partial_η \left[ \hat{R}(z; η) \hat{ρ}(z) \hat{R}^\dagger(z; η) \right]_{η=0}.$$  \hspace{1cm} (17)

The Wigner functional representation of the dynamical equation in (13) or (17) requires a Wigner functional for the generating function of the scintillation operator $\hat{R}(z; η)$, which represents a linear operation of the form given in (14) and (15). The Wigner functional for such a linear process is given by

$$W_\hat{R}[α] = \frac{1}{\det \{1 + T\}} \exp \left[ -2α^* \circ (1 - T) \circ (1 + T)^{-1} \circ α \right],$$  \hspace{1cm} (18)
under the assumption that $1 + T = \delta(a - a') + T(a, a', z)$ is invertible. The derivation of (18) is provided in Appendix A.

Note that $(1 + T)|_{\eta=0} = 2\delta(a - a')$ and $(1 - T)|_{\eta=0} = 0$. It implies that $(1 + T)^{-1}|_{\eta=0} = \delta(a - a')/2$. Therefore, if we define $B \equiv 2(1 - T) \circ (1 + T)^{-1}$, then, by applying derivatives with respect to $\eta$ and setting $\eta = 0$, we get $\partial_\eta B|_{\eta=0} = -iM(a, a', z)$ and $\partial_\eta B^*|_{\eta=0} = iM(a', a, z)$, because $M$ is Hermitian.

In terms of Wigner functionals, the dynamical equation in (17) is represented by:

$$\partial_z W_\rho(z)[\alpha] = \partial_\eta W_{\mathcal{R}^\rho \mathcal{R}^\dagger}[\alpha]|_{\eta=0} = \partial_\eta \int W_\mathcal{R} \left[ \frac{\alpha_a}{2} + \frac{\alpha_b}{2} + \frac{\alpha_c}{2} \right] W_\rho[\alpha_a] W_{\mathcal{R}^\dagger} \left[ \frac{\alpha_a}{2} - \frac{\alpha_b}{2} + \frac{\alpha_c}{2} \right] \times \exp\left[ (\alpha^* - \alpha^*_a) \circ \alpha_b - \alpha^*_b \circ (\alpha - \alpha_a) \right] D[\alpha_a, \alpha_b]|_{\eta=0}$$

$$= \partial_\eta \int \exp\left[ -\frac{1}{4} (\alpha^*_a + \alpha^*_b + \alpha^*_c) \circ B \circ (\alpha_a + \alpha + \alpha_b) \right] \times W_\rho[\alpha_a] \exp\left[ -\frac{1}{4} (\alpha_a + \alpha - \alpha_b) \circ B^* \circ (\alpha^*_a + \alpha^* - \alpha^*_b) \right] \times \exp\left[ (\alpha^* - \alpha^*_a) \circ \alpha_b - \alpha^*_c \circ (\alpha - \alpha_a) \right] D[\alpha_a, \alpha_b]|_{\eta=0}.$$  

Evaluating the derivative with respect to $\eta$ and setting $\eta = 0$, we get

$$\partial_z W_\rho(z)[\alpha] = \int W_\rho[\alpha_a] \left[ \frac{1}{2} (\alpha^*_a + \alpha^*) \circ M \circ \alpha_b + \frac{1}{2} \alpha^*_b \circ M \circ (\alpha_a + \alpha) \right] \times \exp\left[ \alpha^*_b \circ (\alpha_a - \alpha) - (\alpha^*_a - \alpha^*) \circ \alpha_b \right] D[\alpha_a, \alpha_b].$$  

Again, we use a generating function to express the integrand in terms of an exponential function

$$\partial_z W_\rho(z)[\alpha] = \partial_\xi \int W_\rho[\alpha_a] \exp\left[ \alpha^* \circ \left( 1 + i\xi M \right) \circ \alpha_b - \alpha^*_a \circ \left( 1 - i\xi M \right) \circ \alpha_b \right] \alpha^*_b \circ \left( 1 + i\xi M \right) \circ \alpha_a - \alpha^*_b \circ \left( 1 - i\xi M \right) \circ \alpha \right] D[\alpha_a, \alpha_b]|_{\xi=0},$$  

where $\xi$ is the new auxiliary variable. The argument of the exponential function is linear in $\alpha_b$ and $\alpha^*_b$. Therefore, the functional integration over $\alpha_b$ converts the exponential function into a Dirac delta functional, which would replace $\alpha_a$ in the argument of the state in terms of $\alpha$ and $M$. To perform the functional integration over $\alpha_b$, we first perform a change of integration variables

$$\alpha_b \rightarrow \left( 1 - \frac{i\xi}{2} M \right)^{-1} \circ \alpha_c,$$

$$\alpha^*_b \rightarrow \alpha^*_c \circ \left( 1 + \frac{i\xi}{2} M \right)^{-1}.$$  

\[\dagger\] The Wigner functional for the product of operators is obtained by expressing the operators via the Weyl transformation in terms of their respective Wigner functionals. The result leads to the star-product of the Moyal formalism.  

\[\ddagger\]
The functional integrations over \( \alpha_b \) and \( \alpha_a \) then leads to

\[
\partial_z W_\rho(z)[\alpha] = \partial_\xi \left[ \frac{W_\rho \left[ (2 + i\xi M)^{-1} \circ (2 - i\xi M) \circ \alpha \right]}{\sqrt{\det \{1 + \frac{i}{4}\xi^2 M^2\}}} \right]_{\xi=0}.
\] (23)

Now, we evaluate the derivative with respect to \( \xi \) and set \( \xi = 0 \). We note that

\[
\partial_\xi \left( \det \left\{1 + \frac{1}{4}\xi^2 M^2\right\} \right)^{-1/2} \bigg|_{\xi=0} = 0.
\] (24)

Hence,

\[
\partial_z W_\rho(z) = i\alpha^* \circ M \circ \frac{\delta W_\rho}{\delta \alpha^*} - i\alpha \frac{\delta W_\rho}{\delta \alpha} \circ M \circ \alpha,
\] (25)

which represents the first-order unitary dynamics for the multi-photon state propagating through a turbulent atmosphere.

In this form, the equation in (25) would not provide the required dynamics when we apply ensemble averaging. The reason is that the refractive index fluctuation has a zero mean, which implies that

\[
\langle M \rangle = \pi \lambda |a|^2 \delta(a - a').
\] (26)

As a result, an ensemble averaging applied to (25) gives

\[
\partial_z W_\rho(z) = i\pi \lambda \alpha^* \circ |a|^2 1 \circ \frac{\delta W_\rho}{\delta \alpha^*} - i\pi \lambda \frac{\delta W_\rho}{\delta \alpha} \circ |a|^2 1 \circ \alpha,
\] (27)

where \( |a|^2 1 \equiv |a|^2 \delta(a - a') \). The resulting equation in (27) represents free-space propagation without turbulence.

2.3. Second order

To see the effect of the turbulence after an ensemble averaging, one needs to go to second-order in the scintillation operator. For this purpose, (25) is first integrated over \( z \):

\[
W_\rho(z) = W_\rho(z_0) + i \int_{z_0}^{z} \alpha^* \circ M(z_1) \circ \frac{\delta W_\rho(z_1)}{\delta \alpha^*} - \frac{\delta W_\rho(z_1)}{\delta \alpha} \circ M(z_1) \circ \alpha \; dz_1.
\] (28)

Then we substitute the equation back into itself (making the Fourier domain integrals explicit) to obtain the second-order equation

\[
W_\rho(z) = W_\rho(z_0) - i \int_{z_0}^{z} \int_{a_1}^{a_2} \frac{\delta W_\rho(z_0)}{\delta \alpha(a_1)} M(a_1, a_2, z_1) \alpha(a_2) \; d^2 a_1 \; d^2 a_2 \; dz_1
\]
\[
+ i \int_{z_0}^{z} \int_{a_1}^{a_2} \alpha^*(a_1) M(a_1, a_2, z_1) \frac{\delta W_\rho(z_0)}{\delta \alpha^*(a_2)} \; d^2 a_1 \; d^2 a_2 \; dz_1
\]
\[
- \int_{z_0}^{z} \int_{a_1}^{a_2} \int_{a_3}^{a_4} \int_{a_5}^{a_6} \frac{\delta W_\rho(z_0)}{\delta \alpha(a_3)} M(a_3, a_4, z_2) \delta(a_4 - a_1) M(a_1, a_2, z_1) \alpha(a_2)
\]
\[
+ \alpha^*(a_1) M(a_1, a_2, z_1) \delta(a_3 - a_2) M(a_3, a_4, z_2) \frac{\delta W_\rho(z_0)}{\delta \alpha^*(a_4)}
\]
\[
+ \frac{\delta^2 W_\rho(z_0)}{\delta \alpha(a_1) \delta \alpha(a_3)} M(a_3, a_4, z_2) \alpha(a_4) M(a_1, a_2, z_1) \alpha(a_2) \\
- \alpha^*(a_3) M(a_3, a_4, z_2) \frac{\delta^2 W_\rho(z_0)}{\delta \alpha(a_1) \delta \alpha^*(a_4)} M(a_1, a_2, z_1) \alpha(a_2) \\
- \alpha^*(a_1) M(a_1, a_2, z_1) \frac{\delta^2 W_\rho(z_0)}{\delta \alpha^*(a_2) \delta \alpha(a_3)} M(a_3, a_4, z_2) \alpha(a_4) \\
+ \alpha^*(a_1) M(a_1, a_2, z_1) \alpha^*(a_3) M(a_3, a_4, z_2) \frac{\delta^2 W_\rho(z_0)}{\delta \alpha^*(a_2) \delta \alpha^*(a_4)} \\
\times d^2 a_1 d^2 a_2 d^2 a_3 d^2 a_4 dz_2 dz_1,
\]

(29)

In effect, we performed the back-substitution twice, but only kept up to second-order terms, because the third-order terms are at least second-order in \(dz\). As a result, the \(z\)-dependences of all Wigner functionals are given as \(z_0\).

2.4. Ensemble averaging

Now, we can perform the ensemble averaging process. The zeroth-order terms are unaffected. The first-order terms are given by [26]. For the second-order terms, the ensemble averaging involves

\[
\int z_{0}^{z_1} \int_{z_0}^{z_1} \langle M(a_1, a_2, z_1) M(a_3, a_4, z_2) \rangle \ dz_2 \ dz_1 \\
= \int z_{0}^{z_1} \int_{z_0}^{z_1} \pi^2 \lambda^2 |a_1|^2 |a_3|^2 \delta(a_1 - a_2) \delta(a_3 - a_4) \\
+ k^2 \langle N(a_1 - a_2, z_1) N(a_3 - a_1, z_2) \rangle \ dz_2 \ dz_1,
\]

(30)

where we substituted in [4] and removed terms that are first order in \(N\). One can model the stochastic nature of the refractive index fluctuation by

\[
\tilde{n}(x, z') = \int \exp[-i2\pi(a \cdot x + cz)] \chi(a, c) \left[ \frac{\Phi_n(a, c)}{\Delta^3} \right]^{1/2} d^2a dc,
\]

(31)

where \(c\) is the longitudinal spatial frequency component, \(\Delta\) is a dimension parameter on the frequency domain and \(\chi(a, c)\) is a three-dimensional, normally distributed, complex-valued random function. Since \(\tilde{n}\) is a real-valued function, it implies that \(\chi^*(a, c) = \chi(-a, -c)\). Moreover, it is assume that this random function is delta-correlated,

\[
\langle \chi(a_1, c_1) \chi^*(a_2, c_2) \rangle = \Delta^2 \delta(a_1 - a_2) \delta(c_1 - c_2).
\]

(32)

The Kolmogorov power spectral density for the refractive index fluctuations is given by \(\Phi_n = 0.033(2\pi)^3 C_n^2 |k|^{-11/3}\), where \(C_n^2\) is the refractive index structure constant and \(k\) is a three-dimensional wave vector — the Fourier domain variable for the refractive index of the medium (\(k = \{2\pi a, 2\pi c\}\)). The extra power of \((2\pi)^3\) comes from a different convention for the definition of the Fourier transform [40].

Next, we evaluate

\[
\langle N(a, z_1) N(a', z_2) \rangle = \delta(a + a') \int \Phi_n(a, c_1) \exp[-i2\pi c_1(z_1 - z_2)] \ dc_1,
\]

(33)
Multi-photon states in turbulence

where we used (31), (32) and the fact that \( \Phi_n(a, c) \) is symmetric in all its arguments. Under the Markov approximation, one can replace \( \Phi_n(a, c_1) \rightarrow \Phi_n(a, 0) \), so that

\[
\langle N(a, z_1)N(a', z_2) \rangle = \delta(a + a')\delta(z_1 - z_2)\Phi_n(a, 0).
\]

The expression in (30) then becomes

\[
\int_{z_0}^{z_1} \int_{z_0}^{z_1} \langle M(a_1, a_2, z_1)M(a_3, a_4, z_2) \rangle \ dz_2 \ dz_1 = dzk^2\delta(a_1 - a_2 + a_3 - a_4)\Phi_n(a_1 - a_2, 0).
\]

where \( dz = z - z_0 \) and where we dropped a term that is second-order in \( dz \).

2.5. The infinitesimal propagation functional equation

Now, we can substitute (26) and (35) into (29) and take the limit \( dz \rightarrow 0 \). The resulting functional differential equation reads

\[
\partial_z W^\hat{\rho} = i\pi \lambda \int |a|^2 \left[ \alpha^*(a) \frac{\delta W^\hat{\rho}}{\delta \alpha(a)} - \alpha(a) \frac{\delta W^\hat{\rho}}{\delta \alpha^*(a)} \right] \ d^2a
\]

\[
- k^2 \Lambda \int \left[ \alpha(a) \frac{\delta W^\hat{\rho}}{\delta \alpha(a)} + \alpha^*(a) \frac{\delta W^\hat{\rho}}{\delta \alpha^*(a)} \right] \ d^2a
\]

\[
- k^2 \int \left[ \alpha(a_1 - a_0)\alpha(a_2 + a_0)\frac{\delta^2 W^\hat{\rho}}{\delta \alpha(a_1)\delta \alpha(a_2)}
\]

\[
+ \alpha^*(a_1 - a_0)\alpha^*(a_2 + a_0)\frac{\delta^2 W^\hat{\rho}}{\delta \alpha^*(a_1)\delta \alpha^*(a_2)}
\]

\[
- 2\alpha^*(a_2 - a_0)\alpha(a_1 - a_0)\frac{\delta^2 W^\hat{\rho}}{\delta \alpha(a_1)\delta \alpha^*(a_2)} \right] \times \Phi_n(a_0, 0) \ d^2a_0 \ d^2a_1 \ d^2a_2,
\]

where

\[
\Lambda \equiv \int \Phi_n(a, 0) \ d^2a.
\]

The equation in (36), which is our main result, represents the infinitesimal propagation functional equation (IPFE) for the evolution of an arbitrary multi-photon state, propagating through atmospheric turbulence under arbitrary conditions. It has the form of a Fokker-Planck equation for the Wigner functional of the state. The first term on the right is a drift term for free-space propagation, the second term is a drift term for the scintillation and the third is the diffusion term for the scintillation.

3. Solving the IPFE

Apart from some trivial solutions, such as the vacuum state, no general solution has yet been found for the IPFE. Here we make a few observations and suggest approaches that can be used to find solutions for the IPFE.
3.1. Free-space solution

In the case where there is no turbulence, one can use the first-order free-space equation given in (27). A solution for the free-space equation can be obtained by assuming a general form

\[ W_{\bar{\rho},fs}(z) = \exp[-\alpha^* \circ A(z) \circ \alpha - \alpha \circ B(z) \circ \alpha - \alpha^* \circ C(z) \circ \alpha^* + \alpha^* \circ \beta(z) + \eta^*(z) \circ \alpha], \]

(38)

where we ignored a possible normalization factor, \( A(a,a',z) \), \( B(a,a',z) \), and \( C(a,a',z) \) are unknown kernel (or covariance) functions and \( \beta(a,z) \) and \( \eta(a,z) \) are unknown spectral functions. Substituting it into (27), and separating the resulting equation according to the different combinations of contraction with \( \alpha \) and \( \alpha^* \), we obtain five separate differential equations for the three kernels and the complex functions

\[
\begin{align*}
\partial_z A(a_1,a_2,z) &= i\pi \lambda (|a_1|^2 - |a_2|^2) A(a_1,a_2,z) \\
\partial_z B(a_1,a_2,z) &= -i\pi \lambda (|a_1|^2 + |a_2|^2) B(a_1,a_2,z) \\
\partial_z C(a_1,a_2,z) &= i\pi \lambda (|a_1|^2 + |a_2|^2) C(a_1,a_2,z) \\
\partial_z \beta(a,z) &= i\pi \lambda |a|^2 \beta(a,z) \\
\partial_z \eta^*(a,z) &= -i\pi \lambda |a|^2 \eta^*(a,z).
\end{align*}
\]

Their solutions are

\[
\begin{align*}
A(a_1,a_2,z) &= A_0(a_1,a_2) \exp \left[ i\pi \lambda z (|a_1|^2 - |a_2|^2) \right] \\
B(a_1,a_2,z) &= B_0(a_1,a_2) \exp \left[ -i\pi \lambda z (|a_1|^2 + |a_2|^2) \right] \\
C(a_1,a_2,z) &= C_0(a_1,a_2) \exp \left[ i\pi \lambda z (|a_1|^2 + |a_2|^2) \right] \\
\beta(a,z) &= \beta_0(a) \exp \left( i\pi \lambda z |a|^2 \right) \\
\eta^*(a,z) &= \eta_0^*(a) \exp \left( -i\pi \lambda z |a|^2 \right),
\end{align*}
\]

(40)

where \( A_0(a_1,a_2) \), \( B_0(a_1,a_2) \), and \( C_0(a_1,a_2) \) are the initial kernels (or covariance functions) and \( \beta_0(a) \), and \( \eta_0^*(a) \) are the initial spectral functions. Hence, the free-space solution is

\[
W_{\bar{\rho},fs}(z) = \exp \left(-\alpha^* \circ 1P \circ A_0 \circ 1P^* \circ \alpha - \alpha \circ 1P^* \circ B_0 \circ 1P^* \circ \alpha - \alpha^* \circ 1P \circ C_0 \circ 1P \circ \alpha^* + \alpha^* \circ 1P \circ \beta_0 + \eta_0^* \circ 1P^* \circ \alpha \right),
\]

(41)

where

\[
1P = \exp \left( i\pi \lambda z |a|^2 \right) \delta(a - a').
\]

(42)

Another way to view it, is that free-space propagation implies a transformation of the \( \alpha \)’s

\[
\alpha \rightarrow \exp \left(-i\pi \lambda z |a|^2 \right) \alpha \\
\alpha^* \rightarrow \exp \left(i\pi \lambda z |a|^2 \right) \alpha^*.
\]

(43)

As such, the result corresponds to simple free-space propagation in a way that one would expect.
3.2. Gaussian solutions

Including the effect of the turbulent medium, one may consider solutions for the IPFE that have the form of a Gaussian Wigner functional. Unfortunately, we find only trivial solutions.

Consider, for instance the simplest case where

\[ W_\beta(z) = \exp \left[ -\alpha^* \circ A(z) \circ \alpha \right], \]  

with \( A(a, a', z) \) being an unknown \( z \)-dependent kernel function. When we substitute this ansatz into (36), evaluate all the functional derivatives and the \( z \)-derivative, and remove a factor of the original Wigner functional \( W_\beta(z) \) on both sides, we obtain

\[
-\alpha^* \circ \partial_z A(z) \circ \alpha = -i \pi \lambda \int \left( |a|^2 - |a'|^2 \right) \alpha^*(a)(a, a', z)\alpha(a') \ d^2a \ d^2a' \\
+ 2k^2 A \int \alpha^*(a)A(a, a', z)\alpha(a') \ d^2a \ d^2a' \\
- 2k^2 \int \alpha^*(a_2 - a_0)A(a_2, a_1, z)\alpha(a_1 - a_0)\Phi_n(a_0, 0) \ d^2a_0 \ d^2a_1 \ d^2a_2 \\
+ k^2 \int \left[ \alpha^*(a_3)A(a_3, a_1, z)\alpha(a_1 - a_0)\alpha^*(a_4)A(a_4, a_2, z)\alpha(a_2 + a_0) \\
+ \alpha^*(a_1 - a_0)A(a_1, a_3, z)\alpha(a_3)\alpha^*(a_2 + a_0)A(a_2, a_4, z)\alpha(a_4) \\
- 2\alpha^*(a_2 - a_0)A(a_2, a_4, z)\alpha(a_4)\alpha^*(a_3)A(a_3, a_1, z)\alpha(a_1 - a_0) \right] \\
\times \Phi_n(a_0, 0) \ d^2a_0 \ d^2a_1 \ d^2a_2 \ d^2a_3 \ d^2a_4. \]  

We see that the equation does not contain only second-order terms (with single factors of both \( \alpha \) and \( \alpha^* \)), but also fourth-order terms (with two factors of \( \alpha \) and \( \alpha^* \) each). As a result, the equation separates into two equations that must be satisfied separately. The second-order equation is

\[
\partial_z A(a, a', z) = i \pi \lambda \left( |a|^2 - |a'|^2 \right) A(a, a', z) - 2k^2 A A(a, a', z) \\
+ 2k^2 \int A(a + a_0, a' + a_0, z) \Phi_n(a_0, 0) \ d^2a_0, \]  

and the fourth-order equation is

\[
0 = \int \left[ A(a_1, a_2 + a_0, z)A(a_3, a_4 - a_0, z) \\
+ A(a_1 + a_0, a_2, z)A(a_3 - a_0, a_4, z) \\
- 2A(a_1 + a_0, a_2, z)A(a_3, a_4 + a_0, z) \right] \\
\times \Phi_n(a_0, 0) \ d^2a_0 \ d^2a_1 \ d^2a_2 \ d^2a_3 \ d^2a_4, \]  

where we shifted the \( a_0 \) into the arguments of the kernels so that we can removing all the common factors and the identical contractions with the \( \alpha \)'s and \( \alpha^* \)'s. Expressing the kernels in terms of sums and differences of their arguments, we have

\[
0 = \int \left[ A'(a_1 + a_2 + a_0, a_1 - a_2 - a_0, z)A'(a_3 + a_4 - a_0, a_3 - a_4 + a_0, z) \\
+ A'(a_1 + a_2 + a_0, a_1 - a_2 + a_0, z)A'(a_3 + a_4 - a_0, a_3 - a_4 - a_0, z) \right]
\]
Multi-photon states in turbulence

\[-2A'(a_1 + a_2 + a_0, a_1 - a_2 + a_0, z)A'(a_3 + a_4 + a_0, a_3 - a_4 - a_0, z)]
\times \Phi_n(a_0, 0) \, d^2a_0.

(48)

It now follows that, if the kernel only depend on \(a_d\) (the difference in arguments), then the sign of \(a_0\) in the first term can be changed (since \(\Phi_n\) is symmetric) and all the terms would cancel. However, this would also affect the second-order equation, causing the terms associated with the scintillation to cancel, leaving only the free-space propagation effect. Hence, we end up with

\[\partial_z A(a - a', z) = i\pi \lambda (|a|^2 - |a'|^2) A(a - a', z),\]

(49)

The only solutions are those where \(A(a - a', z) \propto \delta(a - a')\), such as the vacuum state.

As a second attempt to solve (36), we introduce some shift terms

\[W_\beta(z) = \exp\left[-\alpha^* \circ A(z) \circ \alpha - \alpha^* \circ \beta(z) - \eta^*(z) \circ \alpha\right].\]

(50)

However, after substituting it into (27) and separating the result into separate equations according to the contactions with \(\alpha\) and \(\alpha^*\), one obtains differential equations for the two complex functions given by

\[\begin{align*}
\partial_z \beta(a, z) &= i\pi \lambda |a|^2 \beta(a, z) - 2k^2 \Lambda \beta(a, z) \\
\partial_z \eta^*(a, z) &= -i\pi \lambda |a|^2 \eta^*(a, z) - 2k^2 \Lambda \eta^*(a, z).
\end{align*}\]

(51)

Their solutions are

\[\begin{align*}
\beta(a, z) &= \exp(i\pi \lambda z |a|^2 - 2k^2 \Lambda z), \\
\eta^*(a, z) &= \exp(-i\pi \lambda z |a|^2 - 2k^2 \Lambda z).
\end{align*}\]

(52)

However, since \(\Lambda\) is a divergent distance, the result is that \(\beta(z) = \eta^*(z) = 0\) for \(z > 0\).

In addition, there are combinations of \(\alpha\)'s and \(\alpha^*\)'s produced on the right-hand side of the equation that are not represented by any term on the left-hand side. In all these cases, the requirement that \(\beta(z) = \eta^*(z) = 0\) is enforced. It thus leads back to the unshifted previous result.

Next, one can try to find a Gaussian solution for (36) that has an anisotropic form

\[W_\beta(z) = \exp\left[-\alpha^* \circ H_0(z) \circ \alpha - \alpha \circ H_1(z) \circ \alpha - \alpha^* \circ H_2(z) \circ \alpha^*\right],\]

(53)

where the \(H_n\)'s are the unknown kernels. The resulting equation separates into several different second-order equation and fourth-order equations. Two of the fourth-order equations are

\[\begin{align*}
0 &= \int H_1(a_1 + a_0, a_2, z)H_1(a_3 - a_0, a_4, z)\Phi_n(a_0, 0) \, d^2a_0 \\
0 &= \int H_2(a_1 + a_0, a_2, z)H_2(a_3 - a_0, a_4, z)\Phi_n(a_0, 0) \, d^2a_0.
\end{align*}\]

(54)

Since \(\Phi_n(a_0, 0)\) is symmetric in \(a_0\), the only nontrivial solutions would require that the remainder of the integrand be antisymmetric in \(a_0\). However, since one can arbitrarily relabel the remaining \(a\)'s one can show that the remainder of the integrand is also symmetric in \(a_0\). Therefore, the only solution for these equations seems to be the trivial solutions \(H_1 = H_2 = 0\). Again it leads us back to original solution.

In conclusion, it seems that the only solution for the IPFE that is in the form of a Gaussian Wigner functional, is the vacuum state.
3.3. Characteristic functional

One way to find a general solution for the infinitesimal propagation equation in (36), is to transform the Wigner functional to its corresponding characteristic functional. The hope is that the result would provide insight into the required form for the solution.

The Wigner functional is given in terms of the characteristic functional by

$$W[\alpha] = \int \exp(\alpha^* \circ \eta - \eta^* \circ \alpha) \chi[\eta] \, D[\eta],$$  \hspace{1cm} (55)

and the inverse process is given by

$$\chi[\eta] = \int W[\alpha] \exp(\eta^* \circ \alpha - \alpha^* \circ \eta) \, D[\alpha].$$  \hspace{1cm} (56)

First, we substitute (55) into (36), with $\eta \rightarrow \eta_0$, and then we apply the inverse process given in (56). The result has the form

$$\partial_z \chi[\eta] = \int \exp(\alpha^* \circ \eta_0 - \eta_0^* \circ \alpha + \eta^* \circ \alpha - \alpha^* \circ \eta) K[\alpha, \eta_0] \chi[\eta_0](z) \, D[\eta_0, \alpha],$$  \hspace{1cm} (57)

where

$$K[\alpha, \eta_0] = i\pi \lambda \int |a|^2 \left[ \alpha^*(a) \eta_0(a) + \eta_0^*(a) \alpha(a) \right] \, d^2a$$

$$- k^2 \Lambda \int \left[ \alpha^*(a) \eta_0(a) - \eta_0^*(a) \alpha(a) \right] \, d^2a$$

$$- k^2 \int \left[ \alpha(a_2) \alpha(a_1) \eta_0^*(a_1 + a_0) \eta_0(a_2 - a_0) + \alpha^*(a_2) \alpha^*(a_1) \eta_0(a_1 + a_0) \eta_0(a_2 - a_0) \right.$$

$$\left. + 2\alpha^*(a_1) \alpha^*(a_2) \eta_0(a_1 - a_0) \eta_0^*(a_2 - a_0) \right] \times \Phi_n(a_0, 0) \, d^2a_0 \, d^2a_1 \, d^2a_2.$$  \hspace{1cm} (58)

For the subsequent calculation, we construct $K[\alpha, \eta_0]$ with the aid of functional derivatives applied to a source functional of the form

$$S[\eta_0, \eta, \nu, \mu] = \int \exp \left( \alpha^* \circ \eta_0 - \eta_0^* \circ \alpha + \eta^* \circ \alpha - \alpha^* \circ \eta + \alpha^* \circ \nu - \nu^* \circ \alpha + \mu^* \circ \eta_0 - \eta_0^* \circ \mu \right) \, D[\alpha],$$  \hspace{1cm} (59)

where $\nu$ and $\mu$ are auxiliary functions. One can define a contraction operator that would produce $K[\alpha, \eta_0]$ from the source functional by replacing

$$\alpha \rightarrow - \frac{\delta}{\delta \nu^*}$$

$$\alpha^* \rightarrow \frac{\delta}{\delta \nu}$$

$$\eta_0 \rightarrow \frac{\delta}{\delta \mu^*}$$

$$\eta_0^* \rightarrow - \frac{\delta}{\delta \mu}.$$  \hspace{1cm} (60)
in (60). The result is a functional differential operator
\[ \mathcal{K} = i\pi \lambda \int |\mathbf{a}|^2 \left[ \frac{\delta}{\delta \nu(\mathbf{a})} \frac{\delta}{\delta \mu^*(\mathbf{a})} + \frac{\delta}{\delta \mu(\mathbf{a})} \frac{\delta}{\delta \nu^*(\mathbf{a})} \right] d^2 a \]
\[ - k^2 \Lambda \int \left[ \frac{\delta}{\delta \nu(\mathbf{a})} \frac{\delta}{\delta \mu^*(\mathbf{a})} - \frac{\delta}{\delta \mu(\mathbf{a})} \frac{\delta}{\delta \nu^*(\mathbf{a})} \right] d^2 a \]
\[ - k^2 \int \left[ \delta \mu(a_1 + a_0) \delta \mu(a_2 - a_0) \delta \nu^*(a_2) \right] \]
\[ + \frac{\delta \nu(a_1) \delta \mu^*(a_1 + a_0) \delta \mu(a_2 - a_0) \delta \nu^*(a_2)}{\delta \mu(a_1 + a_0) \delta \mu(a_2 - a_0) \delta \nu^*(a_2)} \]
\[ + 2 \frac{\delta \nu(a_1) \delta \mu^*(a_1 + a_0) \delta \mu(a_2 - a_0) \delta \nu^*(a_2)}{\delta \mu(a_1 + a_0) \delta \mu(a_2 - a_0) \delta \nu^*(a_2)} \]
\[ \times \Phi_n(a_0, 0) d^2 a_0 \ d^2 a_1 \ d^2 a_2. \] (61)

The equation for the characteristic function is then represented by
\[ \partial_\xi \chi[\eta] = \mathcal{K} \left\{ \int \mathcal{S}[\eta_0, \eta, \nu, \mu] \chi[\eta_0] \mathcal{D}[\eta_0] \right\} \bigg|_{\nu = \mu = 0}. \] (62)

The functional integration over \( \alpha \) in (59) produces a Dirac delta functional together with an exponential
\[ \mathcal{S}[\eta_0, \eta, \nu, \mu] = \delta[\eta_0 - \eta + \nu, \eta^*_0 - \eta^* + \nu^*] \exp(\mu^* \circ \eta_0 - \eta^*_0 \circ \mu). \] (63)

When it is substituted into (62), the functional integration over \( \eta_0 \) would cause the Dirac delta functional to replace the argument of the characteristic functional with expressions containing the auxiliary functions. The resulting equation has the form
\[ \partial_\xi \chi[\eta, \eta^*] = \mathcal{K} \left\{ \chi[\eta - \nu, \eta^* - \nu^*] \exp(\mu^* \circ (\eta - \nu) - (\eta^* - \nu^*) \circ \mu) \right\} \bigg|_{\nu = \mu = 0}. \] (64)

One can see that the operation of \( \mathcal{K} \) on the shifted characteristic functional would lead to a functional differential equation.

We substitute (61) into (64), apply the functional derivatives on the characteristic functional and set \( \nu = \mu = 0 \). The resulting equation reads
\[ \partial_\xi \chi[\eta, \eta^*] = i\pi \lambda \int |\mathbf{a}|^2 \left\{ \eta^*(\mathbf{a}) \frac{\delta \chi[\eta, \eta^*]}{\delta \eta^*(\mathbf{a})} - \eta(\mathbf{a}) \frac{\delta \chi[\eta, \eta^*]}{\delta \eta(\mathbf{a})} \right\} d^2 a \]
\[ - k^2 \Lambda \int \left\{ \eta(\mathbf{a}) \frac{\delta \chi[\eta, \eta^*]}{\delta \eta(\mathbf{a})} + \eta^*(\mathbf{a}) \frac{\delta \chi[\eta, \eta^*]}{\delta \eta^*(\mathbf{a})} \right\} d^2 a \]
\[ - k^2 \int \left\{ \eta(a_1 + a_0) \eta(a_2 - a_0) \frac{\delta^2 \chi[\eta, \eta^*]}{\delta \eta(a_1) \delta \eta(a_2)} \right\} \]
\[ + \eta^*(a_1 + a_0) \eta^*(a_2 - a_0) \frac{\delta^2 \chi[\eta, \eta^*]}{\delta \eta^*(a_1) \delta \eta^*(a_2)} \]
\[ - 2\eta(a_1 - a_0) \eta^*(a_2 - a_0) \frac{\delta^2 \chi[\eta, \eta^*]}{\delta \eta(a_1) \delta \eta^*(a_2)} \]
\[ \times \Phi_n(a_0, 0) d^2 a_0 \ d^2 a_1 \ d^2 a_2. \] (65)

It has the form of a Fokker-Planck equation — exactly the same form as the IPFE for the Wigner functional in (36). As such, the characteristic functional approach does not
bring us much nearer to a solution, but it does indicate that the solution of the IPFE and its functional Fourier transform satisfy the same functional differential equation. It thus suggests that the solution of the IPFE is an eigenstate of the functional Fourier transform. This is indeed true for the Wigner functional of the vacuum state.

3.4. Polynomial solution

Due to the requirement for normalizability of the state, it is not expected that the solution of the IPFE would be a polynomial of finite order. Such polynomials are unbounded and therefore not normalizable. However, any normalizable functional can be represented as a polynomial of infinite order — a transcendental polynomial.

Here, we express the solution in the form of such a transcendental functional polynomial

\[
W_{\text{pol}}[\alpha, \alpha^*](z) = \sum_{m,n=0}^{\infty} \int \alpha^*(a_1) \cdots \alpha^*(a_m) H_{m,n}(a_1, \ldots, a_m, a_1', \ldots, a_n', z) \times \alpha(a_1') \cdots \alpha(a_n') \, d^2a_1 \cdots d^2a_m \, d^2a_1' \cdots d^2a_n' = \sum_{m,n=0}^{\infty} \left( \prod m \alpha^* \right) \odot H_{m,n}(z) \odot \left( \prod n \alpha \right),
\]

where \(\odot\) represents multiple contractions, connecting the kernels \(H_{m,n}\) to all the \(\alpha^*\)'s and \(\alpha\)'s. Note that the kernels are symmetric with respect to any perturbation among \(\{a_1 \ldots a_m\}\) or among \(\{a_1' \ldots a_n'\}\).

When we substitute the expression for the functional polynomial into the IPFE in (36), we get an expression that can be separated into separate equations for every order. These equations are of the form

\[
\partial_z H_{m,n}(z) = i\pi\lambda (m|a_1|^2 - n|a_1'|^2) H_{m,n}(a_1, \ldots, a_m, a_1', \ldots, a_n', z) - k^2 \Lambda(m + n) H_{m,n}(a_1, \ldots, a_m, a_1', \ldots, a_n', z) - k^2 \int [m(m - 1) H_{m,n}(a_1 + a_0, a_2 - a_0, \ldots, a_m, a_1', \ldots, a_n', z) + n(n - 1) H_{m,n}(a_1, \ldots, a_m, a_1' + a_0, a_2' - a_0, \ldots, a_n', z)] \Phi_n(a_0, 0) \, d^2a_0.
\]

Due to the integer factors, which are produced by the functional derivatives, the equations simplify for lower values of \(m\) and \(n\). For \(m \geq 2\) and \(n \geq 2\) the equations are of the general form, given in (67). We note that the solution for \(H_{n,m}(z)\) is always the complex conjugate of the solution for \(H_{m,n}(z)\).
The first few equations in the sequence are
\[
\begin{align*}
\partial_z H_{0,0}(z) &= 0, \\
\partial_z H_{1,0}(a_1, z) &= \mp \lambda|a_1|^2 H_{1,0}(a_1, z) - k^2\Lambda H_{1,0}(a_1, z) \\
\partial_z H_{0,1}(a_1', z) &= -i\pi\lambda|a_1'|^2 H_{0,1}(a_1', z) - k^2\Lambda H_{0,1}(a_1', z) \\
\partial_z H_{1,1}(a_1, a_1', z) &= i\mp \lambda \left[|a_1|^2 - |a_1'|^2\right] H_{1,1}(a_1, a_1', z) - 2k^2\Lambda H_{1,1}(a_1, a_1', z) \\
&\quad + 2k^2 \int H_{1,1}(u + a_0, a_1' + a_0, z) \Phi_a(a_0, 0) \, d^2a_0.
\end{align*}
\]  

The first equation in (68) implies that $H_{0,0}$ is a constant independent of $z$. It can thus act as a normalization constant for the state. The solutions for $H_{1,0}(a_1, z)$ and its complex conjugate are similar to those in (52)
\[
\begin{align*}
H_{1,0}(a_1, z) &= B_{1,0}(a_1) \exp[i\pi\lambda z|a_1|^2 - k^2\Lambda z] \\
H_{0,1}(a_1', z) &= B_{0,1}(a_1') \exp[-i\pi\lambda z|a_1'|^2 - k^2\Lambda z],
\end{align*}
\]

where $B_{1,0}(a_1)$ and $B_{0,1}(a_1')$ are the initial spectral functions at $z = 0$. As in the previous situation, these solutions decay to zero on a scale equivalent to $z \sim 1/(k^2\Lambda)$. The equation for $H_{1,1}(a_1, a_1', z)$ is equivalent to the IPE for a single-photon state, which has been solved in [42] under the quadratic structure function approximation. The solution is in the form of an integral
\[
H_{1,1}(a_1, a_1', z) = \int B_{1,1}(a_1 - u, a_1' - u) L(a_1, a_1', u, z) \, d^2u,
\]

where $L(a_1, a_1', u, z)$ is a kernel function, given in [12] for the quadratic structure function approximation.

All the remaining equations in the sequence of equations given in (67) still need to be solved. It is not at this time certain that a generic solution can be found for arbitrary orders in (67). If such generic solutions can be found, it is still not certain that such solutions would produce results that can be summed into a closed form to serve as a general solution for the functional differential equation.

4. Conclusion

The evolution of an arbitrary photonic quantum state propagating through a turbulent atmosphere is considered. An infinitesimal propagation approach is used to obtain a Fokker-Planck equation for the Wigner functional of the state — the IPFE. Apart from the $z$-derivatives, all the other derivatives in the equation are functional derivatives.

We do not provide a general solution for the IPFE. However, we show that without turbulence, the solution is in the form as expected for free-space propagation without turbulence. Considering the possibility for a solution in the form of a Gaussian functional, we find that the only solution of this form is the vacuum state.

The use of the characteristic functional to obtain a general solution is also considered. It leads to another functional differential equation for the characteristic functional that
has exactly the same form as the IPFE. One can therefore concluded that a general solution of the IPFE would be an eigenstate of the functional Fourier transform.

Finally we propose a general approach to find a solution, expressing it as an infinite order polynomial functional, which can then be decoupled into an infinite set of uncoupled differential equations. It is not sure whether an approach exists with which all such equations can be solved.

Acknowledgement

The research for this work was supported in part by the National Research Foundation (NRF) of South Africa (Grant Number: 118532).

Appendix A. Wigner functional of a linear process

Consider a linear operation for a single-photon state, expressed as a generalization of the single-photon projection operator, given by

\[ \hat{P}(1) = \int |k\rangle P(k,k') \langle k'| dkd'k', \] (A.1)

where \( P(k,k') \) represents the linear transformation to be performed on the angular spectrum (Fourier domain wave function) of the photon and \( |k\rangle \) denotes the elements of a momentum basis. The generalization to arbitrary numbers of particles can then be represented as a sum of tensor products

\[ \hat{P} = \sum_{m=0}^{\infty} \frac{1}{m!} \left[ \int |k\rangle P(k,k') \langle k'| dkdk' \right]^\otimes m, \]

where \( \exp \otimes (\cdot) \) is defined such that all products in its expansion are tensor products and the first term in the expansion involves only the vacuum state \( |\text{vac}\rangle \langle \text{vac}| \).

To represent the operator as a Wigner functional, we use a coherent state assisted approach \[30\]. It requires that the spatial degrees of freedom be represented in the Fourier domain, as in (A.2). Then, we need to compute the overlap of the operator with coherent states of both sides

\[ \langle \alpha_1 | \hat{P} | \alpha_2 \rangle = \sum_{m=0}^{\infty} \frac{1}{m!} \langle \alpha_1 | \left[ \int |k\rangle P(k,k') \langle k'| dkdk' \right]^\otimes m | \alpha_2 \rangle \]

\[ = \sum_{m=0}^{\infty} \frac{1}{m!} \int \langle \alpha_1 | \prod_p a(k_p) \rangle |\text{vac}\rangle \prod_p P(k_p,k'_p) \]

\[ \times \langle \text{vac} | \prod_p a(k'_p) \rangle | \alpha_2 \rangle \prod_p dk_p dk'_p \]

\[ = \langle \alpha_1 | \text{vac} \rangle \langle \text{vac} | \alpha_2 \rangle \sum_{m=0}^{\infty} \frac{1}{m!} \prod_p \int a_1^*(k_p) P(k_p,k'_p | \alpha_2 | \alpha_2 \rangle dkdk' \]
Multi-photon states in turbulence

\[ = \exp \left( -\frac{1}{2}|\alpha_1|^2 - \frac{1}{2}|\alpha_2|^2 + \alpha_1^* \circ P \circ \alpha_2 \right). \]  

(A.3)

We now use the result in (A.3) to compute the Wigner functional for a general linear process. Substituting it into the expression for the Wigner functional (see [30]), and performing the functional integrations over \( \alpha_1 \) and \( \alpha_2 \), we obtain

\[
W_P[q,p] = \int \exp \left( -2|\alpha|^2 + 2\alpha^* \circ \alpha_1 + 2\alpha_2^* \circ \alpha - |\alpha_1|^2 - |\alpha_2|^2 \\
- \alpha_2^* \circ \alpha_1 + \alpha_1^* \circ P \circ \alpha_2 \right) D[\alpha_1, \alpha_2] \\
= \frac{1}{\det \{1 + P\}} \exp \left[ -2\alpha^* \circ (1 - P) \circ (1 + P)^{-1} \circ \alpha \right],
\]

(A.4)

where it is assumed that \((1 + P)\) is invertible and

\[ \det \{1 + P\} \equiv \exp \left[ \text{tr} \{\ln(1 + P)\} \right]. \]  

(A.5)
