UNDERSTANDING SPARSE JL FOR FEATURE HASHING

MEENA JAGADEESAN
Harvard University

ABSTRACT. Feature hashing and more general projection schemes are commonly used in machine learning to reduce the dimensionality of feature vectors. The goal is to efficiently project a high-dimensional feature vector living in \( \mathbb{R}^n \) into a lower-dimensional space \( \mathbb{R}^m \), while approximately preserving Euclidean norm. These schemes can be constructed using sparse random projections, for example using a sparse Johnson-Lindenstrauss (JL) transform. In practice, feature vectors often have a low \( \ell_{\infty} \)-to-\( \ell_2 \) norm ratio, and for this restricted set of vectors, many sparse JL-based schemes can achieve the norm-preserving objective with smaller dimension \( m \) than is necessary for the scheme on the full space \( \mathbb{R}^n \). A line of work introduced by Weinberger et. al (ICML ’09) analyzes the sparse JL transform with one nonzero entry per column, which is a standard feature hashing scheme. Recently, Freksen, Kamma, and Larsen (NIPS ’18) closed this line of work by proving an essentially tight tradeoff between \( \ell_{\infty} \)-to-\( \ell_2 \) norm ratio, distortion, failure probability, and dimension \( m \) for this feature hashing scheme.

We study more general projection schemes that are constructed using sparse JL transforms permitted to have more than one (but still a small fraction of) nonzero entries per column. Our main result is an essentially tight tradeoff between \( \ell_{\infty} \)-to-\( \ell_2 \) norm ratio, distortion, failure probability, and dimension \( m \) for a general sparsity \( s \), that generalizes the result of Freksen et. al. We also connect our result to the sparse JL literature by showing that it implies lower bounds on dimension-sparsity tradeoffs that essentially match upper bounds by Cohen (SODA ’16). Moreover, our proof introduces a new perspective on bounding moments of certain random variables, that could be useful in other settings in theoretical computer science.

1. INTRODUCTION

Projection schemes such as feature hashing are influential in machine learning to help manage large data [10]. The goal is to reduce the dimensionality of feature vectors: more specifically, to project a high-dimensional feature vector living in \( \mathbb{R}^n \) into a lower dimensional space \( \mathbb{R}^m \) (where \( m \ll n \)), while preserving \( \ell_2 \) norm up to distortion \( 1 \pm \epsilon \) with high probability. This enables the parameter vector of a classifier to live in \( \mathbb{R}^m \), while approximately preserving the \( \ell_2 \) norm of the \( n \)-dimensional feature vector. In this context, feature hashing was first introduced by Weinberger et. al [26] for document-based classification tasks such as email spam filtering. For such tasks, feature hashing yields a lower dimensional embedding of a high-dimensional feature vector derived from a bag-of-words model. Since then, feature hashing has become a mainstream approach [25], applied to numerous domains including ranking text documents [2], compressing neural networks [6], and protein sequence classification [4].

Dimensionality reduction schemes for feature vectors fit nicely into the random projection literature. In fact, the feature hashing scheme in [26] can be viewed as a \( m \times n \) matrix with one nonzero entry randomly chosen from \( \{-1,1\} \). The geometry-preserving objective can be expressed mathematically as follows: for error \( \epsilon > 0 \) and failure probability \( \delta \), the goal is to construct a probability distribution \( \mathcal{A} \) over \( m \times n \) real matrices that satisfies the following condition for vectors \( x \in \mathbb{R}^n \):

\[
P_{A \in \mathcal{A}}[(1 - \epsilon) \|x\|_2 \leq \|Ax\|_2 \leq (1 + \epsilon) \|x\|_2] > 1 - \delta.
\]

The mathematical result that underlies the random projection literature is the Johnson-Lindenstrauss lemma, which gives an upper bound on the dimension \( m \) achievable by a probability distribution \( \mathcal{A} \) that satisfies (1):

**Lemma 1.1 (Johnson-Lindenstrauss [16])** For any positive integer \( n \) and parameters \( 0 < \epsilon, \delta < 1 \), there exists a probability distribution \( \mathcal{A} \) over \( m \times n \) matrices with \( m = \Theta(\epsilon^{-2} \log(1/\delta)) \) satisfying (1).

---

E-mail address: mjagadeesan@college.harvard.edu.
The optimality of the dimension $m$ achieved by Lemma 1.1 was recently proven in [17, 15].

For many applications, it can be useful to consider probability distributions over sparse matrices (matrices with a small number of nonzero entries per column), both to speed up the projection time and to preserve the sparsity of the original vectors (up to a multiplicative factor). In this context, Kane and Nelson [18] constructed sparse JL distributions (which we define formally in Section 1.1) that achieve the same (optimal) dimension as Lemma 1.1 while also satisfying a sparsity property. They proved the following:

**Theorem 1.2 (Sparse JL)** For any positive integer $n$ and $0 < \epsilon, \delta < 1$, any sparse JL distribution $\mathcal{A}_{s,m}$ (defined formally in Section 1.1) over $m \times n$ matrices with dimension $m = \Theta(\epsilon^{-2}\log(1/\delta))$ and $s = \Theta(\epsilon^{-1}\log(1/\delta))$ nonzero elements per column satisfies [1]

They also proved that for their construction of sparse JL distributions, the sparsity $s = \Theta(\epsilon^{-1}\log(1/\delta))$ is optimal for $m = \Theta(\epsilon^{-2}\log(1/\delta))$.

Cohen [7] extended the upper bound to show a lower sparsity is possible with an appropriate gain in dimension. This result implies the following dimension-sparsity tradeoffs:

**Theorem 1.3 (Dimension-Sparsity Tradeoffs)** There exists constants $C_S, C_M > 0$ such that for any $0 < \epsilon, \delta < 1$ and $1 \leq s \leq C_S\epsilon^{-1}\log(1/\delta)$, if $\mathcal{A}_{s,m}$ is a uniform sparse JL distribution (defined formally in Section 1.1), then it satisfies [1] if:

$$m \geq \min(2\epsilon^{-2}/\delta, C_M\epsilon^{-2}\log(1/\delta)e^\epsilon s^{1/2}C_S\epsilon^{-1}e^{-\delta})).$$

The sparse JL distribution has particularly close ties to feature hashing. In particular, the feature hashing scheme proposed by Weinberger [26] can be viewed as a special case of this distribution with $s = 1$. Interestingly, in practice, feature hashing performs much better than the theoretical results, such as Theorem 1.2 and Theorem 1.3, would indicate [12]. An explanation for this phenomenon is that the highest error terms stem from vectors with mass concentrated on a very small number of entries, while in practice, the mass on feature vectors is typically spread out over many coordinates. This motivates studying the tradeoff space for vectors restricted to low $l_\infty$ to $l_2$ ratio.

More formally, take $S_v$ to be $\{x \in \mathbb{R}^n \mid \|x\|_1/\|x\|_2 \leq \delta\}$, so that $S_1 = \mathbb{R}^n$ and $S_v \subseteq S_w$ for $0 \leq v < w \leq 1$. Let $v(m, \epsilon, \delta, s)$ be the sup over all $0 \leq v \leq 1$ such that (1) holds on $S_v$ for a sparse JL distribution with sparsity $s$ and dimension $m$. For the case of $s = 1$, a line of work [26, 11, 19, 9, 18] subsequently improved upper and lower bounds on $v(m, \epsilon, \delta, 1)$, and was recently closed by Freksen, Kamma, and Larsen [12]:

**Theorem 1.4 ([12])** For every $\epsilon, \delta \in (0, 1)$, if $p = \log \epsilon(1/\delta)$, there exist constants $C_{M_1}, C_{M_2} > 0$ such that $v(m, \epsilon, \delta, 1) = \Theta(f(m, \epsilon, \delta))$ where:

$$f(m, \epsilon, \delta) = \begin{cases} 1 & \text{if } m \geq 2\epsilon^{-2}e^{p} \\ 0 & \text{if } m \leq C_{M,1}\epsilon^{-2}p \\ \epsilon \min \left(\log \frac{\epsilon}{p}, \frac{\sqrt{\log \frac{\epsilon e^{2}}{p}}}{\sqrt{p}}\right) & \text{if } C_{M,2}\epsilon^{-2}p \leq m < 2\epsilon^{-2}e^{p} \end{cases}$$

While Theorem 1.4 is restricted to the case of $s = 1$, dimensionality reduction schemes constructed using sparse random projections with $s > 1$ are also commonly used to project feature vectors in practice. For example, sparse JL-like methods (with $s > 1$) have been used to project feature vectors in machine learning domains including visual tracking [24], face recognition [3], and recently in ELM (a type of feedforward neural network) [5]. Now, a variant of sparse JL is even included in the mainstream Python sklearn library for machine learning [10]. Given the $l_\infty$ to $l_2$ ratio properties of feature vectors common in practice, it is natural to explore how sparse JL performs on these vectors by studying $v(m, \epsilon, \delta, s)$.

In this paper, we settle the question of how $v(m, \epsilon, \delta, s)$ varies for a general sparsity $s$. We compute essentially tight bounds on $v(m, \epsilon, \delta, s)$, thus generalizing Theorem 1.4. Our result elucidates how $v(m, \epsilon, \delta, s)$

---

1. In [23], it was shown that for any distribution over matrices, a sparsity of $\Omega(\epsilon^{-1}\log(1/\delta)/\log(1/\epsilon))$ is necessary to satisfy [1].

matches up to constants factors on the exponent in the dimension sizes. In particular, there exist constants \( C_{\delta}, C_{s}, C_{M}, C_{t} \geq 0 \) such that if \( 0 < \varepsilon < C_{\delta} \), \( 0 < \varepsilon < C_{s} \), \( 1 \leq s \leq C_{s} \varepsilon^{-1} \log_{e}(1/\delta) \), and \( m \geq C_{s} \varepsilon^{-2} \log_{e}(1/\delta) \), then, for \( g_{C_{M}, C_{s}, C_{t}} \) defined below:

\[
v(m, \varepsilon, \delta, s) \geq \min(1, g_{C_{M}, C_{s}, C_{t}}(m, \varepsilon, \log_{e}(1/\delta), s)).
\]

**Theorem 1.6** Suppose that \( \mathcal{A}_{s,m} \) is a uniform sparse JL distribution (defined formally in Section 1.1). There exist constants \( C_{\delta}, C_{s}, C_{M,1}, C_{M,2}, C_{E,1}, C_{E,2}, C_{c}, C_{s} \geq 0 \) such that if \( 0 < \varepsilon < C_{\delta} \), \( 0 < \varepsilon < C_{s} \), \( 1 \leq s \leq C_{s} \varepsilon^{-1} \log_{e}(1/\delta) \), and \( m \leq \varepsilon^{-2} C_{E,3} \log_{e}(1/\delta) \), and for \( h_{C_{M,1}, C_{M,2}, C_{E,1}, C_{c}}(m, \varepsilon, \log_{e}(1/\delta), s) \leq 0.5 \), then:

\[
v(m, \varepsilon, \delta, s) \leq h_{C_{M,1}, C_{M,2}, C_{E,1}, C_{c}}(m, \varepsilon, \log_{e}(1/\delta), s).
\]

In these bounds, functions \( g \) and \( h \) are defined as follows:

\[
g_{C_{M}, C_{s}, C_{t}}(m, \varepsilon, p, s) = \begin{cases} 
1 & \text{if } m \geq \min(2 \varepsilon^{-2} p^{2}, \varepsilon^{-2} C_{E,1} \varepsilon^{-1} s) \\
C_{v} \varepsilon \sqrt{\log_{e}(\frac{m}{p})} & \text{if } m \geq \max(s \cdot \varepsilon C_{E,1} \varepsilon^{-1}, C_{M} \varepsilon^{-2} p) \\
C_{v} \sqrt{\varepsilon} \min\left(\frac{\log_{e}(\frac{m}{p})}{p}, \frac{\log_{e}(\frac{m}{p})}{\sqrt{p}}\right) & \text{else if } C_{M} \varepsilon^{-2} p \leq m < s \cdot \varepsilon C_{E,1} \varepsilon^{-1}
\end{cases}
\]

\[
h_{C_{M,1}, C_{M,2}, C_{E,1}, C_{c}}(m, \varepsilon, p, s) = \begin{cases} 
0 & \text{if } m \leq C_{M,1} \varepsilon^{-2} p \\
C_{v} \varepsilon \sqrt{\log_{e}(\frac{m}{p})} & \text{if } m \geq \max\left(s \cdot \varepsilon C_{E,1} \varepsilon^{-1}, C_{M,2} \varepsilon^{-2} p\right) \\
C_{v} \sqrt{\varepsilon} \min\left(\frac{\log_{e}(\frac{m}{p})}{p}, \frac{\log_{e}(\frac{m}{p})}{\sqrt{p}}\right) & \text{else if } C_{M,2} \varepsilon^{-2} p \leq m < s \cdot \varepsilon C_{E,1} \varepsilon^{-1}
\end{cases}
\]

Using Theorem 1.6 we prove the following dimension-sparsity lower bound:

**Corollary 1.7** There exists constants \( C_{\delta}, C_{s}, C_{c}, C_{t} > 0 \) such that if \( 0 < \varepsilon < C_{\delta}, 0 < \varepsilon < C_{s}, \) and \( C \leq s \leq C_{s} \varepsilon^{-1} \log_{e}(1/\delta) \), and \( \mathcal{A}_{s,m} \) is a uniform sparse JL distribution (defined formally in Section 1.1), then \( v(m, \varepsilon, \delta, s) \leq 1/2 \) when:

\[
m \leq \min\left(\varepsilon^{-2} C_{t} \log_{e}(1/\delta), \varepsilon^{-2} \log_{e}(1/\delta) e^{\frac{C_{t} \log_{e}(1/\delta) e^{-1}}{s}}\right).
\]

We remark that for a uniform sparse JL distribution\(^3\), the lower bound on \( v(m, \varepsilon, \delta, s) \) in Theorem 1.5 essentially matches the upper bound on \( v(m, \varepsilon, \delta, s) \) in Theorem 1.6 and the dimension-sparsity lower bound in Corollary 1.7 essentially matches the known upper bound in Theorem 1.3. Moreover, the dimension-sparsity upper bound that we obtain in Theorem 1.5 recovers Theorem 1.3 and also generalizes the results to non-uniform sparse JL distributions. More precisely, when \( m \geq \min(2 \varepsilon^{-2} p^{2}, \varepsilon^{-2} C_{E,1} \varepsilon^{-1} s) \), where \( p = \log_{e}(1/\delta) \), we know that \( v(m, \varepsilon, \delta, s) = 1 \) by Theorem 1.5, which means that (1) holds on the full space \( \mathbb{R}^{m} \). This produces the same bound as in Theorem 1.3 for a more general family of sparse JL distributions. When \( m \leq C_{M,1} \varepsilon^{-2} \log_{e}(1/\delta) \), we know that \( v(m, \varepsilon, \delta, s) = 0 \) by Theorem 1.6. For the remaining regimes, \( \sqrt{\varepsilon} \sqrt{\log_{e}(\frac{m}{p})}/\sqrt{p} \) and \( \sqrt{\varepsilon} \min\left(\frac{\log_{e}(\frac{m}{p})}{p}, \frac{\log_{e}(\frac{m}{p})}{\sqrt{p}}\right) \), we see Theorem 1.5 and Theorem 1.6 match up to constant factors. Furthermore, the boundaries between the regimes in Theorem 1.5 and Theorem 1.6 match up to constants factors on the exponent in the dimension \( m \). Finally, the bound in Corollary 1.7 also matches Theorem 1.3 up to constants factors on the exponent in the dimension \( m \).

---

\(^3\)When \( s = 1 \), every sparse JL distribution is a uniform sparse JL distribution, and this is a common choice even for \( s > 1 \).
We compare our bound on $v(m, \varepsilon, \delta, s)$ for a general sparsity $s$ to the special case of $s = 1$. Observe that the 
$\sqrt{s} \min \left( \log \left( \frac{me}{p} \right) / p, \sqrt{\log \left( \frac{me}{p} \right)} / \sqrt{p} \right)$ regime matches the $s = 1$ case with an extra factor of $\sqrt{s}$. However, there is also an extra regime\(^4\) for $v(m, \varepsilon, \delta, s)$ when $m \geq \max (s \cdot e^{C_3 \log (1/\delta)} e^{-1/\delta}, C_4 e^{-2 \log (1/\delta)}).$ Intuitively, we expect such a regime to arise for large enough $s$ for the following reason. At $s = \Theta(e^{-1 \log (1/\delta)})$ and $m = \Theta(e^{-2 \log (1/\delta)})$, we know by Theorem 1\(^5\) that $v(m, \varepsilon, \delta, s) = 1$, but if $\varepsilon$ is a constant, then the first branch of the min expression, i.e. $\sqrt{s} \log \left( \frac{me}{p} \right) / p$, gives us a bound of $\Theta \left( \frac{1}{\sqrt{\log (1/\delta)}} \right)$ in this case, while the second branch gives us the desired bound of 1. Thus, it is natural that the first branch disappears for sufficiently large $m$.

The proof boils down to bounding the moments of a certain random variable. Although this random variable has been analyzed in\(^{[18]}^{[12]}\), the existing methods could not be adapted to this setting, for reasons we discuss in Section 1.1, so new methods are needed. Unlike traditional approach in the JL literature of computing these moments via combinatorial methods\(^{[12]}^{[18]}^{[1]}^{[22]}\), our paper provides a new perspective on proving these moment bounds. We analyze these moments using methods grounded in intuition from probability theory, but that have not appeared in the theoretical computer science literature (to our knowledge). We view the random variable structurally, and construct and apply general facts on moments of random variables with this structure which we believe could be useful in other settings, given the ubiquity of moment and tail bounds in theoretical computer science.

1.1. Preliminaries and Outline for the Paper. Let $\mathcal{A}_{s,m}$ be a **sparse JL distribution** if the entries of a matrix $A \in \mathcal{A}_{s,m}$ are generated as follows. Let $A_{ri} = \eta_{ri} \sigma_{ri} / \sqrt{s}$ where $\{\sigma_{ri}\}_{r \in [m], i \in [n]}$ and $\{\eta_{ri}\}_{r \in [m], i \in [n]}$ are defined as follows:

- The families $\{\sigma_{ri}\}_{r \in [m], i \in [n]}$ and $\{\eta_{ri}\}_{r \in [m], i \in [n]}$ are independent from each other.
- The variables $\{\sigma_{ri}\}_{r \in [m], i \in [n]}$ are i.i.d. Rademachers ($\pm 1$ random variables).
- The variables $\{\eta_{ri}\}_{r \in [m], i \in [n]}$ are identically distributed Bernoulli random variables with expectation $s/m$.
- The $\{\eta_{ri}\}_{r \in [m], i \in [n]}$ are independent across columns but not independent within each column. For every column $1 \leq i \leq n$, it holds that $\sum_{r=1}^{m} \eta_{ri} = s$. The random variables are **negatively correlated**, i.e. for every subset $S \subseteq [m]$ and every column $1 \leq i \leq n$, it holds that $E\left[ \prod_{r \in S} \eta_{ri} \right] \leq \prod_{r \in S} E[\eta_{ri}]$.

Let $\mathcal{A}_{s,m}$ be a **uniform sparse JL distribution** if for every $1 \leq i \leq n$, $\{\eta_{ri}\}_{r \in [m]}$ is the distribution defined by uniformly choosing exactly $s$ of these variables to be 1. This definition is commonly used. When $s = 1$, observe that every sparse JL distribution is a uniform sparse JL distribution, but for $s > 1$, this is not the case.

We use the following notation in our analysis. For any random variable $X$ and value $p \geq 1$, we use $\|X\|_p$ to denote the $p$-norm $\left( E[|X|^p] \right)^{1/p}$, where $E$ denotes the expectation. Given two scalar quantities $Q_1$ and $Q_2$ that are functions of some parameters, we use $Q_1 \asymp Q_2$ to denote that there exist positive universal constants $C_1 \leq C_2$ such that $C_1 Q_2 \leq Q_1 \leq C_2 Q_2$, and we use $Q_1 \lesssim Q_2$ (resp. $Q_1 \gtrsim Q_2$) to denote that there exists a positive universal constant $C$ such that $Q_1 \leq C Q_2$ (resp. $Q_1 \geq C Q_2$).

For every $[x_1, \ldots, x_n] \in \mathbb{R}^n$ such that $\|x\|_2 = 1$, we need to analyze tail bounds of an error term, which for the sparse JL construction is the following random variable:

$$\|Ax\|_2^2 - 1 = \frac{1}{s} \sum_{i \neq j=1}^{m} \eta_{ri} \eta_{sj} \sigma_{ri} \sigma_{sj} x_i x_j := R(x_1, \ldots, x_n).$$

An upper bound on the tail probability of $R(x_1, \ldots, x_n)$ is needed to prove Theorem 1.5, and a lower bound is needed to prove Theorem 1.6. For the upper bound, we use Markov’s inequality like in\(^{[12]}^{[18]}^{[1]}^{[22]}\), and for the lower bound, we use the Paley-Zygmund inequality\(^5\) like in\(^{[12]}\). Markov’s inequality gives a tail upper bound from upper bounds on random variable moments, and the Paley-Zygmund inequality gives a tail

---

\(^4\)This regime does not arise in the $s = 1$ case, since it is always dominated by $2e^{-2}/\delta$.

\(^5\)The Paley-Zygmund inequality and its relevant corollary are presented in Section 8.
lower bound from upper and lower bounds on random variable moments. As a result, the key ingredient of our analysis is a tight bound for $\|R(x_1, \ldots, x_n)\|_q$ on $S_v = \{ x \in \mathbb{R}^n \mid \|x\|_2 \leq v \}$ at each threshold $v$ value.

We remark that it is not clear how to adapt existing approaches for studying moments of $\|R(x_1, \ldots, x_n)\|_q$ to obtain this bound. The moment bound that we obtain is more general than the bounds in [18] for $\|R(x_1, \ldots, x_n)\|_q$ on $\mathbb{R}^n = S_1$ and the bound in [12] for $\|R(x_1, \ldots, x_n)\|_q$ on each $S_v$ for the special case of sparsity $s = 1$. Moreover, it is not clear how to adapt the combinatorial approach in [18] to yield tight bounds on $S_v$ for $v < 1$ or how to adapt the combinatorial approach in [12] to a general sparsity $s$. The non-combinatorial approach[6] in [8] for bounding $\|R(x_1, \ldots, x_n)\|_q$ on $\mathbb{R}^n = S_1$ also turns out to not be sufficiently precise on $S_v$ at critical $v$ values, for reasons we discuss in Section 2.

Thus, we require new tools for our moment bound. Our analysis provides a new perspective inspired by the probability theory literature that differs from the existing approaches in the JL literature. We believe our style of analysis is less brittle than combinatorial approaches [12] [18] [11] [22]: in this setting, once the sparsity case is recovered, it becomes straightforward to generalize to other sparsity values. Moreover, our approach can yield greater precision than the existing non-combinatorial approaches [8] [7] [14], which is necessary for this setting.

In Section 2, we present our analysis of the moments of $R(x_1, \ldots, x_n)$. In Section 3, we prove the tail bounds in Theorem [1.5] and Theorem [1.6] from these moment bounds.

2. BOUNDING THE MOMENTS OF $R(x_1, \ldots, x_n)$

Our approach takes advantage of the structure of the random variable as a quadratic form of Rademachers ($\pm 1$ random variables) with random variable coefficients. For the upper bound, we need to analyze $\|R(x_1, \ldots, x_n)\|_q$ for general vectors $[x_1, \ldots, x_n]$. For the lower bound, we only need to show $\|R(x_1, \ldots, x_n)\|_q$ is large for single vector in each $S_v$, and we choose this vector to be $[v, \ldots, v, 0, \ldots, 0]$. We analyze these moments using general moment bounds for Rademacher linear and quadratic forms.

Though Cohen, Jayram, and Nelson [8] also view $R(x_1, \ldots, x_n)$ as a quadratic form, we show that their approach is not sufficiently precise for our setting. They upper bound the moments of $R(x_1, \ldots, x_n)$ by the gaussian case through considering:

$$\tilde{R}(x_1, \ldots, x_n) = \frac{1}{s} \sum_{r=1}^{m} \sum_{i \neq j} \eta_{ri} \eta_{rj} g_{ri} g_{rj} x_i x_j$$

where the $g_{ri}$ are i.i.d standard gaussians. They use the fact Rademachers are subgaussian to conclude that $\|\tilde{R}(x_1, \ldots, x_n)\|_q \leq \|\tilde{R}(x_1, \ldots, x_n)\|_q$. In order to obtain upper bounds on $\|R(x_1, \ldots, x_n)\|_q$, they use the Hanson-Wright bound [13], a tight bound on moments of gaussian quadratic forms. However, we need different technical tools for two reasons.

1. First, in order to prove Theorem 1.6, we need to lower bound $\|R(x_1, \ldots, x_n)\|_q$, and thus cannot simply consider $\|\tilde{R}(x_1, \ldots, x_n)\|_q$.

2. Second, even for Theorem 1.5, using $\|\tilde{R}(x_1, \ldots, x_n)\|_q$ as a upper bound for $\|R(x_1, \ldots, x_n)\|_q$ is not sufficiently strong. In Appendix A, we give a counter-example, i.e. a vector $x$, where $\|\tilde{R}(x_1, \ldots, x_n)\|_q$ is too large to recover Theorem 1.5.

Thus, we cannot use the Hanson-Wright bound in this setting, and need to come up with a better bound on $\|R(x_1, \ldots, x_n)\|_q$ that does not implicitly replace Rademachers by gaussians.

In our approach, we make use of stronger moment bounds for Rademacher linear and quadratic forms, some of which are known to the probability theory community through Latala’s work in [21] [20] and some of which are new. It is important to note that the bounds in [21] [20] target the setting where the coefficients are scalars.

6 A similar non-combinatorial approach for a sign-consistent variant of the JL distribution is given in [14], and a different non-combinatorial approach for subspace embeddings is given in [7]. However, both of these approaches suffer from issues in this setting that are similar to [8].

7 The second point is similar in flavor to the conceptual point made in [14], where a sign-consistent variant of sparse JL was analyzed using an upper bound for Rademacher quadratic forms. However, the bound in [14] also turns out to be loose in this setting and also can’t be used to obtain either a sufficiently tight upper bound or a lower bound for $R(x_1, \ldots, x_n)$. 

In our setting, however, the coefficients are themselves random variables, and we need to make use of bounds that are *tractable* to analyze in this setting, which involves creating new bounds to handle some cases. Given the ubiquity of moment and tail bounds in theoretical CS, we believe that these methods could be useful in other settings.

Our strategy for obtaining both an upper and lower bound on $R(x_1, \ldots, x_n)$ is to break down into rows. We define

$$Z_r(x_1, \ldots, x_n) := \sum_{1 \leq i < j \leq n} \eta_{r,i} \eta_{r,j} \sigma_{r,i} \sigma_{r,j} x_i x_j$$

so that $R(x_1, \ldots, x_n) = \frac{1}{s} \sum_{r=1}^m Z_r(x_1, \ldots, x_n)$. We analyze the moments of $Z_r(x_1, \ldots, x_n)$ using the technical tools mentioned above. After obtaining these bounds, it remains to move from moments of $Z_r(x_1, \ldots, x_n)$ to moments of $R(x_1, \ldots, x_n)$. For the upper bound, we make use of the negative correlations between the $\eta_{r,i}$ random variables to upper bound by the independent case, and then we apply a general result for sums of i.i.d random variables. For the lower bound, this step requires more care, even though we restrict to a uniform sparse JL distribution, since we must show that the negative correlations induced by having exactly $s$ nonzero entries per column do not lead to significant loss. We use a general result to reduce to bounding moments of products of rows, and then use a counting argument tailored to this setting to obtain a lower bound in terms of moments of individual rows.

Our main results are the following bounds. We prove the following upper bound that holds for all vectors in the $l_2$ unit ball with bounded $l_\infty$ norm.

**Lemma 2.1** First, it is true that

$$\|R(x_1, \ldots, x_n)\|_2 \leq \frac{\sqrt{q}}{\sqrt{m}}.$$

Let $2 < q \leq m$ be an even integer. Let $\|x\|_\infty \leq v$ and $\|x\|_2 = 1$. If $\frac{\sqrt{q}}{\sqrt{m}} \geq q$, then

$$\|R(x_1, \ldots, x_n)\|_q \leq \frac{\sqrt{q}}{\sqrt{m}}.$$

If $\frac{\sqrt{q}}{\sqrt{m}} < q$, suppose there exists a constant $C_2 \geq 1$ such that $C_2 q^2 m v^4 \geq s^2$. Then, $\|R(x_1, \ldots, x_n)\|_q \leq f$ where:

$$f = \begin{cases} \max \left( \frac{\sqrt{q}}{\sqrt{m}}, \frac{C_{2}^{1/3} q^2 v^2}{s \log(qm^2/s^2)} \right) & \text{if } \log(qm^2/s^2) \leq 2, \log(qm^2/s) \leq q \\ \frac{\sqrt{q}}{\sqrt{m}} & \text{if } \log(qm^2/s^2) \leq 2, \log(qm^2/s) > q \\ \max \left( \frac{\sqrt{q}}{\sqrt{m}}, \frac{q v^2}{s \log(qmv^2/s)} \right) \min \left( \frac{C_{2}^{1/3} q^2 v^2}{s \log(qm^2/s^2)}, \frac{q}{s \log(m/s)} \right) & \text{if } \log(qm^2/s^2) > 2, \log(qm^2/s) \leq q \\ \frac{\sqrt{q}}{\sqrt{m}} \frac{q v^2}{s \log(qmv^2/s^2)} & \text{if } \log(qm^2/s^2) > 2, \log(qm^2/s) > q. \end{cases}$$

We also prove a lower bound for vectors $[v, \ldots, v, 0, \ldots, 0]$ with $\frac{1}{q}$ nonzero entries.

**Lemma 2.2** Suppose $\mathcal{A}_{s,m}$ is a uniform sparse JL distribution. Let $2 \leq q \leq m$ be a power of 2, and suppose that $0 < v \leq 0.5$, and $\frac{1}{q}$ is an even integer. If $q v^2 \leq s$, then

$$\|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq \frac{\sqrt{q}}{\sqrt{m}}.$$ 

If $m \geq q$, $2 \leq \log(qm^2/s^2) \leq q$, $2q v^2 \leq 0.5 s \log(qm^4/s^2)$, and $s \leq m/2$, then:

$$\|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq \frac{q v^2}{s \log(qm^4/s^2)}.$$ 

If $v \leq \frac{\sqrt{\log(m/s)}}{\sqrt{q}}$, $1 \leq \log(qm^2/s) \leq q$, and $s \leq m/2$, then:

$$\|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq \frac{q^2 v^2}{s \log^2(qm^2/s)}.$$
In Section 2.1, we present useful moment bounds for Rademacher forms and other combinations of random variables. In Section 2.2, we obtain upper bounds for \( \|Z_r(x_1, \ldots, x_n)\|_T \) and lower bounds for \( \|Z_r(v, \ldots, v, 0, \ldots, 0)\|_T \) and necessary variants. In Section 2.3, we combine the moments of each row to prove Lemma 2.1 and Lemma 2.2.

2.1. Useful Moment Bounds. To obtain a lower bound on the moments of \( Z_r(x_1, \ldots, x_n) \), we make use of the following tight bound on moments of quadratic forms of Rademacher random variables with random variable coefficients. We derive this bound from Łatała’s bound\(^8\) on Rademacher quadratic forms \([\text{21}]\), and we defer the proof of this lemma from Łatała’s result to Appendix B.

**Lemma 2.3** Let \( T \) be an even integer, \( \{\sigma_i\}_{1 \leq i \leq n} \) be independent Rademachers, and \( \{Y_{i,j}\}_{1 \leq i, j \leq n} \) be a \( n \times n \) symmetric, nonnegative random matrix with zero diagonal (i.e. \( Y_{i,i} = 0 \)) such that \( \{Y_{i,j}\}_{1 \leq i, j \leq n} \) is independent from \( \{\sigma_i\}_{1 \leq i \leq n} \). If \( W_i = \sqrt{\sum_{1 \leq j \leq n} Y_{i,j}^2} \), then:

\[
\left\| \sum_{1 \leq i, j \leq n} Y_{i,j} \sigma_i \sigma_j \right\|_T \simeq \sup_{\|b\|_1, \|c\|_2 \leq \sqrt{T}, \|b\|_\infty, \|c\|_{\infty} \leq 1} \left\| \sum_{1 \leq i, j \leq n} Y_{i,j} b_i c_j \right\|_T + \left\| \sum_{1 \leq i \leq n} W(i) + \sqrt{T} \right\|_T \sum_{1 \leq i \leq n} W(i)^2 \right\|_T
\]

where \( W(1) \geq W(2) \geq \ldots \geq \ldots W(n) \) is a permutation of \( W_1, \ldots, W_n \).

Since the estimate in Lemma 2.3 is tight, it could also theoretically be used to upper bound moments of \( Z_r(x_1, \ldots, x_n) \) for general vectors. However, when \( \bar{x} \) is not of the form \([v, \ldots, v, 0, \ldots, 0] \), the expression becomes challenging to analyze tightly. Specifically, the sup term, which can be viewed as a generalization of an operator norm to an \( \ell_2 \) ball cut out by \( \ell_\infty \) hyperplanes, becomes difficult to analyze since the \( Y_{i,j} = \eta_{i,j} \eta_i x_i x_j \) do not have nice symmetry properties in this case. As a result, we instead make use of the simpler estimates that avoid an operator-norm-like term.

Linear forms naturally arise in the upper bound since

\[
Z_r(x_1, \ldots, x_n) = \left( \sum_{1 \leq i \leq n} \eta_{i,r} \sigma_i |x_i|^2 \right)^2 - \left( \sum_{1 \leq i \leq n} \eta_{i,r} \right)^2 \leq \left( \sum_{1 \leq i \leq n} \eta_{i,r} \sigma_i |x_i|^2 \right)^2 .
\]

Łatała \([\text{20}]\) presents a general expression for moments of weighted sums of symmetric random variables. However, it turns out that using a vanilla linear form bound here\(^9\) is weak due to the loss arising from ignoring the \( \sum_{1 \leq i \leq n} \eta_{i,r} \sigma_i x_i^2 \) term. Thus, we need to create a generalized bound tailored to squares of linear forms with a zero diagonal. Since random variables with a zero diagonal are common in the JL literature \([\text{18} \text{1} \text{1} \text{22}]\), we believe this moment bound could of broader use.

**Lemma 2.4** Suppose that \( Y_1, Y_2, \ldots, Y_n \) are i.i.d symmetric random variables and suppose that \( x = [x_1, \ldots, x_n] \) satisfy \( \|x\|_2 = 1 \) and \( \|x\|_\infty \leq v \). Let \( T \) be an even natural number. Then, we have that

\[
\left\| \sum_{i \neq j} Y_i Y_j x_i x_j \right\|_T \simeq v^2 \left( \sup_{1 \leq t \leq T/2} \frac{T^2}{t^2} \left( \frac{1}{Tv^2} \right)^{1/2} \left\| Y_i \right\|_{2t}^2 \right).
\]

**Proof.** Let \( t = v \left( \sup_{1 \leq k \leq T/2} \frac{T}{t} \left( \frac{1}{Tv^2} \right)^{1/(2k)} \left\| Y_i \right\|_{2k} \right) \). Observe that

\[
E \left[ \left( \sum_{i \neq j} \frac{Y_i Y_j x_i x_j}{t^2} \right)^T \right] \leq \sum_{d_1 + d_2 + \ldots + d_n = T, d_i \leq T/2} \frac{2T!}{2d_1! \ldots 2d_n!} \prod_{i=1}^n E \left[ \left( \frac{Y_i x_i}{t} \right)^{2d_i} \right] \leq C^T \sum_{d_1 + d_2 + \ldots + d_n = T, d_i \leq T/2} \frac{(2T)^{2T}}{(2d_1)^{2d_1} \ldots (2d_n)^{2d_n}} \prod_{i=1}^n E \left[ \left( \frac{Y_i x_i}{t} \right)^{2d_i} \right].
\]

\(^8\)In fact, Łatała shows moment bounds for much more general quadratic forms, but for the application to JL, we only need the bound in the special case of Rademachers.

\(^9\)It turns out that we need the linear form bound in \([\text{20}]\) for a different part of the analysis, and we defer its statement to Section 2.2.2.
show the following lower bound on 
\[ \|E_i\| \leq \frac{Y_i}{T} \] 
and the statement follows from taking 1

\[ \text{Lemma 2.5 (of i.i.d symmetric random variables.)} \]

Proof. Technical reasons discussed in Section 2.3:

Now, we use the fact that \( |x_i| \leq v \) and the condition on \( t \) to obtain that this is bounded by

\[ C^T \prod_{i=1}^{n} \left( 1 + \frac{x_i^2}{v^2} \sum_{1 \leq d \leq T/2} \left( \frac{Y_i \|E_i\|_{2d}}{vdT} \right)^{2d} \right) \leq C^T \prod_{i=1}^{n} \left( 1 + T x_i^2 \right) \leq C^T \prod_{i=1}^{n} e^{T x_i^2} \leq C^T e^T. \]

\[ \square \]

In order to combine rows in the upper bound\[10\] we use the following result from [20] on moments of sums of i.i.d symmetric random variables.

**Lemma 2.5 ([20])** Suppose that \( q \) is an even natural number. Suppose that \( Y_1, \ldots, Y_n \) are i.i.d symmetric random variables. Then:

\[ \left\| \sum_{i=1}^{n} Y_i \right\|_q \leq \sup_{2 \leq T \leq q} \frac{q}{T} \left( \frac{n}{q} \right)^{1/T} \|Y_i\|_T. \]

In the lower bound, to combine rows, we make use of the following bound on sums of certain (potentially correlated) sums of identically distributed random variables. The result follows from expanding moments, and we defer the proof to Appendix B.

**Proposition 2.6** Let \( Y_1, \ldots, Y_n \) be identically distributed (but not necessarily independent) random variables, such that the joint distribution is a symmetric function of \( Y_1, \ldots, Y_n \) and for any integers \( d_1, \ldots, d_n \geq 0 \), it is true that \( \mathbb{E}[\prod_{i=1}^{n} Y_i^{d_i}] \geq 0 \). For any natural number \( q \) and natural number \( T \) that divides \( q \), it is true that

\[ \left\| \sum_{i=1}^{n} Y_i \right\|_q \geq T \left( \frac{n}{q} \right)^{T/q} \|Y_i\|_T \]

Proof. The proof follows from expanding \( \mathbb{E}[\left( \sum_{i=1}^{n} Y_i \right)^q] \) and using the fact that \( \mathbb{E}[\prod_{i=1}^{n} Y_i^{d_i}] \geq 0 \) so that we can restrict to a subset of the terms. By the symmetry of the joint distribution, we know that for \( 1 \leq r_1 \neq r_2 \neq r_T \leq n \), we know that \( \mathbb{E}[Y_1^{q_1/T} \ldots Y_r^{q_r/T}] = \mathbb{E}[Y_1^{q_1/T} \ldots Y_T^{q_T/T}] \). The number of terms of the form \( \mathbb{E}[Y_1^{q_1/T} \ldots Y_T^{q_T/T}] \) in \( \mathbb{E}[\left( \sum_{i=1}^{n} Y_i \right)^q] \) is:

\[ \left( \begin{array}{c} n \\ T \end{array} \right) \left( \begin{array}{c} q \\ q/T, q/T, \ldots, q/T \end{array} \right) \geq C^q \left( \frac{n}{T} \right)^T \left( \frac{q!}{(q/T)!} \right)^T \geq C^q \left( \frac{n}{q} \right)^T T^q \geq C^q \left( \frac{n}{q} \right)^T T^q. \]

This implies that

\[ \mathbb{E} \left[ \left( \sum_{i=1}^{n} Y_i \right)^q \right] \geq C^q \left( \frac{n}{q} \right)^T T^q \mathbb{E} \left[ Y_1^{q_1/T} \ldots Y_T^{q_T/T} \right] \]

and the statement follows from taking \( 1/q \)th powers.

\[ \square \]

2.2. Analyzing each row. We analyze the moments of \( Z_r(x_1, \ldots, x_n) \) using the tools from Section 2.1. We show the following lower bound on \( \|Z_r(v_1, \ldots, v, 0, \ldots, 0)\|_q \) as well as

\[ \left\| Z_r(v_1, \ldots, v, 0, \ldots, 0)I_{\sum_{i=1}^{n} \eta_i = 2} \right\|_T \]

for technical reasons discussed in Section 2.3:

---

\[ ^{10} \text{In Section 2.3 we describe why we can reduce to the case of independent rows.} \]
Lemma 2.8 If $\mathscr{A}_{s,m}$ is a uniform sparse JL distribution, $v \leq \frac{\sqrt{\log(m/s)}}{\sqrt{\eta}}$, $N := \frac{1}{v}$ is even, then the following bound is true:

$$\|Z_1(v, \ldots, v, 0, \ldots, 0)\|_2 \geq \frac{s}{m}.$$  

If $s \leq m/2$, and $T \geq \frac{sc}{mv^2}$ is even, then the following bounds are true:

$$\|Z_1(v, \ldots, v, 0, \ldots, 0)\|_T \geq \begin{cases} \frac{T^2v^2}{\log\left(\frac{mvT}{s}\right)} & \text{for } 1 \leq \log(mv^2T/s) \leq T, v \leq \frac{\sqrt{\log(m/s)}}{\sqrt{T}} \\
2^2 \left(\frac{s}{mTv^2}\right)^{2/T} & \text{for } \log(mv^2T/s) > T
\end{cases}$$

$$\|Z_1(v, \ldots, v, 0, \ldots, 0)I_{\Sigma_{i=1}^N \eta_i=2}\|_T \geq v^2 \left(\frac{s}{mTv^2}\right)^{2/T}.$$  

We show the following upper bound on $\|Z_r(x_1, \ldots, x_n)\|_q$:

Lemma 2.8 If $\|x\|_\infty \leq v$ and $\|x\|_2 \leq 1$, then we have that:

$$\|Z_r(x_1, \ldots, x_n)\|_T \leq \begin{cases} \frac{T^2s}{m} & \text{for } T = 2, 3 \leq T \leq \frac{sc}{mv^2} \\
\min\left(\frac{T^2v^2}{\log(\frac{mvT}{s})}, \frac{T}{\log(m/s)}\right) & \text{for } T \geq 3, T \geq \frac{sc}{mv^2}, \log(Tmv^2/s) \leq T \\
v^2 \left(\frac{s}{mTv^2}\right)^{2/T} & \text{for } T \geq 3, T \geq \frac{sc}{mv^2}, \log(Tmv^2/s) > T
\end{cases}$$

In Section 2.2.1 we prove Lemma 2.7 In Section 2.2.2 we prove Lemma 2.8

2.2.1. Proof of Lemma 2.7 The key ingredient of the proof is Lemma 2.3 (for Rademacher quadratic forms). We can view $Z_r(v, \ldots, v, 0, \ldots, 0)$ as the following quadratic form:

$$Z_r(v, \ldots, v, 0, \ldots, 0) = v^2 \sum_{1 \leq i \neq j \leq N} \eta_{r,i} \eta_{r,j} \sigma_{r,i} \sigma_{r,j},$$

where $N = \frac{1}{v}$. Since the support of $\eta_{r,i}$ is $\{0, 1\}$ and due to symmetry of this random variable, it is tractable to analyze the expressions in Lemma 2.3.

Proof of Lemma 2.7 First, we handle the case of $T = 2$:

$$\mathbb{E}[Z_r(v, \ldots, v, 0, \ldots, 0)]^2 = v^4 \mathbb{E} \left[ \left( \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \sigma_{r,i} \sigma_{r,j} \right)^2 \right]$$

$$= 2v^4 \mathbb{E} \left[ \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \right] = 2v^4 \left(\frac{s}{m}\right)^2 N(N-1) \geq \frac{4v^4N^2v^2}{m^2} = \frac{s^2}{m^2}$$

as desired.

Now we handle $T > 2$. We know that $\|Z_1(v, \ldots, v)\|_T = v^2 \|\Sigma_{i \neq j} \eta_{1,i} \eta_{1,j} \sigma_{1,i} \sigma_{1,j}\|_T$. Fix $1 \leq M \leq \min(N, T)$. We use Lemma 2.3 with $Y_{i,j} = \eta_{1,i} \eta_{1,j} = \eta_{1,i} \eta_{1,j} I_{M=\Sigma_{i=1}^N \eta_i}$ to compute $\|\Sigma_{i \neq j} \eta_{1,i} \eta_{1,j} \sigma_{1,i} \sigma_{1,j} I_{M=\Sigma_{i=1}^N \eta_i}\|_T$. We will then aggregate over $1 \leq M \leq T$ and not even count $T < M \leq N$. We see that $W_i = \sqrt{\Sigma_{1 \leq j \neq i \leq N} Y_{i,j}^2} = I_{M=\Sigma_{i=1}^N \eta_i} \eta_{1,i} \sqrt{\Sigma_{1 \leq j \neq i \leq N} \eta_{1,j}^2}$. This means that if $i > M$, then we know that $W(i) = 0$. If $i \leq M$, then we know that $W(i) = I_{M=\Sigma_{i=1}^N \eta_i} \eta_{1,i} \sqrt{M-1}$. We only use the operator-norm-like term in the lower bound. Observe that $I_{M=\Sigma_{i=1}^N \eta_i} \eta_{1,j} \sup_{\|b\|_2 \leq \sqrt{T}, \|\sigma\|_2 \leq \sqrt{T}} \Sigma_{1 \leq i \neq j \leq N} \sum_{1 \leq i \neq j} \eta_{1,i} \eta_{1,j} b_i c_j$ is equal to

$$\sup_{I_{M=\Sigma_{i=1}^N \eta_i}} \sup_{\|b\|_2 \leq \sqrt{T}, \|\sigma\|_2 \leq \sqrt{T}} \Sigma_{1 \leq i \neq j \leq N} b_i c_j \geq I_{M=\Sigma_{i=1}^N \eta_i} \eta_{1,i} M(M-1),$$

where we set $b_i = 1$ on all $i$ such that $\eta_{1,i} = 1$ and $c_j = 1$ on all $j$ such that $\eta_{1,j} = 1$. As long as $M \geq 2$, it is thus true that:

$$\|\Sigma_{i \neq j} \eta_{1,i} \eta_{1,j} \sigma_{1,i} \sigma_{1,j} I_{M=\Sigma_{i=1}^N \eta_i}\|_T \geq I_{M=\Sigma_{i=1}^N \eta_i} \eta_{1,i} M(M-1) \geq I_{M=\Sigma_{i=1}^N \eta_i} \eta_{1,i} M^2.$$
Since the events \( M = \sum_{i=1}^{N} \eta_{1,i} \) are disjoint, we know that:

\[
\mathbb{E} \left[ \sum_{i \neq j} \eta_{1,i} \eta_{1,j} \sigma_{1,i} \sigma_{1,j} \right]^T \geq \sum_{M=2}^{\min(T,N)} \mathbb{E} \left[ \sum_{i \neq j} \eta_{1,i} \eta_{1,j} \sigma_{1,i} \sigma_{1,j} I_{M=\sum_{i=1}^{N} \eta_{1,i}} \right]^T \\
\geq C^{-T} \sum_{M=2}^{\min(T,N)} \mathbb{E} \left[ I_{M=\sum_{i=1}^{N} \eta_{1,i}} M^2 \right]^T \\
= C^{-T} \sum_{M=2}^{\min(T,N)} \mathbb{P}[M = \sum_{i=1}^{N} \eta_{1,i}] M^{2T} \\
= \sum_{M=2}^{\min(T,N)} \left( \frac{N}{M} \right) \left( \frac{s}{m} \right)^M \left( 1 - \frac{s}{m} \right)^{N-M} M^{2T} \\
\geq C^{-T} \sum_{M=2}^{\min(T,N)} \left( \frac{N}{mT} \right) \left( \frac{T}{M} \right)^{M} \left( 1 - \frac{s}{m} \right)^{N-M} M^{2T} \\
\geq C^{-T} \sum_{M=2}^{\min(T,N)} \left( \frac{s}{mTv^2} \right)^M \left( 1 - \frac{s}{m} \right)^{N-M} M^{2T} \\
\geq C_2^{-T} \sum_{M=2}^{\min(T,N)} \left( \frac{s}{mTv^2} \right)^M M^{2T}
\]

where the last line follows from the fact that since \( T \geq \frac{m}{sv^2} \) and \( s \leq m/2 \), we know that:

\[
\left( 1 - \frac{s}{m} \right)^{\frac{N-M}{T}} \geq \left( 1 - \frac{s}{m} \right)^{\frac{N}{T}} \geq \left( 1 - \frac{s}{m} \right)^{\frac{n_m^2}{m}} \geq \left( 1 - \frac{s}{m} \right)^{\frac{1}{T}} \geq 0.25.
\]

Taking the \( 1/T \)th power and setting \( t = T/M \), we obtain, up to constants:

\[
\sup_{2 \leq M \leq \min(T,N)} \left( \frac{s}{mTv^2} \right)^{M/T} \geq \sup_{\max(1, T/N) \leq t \leq T/2} \left( \frac{T^2}{t^2} \right) \left( \frac{s}{mTv^2} \right)^{1/t}.
\]

which we will convert to the desired form at the end of the proof. We can take a derivative to obtain the two expressions in the lemma statement at the following regimes of parameters: \( T v^2 \leq \log(Tmv^2/s) \leq T \) and \( \log(Tmv^2/s) > T \). The second regime aligns with the lemma statement. Thus it suffices to show that when \( v \leq \sqrt{\frac{\log(m/s)}{T}} \), it is true that \( T v^2 \leq \log(Tmv^2/s) \). This is a straightforward calculation.\(^\text{11}\)

Now, we consider the case that we only include the \( I_{\sum_{j=1}^{N} \eta_{1,j}=2} \) random variable. We obtain the desired lower bound of

\[
\left( \frac{N}{2} \right) \left( \frac{s}{m} \right)^2 \left( 1 - \frac{s}{m} \right)^{N-2} \geq C^{-T} \left( \frac{s}{mTv^2} \right)^2.
\]

\[\square\]

2.2.2. Proof of Lemma 2.8 For this proof, recall the issues discussed in Section 2.1 with using Lemma 2.3 or a naive linear form to upper bound \( \|Z_r(x_1, \ldots, x_n)\|_q \). For these reasons, we use Lemma 2.4 (our moment bound for squared linear forms with zero diagonal) and obtain:

**Lemma 2.9** If \( \|x\|_\infty \leq v \) and \( \|x\|_2 \leq 1 \), then we have that:

\[
\|Z_r(x_1, \ldots, x_n)\|_T = \left\| \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \sigma_{r,i} \sigma_{r,j} x_i x_j \right\|_T \leq v^2 \left( \sup_{1 \leq t \leq T/2} \frac{T^2}{t^2} \left( \frac{s}{mTv^2} \right)^{1/t} \right).
\]

Proof. This can be seen by simply taking \( Y_i = \eta_{r,i} \sigma_{r,i} \) in Lemma 2.4 \[\square\]

\(^\text{11}\)In fact, \( v = \sqrt{\frac{\log(m/s)}{T}} \) is very close to the value where \( T v^2 = \log(Tmv^2/s) \), so this approximation is essentially tight.
It turns out that using only this bound would lose the $m \geq s \cdot e^{Cs\rho^{-1}}$ branch in Theorem 1.5. The lower bound on moments of $\|Z_r(v, \ldots, v, 0, \ldots, 0)\|_T$ in Lemma 2.7 sheds light on where this loss may be arising. We see that the problematic case is when $v \geq \frac{\sqrt{\log(m/s)}}{\sqrt{T}} := v_1$, and so we require a new bound for this regime. Since the vector $[v_1, \ldots, v_1, 0, \ldots, 0]$ is in $S_v$ when $v_1 \leq v$, we can’t hope to beat the bound of $\|Z_r(v_1, \ldots, v_1, 0, \ldots, 0)\|_T \geq mT v_1^2 \log(T m^2/v_1^2) \approx \frac{T}{\log(m/s)}$ from Lemma 2.7. We show that we can match this value:

**Lemma 2.10** Suppose that $x = [x_1, \ldots, x_n]$ satisfy $\|x\|_2 = 1$ and $\|x\|_\infty < v$. If $T \geq \frac{m}{m^2 v^2}$, $T \geq 3$, $T \geq \log(m/s)$, then:

$$\|Z_r(x_1, \ldots, x_n)\|_T = \left| \begin{array}{c} N_{i,j} \cdot N_{i,j} \cdot S_{i,j} \cdot S_{i,j} \cdot x_j \end{array} \right| T \leq \left| \begin{array}{c} \sum_{i \neq j} N_{i,j} \cdot N_{i,j} \cdot S_{i,j} \cdot S_{i,j} \cdot x_j \end{array} \right| T \leq \frac{T m^2}{\log(m/s)}.$$

The proof of this bound requires a new technique that handles larger $|x_i|$ entries, while still managing the many smaller $|x_i|$ that are still allowed to be present. We separate out $|x_i| \geq \frac{\sqrt{\log(m/s)}}{\sqrt{T}}$ and $|x_i| \leq \frac{\sqrt{\log(m/s)}}{\sqrt{T}}$. In the quadratic form formulation of $R(x_1, \ldots, x_n)$, this separation cannot be carried out, since there would be cross-terms between $|x_i| \geq \frac{\sqrt{\log(m/s)}}{\sqrt{T}}$ and $|x_i| \leq \frac{\sqrt{\log(m/s)}}{\sqrt{T}}$. As a result, we require the linear form bound in [20] for $|x_i| \leq \frac{\sqrt{\log(m/s)}}{\sqrt{T}}$ (and it is sufficiently tight in this regime). We use Proposition 2.11 which theoretically can be derived from Theorem 2 in [21]. We give an alternate proof of this proposition, which is very similar to the proof of Lemma 2.4 in Appendix B.

**Proposition 2.11** Suppose that $T \geq 1$ is an integer. Suppose that $Y_1, Y_2, \ldots, Y_n$ are i.i.d symmetric random variables and suppose that $x = [x_1, \ldots, x_n]$ satisfy $\|x\|_2 \leq 1$ and $\|x\|_\infty < v$. Then, we have that

$$\left| \sum_{i} Y_{ix} \right|_2 \leq \left( \sup_{1 \leq i \leq T} \frac{T}{t} \left( \frac{1}{TV^2} \right)^{\frac{1}{2}} \|Y_i\|_2 \right).$$

We now prove Lemma 2.10 from Proposition 2.11.

**Proof of Lemma 2.10** WLOG, assume that $|x_1| \geq |x_2| \geq \ldots \geq |x_n|$. Let $P = \left[ \log(m/s) / T \right]$. We know that

$$\left| \sum_{i} \eta_{i,j} \cdot S_{i,j} \cdot S_{i,j} \cdot x_j \right|_2 \leq \left| \sum_{1 \leq i \leq P} \eta_{i,j} \cdot S_{i,j} \cdot x_j \right|_2 + \left| \sum_{i > P} \eta_{i,j} \cdot S_{i,j} \cdot x_j \right|_2.$$

For $1 \leq i \leq P$, we use the bound $\left| \sum_{1 \leq i \leq P} \eta_{i,j} \cdot S_{i,j} \cdot x_j \right| \leq \sum_{i} |x_i| \leq \sqrt{\frac{T}{\log(m/s)}} \leq 2 \sqrt{\frac{T}{\log(m/s)}}$. For the remaining terms, we take $Y_i = \eta_{i,j} \cdot S_{i,j}$ in Lemma 2.11 to obtain the upper bound for $x_i \leq v':= \frac{\sqrt{\log(m/s)}}{\sqrt{T}}$ and $\|x\|_2 \leq 1$:

$$\left| \sum_{i} \eta_{i,j} \cdot S_{i,j} \cdot x_j \right|_2 \leq v' \left( \sup_{1 \leq i \leq T} \frac{T}{t} \left( \frac{s}{mT v'^2} \right)^{\frac{1}{2}} \right).$$

Based on the conditions in this lemma statement, we know that $\frac{mT v'^2}{s} = \frac{mT \log(m/s)}{2T} = \frac{mT \log(m/s)}{2} \geq e$. Thus taking a derivative, we obtain that this can be upper bounded by taking $t = \log(m T v'^2/s)$ which yields:

$$\frac{T v' \log(m T v'^2/s)}{\log(m T v'^2/s)} = \frac{m T v'}{\log(m/s) - \log \log(m/s)} \leq 0.5 \log(m/s) = 2 \sqrt{\frac{T}{\log(m/s)}}.$$

Finally, combining Lemma 2.9 and Lemma 2.10 yields Lemma 2.8.

---

12. Observe that the upper endpoint of $T$ on the sup expression does not match with the upper endpoint of $T/2$ on the sup expression in Lemma 2.9 and in fact, it turns out that this bound is not sufficiently strong to recover Theorem 1.6. This is sufficiently tight here, since we are focusing on the case where $\log(T m^2/v^2)$ is small.
Proof of Lemma 2.8 We apply Lemma 2.9 at $T = 2$ to directly obtain $\frac{T_s}{m}$, and for $T \geq 3$, we apply Lemma 2.9 and take a derivative to obtain:

$$\left\| \sum_{i \neq j} \eta_{ri} \eta_{rj} \sigma_{ri} \sigma_{rj} x_i x_j \right\|_T \leq \sqrt{\frac{T_s^2}{m^2} \log(mTv^2/s)^2},$$

for $se \geq mTv^2$

$$\left\| \sum_{i \neq j} \eta_{ri} \eta_{rj} \sigma_{ri} \sigma_{rj} x_i x_j \right\|_T \leq \sqrt{\left( \frac{T_s}{m} \right)^2 \log(mTv^2/s)^2},$$

for $se \leq mTv^2, \log(Tmv^2/s) \leq T$.

$$\left\| \sum_{i \neq j} \eta_{ri} \eta_{rj} \sigma_{ri} \sigma_{rj} x_i x_j \right\|_T \leq \sqrt{\left( \frac{s}{mTv^2} \right)^2},$$

for $\log(Tmv^2/s) \geq T, se \leq mTv^2$.

We also include the bound from Lemma 2.10 in the middle regime. □

2.3. Combining rows to bound $\|R(x_1, \ldots, x_n)\|_q$. Now, we show to move from bounds on moments of individual rows (i.e. $Z_r(x_1, \ldots, x_n)$) to bounds on moments of $R(x_1, \ldots, x_n)$. In Section 2.3.1 we obtain an upper bound on $\|R(x_1, \ldots, x_n)\|_q$, thus proving Lemma 2.1. In Section 2.3.2 we obtain a lower bound on $\|R(x_1, \ldots, x_n)\|_q$, thus proving Lemma 2.2.

2.3.1. Proof of Lemma 2.1 Since the $\eta_{ri}$ are negatively correlated, we can always upper bound the moments of $R(x_1, \ldots, x_n)$ by the case of a sum of independent random variables.\(^{13}\) $Z'_r(x_1, \ldots, x_n) \sim Z_r(x_1, \ldots, x_n)$. That is, $s \cdot \|R(x_1, \ldots, x_n)\|_q$ can be written as:

$$\left\| \sum_{r=1}^m Z_r(x_1, \ldots, x_n) \right\|_q \leq \sup_{2 \leq T \leq q} \frac{q}{T} \left( \frac{m}{q} \right)^{1/T} \|Z_1(x_1, \ldots, x_n)\|_T, \quad (2)$$

where the last inequality follows from Lemma 2.8. Thus, it remains to analyze the sup expression. It turns out that each regime of bounds in Lemma 2.8 collapses to one value, so the different regimes in Lemma 2.8 correspond to different parts of the max expressions in Lemma 2.1. Depending on the parameters, some of these regimes may not exist, as is reflected by branches of the max expression sometimes vanishing in Lemma 2.8. We defer the computation to Appendix C.

2.3.2. Proof of Lemma 2.2 Moving from a lower bound on the moments of individual rows given by Lemma 2.7 to moments of $R(v, \ldots, v, 0, \ldots, 0)$ is more delicate. Unlike in the upper bound, the negative correlations between random variables require some care to handle, even with the simplification that the $s$ nonzero entries in a column are chosen uniformly at random. For example, the conditional distribution of $\eta_{r+1,1} | \eta_{1,1} = \eta_{2,1} = \ldots = \eta_{s,1} = 1$ is 0, while the marginal distribution of $\eta_{r+1,1}$ has expectation $s/m$. One aspect that simplifies our analysis is that we know from our proof of Lemma 2.4 which moments of $Z_r(x_1, \ldots, x_n)$ are critical in the sup expression in (2). We only need to account for these particular moments in our lower bound approach. It turns out that the three critical values are $q/T = 2, q/T = q$, and $q/T = \log(qmv^2/s^2)$.

For $q/T = q$, where rows are isolated, we can directly obtain a bound from Lemma 2.6 and Lemma 2.7 to obtain.

Lemma 2.12 Suppose $\mathcal{A}_{s,m}$ is a uniform sparse JL distribution. Suppose that $q$ is even, $q \geq \frac{se}{mv^2}, 1 \leq \log(qmv^2/s) \leq q, v \leq \sqrt{\frac{\log(m/s)}{\sqrt{q}}}$ and $s^2 \leq s$. Then it is true that:

$$\|R(v, \ldots, v)\|_q \geq \frac{q^2v^2}{s^2\log^2(\frac{qmv^2}{s})}.$$ 

Proof. By Lemma 2.6 with $T = 1$, we have that:

$$\|R(v, \ldots, v)\|_q \geq \frac{m^{1/q}}{s} \|Z_1(v, \ldots, v)\|_q \geq \frac{1}{s} \|Z_1(v, \ldots, v)\|_q.$$ 

Now, we apply Lemma 2.7 to obtain the desired expression. □

\(^{13}\)This can easily be seen by expanding.
For $q/T = 2$ and $q/T = \log(qmv^4/s^2)$, we make use of the following lemma that relates moments of products of rows to products of moments of rows by taking advantage of either $s$ and $1/s$ being sufficiently large. This method essentially uses a counting argument to show that not too many terms vanish as a result of negative correlations, and requires adding in an indicator for the number of nonzero entries in a row being 2 for some cases (which is sufficient to prove Lemma 2.2). We defer the proof to Appendix D.

Lemma 2.13 Suppose $\mathcal{A}_{s,m}$ is a uniform sparse JL distribution. If $1 \leq T \leq q/2$ is an integer, $q/T$ is an even integer, and $2TV^2 \leq s$, then:

$$\|T_{i=1}^T Z_i(v_1, \ldots, v_0, \ldots, 0)\|^{1/T}_{q/T} \geq \begin{cases} \|Z_i(v_1, \ldots, v_0, \ldots, 0)\|_2 & \text{if } T = q/2 \\ \|Z_i(v_1, \ldots, v_0, \ldots, 0)\|_{L_{sT-1, \eta_i=2}} & \text{if } 1 \leq T \leq q/2. \end{cases}$$

Now we can use Lemma 2.6 coupled with Lemma 2.13 and Lemma 2.7 to handle the cases of $q/T = 2, \log(qmv^4/s^2)$ and obtain the following bounds. For $q/T = 2$, we obtain:

Lemma 2.14 Suppose $\mathcal{A}_{s,m}$ is a uniform sparse JL distribution. If $q$ is an even integer, $qv^2 \leq 1$, and $1/v$ is an even integer, then it is true that:

$$\|R(v_1, \ldots, v_0, \ldots, 0)\|_q \lesssim \left(\frac{q}{m}\right)^{1/2}.$$  

Proof of Lemma 2.14 Take $T = q/2$ in Lemma 2.13 and $qv^2 \leq s$. Then we have that:

$$\|R(v_1, \ldots, v_0, \ldots, 0)\|_q \gtrsim \frac{q}{s} \left(\frac{m}{q}\right)^{1/2} \|Z_1(v_1, \ldots, v_0, \ldots, 0)\|_2.$$  

Now, by Lemma 2.7, we can see that $\|Z_1(v_1, \ldots, v_0, \ldots, 0)\|_2 \gtrsim \frac{s}{m}$. Thus, our bound becomes:

$$\frac{q}{s} \left(\frac{m}{q}\right)^{1/2} \frac{s}{m} = \left(\frac{q}{m}\right)^{1/2}.$$  

For $q/T = \log(qmv^4/s^2)$, we similarly obtain the following bound, whose proof we defer to Appendix D.

Lemma 2.15 Suppose $\mathcal{A}_{s,m}$ is a uniform sparse JL distribution. Suppose that $q$ is a power of 2, $2qv^2 \leq 0.5s\log(qmv^4/s^2)$, $1/s$ is even, $2 \leq \log(qmv^4/s^2) \leq q$, and $m \geq q$. Then it is true that:

$$\|R(v_1, \ldots, v)\|_q \gtrsim \frac{qv^2}{s\log(qmv^4/s^2)}.$$

With these bounds, Lemma 2.2 follows.

Proof of Lemma 2.2 We combine Lemma 2.12, Lemma 2.14, and Lemma 2.15.

3. PROOF OF MAIN RESULTS

Now that we have proven bounds on $\|R(x_1, \ldots, x_n)\|_q$ in Lemma 2.1 and Lemma 2.2, we prove our main results: Theorem 1.5, Theorem 1.6, and Corollary 1.7. Our proofs require the following cleaner bounds on moments of $\|R(x_1, \ldots, x_n)\|_q$ that follow simplifying the bounds in Lemma 2.1 and Lemma 2.2 at the target values of $v$. We defer the proofs of these lemmas, which boil down to function bounding and simplification, to Appendix E.

Lemma 3.1 Suppose that $0 < \varepsilon < C_\varepsilon$ and $0 < \delta < C_\delta$ for some constants $C_\varepsilon, C_\delta$. There exist constants $C_{\varepsilon, \delta, /} C_{\varepsilon, /}, C_{\varepsilon, \delta, /}, C_{\varepsilon, /}, C_{\varepsilon, /} > 0$ such that for $0 < \varepsilon < C_\varepsilon, 0 < \delta < C_\delta$, $1 \leq s \leq C_{\varepsilon, \delta, /} \log(1/\delta)$, and $C_{\varepsilon, \delta, /} \log(1/\delta) \leq m < 2\varepsilon^{-2}/\delta$, and if $v \leq g_{\varepsilon, /}(m, \varepsilon, \log(1/\delta), s)$, and $p$ is $\log(1/\delta)$ rounded up to the nearest even integer, then we have that:

$$\|R(x_1, \ldots, x_n)\|_p \leq \frac{\varepsilon}{2}.$$
Proof of Theorem 1.5 To get the case where $m \geq 2e^{-2}/\delta$, we take $q = 2$ in Lemma 2.1 and apply Chebyshev’s inequality. Otherwise, we use Lemma 3.1 to see that $\|R(x_1,\ldots,x_n)\|_p \leq \frac{D}{\sqrt{p}}$. By Markov’s inequality, this means that $\mathbb{P}[\|Ax\|_2^2 - 1 \geq \varepsilon]$ can be expressed as:

$$
\mathbb{P}[\|R(x_1,\ldots,x_n)\|_p \geq \varepsilon] = \mathbb{P}[R(x_1,\ldots,x_n)^p \geq \varepsilon^p] \leq \varepsilon^{-p} \mathbb{E}[R(x_1,\ldots,x_n)]^p \leq \delta.
$$

Now, we observe that there exists a constant $C_U$ such that when $m \geq 2e^{-2}p e^{-\frac{C_U \varepsilon^2}{\varepsilon^2}}$, we have that $C_U \varepsilon^2 \sqrt{\log(me^2)} \geq 1$, so we know that $\varepsilon(m,\delta) = 1$ in this case. Moreover, we need to take a min with 1 in general since $v$ is defined to be the sup over $[0,1]$ and $S_i = S_1$ for $v \geq 1$.

To upper bound $v(m,\varepsilon,\delta,s)$, we need to lower bound the tail probability of $R(x_1,\ldots,x_n)$. The main tool that we use is the Paley-Zygmund inequality:

Lemma 3.3 (Paley-Zygmund) Suppose that $Z$ is a nonnegative random variable with finite variance. Then,

$$
\mathbb{P}[Z > 2^{-1} \mathbb{E}[Z]] \geq \frac{\mathbb{E}[Z]^2}{4 \mathbb{E}[Z^2]}.
$$

For our setting, we use the Paley-Zygmund inequality applied to $q$th moments:

Lemma 3.4 Suppose that $K > 0$ and $Z$ is a nonnegative random variable, such that $\|Z\|_q \geq 2K$ and $\|Z\|_{2q}$ is finite. Then,

$$
\mathbb{P}[Z > K] \geq 0.25 \left( \frac{\|Z\|_q}{\|Z\|_{2q}} \right)^{2q}.
$$

Proof of Lemma 3.4 We apply Lemma 3.3 to $Z^p$ to obtain that:

$$
\mathbb{P}[Z^p > 2^{-1} \mathbb{E}[Z^p]] \geq 0.25 \frac{\mathbb{E}[Z^p]^2}{\mathbb{E}[Z^{2p}]} = 0.25 \left( \frac{\|Z\|_p}{\|Z\|_{2p}} \right)^{2p}.
$$

If $\|Z\|_p \geq 2K$, then we know that

$$
\mathbb{P}[Z > K] = \mathbb{P}[Z^p > K^p] \geq \mathbb{P}[Z^p > 2^{-p} \mathbb{E}[Z^p]] \geq \mathbb{P}[Z^p > 2^{-1} \mathbb{E}[Z^p]]
$$

and then we can apply the above result.

Now, we use Lemma 3.4 and Lemma 3.2 to prove Theorem 1.6

Proof of Theorem 1.6 Let $p = \log(1/\delta)$ and $q$ be a power of 2 in $[\frac{p}{2}, \frac{p-2}{2 \log_2(D)}]$ where $D' = \min(1/e,D)$. By Lemma 3.4 (with $K = \varepsilon$) and Lemma 3.2 it follows that $\mathbb{P}[\|Ax\|_2^2 - 1 \geq \varepsilon]$ can be expressed as:

$$
\mathbb{P}[R(v,\ldots,v,0,\ldots,0) > \varepsilon] \geq 0.25 \frac{\|R(v,v,\ldots,v,0,\ldots,0)\|_q}{\|R(v,v,\ldots,v,0,\ldots,0)\|_{2q}} \geq 0.25 D^{2q} \geq \delta.
$$

We now prove Corollary 1.7
Proof of Corollary 1.7. Let’s set $C_{\varepsilon} = \frac{\sqrt{\log(16e^2)}}{\varepsilon}$. This solves to $m = \varepsilon^{-2} p C_{\varepsilon}$. for some constant $C_L$ as desired. Now, we set $C$ to be sufficiently large so that this is greater than $C_{\varepsilon}$. □

APPENDIX A. HANSON-WRIGHT IS TOO LOOSE EVEN FOR $s = 1$

We consider

$$\tilde{R}(x_1, \ldots, x_n) = \frac{1}{s} \sum_{r=1}^{m} \sum_{i \neq j} \eta_{r,i} \eta_{r,j} g_{r,i} g_{r,j} x_i x_j$$

where the $g_{r,i}$ are i.i.d standard gaussians. However, we consider $p$ equal to $\log(1/\delta)$ rounded up to the nearest even integer, and we consider a vector of the form $[v, \ldots, v, 0, \ldots, 0]$ where $\frac{v}{p}$ is an integer and $v \geq 0$. We show $\| \tilde{R}(v, \ldots, v, 0, \ldots, 0) \|_p \geq o(\varepsilon)$ for a certain $v$ value, where we know it to be true that $\| \tilde{R}(v, \ldots, v, 0, \ldots, 0) \|_p \lesssim \varepsilon$.

Let’s consider a vector $[v, \ldots, v, 0, \ldots, 0]$ where $\frac{v}{p}$ is an integer and $v \geq 0$. We apply the Hanson-Wright bound (which is tight for gaussians) to obtain:

$$\| \tilde{R}(v, \ldots, v, 0, \ldots, 0) \|_p \gtrsim p v^2 \left\| \sum_{\|x\|_2 \leq 1, \|y\|_2 \leq 1 \leq i \neq j \leq N} \eta_{i,j} \eta_{i,j} x_i y_j \right\|_p \gtrsim \sum_{\|x\|_2 \leq 1, \|y\|_2 \leq 1 \leq i \neq j \leq N} \eta_{i,j} \eta_{i,j} x_i y_j .$$

Let $M = \sum_{i=1}^{N} \eta_{i,i}$. Let $S \subseteq [N]$ be the set of indices where $\eta_{i,i} = 1$. We can set the vector to $x_i = y_i = \frac{1}{\sqrt{M}}$ for all $i \in S$ and 0 elsewhere. This gives us:

$$\left\| \sum_{\|x\|_2 \leq 1 \leq i \neq j \leq N} \eta_{i,j} \eta_{i,j} x_i y_j \right\|_p \gtrsim \| M - 1 \|_p = \left\| \sum_{i=1}^{N} \eta_{i,i} - 1 \right\|_p \gtrsim \left\| \sum_{i=1}^{N} \eta_{i,i} \geq 2 \sum_{i=1}^{N} \eta_{i,i} \right\|_p .$$

We can expand out this moment to obtain:

$$E \left[ \left( \sum_{i=1}^{N} \eta_{i,i} \right)^p \right] \geq C^p \sum_{M=2}^{p} \binom{N}{M} M^p \left( \frac{s}{m} \right)^{M} (1 - \frac{s}{m})^{M} \geq C^p \sum_{M=2}^{p} \binom{N}{p} (\frac{p}{M})^M M^p \left( \frac{s}{m} \right)^M (1 - \frac{s}{m})^M$$

$$= C^p \sum_{M=2}^{p} \left( \frac{s}{pmv^2} \right)^M M^p \left( \frac{p}{M} \right)^M (1 - \frac{s}{m})^M .$$

Since $M \leq p$, we know that $(\frac{p}{M})^M \geq 1$. Moreover, as long as $p \geq \frac{4e}{mv^2}$, we know that $(1 - \frac{s}{m})^{M/p} \geq (1 - \frac{s}{m})^{N/p} \geq (1 - \frac{s}{m})^{\frac{n}{p}} \geq 0.3$. Thus we obtain a bound of

$$D^p \sum_{M=2}^{p} \left( \frac{s}{pmv^2} \right)^M .$$

If $2 \leq \log(\frac{p}{pmv^2}) \leq p$ (which can be written as $1 \leq \log(pm v^2 / s) \leq \frac{p}{2}$), then we know that:

$$pv^2 \left\| \sum_{\|x\|_2 \leq 1 \leq i \neq j \leq N} \eta_{i,j} \eta_{i,j} x_i y_j \right\|_p \gtrsim \frac{p^2 v^2}{\log(pm v^2 / s)} .$$

Let’s try to show that when $s = 1$, the bound $v = \sqrt{\frac{\log(p / \delta)}{p}}$ will not work (even though we do know it should hold in some of these cases). In this case, we know that:

$$1 \leq \frac{pm v^2}{e} = \log^2(m \epsilon) \frac{m \epsilon}{p \epsilon} .$$
If we have that \( \log\left(\frac{me}{p}\right) \leq \sqrt{p} \), then we know that \( v \leq \frac{1}{\sqrt{p}} \) and \( \log(pm^2) \leq \frac{p}{2} \). However, the bound

\[
\frac{p^2v^2}{\log(pm^2)} \geq \varepsilon \log\left(\frac{me}{p}\right) \geq \varepsilon \log\left(\frac{me}{p}\right) = o(\varepsilon).
\]

**APPENDIX B. PROOF OF USEFUL MOMENT BOUNDS**

First, we prove Lemma 2.3. It follows from Latala’s tight bound \(^{[21]}\) on moments of quadratic forms of Rademacher\(^{[14]}\).

**Lemma B.1** \(^{[21]}\) Let \( T \) be an even natural number. Let \( \sigma_1, \ldots, \sigma_n \) be independent Rademachers and let \( (a_{i,j}) \) a symmetric matrix with zero diagonal. Then:

\[
\left\| \sum_{1 \leq i,j \leq n} a_{i,j} \sigma_i \sigma_j \right\|_T \simeq \left( \sup_{\|b\|_2 \leq \sqrt{T}, \|b\|_\infty \leq 1} \sum_{1 \leq i,j \leq n} a_{i,j} b_i b_j \right) + \sum_{1 \leq i \leq T} A_i^* + \sqrt{T} \left( \sum_{T < t \leq n} (A_i^*)^2 \right)
\]

where \( A_i = \sqrt{\sum_{1 \leq j \leq n} a_{i,j}^2} \) and \( A_1^* \geq A_2^* \geq \ldots \geq A_n^* \) is a permutation of \( A_1, \ldots, A_n \).

To prove Lemma 2.3 we apply Lemma B.1 to the case where the \( a_{i,j} \) are themselves random variables:

**Proof of Lemma 2.3** Let \( Q = \sum_{1 \leq i \neq j \leq n} Y_{i,j} \sigma_i \sigma_j \). Applying Lemma B.1 we have that:

\[
(\mathbb{E}_Y \sigma_i [Q_T])^{1/T} = (\mathbb{E}_Y \mathbb{E}_\sigma [Q_T])^{1/T}
\]

\[
= \mathbb{E}_Y \left[ \left\| \sum_{1 \leq i,j \leq n} Y_{i,j} \sigma_i \sigma_j \right\|_T \right]^{1/T}
\]

\[
\simeq \left( \sup_{\|b\|_2 \leq \sqrt{T}, \|b\|_\infty \leq 1} \sum_{1 \leq i,j \leq n} Y_{i,j} b_i b_j \right) + \sum_{1 \leq i \leq T} W_i + \sqrt{T} \left( \sum_{T < t \leq n} W_t^2 \right)
\]

where the last line follows from the fact that the \( Y_{i,j} \) are nonnegative, so each term is nonnegative, so the triangle inequality results in at most a factor of 2 of gain.

Now, we present a proof of Proposition 2.11

**Proof of Proposition 2.11** Let \( v = \left( \sup_{1 \leq k \leq T} \frac{T}{k} \left( \frac{1}{T^{1/2k}} \right) \left\| Y_i \right\|_{2k} \right)^{1/(2k)} \). Observe that

\[
\mathbb{E}_i \left( \sum_{i} Y_{X_i} \right)^{2T} = \sum_{d_1 + d_2 + \ldots + d_n = T, d_i \leq T} \frac{2T!}{2d_1! \ldots 2d_n!} \prod_{i=1}^{n} \mathbb{E} \left( \frac{Y_{X_i}}{t} \right)^{2d_i}
\]

\[
\leq C^T \sum_{d_1 + d_2 + \ldots + d_n = T, d_i \leq T} \frac{(2T)^{2T}}{(2d_1)^{2d_1} \ldots (2d_n)^{2d_n}} \prod_{i=1}^{n} \mathbb{E} \left( \frac{Y_{X_i}}{t} \right)^{2d_i}
\]

\[
\leq C^T \sum_{i=1}^{n} \left( \frac{2T}{\max_{d_i}} \right)^{2d_i} \sum_{0 \leq d_i \leq T} \frac{(2T)^{2d_i}}{(2d_i)^{2d_i}} \prod_{i=1}^{n} \mathbb{E} \left( \frac{Y_{X_i}}{t} \right)^{2d_i}
\]

\[
= C^T \prod_{i=1}^{n} \left( 1 + \sum_{1 \leq d_i \leq T} \frac{(T X_i \left\| Y_i \right\|_{2d_i} v)}{vd_i t} \right)^{2d_i}
\]

\(^{14}\)In \([21]\), there is a generalization of Lemma B.1 to much more general quadratic forms, but for the application to JL, we only need the bound in the special case of Rademachers.
Now, we use the fact that \(|x_i| \leq v|\) and the condition on \(t\) to obtain that this is bounded by
\[
C^T \prod_{i=1}^{n} \left(1 + \frac{x_i^2}{v^2} \sum_{1 \leq d_i \leq T} \left(\frac{T v \|Y_i\|_{2d_i}}{d_i t}\right)^{2d_i}\right) \leq C^T \prod_{i=1}^{n} \left(1 + T x_i^2\right) \leq C^T \prod_{i=1}^{n} e^{T x_i^2} \leq C^T e^T.
\]

\[\square\]

**APPENDIX C. PROOFS OF AUXILIARY LEMMAS FOR LEMMA 2.3**

First, we use Lemma 2.5 and Lemma 2.8 to prove a upper bound \(\|R(x_1, \ldots, x_q)\|_q\) that is not quite in the desired form for Lemma 2.1.

**Lemma C.1** Let \(2 \leq q \leq m\) be an even integer and \(x_1 \leq v\) and \(\|x\|_2 = 1\). If \(\frac{sv}{mv} \geq q\), then:
\[
\|R(x_1, \ldots, x_n)\|_q \lesssim \alpha_1(q, v, s, m).
\]
If \(\log(qmv^2/s) > q\) then we have
\[
\|R(x_1, \ldots, x_n)\|_q \lesssim \max(\alpha_1(q, v, s, m), \alpha_2(q, v, s, m)).
\]
In all other cases, we have that
\[
\|R(x_1, \ldots, x_n)\|_q \lesssim \max(\alpha_1(q, v, s, m), \alpha_2(q, v, s, m), \min(\alpha_3(q, v, s, m), \alpha_4(q, v, s, m))).
\]
The functions are defined as follows.
\[
\alpha_1(q, v, s, m) = \frac{\sqrt{q}}{\sqrt{m}}
\]
\[
\alpha_2(q, v, s, m) = \begin{cases} 
\frac{q v^2 e}{s \log(qmv^2/s^2)} & \text{for } \log(qmv^2/s^2) \geq 2 \\
\frac{q v^2}{s \sqrt{m}} & \text{for } \log(qmv^2/s^2) \leq 2
\end{cases}
\]
\[
\alpha_3(q, v, s, m) = \frac{q v^2 e}{s \log(m/s)} \sup_{T \leq q, T \geq \frac{sv}{mv}, \text{max}(\log(m/s), T/s)} \left(\frac{T}{\log^2(mv^2/s)}\right) \left(\frac{s}{qv^2}\right)^{1/T}
\]
\[
\alpha_4(q, v, s, m) = \frac{q v^2 e}{s \log(m/s)} \left\{ \begin{array}{ll} 
1 & \text{for } \log(qmv^2/s^2) \geq 2 \\
\left(\frac{s}{qv^2}\right)^{1/\log(mv^2/s)} & \text{else}
\end{array} \right.
\]

**Proof of Lemma C.1** As we discussed in Section 2.3 it suffices to bound
\[
\frac{1}{s} \sup_{2 \leq T \leq q} \frac{q}{T} \left(\frac{m}{q}\right)^{1/t} \|Z_1(x_1, \ldots, x_n)\|_t.
\]
Our bounds on \(\|Z_1(x_1, \ldots, x_n)\|_t\) are based on Lemma 2.8. We split into cases based on the \(T\) value, and how it separates into different cases in Lemma 2.8. Let
\[
\beta_1(q, v, s, m) = \frac{1}{s} \sup_{T=2, 3 \leq T \leq \frac{sv}{mv}} \frac{q}{T} \left(\frac{m}{q}\right)^{1/t} \|Z_1(x_1, \ldots, x_n)\|_t,
\]
\[
\beta_2(q, v, s, m) = \frac{1}{s} \sup_{\text{max}(3, \frac{sv}{mv}) \leq T \leq \log(mv^2/s)} \frac{q}{T} \left(\frac{m}{q}\right)^{1/t} \|Z_1(x_1, \ldots, x_n)\|_t.
\]
\[
\beta_{34}(q, v, s, m) = \frac{1}{s} \sup_{T \geq \text{max}(3, \frac{sv}{mv}, \log(mv^2/s))} \frac{q}{T} \left(\frac{m}{q}\right)^{1/t} \|Z_1(x_1, \ldots, x_n)\|_t.
\]
Let $\beta_3$ branch arise when we use the $\frac{T^2 x^2}{\log(Tmv^2/s^2)}$ for the $\|Z_1(x_1, \ldots, x_n)\|_T$ bound, and let the $\beta_4$ branch arise when we use $\frac{T^2 v^2}{s \log(m/s)}$ for the $\|Z_1(x_1, \ldots, x_n)\|_T$ bound. Thus, we know that

$$\beta_{34}(q,v,s,m) \leq \min(\beta_3(q,v,s,m), \beta_4(q,v,s,m)).$$

When $\frac{se}{mv^2} \geq q \geq T$, we see that only the $\alpha_1(q,v,s,m)$ term arises. When $\log(Tmv^2/s) \geq T$ (which can be written as $\frac{T}{\log(Tmv^2/s)} \geq 1$) for all $\frac{se}{mv^2} \leq T \leq q$, we see that $\alpha_{34}$ does not arise. Let $x = Tmv^2/s$. Then we know that $x \geq e$ based on the condition $T \geq \frac{se}{mv^2}$. The condition $\frac{T}{\log(Tmv^2/s)} \geq 1$ can be written as $\frac{s}{mv^2 \log x}$. This is an increasing function for $x \geq e$, and so if this condition is not met at $T = q$, then it is never going to be met.

We write this condition as $\log(qmv^2/s) \geq q$. In all other cases, we include all three terms. Thus, it suffices to produce bounds $\alpha_1(q,v,s,m), \ldots, \alpha_4(q,v,s,m)$ such that $\beta_1(q,v,sm) \lesssim \alpha_i(q,v,s,m)$, which is what we do for the remainder of the analysis.

First, we handle the $\beta_1(q,v,s,m)$ term. We see that

$$\beta_1(q,v,s,m) = \frac{1}{s} \sup_{2 \leq T \leq \frac{se}{mv^2}} \frac{q}{T} \left( \frac{m}{q} \right)^{1/T} Ts = \frac{1}{s} \frac{q}{m} \left( \frac{m}{q} \right)^{1/T} \leq \frac{q}{m} \left( \frac{m}{q} \right)^{1/2} = \sqrt{q/m}.$$

Now, we handle the $\beta_2(q,v,s,m)$ term. We obtain a bound for $\|Z_r\|_T \lesssim v^2 \left( \frac{s}{mv^2} \right)^{2/T}$. The expression becomes:

$$\beta_2(q,v,s,m) = \frac{1}{s} \sup_{T \geq \frac{se}{mv^2}, 3T \leq \log(mv^2/s)} \frac{qv^2}{T} \left( \frac{m}{q} \right)^{1/T} \left( \frac{s}{mv^2} \right)^{2/T}$$

$$= \frac{1}{s} \sup_{T \geq \frac{se}{mv^2}, 3T \leq \log(mv^2/s)} \frac{qv^2}{T} \left( \frac{s}{mv^2} \right)^{2/T}$$

$$\leq \frac{1}{s} \sup_{T \geq \frac{se}{mv^2}, 3T \leq \log(mv^2/s)} \frac{qv^2}{T} \left( \frac{s^2}{qm} \right)^{1/T}.$$

Suppose that $\log(qmv^4/s^2) \geq 2$. In this case, we have that this expression is upper bounded by $T = \log(qmv^4/s^2)$. When we plug this into the expression, we obtain $\frac{q}{s \log(qmv^4/s^2)}$. Otherwise, if $\log(qmv^4/s^2) \leq 2$, then this expression is upper bounded by $T = 3$:

$$\frac{qv^2}{s} \left( \frac{s^2}{qm} \right)^{1/3} = C_1 C_2 \frac{q^{2/3} v^{2/3}}{s^{1/3} m^{1/3}}.$$

We know that that $\frac{q^{2/3} v^{2/3}}{s^{1/3} m^{1/3}} \leq \sqrt{q/m}$ because this reduces to

$$\frac{q^{1/6} v^{2/3} m^{1/6}}{s^{1/3}} = \left( \frac{qmv^4}{s^2} \right)^{1/6} \leq e^{1/3}.$$

Now, we handle the $\beta_4(q,v,s,m)$ term.

$$\beta_4(q,v,sm) = \frac{1}{s} \sup_{T \geq \frac{se}{mv^2}, 3T \leq \log(mv^2/s)} \frac{q}{T} \left( \frac{m}{q} \right)^{1/T} \frac{T}{\log(m/s)}$$

$$\leq \frac{q}{s} \sup_{T \geq \frac{se}{mv^2}, 3T \leq \log(mv^2/s)} \frac{mv^2}{s} \frac{1}{T} \left( \frac{s}{q^2} \right)^{1/T}$$

$$\leq \frac{qe}{s \log(m/s)} \sup_{T \geq \frac{se}{mv^2}, 3T \leq \log(mv^2/s)} \left( \frac{s}{q^2} \right)^{1/T}.$$
Observe that if \( \log(qmv^A/s^2) \geq 2 \), if \( s \leq qv^2 \), this is bounded by 1, and if \( s \geq qv^2 \), this is bounded by \( \left( \frac{s}{qv^2} \right)^{1/\log((mv^2)/s)} \). We see that \( \frac{s}{qv^2} \leq \frac{mv^2}{s} \), so \( \left( \frac{s}{qv^2} \right)^{1/\log((mv^2)/s)} \leq \left( \frac{mv^2}{s} \right)^{1/\log((mv^2)/s)} \leq e \). Thus this is bounded by \( \frac{q}{s \log((mv^2)/s)} \).

Now, we handle the \( \beta_3(q, v, s, m) \) term. In this case, the expression becomes:

\[
\beta_3(q, v, s, m) = \frac{1}{s} \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)T} qv^2T \frac{T}{q} \frac{T^2}{\log^2((mv^2)/s)}
\]

\[
\leq \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)} \frac{qv^2T}{s} \frac{T}{\log^2((mv^2)/s)} \left( \frac{s}{qv^2} \right)^{1/\log((mv^2)/s)}
\]

\[
\leq \frac{qv^2e}{s} \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)} \frac{T}{\log^2((mv^2)/s)} \left( \frac{s}{qv^2} \right)^{1/\log((mv^2)/s)}
\]

We use some function bounding arguments to come with a simpler bound for \( \alpha_3 \) for sufficiently large \( v \).

**Lemma C.2** Assume that \( C_2q^3mv^A \geq s^2 \) for some \( C_2 \geq 1 \). Then it is true that

\[
\frac{qv^2e}{s} \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)} \frac{T}{\log^2((mv^2)/s)} \left( \frac{s}{qv^2} \right)^{1/\log((mv^2)/s)} \leq \frac{C_2^{1/3}q^2v^2e^5}{s \log^2((mv^2)/s)}.
\]

**Proof of Lemma C.2** With the assumptions that we made we know that \( \frac{s}{qv^2C_2^2} \leq \frac{mv^2}{s} \). This implies that our expression becomes:

\[
E = \frac{qv^2e}{s} \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)} \frac{T}{\log^2((mv^2)/s)} \left( \frac{s}{qv^2} \right)^{1/\log((mv^2)/s)}
\]

\[
= \frac{qv^2e}{s} \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)} C_2^{1/3} \frac{T}{\log^2((mv^2)/s)} \left( \frac{s}{C_2q^3v^2} \right)^{1/\log((mv^2)/s)}
\]

\[
\leq \frac{qv^2e^2}{s} C_2^{1/3} \sup_{T \geq \frac{mv^2}{s}3, \log((mv^2)/s)} \frac{T}{\log^2((mv^2)/s)} q^{2/3}
\]

Now, we just need to bound

\[
\sup_{T_{\text{min}} \leq T \leq q} \frac{T^{2/3}}{\log^2((mv^2)/s)} \leq \max \left( \sup_{T_{\text{min}} \leq T \leq q} \frac{T^{2/3}}{\log^2((mv^2)/s)}, \sup_{T_{\text{min}} \leq T \leq \log^2((mv^2)/s)} \frac{T^{2/3}}{\log^2((mv^2)/s)} \right)
\]

\[
\leq \max \left( \sup_{T_{\text{min}} \leq T \leq q} \frac{T^{2/3}}{\log^2((mv^2)/s)}, e^2 \sup_{\max(T_{\text{min}}, \log^2((mv^2)/s)) \leq q} \frac{T}{\log^2((mv^2)/s)} \right)
\]

First, we handle the second term. We know that \( T_{\text{min}} \geq \frac{se}{mv^2} \). Let \( Q = \frac{T}{mv^2} \). Observe that \( Q \geq e \). We see that

\[
e^2 \sup_{\max(T_{\text{min}}, \log^2((mv^2)/s)) \leq q \leq \log^2((mv^2)/s)} \frac{T}{\log^2((mv^2)/s)} \leq e^2 \frac{s}{mv^2} \sup_{e \leq \frac{Q}{mv^2} \leq \frac{Q}{mv^2}} \frac{Q}{\log^2(Q)}
\]

We see that setting \( Q \) to its maximum value achieves with a factor of \( e \) of the maximum. Thus, we obtain that this is upper bounded by \( e^3 \frac{q}{\log^2((mv^2)/s)} \).
Now, we just need to handle the first term. If \( T_{\text{min}} \geq (\log q)/10 \), then we are done. Let’s take a log to obtain:

\[
\log T - 2 \log \log (mv^2T/s) + \frac{2}{T} \log(q).
\]

The derivative is:

\[
\frac{1}{T} - \frac{2}{T \log (mv^2T/s)} - \frac{2}{T^2} \log(q).
\]

The sign of the derivative is the same as:

\[
1 - \frac{2}{\log (mv^2T/s)} - \frac{2 \log q}{T}.
\]

We know that \( 1 - \frac{2}{\log (mv^2T/s)} \leq 1 \). Since \( T \leq \log q \), we know that the last term is \(-\frac{2 \log q}{T} \leq -2 \). Thus, the derivative is negative, so we just need to consider \( T_{\text{min}} = T \), where the expression is:

\[
e^3 \frac{T_{\text{min}}q^{2/T_{\text{min}}}}{\log^2 (mv^2T_{\text{min}}/s)} \leq e^3 \frac{(\log q)q^{2/3}/\log^2 (mv^2T_{\text{min}}/s)}{\log (mv^2T_{\text{min}}/s)} \leq e^3 \frac{q^{3/4}}{\log^2 (mv^2T_{\text{min}}/s)}.
\]

Thus, to upper bound by \( \frac{q}{\log (mv^2q/s)} \), it suffices to show:

\[
\frac{\log^2 (mv^2q/s)}{\log^2 (mv^2T_{\text{min}}/s)} \leq q^{0.25}.
\]

If \( \frac{s}{mv^2} \leq 1 \), the ratio is at most

\[
\frac{\log (mv^2q/s)}{\log (mv^2T_{\text{min}}/s)} \leq \frac{\log (mv^2/s)}{\log (mv^2/s)} + \frac{\log q}{\log T_{\text{min}}} \leq \frac{\log q}{\log e} \leq \log q.
\]

If \( \frac{s}{mv^2} \geq 1 \), then \( qmv^2/s \leq q \) and \( T_{\text{min}} \geq \frac{se}{mv^2} \), we know:

\[
\frac{\log (mv^2q/s)}{\log (mv^2T_{\text{min}}/s)} \leq \frac{\log(q)}{\log(e)} \leq \log q.
\]

Now, we combine Lemma \( \text{C.1} \) and Lemma \( \text{C.2} \) to prove Lemma \( \text{2.1} \).

**Proof of Lemma \( \text{2.1} \).** First, we compute the second moment by hand:

\[
\mathbb{E}[R(x_1, \ldots, x_n)]^2 = \frac{1}{s^2} \mathbb{E} \left[ \left( \sum_{r=1}^{m} \sum_{i \neq j} \eta_i \eta_r \sigma_i \sigma_r x_i x_j \right)^2 \right]
\]

\[
= \frac{2}{s^2} \mathbb{E} \left[ \sum_{r=1}^{m} \sum_{i \neq j} \eta_i \eta_r \sigma_i \sigma_r x_i^2 x_j^2 \right]
\]

\[
\leq \frac{2}{m} \left( \sum_{i=1}^{n} x_i^2 \right)
\]

\[
= \frac{2}{m}.
\]

For \( 2 < q \leq m \), we apply Lemma \( \text{C.1} \) and Lemma \( \text{C.2} \). We only include \( \alpha_4 \) when \( \log(qmv^4/s^2) \geq 2 \) to simplify the bound. The bound follows.
We prove Lemma 2.13

Proof of Lemma 2.13 First, we show the following fact: Suppose that there are $T$ distinguishable buckets and we want to assign an ordered pair of 2 unequal elements in $[N]$ to each bucket so that the total number of times that any element $i \in [N]$ shows up is $\leq s$. We show that the number of such assignments is at least $C_T N^{2T}$ for some constant $C$. To prove this, we first consider the case where $N \geq 2T$. In this case, we have that the number of such assignments is at least:

$$N(N - 1)(N - 2) \ldots (N - 2T + 1) \geq C_T^T N^{2T}.$$  

Now, if $N < 2T$, then we define:

$$\beta = \left\lceil \frac{2T}{N} \right\rceil = \left\lceil 2Tv^2 \right\rceil \leq s.$$  

By construction, we know that $\beta N \geq 2T$. We partition $2T$ into $\beta$ blocks, each of size $N$, until potentially the last block, which may be smaller. Let’s assume that each block is a permutation of $1, \ldots, N$, and the last block is $2T - (\beta - 1)(N)$ non-equal numbers drawn from $1, \ldots, N$. (this satisfies the unequal ordered pair condition). Then the number of assignments is $(N!)^{\beta-1} \cdot (N)(N - 1) \ldots (N - (2T - (\beta - 1)(N)) + 1)$. This is at least as big as $C_T^T N^{2T}$ for some constant $C_1$.

First, we handle the case where $q/T = 2$. Since we have a uniform sparse JL distribution, we know that for $1 \leq x \leq s$:

$$\mathbb{E}[\eta_1, \ldots, \eta_s, 1] \geq \frac{s(s - 1) \ldots (s - x + 1)}{(m)(m - 1) \ldots (m - x + 1)} \geq C_2 x \left(\frac{s}{m}\right)^x.$$  

We know that

$$Z_r^2 = 2 \left( \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \right) + Y_r,$$  

where $Y_r$ has expectation 0. In this case we have that

$$Z_r^2 \ldots Z_r^2 = 2^T \left( \sum_{i_1 \neq j_1, \ldots, i_T \neq j_T} \prod_{k=1}^{T} \eta_{k,i_k} \eta_{k,j_k} \right) + Q.$$  

where $Q$ consists of terms that contain a factor of some $Y_r$. Due to the independence of the Rademachers, the expectation of any term that contains a factor of $Y_r$ has expectation 0, which implies that:

$$\mathbb{E}[Z_r^2 \ldots Z_r^2] = v^{2T} 2^T \mathbb{E} \left[ \left( \sum_{i_1 \neq j_1, \ldots, i_T \neq j_T} \prod_{k=1}^{T} \eta_{k,i_k} \eta_{k,j_k} \right) \right].$$  

Let $\eta_{r,i} \sim \eta_{r,j}$ be independent random variables. Suppose that

$$Z_r' := v^{2T} \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \sigma_{r,i} \sigma_{r,j}.$$  

We know that

$$Z_r^2 = 2 \left( \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \right) + Y'_r,$$  

where $Y'_r$ has expectation 0. This means that:

$$Z_r^2 \ldots Z_r^2 = v^{2T} 2^T \left( \sum_{i_1 \neq j_1, \ldots, i_T \neq j_T} \prod_{k=1}^{T} \eta_{k,i_k} \eta_{k,j_k} \right) + Q'$$  

where $Q'$ consists of terms that contain a factor of some $Y'_r$. For similar reasons, this implies that

$$\mathbb{E}[Z_r^2 \ldots Z_r^2] = v^{2T} 2^T \mathbb{E} \left[ \left( \sum_{i_1 \neq j_1, \ldots, i_T \neq j_T} \prod_{k=1}^{T} \eta_{k,i_k} \eta_{k,j_k} \right) \right].$$
Let’s view \( \prod_{k=1}^T \eta_{k,i} \) and \( \prod_{k=1}^T \eta_{k,j} \) as terms in a sum. In the second expression, every term has expectation \( (\frac{s}{m})^{2T} \), and there are at most \( N^{2T} \) terms. In the first expression, if there are \( >s \) copies of any \( i_k \) value, then the expectation is 0. Otherwise, the expectation varies between \( C_2^{-2T} \left( \frac{s}{m} \right)^{2T} \) and \( \left( \frac{s}{m} \right)^{2T} \). By the counting argument, we know that there are at least \( C_1^{-2T} N^{2T} \) terms. This implies that
\[
||Z_1 \ldots Z_T||_2 \geq C^T ||Z'_1 \ldots Z'_T||_2 = C^T ||Z'_1||_2^T = C^T ||Z_1||_2^T
\]
as desired.

Now, we handle the case of the general \( q/T \). Since we have a uniform sparse JL distribution, we know that for \( 1 \leq x \leq s \):
\[
\mathbb{E}[\eta_{1,1} \ldots \eta_{x,x}] \geq \frac{s(s-1) \ldots (s-x+1)}{(m-1) \ldots (m-x+1)} \geq C_2^{-x} \left( \frac{s}{m} \right)^x.
\]
We know that
\[
(Z_r)^{q/T} = 2^{q/T - 1} \sum_{i \neq j} (\eta_{r,i} \eta_{r,j})^{q/T} + Y_r,
\]
where \( Y_r \) has expectation \( \geq 0 \). In this case we have that
\[
(Z_1 \ldots Z_T)^{q/T} = 2^{q/T - 2T} \left( \sum_{i_j \neq i_l, i_m \neq i_r} \prod_{k=1}^T (\eta_{k,i} \eta_{k,j})^{q/T} \right) + Q,
\]
where \( Q \) has expectation \( \geq 0 \). This implies that:
\[
\mathbb{E}[Z_1^{q/T} \ldots Z_T^{q/T}] \geq v^{2T} 2^{q/T - 2T} \mathbb{E} \left[ \left( \sum_{i_j \neq i_l, i_m \neq i_r} \prod_{k=1}^T (\eta_{k,i} \eta_{k,j})^{q/T} \right) \right].
\]
Let \( \eta_{r,i} \sim \eta_{r,j} \) be independent random variables, and let \( M'_r = \sum_{i=1}^N \eta_{r,i} \). Suppose:
\[
Z'_r := v^{2T} \sum_{i \neq j} \eta_{r,i} \eta_{r,j} \sigma_{r,i} \sigma_{r,j}.
\]
We know that
\[
(Z'_r I_{M'_r=2})^{q/T} = 2^{q/T - 1} \sum_{i \neq j} (\eta_{r,i} \eta_{r,j} I_{M'_r=2})^{q/T} + Y'_r,
\]
where \( Y'_r \) has expectation 0. In this case we have that
\[
(Z'_r I_{M'_r=2} \ldots Z'_r I_{M'_r=2})^{q/T} = 2^{q/T - 2T} \left( \sum_{i_j \neq i_l, i_m \neq i_r} \prod_{k=1}^T (\eta_{k,i} \eta_{k,j} I_{M'_r=2})^{q/T} \right) + Q',
\]
where \( Q' \) consists of terms that contain a factor of some \( Y'_r \). For similar reasons to the above, we have that:
\[
\mathbb{E}[Z'_1 \ldots Z'_T] = v^{2T} 2^{q/T - 2T} \mathbb{E} \left[ \left( \sum_{i_j \neq i_l, i_m \neq i_r} \prod_{k=1}^T (\eta_{r,i} \eta_{r,j} I_{M'_r=2})^{q/T} \right) \right].
\]
Let’s view \( \prod_{k=1}^T (\eta_{k,i} \eta_{k,j})^{q/T} \) and \( \prod_{k=1}^T (\eta_{k,i} \eta_{k,j} I_{M'_r=2})^{q/T} \) as terms in a sum. In the second expression, every term has expectation \( \leq \left( \frac{s}{m} \right)^{2T} \) the indicator can only reduce the expectation, and there are at most \( N^{2T} \) terms. In the first expression, if there are \( >s \) copies of any \( i_k \) value, then the expectation is 0. Otherwise, the expectation varies between \( C_2^{-2T} \left( \frac{s}{m} \right)^{2T} \) and \( \left( \frac{s}{m} \right)^{2T} \). By the counting argument, we know that there are at least \( C_1^{-2T} N^{2T} \) terms. This implies that
\[
||Z_1 \ldots Z_T||_2^{q/T} \geq C^T ||Z'_1 I_{M'_r=2} \ldots Z'_r I_{M'_r=2}||_2^{q/T} = C^T ||Z'_1 I_{M'_r=2}||_2^T = C^T ||Z_1 I_{M_1=2}||_2^{q/T}
\]
as desired. \( \square \)

We also use Lemma 2.6 coupled with Lemma 2.13 to handle the case of \( q/T = \log(qmv^4/s^2) \) and prove Lemma 2.15.
Proof of Lemma 2.15] Let’s let \( f(x) \) be the function that rounds \( x \) to the nearest power of 2. By the conditions, we know that \( 2 \leq f(\log(qm^4/s^2)) \leq q \). Now, we want the condition \( 2q^2 \leq sf(\log(qm^4/s^2)) \) to be satisfied. If \( f(\log(qm^4/s^2)) \geq \log(qm^4/s^2) \), then this is implied by \( 2q^2 \leq s\log(qm^4/s^2) = s\max(\log(qm^4/s^2), 2) \), which is a strictly weaker condition than the one given in the lemma statement. If \( f(\log(qm^4/s^2)) \leq \log(qm^4/s^2) \), then \( f(\log(qm^4/s^2)) \geq 0.5 \log(qm^4/s^2) \) and so \( 2q^2 \leq 0.5s\log(qm^4/s^2) \leq sf(\log(qm^4/s^2)) \) gives the desired condition.

We use the fact that \( \log(qm^4/s^2)/2 \leq f(\log(qm^4/s^2)) \leq 2\log(qm^4/s^2) \). We apply Lemma 2.13 with \( T = \frac{q}{f(\log(qm^4/s^2))} \) and Lemma 2.7 to see that if we have the additional condition that \( f(\log(qm^4/s^2)) \geq \frac{se}{mv^2} \), then we know that:

\[
\|R(v, \ldots, v)\|_q \geq \frac{q}{sf(\log(qm^4/s^2))} \left( \frac{m}{q} \right)^{1/f(\log(qm^4/s^2))} \|Z_1(v, \ldots, v)\|_{L=2} \frac{1}{f(\log(qm^4/s^2))} \]
\[
\geq \frac{q^2}{2\log(qm^4/s^2)} \left( \frac{m}{q} \right)^{1/f(\log(qm^4/s^2))} \left( \frac{s}{m\log(qm^4/s^2)} \right)^{1/f(\log(qm^4/s^2))} \frac{1}{f(\log(qm^4/s^2))} \]
\[
\geq \frac{q^2}{s\log(qm^4/s^2)} \left( \frac{s^2}{qmq^4} \right) \frac{1}{f(\log(qm^4/s^2))} \frac{1}{f(\log(qm^4/s^2))} \]
\[
\geq \frac{q^2}{s\log(qm^4/s^2)} \frac{1}{f(\log(qm^4/s^2))} \frac{1}{f(\log(qm^4/s^2))}.
\]

Now, we see that

\[
\frac{mv^2}{se} = \sqrt{\frac{qm^4}{s^2}} \frac{1}{e^{\sqrt{q}}} \frac{\sqrt{m}}{\sqrt{q}} \geq \sqrt{m} \frac{1}{\sqrt{q}} \geq 1.
\]

This implies that \( \frac{se}{mv^2} \leq 1 \), so the condition of \( f(\log(qm^4/s^2)) \geq 2 \geq \frac{se}{mv^2} \) is automatically satisfied. \( \square \)

**Appendix E. Proofs of Lemma 3.1 and Lemma 3.2**

First, we show how Lemma 2.1 implies Lemma 3.1. The proof involves simplifying and bounding the function at the target \( v \) value.

**Proof of Lemma 3.1** We plug \( q = p \) into Lemma 2.1. We use this relaxed version of the bound:

\[
\|R(x_1, \ldots, x_n)\|_q \leq \begin{cases} 
\max \left( \frac{\sqrt{q}}{m} \frac{C_{13/2}^{1/2} q^{1/2}}{s\log(qm^4/s^2)} \right) & \text{if } \log(qm^4/s^2) \leq 2 \\
\max \left( \frac{\sqrt{q}}{m} \frac{q^2}{s\log(qm^4/s^2)} \min \left( \frac{C_{13/2}^{1/2} q^{1/2}}{s\log(qm^4/s^2)}, \frac{q}{s\log(qm^4/s^2)} \right) \right) & \text{if } \log(qm^4/s^2) > 2
\end{cases}
\]

Suppose that the absolute constant on the upper bounds is \( \leq C' \). Let \( C = \max(C', 1) \) (we take \( C \) to be the constant on the upper bounds). Let’s take \( C_{1/2} = 0.25 \sqrt{C}, C_{1/2} = \min \left( \frac{0.1}{C_{1/2}^2}, C_{1/2} \right), C_S = 4C, C_M = \max \left( \frac{1}{C_{1/2}}, 16C^2, \frac{1}{C_{1/2}}, e \right) \).

For the remainder of the analysis, we assume that \( m \geq C_M \varepsilon^{-2} p \) and \( m < 2e^{-2} \).

First, observe \( m \geq 16C^2 e^{-2} p \) gives us that

\[
C \sqrt{m} \leq 0.25 \varepsilon
\]

regardless of \( v \).
Now, let's take \( v = \frac{C_{v,2} \sqrt{q} \log \frac{me^2}{p}}{\sqrt{p}} \). First, we show that \( \log(pm^4/s^2) \geq \log(me^2/p) \geq 2 \). Using the fact that \( m \geq e^{1/2} e^{-2} p \), we see that
\[
C_{v,2}^4 \log^2(me^2/p) \geq C_{v,2}^4 \frac{1}{C_{v,2}^2} = 1.
\]
Since \( m \geq e^{2} e^{-2} p \), this implies that
\[
\log(pm^4/s^2) = \log(C_{v,2}^4 \log^2(me^2/p)) + \log(me^2/p) \geq \log(me^2/p) \geq 2.
\]
Observe that since \( pm^4 \geq e^{2} s^2 \), we directly know that \( p^3 m^2 \geq s^2 \) so we can take \( C_2 = 1 \).

We show that \( C_{s \log(pm^4/s^2)} \leq 0.25 \varepsilon \). Let's observe that
\[
\frac{C_{p} v^2}{s \log(pm^4/s^2)} \leq \frac{CC_{v,2}^2 \varepsilon \log(me^2/p)}{\log(me^2/p)} = CC_{v,2}^2 \varepsilon
\]
Since \( C_{v,2} = \frac{0.25}{\sqrt{e}} \), we get a bound of \( 0.25 \varepsilon \).

Now, we show that \( C_{s \log(m/s)} \leq 0.25 \varepsilon \) when \( m \geq s \cdot e^{\frac{C_{v,2} - 1}{s}} \). We need it to be true that \( s \log(m/s) \geq 4Cp \varepsilon^{-1} \).

This can be written as \( \log(m/s) \geq \frac{4Cp \varepsilon^{-1}}{s} \). Since \( C_S = 4C \), this can be written as: \( m \geq s \cdot e^{\frac{C_{v,2} - 1}{s}} \), as desired.

These facts combined imply that when \( m \geq s \cdot e^{\frac{C_{v,2} - 1}{s}} \), taking \( v = C_{v,2} \sqrt{s \log(pm^4/s^2)} \cdot \frac{q}{\sqrt{p}} \cdot \min \left( \frac{C_{v,2}^{1/3} p^2 v^2}{\log^2(qmv^4/s^2)}, \frac{s \log(m/s)}{s \log^2(qmv^4/s^2)} \right) \),
\[
\|R(x_1, \ldots, x_2)\| \leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \cdot \frac{q v^2}{s \log(qmv^4/s^2)}, \frac{q}{s \log(m/s)} \right) \leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \cdot \frac{q v^2}{s \log(qmv^4/s^2)}, \frac{q}{s \log(m/s)} \right) \leq 0.25 \varepsilon.
\]

Now, we just need to handle the case where \( m \leq s \cdot e^{C_{v,2} - 1} \). Observe that we can set \( C_2 = \frac{1}{C_{v,1}} \) and using the fact that \( C_{v,1} \leq C_{v,2} \), we obtain that
\[
\frac{C_2 p^3 m v^4}{s^2} \geq \frac{C_2 p^3 m^2}{s^2} \min(C_{v,1}, C_{v,2})^4 \left( \frac{\sqrt{E} s}{p} \right)^4 = C_2 C_{v,1}^4 \frac{m e^2}{p} \geq C_2 C_{v,1}^4.
\]

Thus, this is lower bounded by 1 when \( C_2 = \frac{1}{C_{v,1}} \).

Let's first take \( v = C_{v,1} \sqrt{E} \frac{\log \left( \frac{m e^2}{p} \right)}{s}. \) We show that \( \frac{CC_{v,1}^{1/3} p^2 v^2}{s \log^2(pm^4/s^2)} \leq 0.1 \varepsilon \). Observe that
\[
CC_{v,1}^{1/3} p^2 v^2 = \frac{\varepsilon CC_{v,1}^{1/3} C_{v,1} \log^2 \left( \frac{m e^2}{p} \right)}{\log^2 \left( C_{v,1}^{1/3} \log^2 \left( \frac{m e^2}{p} \right) \right)} = \varepsilon CC_{v,1}^{1/3} C_{v,1} \log^2 \left( \frac{m e^2}{p} \right) \left( \log \left( \frac{m e^2}{p} \right) + \log \left( C_{v,1} \log^2 \left( \frac{m e^2}{p} \right) \right) \right)^2.
\]

Now, since \( m \geq e^{1/C_{v,1}} e^{-2} p \), we know that \( \log(C_{v,1} \log^2 \left( \frac{m e^2}{p} \right)) \geq 0 \). Thus we can bound the above expression by:
\[
\frac{\varepsilon CC_{v,1}^{1/3} \log^2 \left( \frac{m e^2}{p} \right)}{\log^2 \left( \frac{m e^2}{p} \right)} = \varepsilon CC_{v,1}^{2/3} \leq 0.1 \varepsilon,
\]
where the last inequality uses the fact that \( C_{v,1} \leq \frac{0.1}{C_{v,1}^{1/3}} \).

Let's now consider how the term \( \frac{p v^2}{s \log(pm^4/s^2)} \) changes as a function of \( v \). This term only arises in the bound if \( \log(pm^4/s^2) \geq 2 \). First, we show this is an increasing function of \( v \). Let \( w = pm^4/s^2 \). We see that
\[
\frac{p^2}{s \log(pm^2/s)} = \frac{s \log w}{\sqrt{pm \log w}}.
\] We observe that this is an increasing function of \( w \) as long as \( w \geq e^2 \), which is exactly our restriction on \( w \). Thus, \( \frac{p^2}{s \log(pm^2/s)} \) is an increasing function of \( v \) in this range.

Now, we consider how the \( \frac{C_{1/3} p^2 v^2}{s \log(pm^2/s)} \) term changes a function of \( v \). This term only arises in the bound if \( \log(pm^2/s) \geq 1 \). First, we show that \( f(v) \leq 2f(v') \) if \( v \leq v' \). Let \( w = pm^2/s^2 \). We see that \( \frac{p^2 v^2}{s \log(pm^2/s)} = \frac{w^2}{pm \log w} \). We observe that this is an increasing function of \( w \) as long as \( w \geq e^2 \). When \( e \leq w \leq e^2 \), observe that this is bounded by at most a factor of 2 above any other \( w \) value.

Now, let's let

\[
v = \sqrt{\varepsilon} \min \left( C_{v,1} \frac{\log(mv^2/p)}{p}, C_{v,2} \sqrt{\log(mv^2/p)} \right).
\]

We show that

\[
\|R(x_1, \ldots, x_n)\|_q \leq 0.25\varepsilon.
\]

If \( \log(pm^2/s) \leq 1 \), then we know that the bound is actually \( \frac{\sqrt{q}}{\sqrt{m}} \), which already have already handled, so we directly know that

\[
\|R(x_1, \ldots, x_n)\|_q \leq 0.25\varepsilon.
\]

Thus, we can assume that \( \log(pm^2/s) \geq 1 \) for the remainder of the analysis.

First, suppose that \( v = \sqrt{\varepsilon} \min \left( C_{v,1} \frac{\log(mv^2/p)}{p}, C_{v,2} \sqrt{\log(mv^2/p)} \right) = C_{v,1} \sqrt{\varepsilon} \frac{\log(mv^2/p)}{p} \). If \( \log(pm^4/s^2) \leq 2 \), then we know that

\[
\|R(x_1, \ldots, x_n)\|_q \leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \frac{C_{1/3} q^2 v^2}{s \log^2(qm^2/s^2)} \right) \leq 0.25\varepsilon.
\]

Otherwise, we know that \( \log(pm^4/s^2) > 2 \). We show that \( \frac{p^2}{s \log(pm^4/s^2)} \leq 0.25\varepsilon \). We know that \( v \leq C_{v,2} \sqrt{\varepsilon} \frac{\log(mv^2/p)}{\sqrt{p}} \), where \( \log(pm^4/s^2) \geq 2 \). At \( C_{v,2} \sqrt{\varepsilon} \frac{\log(mv^2/p)}{\sqrt{p}} \), we know that the expression is upper bounded by \( 0.25\varepsilon \). Since the \( \frac{m^2}{s \log(qm^2/s^2)} \) term is an increasing function of \( v \) in this regime, this means that we get a bound of \( 0.25\varepsilon \) in this case too. Thus, we know that:

\[
\|R(x_1, \ldots, x_n)\|_q \leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \frac{q v^2}{s \log^2(qm^2/s^2)}, \min \left( \frac{C_{1/3} q^2 v^2}{s \log^2(qm^2/s)}, \frac{q}{s \log(m/s)} \right) \right)
\]

\[
\leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \frac{q v^2}{s \log^2(qm^2/s^2)}, \frac{C_{1/3} q^2 v^2}{s \log^2(qm^2/s)} \right)
\]

\[
\leq 0.25\varepsilon
\]

Now, suppose that \( v = \sqrt{\varepsilon} \min \left( C_{v,1} \frac{\log(mv^2/p)}{p}, C_{v,2} \sqrt{\log(mv^2/p)} \right) = C_{v,1} \sqrt{\varepsilon} \frac{\log(mv^2/p)}{p} \). We know that \( \log(pm^4/s^2) \geq 2 \) here. Since \( v \leq C_{v,1} \sqrt{\varepsilon} \frac{\log(mv^2/p)}{p} \), we obtain a bound of \( 2 \cdot 0.1\varepsilon = 0.2\varepsilon \). This means:

\[
\|R(x_1, \ldots, x_n)\|_q \leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \frac{q v^2}{s \log^2(qm^2/s^2)}, \min \left( \frac{C_{1/3} q^2 v^2}{s \log^2(qm^2/s)}, \frac{q}{s \log(m/s)} \right) \right)
\]

\[
\leq C \max \left( \frac{\sqrt{q}}{\sqrt{m}} \frac{q v^2}{s \log^2(qm^2/s^2)}, \frac{C_{1/3} q^2 v^2}{s \log^2(qm^2/s)} \right)
\]
\begin{proof}

We use Lemma \ref{lem:main} but put in an absolute constant. Let \( D_2 > 0 \) be such that: if \( \frac{v}{m\epsilon} \geq q \), then

\[ \|R(x_1, \ldots, x_n)\|_q \leq D_2 \frac{\sqrt{q}}{\sqrt{m}}. \]

Otherwise, if \( q^3 m v^4 \geq s^2 \), then \( \|R(x_1, \ldots, x_n)\|_q \) is upper bounded by:

\[ D_2 \begin{cases} 
\max \left( \frac{\sqrt{q}}{\sqrt{m}} \sqrt[4]{\frac{q v^2}{s \log^2(qm v/s)}} \right) & \text{if } \log(qm v/s^2) \leq 2, \log(qm v/s) \leq q
\\
\max \left( \frac{\sqrt{q}}{\sqrt{m}} \sqrt[4]{\frac{4096 q v^2}{s log(qm v/s^2) \log(m/s)}} \right) & \text{if } \log(qm v/s^2) > 2, \log(qm v/s) \geq q
\\
\max \left( \frac{\sqrt{q}}{\sqrt{m}} \sqrt[4]{\frac{4096 q v^2}{s log(qm v/s^2) \log(m/s)}} \right) & \text{if } \log(qm v/s^2) > 2, \log(qm v/s) > q.
\end{cases} \]

We use Lemma \ref{lem:main} but put in an absolute constant \( D_1 > 0 \) (which we take to be \( \leq 1 \)). Let \( 2 \leq q \leq m \) be an even integer, and suppose that \( 0 < v \leq 0.5 \) and \( \frac{v}{m \epsilon} \) is an even integer. If \( q v^2 \leq s \), then

\[ \|R(x_1, \ldots, x_n)\|_q \geq D_1 \frac{\sqrt{q}}{\sqrt{m}}. \]

If \( m \geq q \), \( 2 \leq \log(qm v^4/s^2) \leq q \), \( 2 q v^2 \leq 0.5 s \log(qm v^4/s^2) \), and \( s \leq m/2 \) then:

\[ \|R(x_1, \ldots, x_n)\|_q \geq D_1 \frac{4096 q v^2}{s \log(qm v^4/s^2)}. \]

If \( v \leq \frac{\sqrt{\log(m/s)}}{\sqrt{q}} \) and \( 1 \leq \log(qm v^2/s) \leq q/2 \), and \( s \leq m/2 \), then:

\[ \|R(x_1, \ldots, x_n)\|_q \geq D_1 \frac{q^2 v^2}{s \log^2(qm v^2/s)}. \]

Let \( D = \frac{D_1}{4D_2} \). It suffices to show that for \( v \) defined in the lemma statement:

\[ \frac{\|R(v, v, \ldots, v, 0, \ldots, 0)\|_q}{\|R(v, v, \ldots, v, 0, \ldots, 0)\|_q} \geq D. \]

First, we suppose that \( 0 < v \leq 0.5 \) such that \( \frac{v}{m \epsilon} \geq q \) and \( q v^2 \leq s \). We see that

\[ \|R(x_1, \ldots, x_n)\|_q \sim \frac{\sqrt{q}}{\sqrt{m}} \]

in this case. A stronger version of these conditions is that \( 0 < v \leq 0.5 \) and \( v^2 \leq \frac{s v}{2 m \epsilon} \). Thus, we can take \( v = \psi \) for any sufficiently small \( \psi \). We know that:

\[ D_1 \frac{\sqrt{q}}{\sqrt{m}} \leq \|R(x_1, \ldots, x_n)\|_q \leq D_2 \frac{\sqrt{q}}{\sqrt{m}}. \]

. Thus, we have that

\[ \frac{\|R(v, v, \ldots, v, 0, \ldots, 0)\|_q}{\|R(v, v, \ldots, v, 0, \ldots, 0)\|_q} \geq \frac{D_1}{\sqrt{2} D_2} \geq D. \]

When \( m \leq 0.25 D_1^2 q \epsilon^{-2} \), which can be written as \( m \leq C_{M,1} \epsilon^{-2} p \) for some constant \( C_{M,1} \), we know that

\[ \|R(v, v, \ldots, v, 0, \ldots, 0)\|_q \geq D_1 \frac{\sqrt{q}}{\sqrt{m}} \geq 2 \epsilon \text{ as desired.} \]

\end{proof}
Now, we handle the case where \( m \geq C_{M,1}e^{-2}p \). Let \( f_1 = 4\sqrt{\frac{\log(me)}{q}} \) and let \( f_2 = \sqrt{\frac{\log(me^2)}{q}} \). First, we handle the condition of \( q^3mv^4 \geq s^2 \). We enforce the condition \( C_{v,1}, C_{v,2} \geq 1 \). Assuming that \( v \geq \frac{\sqrt{s}}{q} \) (which is true at the two values of \( v \) that we consider), we know:

\[
\frac{q^3mv^4}{s^2} \geq \frac{me^2}{q} \geq 1.
\]

Also, we make \( m \geq 2C^2e^{-2}q \), so that \( \sqrt{\frac{2q}{m}} \leq \sqrt{\frac{2q}{2C^2e^{-2}q}} = \frac{e}{C} \).

Consider \( v = C_{v,2}\sqrt{\frac{esf_2}{q}} \). We first check that the conditions for the upper bound are satisfied. We have that \( \frac{qmv^4}{s^2} = C_{v,2}^4 \frac{me^2}{q} \log^2\left(\frac{me^2}{q}\right) \). Observe that when \( m \geq e^2e^{-2}q \) and \( C_{v,2} \geq 1 \), this is lower bounded by \( e^2 \), so \( \log(qmv^4/s^2) \geq 2 \). Also, we have that \( \frac{qmv^4}{se} = \sqrt{qm} \sqrt{2} \geq 1 \). Now, we check the additional conditions needed for the lower bound. Observe that

\[
\frac{2qv^2}{s} = 2eC_{v,2}^4 \log\left(\frac{me^2}{q}\right) \leq 0.5C_{v,2}^4 \frac{me^2}{q} \log^2\left(\frac{me^2}{q}\right) = 0.5\log(qmv^4/s^2)
\]
as desired. We check that \( \log(qmv^4/s^2) \leq q \). It suffices to show that

\[
\frac{me^2}{q} \log^2\left(\frac{me^2}{q}\right) \leq e^q \frac{e}{C_{v,2}^2}
\]

Using the condition that \( m \leq e^{-2}q^{e^2}/q^{C_{v,2}^2} \) where we obtain that

\[
\frac{me^2}{q} \log^2\left(\frac{me^2}{q}\right) \leq \frac{e^q}{q^{2C_{v,2}^2}} \log^2\left(\frac{me^2}{q}\right) \leq \frac{e^q}{q^{2C_{v,2}^2}} \log^2\left(\frac{me^2}{q}\right) \leq \frac{e^q}{C_{v,2}^2}
\]
as desired. Now, we compute the value of \( \frac{q^2v^2}{s\log(qmv^4/s^2)} \) at this bound. We obtain:

\[
\frac{q^2v^2}{s\log(qmv^4/s^2)} = C_{v,2}^2 \frac{\log(me^2/q)}{\log\left(\frac{me^2}{q}\right) + \log \left(16C_{v,1}^2 \log^2\left(\frac{me^2}{q}\right)\right)}
\]

Consider \( v = C_{v,1}f_1 \). We first check that the conditions for the upper bound are satisfied. In this case, we have that \( \frac{qmv^4}{s^2} = 16C_{v,1}^2 \frac{me^2}{q} \log^2\left(\frac{me^2}{q}\right) \). Observe that when \( C_{v,1} \geq 1 \) and \( m \geq e^2e^{-2}q \), this is lower bounded by \( e \), so \( \log(qmv^4/s^2) \geq 1 \). Now, we claim that when \( f_1 \leq f_2 \), the other necessary conditions are satisfied (also for the lower bound). We check that \( \log(qmv^4/s^2) \leq q/4 \). In this case, using that \( m \leq e^{-2}q^e \), we have:

\[
\frac{4\log(me^2/q)}{q} \leq \sqrt{\log(me^2/q)} \sqrt{q} \leq q/4.
\]

This means that \( \log(me^2/q) \leq \sqrt{q} \sqrt{\log(me^2/q)}/4 \leq q/4 \). Observe that

\[
\log(qmv^4/s^2) = \log(16C_{v,1}^2) + \log(me^2/q) + 2\log \log(me^2/q)
\leq \log(16C_{v,1}^2) + \frac{q}{4} + 2\log \log q
\leq \frac{q}{2}.
\]

At this value, observe that:

\[
\frac{q^2v^2}{s\log^2(qmv^4/s^2)} = 16C_{v,1}^2 \frac{\log(me^2/q)}{\log\left(\frac{me^2}{q}\right) + \log \left(16C_{v,1}^2 \log^2\left(\frac{me^2}{q}\right)\right)}^2.
\]

Let \( C = D_1 \). Let’s set \( \sqrt{\frac{q}{e}} \leq C_{v,2} = C_{v,1} = C_v \leq 4\sqrt{\frac{q}{e}} \). Using the fact that \( v^2 \leq 0.5 \) (so \( \frac{q}{v} \geq 2 \)), this means that \( \frac{q}{v} \) has can take on at least 3 different powers of 2. Let’s observe that when \( 16C_{v,1}^2 \log^2\left(\frac{me^2}{q}\right) \leq \frac{me^2}{q} \) (we can
get this condition by saying that $m \geq C_{M,2} e^{-2} q$ for a sufficiently large $C_{M,2}$ and $16C_v^2 \log^2(me/q) \geq 1$ (we can get this condition by saying that $m \geq C_{M,2} e^{-2} q$ for a sufficiently large $C_{M,2}$), we know that 

$$\frac{4e}{C} \leq 4C_v^2 e \leq \frac{q^2 \sqrt{v}}{s \log^2(qmv^2/s)} \leq 16C_v^2 e \leq \frac{256e}{C}.$$ 

Suppose that $C_v^4 \log^2(me^2/q) \leq \frac{me}{q}$ (we can get this condition by saying that $m \geq C_{M,2} e^{-2} q$ for a sufficiently large $C_{M,2}$) and $C_v^4 \log^2(me^2/q) \geq 1$ (we can get this condition by saying that $m \geq C_{M,2} e^{-2} q$ for a sufficiently large $C_{M,2}$). Let’s observe that 

$$4096C_v^2 e \geq \frac{4096^2}{s \log^2(qmv^2/s)} \geq 2048C_v^2 e \geq \frac{2048e}{C}.$$ 

Let $m' = s \cdot e^{e^{C_v}}$. When $m \leq m'$, we know that $\frac{q}{s \log(m/s)} \leq \frac{1024e}{C}$ and when $m \leq m'$, we know that $\frac{q}{s \log(m/s)} \geq \frac{1024e}{C}$.

Let’s consider $v = \frac{\sqrt{\log(m/s)}}{\sqrt{q}}$. In this case, we have that $\frac{q m}{s} = \frac{m}{s} \log \left(\frac{m}{s}\right)$. Observe that when $m \geq e^2 s$, this is lower bounded by $e^2$, so $\log(qmv^2/s) \geq 2$. At this case, we have that: 

$$\frac{q^2 \sqrt{v}}{s \log^2(qmv^2/s)} = \frac{q \log(m/s)}{s \log^2 \left(\frac{m}{s} \log \left(\frac{m}{s}\right)\right)} \geq \frac{q \log(m/s)}{4s \log^2 \left(\frac{m}{s}\right)} = \frac{q}{4s \log \left(\frac{m}{s}\right)}.$$ 

We know that if $\frac{q^2 \sqrt{v}}{s \log^2(qmv^2/s)} \leq \frac{q^2 \sqrt{v}}{s \log(qmv^2/s)}$ and $qmv^2/s \geq e$ and $qmv^2/s \geq e^2$, then it is true that $v_1 \leq v_2$. Let $v_1 = C_v \sqrt{s} f_1$. Then $m \leq m'$, we know that 

$$\frac{q^2 \sqrt{v}}{s \log^2(qmv^2/s)} \leq \frac{256e}{C} \leq \frac{q}{4s \log \left(\frac{m}{s}\right)} \leq \frac{q^2 \sqrt{v}}{s \log^2(qmv^2/s)}.$$ 

Thus, we have that $v_1 \leq v = \frac{\log(m/s)}{\sqrt{q}}$ as desired.

The first case is $m \leq m'$ and $f_2 \leq f_1$. We set $v = C_v \sqrt{s} f_2 = C_v \sqrt{s} \frac{\sqrt{\log \left(\frac{m}{s}\right)}}{\sqrt{q}}$.

$$\|R(v, \ldots, v)\|_q \geq D_1 \frac{4096q^2}{s \log(qmv^2/s)}.$$ 

For the upper bound, we see that $\log(2qmv^2/s^2) > \log(qmv^2/s^2) \geq 2$ and $\sqrt{\frac{q}{m}} \leq \tilde{\varepsilon}$. Here, we have that 

$$\|R(v, \ldots, v)\|_2 \leq \begin{cases} D_2 \max \left(\frac{\sqrt{q}}{s \log(qmv^2/s)} \frac{8192q^2}{\log(2qmv^2/s)} \right) & \text{if } \log(2qmv^2/s) \leq 2q \\ D_2 \max \left(\frac{\sqrt{q}}{s \log(qmv^2/s)} \frac{8192q^2}{\log(2qmv^2/s)} \right) & \text{if } \log(2qmv^2/s) > 2q \end{cases}.$$ 

Now, we use the fact that $v \leq C_v \sqrt{s} f_1 := v_1$ to see that: 

$$\frac{4q^2 \sqrt{v}}{s \log(2qmv^2/s)} \leq \frac{8q^2 \sqrt{v}}{s \log(qmv^2/s)} \leq \frac{8q^2 \sqrt{v}}{s \log(qmv^2/s)} \leq 2048e \frac{C_v^2 e}{C}.$$ 

We also observe that since $2qmv^2/s \leq (qmv^2/s)^2$, we know: 

$$\frac{8192q^2}{2s \log(2qmv^2/s)} \geq \frac{8192q^2}{s \log(qmv^2/s)} \geq \frac{2048e}{C}.$$ 

This, coupled with the guarantee on $\sqrt{\frac{q}{m}}$, implies we have an upper bound of: 

$$\|R(v, \ldots, v)\|_2 \leq D_2 \frac{8192q^2}{s \log(2qmv^2/s)}.$$
Thus, we have that
\[ \|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq \frac{D_1}{2D_2} \geq D. \]

Moreover, we have that
\[ \|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq \frac{4096q^2}{s \log(qmv^2/s)} \geq \frac{D_1}{2D_2} = 2048 \varepsilon. \]

The next case is \( f_1 \leq f_2 \) and \( m \leq m' \). We set \( v = C_v \sqrt{E} s \frac{4\log(\frac{m}{q})}{q} \). Since \( f_1 \leq f_2 \), we know that \( \log(qmv^2/s^2) \leq q \). Thus we know:
\[ \|R(v, \ldots, v)\|_q \geq \begin{cases} D_1 \max \left( \frac{4096q^2}{q^2}, \frac{4q^2}{s \log(qmv^2/s)} \right) & \text{if } \log(qmv^2/s^2) \geq 2, q^2 \leq s \\ D_1 \frac{q^2}{s \log(qmv^2/s)} & \text{else} \end{cases}. \]

For the upper bound, we know that:
\[ \|R(v, \ldots, v)\|_q \leq \begin{cases} D_2 \max \left( \frac{2q^2}{s \log(qmv^2/s)}, \frac{8192q^2}{q^2}, \frac{4q^2}{s \log(qmv^2/s)} \right) & \text{if } \log(2qmv^4/s) > 2 \\ D_2 \max \left( \frac{2q^2}{s \log(qmv^2/s)}, \frac{8192q^2}{q^2}, \frac{4q^2}{s \log(qmv^2/s)} \right) & \text{if } \log(2qmv^4/s) \leq 2 \end{cases}. \]

We need to handle the case that \( s \leq qv^2 \). By construction, we know that \( v \leq C_v \sqrt{Es} \). Thus, this implies that \( \frac{s}{q} \leq C_v^2 \varepsilon s \), so \( \varepsilon^{-1} \leq qC_v^2 \). First, we show that if \( m \leq \varepsilon^{-2} e^{D^2/8} \), then it is true that \( f_1 \leq D f_2 \). It suffices to show that
\[ \log(1/e) + \log(me^2/q) \leq \frac{\sqrt{qD}}{4} \sqrt{\log(me^2/q)}. \]

Since \( \log(1/e) \leq \log(C_vq) \leq \frac{\sqrt{qD}}{8} \), it suffices to show that
\[ \log(me^2/q) \leq \frac{1}{8} \sqrt{qD} \sqrt{\log(me^2/q)}. \]

It suffices to show that:
\[ \sqrt{\log(me^2/q)} \leq \frac{1}{8} \sqrt{qD}. \]

This is true based on the condition on \( m \). Let \( v' = C_vD \sqrt{Es} f_2 \). Assuming that \( \log(qmv^4/s) \geq 2 \), we know that \( \frac{8192q^2}{s \log(qmv^2/s)} \) can be upper bounded by:
\[ \frac{8192q^2}{s \log(qmv^2/s)} \leq \frac{8192q^2}{s \log(qmv^2/s)} = \frac{8192D^2 C_v^2 e \log(me^2/q)}{\log(me^2/q) + \log(C_v^4 D^4 \log^2(me^2/q))} \leq 8192D^2 C_v^2 e \leq \frac{8192D^2 e}{C} \]
as long as \( \log^2(me/q) C_v^4 D^4 \geq 1 \). Observe also that:
\[ \frac{4q^2 v^2}{s \log^2(2qmv^2/s)} \geq \frac{q^2 v^2}{s \log(qmv^2/s)} \geq 4C_v^2 e \geq \frac{4e}{C}. \]

We can set \( D = 64 \) to obtain that
\[ \frac{8192D^2 e}{C} \leq \frac{4q^2 v^2}{s \log^2(2qmv^2/s)}. \]

This, coupled with the guarantee on \( \sqrt[4]{q} \), implies that our upper bound becomes:
\[ \|R(v, \ldots, v)\|_q \leq \begin{cases} D_2 \frac{4q^2 v^2}{s \log^2(2qmv^2/s)} & \text{if } \log(2qmv^4/s) \leq 2 \text{ or } \log(qmv^4/s) \geq 2, qv^2 \geq s \\ D_2 \max \left( \frac{8192q^2}{s \log(qmv^2/s)}, \frac{4q^2 v^2}{s \log(qmv^2/s)} \right) & \text{else} \end{cases}. \]

We now show that we can tweak \( C_v \) within the factor of \( 2^{1/4} \) range permitted to show that we can ensure that it is not true that \( 2 - \log 2 < \log(qmv^4/s) \leq 2 \). Observe that multiplying by a factor of \( 2^{1/4} \) in this case yields
\[
\log(2qm^4/s) > 2 \text{ and dividing by a factor of } 2^{1/4} \text{ yields } \log(qm^4/s) \leq 2 - \log 2. \text{ Thus, at least one of the } C_v \text{ values that yields a power of 2 for } \frac{1}{v} \text{ will work. Thus, we have that}
\[
\frac{\|R(v, \ldots, v, 0, \ldots, 0)\|_q}{\|R(v, \ldots, v, 0, \ldots, 0)\|_{2q}} \geq \frac{D_1}{4D_2} = D.
\]
Moreover, we have that:
\[
\|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq D_1 \cdot \frac{q^2v^2}{s\log^2(qm^4/s)} \geq D_1 \frac{4\epsilon}{C} = 4\epsilon
\]
The next case is that \(m > m'\). We set \(v = C_v \sqrt{\epsilon \frac{\log (\frac{m^2}{q})}{\sqrt{q}}}\). We know:
\[
\|R(v, \ldots, v)\|_q \geq D_1 \frac{4096q^2}{s\log(qm^4/s)}.
\]
For the upper bound, we see that \(\log(2qm^4/s^2) > \log(qm^4/s^2) > 2\). We know:
\[
\|R(v, \ldots, v)\|_{2q} \leq \begin{cases} D_2 \max \left( \frac{\sqrt{2q}}{\sqrt{m}} \frac{8192q^2}{s\log(2qm^4/s)}, \frac{2q}{s\log(m/s)} \right) & \text{if } \log(2qm^4/s) \leq 2q \\ D_2 \max \left( \frac{\sqrt{2q}}{\sqrt{m}} \frac{8192q^2}{s\log(2qm^4/s)}, \frac{2q}{s\log(m/s)} \right) & \text{if } \log(2qm^4/s) > 2q \end{cases}
\]
This can be relaxed to:
\[
\|R(v, \ldots, v)\|_{2q} \leq D_2 \max \left( \frac{\sqrt{2q}}{\sqrt{m}}, \frac{8192q^2}{s\log(2qm^4/s)}, \frac{2q}{s\log(m/s)} \right).
\]
Now, we know that
\[
\frac{2q}{s\log(m/s)} \leq \frac{2048\epsilon}{C} \leq \frac{4096q^2}{s\log(qm^4/s)} = \frac{8192q^2}{2s\log(qm^4/s)} \leq \frac{8192q^2}{s\log(2qm^4/s)}.
\]
This coupled with what we know about \(\sqrt{2q} \sqrt{m}\) means that:
\[
\|R(v, \ldots, v)\|_{2q} \leq D_2 \frac{8192q^2}{s\log(2qm^4/s)}.
\]
Thus, we have that
\[
\frac{\|R(v, \ldots, v, 0, \ldots, 0)\|_q}{\|R(v, \ldots, v, 0, \ldots, 0)\|_{2q}} \geq \frac{D_1}{2D_2} = D.
\]
Moreover, we have that
\[
\|R(v, \ldots, v, 0, \ldots, 0)\|_q \geq D_1 \cdot \frac{4096q^2}{s\log(qm^4/s)} \geq D_1 \frac{2048\epsilon}{C} = 2048\epsilon.
\]
We need the condition on \(q\) not being more than a constant factor away from \(p = \log(1/\delta)\), because we want to conclude that \(\epsilon^{-2}q = \Theta(\epsilon^{-2}p), \sqrt{\epsilon s} \sqrt{\log(\frac{m^2}{q})} \leq \Theta \left( \sqrt{\epsilon s} \sqrt{\log(\frac{m^2}{q})} \right), \text{ and } \sqrt{\epsilon s} \log(\frac{m^2}{q}) \leq \Theta \left( \sqrt{\epsilon s} \log(\frac{m^2}{p}) \right). \)
\]
