Abstract

Reducing communication in training large-scale machine learning applications on distributed platform is still a big challenge. To address this issue, we propose a distributed hierarchical averaging stochastic gradient descent (Hier-AVG) algorithm with infrequent global reduction by introducing local reduction. As a general type of parallel SGD, Hier-AVG can reproduce several popular synchronous parallel SGD variants by adjusting its parameters. We show that Hier-AVG with infrequent global reduction can still achieve standard convergence rate for non-convex optimization problems. In addition, we show that more frequent local averaging with more participants involved can lead to faster training convergence. By comparing Hier-AVG with another popular distributed training algorithm K-AVG, we show that through deploying local averaging with fewer number of global averaging, Hier-AVG can still achieve comparable training speed while frequently get better test accuracy. This indicates that local averaging can serve as an alternative remedy to effectively reduce communication overhead when the number of learners is large. Experimental results of Hier-AVG with several state-of-the-art deep neural nets on CIFAR-10 and ImageNet-1K are presented to validate our analysis and show its superiority.

1 Introduction

Since current deep learning applications such as video action recognition and speech recognition with huge inputs can take days even weeks to train on a single GPU, efficient parallelization at scale is critical to accelerating training of such longtime running machine learning applications. Instead of using the classical stochastic gradient descent (SGD) algorithm originated from the seminal paper by Robbins and Monro [1951] as a solver, a number of parallel and distributed stochastic gradient descent algorithms have been proposed during the past decade (e.g., see Zinkevich et al. [2010], Recht et al. [2011], Dean et al. [2012], Dekel et al. [2012]). The first synchronous parallel SGD Zinkevich et al. [2010] is a naive parallelization of the sequential mini-batch SGD. Global reductions (averaging) after each local SGD step can incur costly communication overhead when the number of learners is large. The scaling of synchronous SGD is fundamentally limited by the batch size. Asynchronous SGD (ASGD) algorithms such as Recht et al. [2011], Dean et al. [2012], Dekel et al. [2012] have been popular recently for training deep-learning applications. With ASGD, each learner independently computes gradients for their data samples, and updates asynchronously relative to other learners (hence the name ASGD) the parameters maintained at the parameter server (e.g., see Dean et al. [2012], Li et al. [2014]). ASGD algorithms face their own challenges when the number of learners is large. A single parameter server oftentimes does not serve the aggregation requests fast enough. On the other hand, a sharded server though alleviates the aggregation bottleneck but introduces inconsistencies for parameters distributed on multiple shards. It is also challenging for ASGD implementations to manage the staleness of gradients which is proportional to the number of learners Li et al. [2014].

Many recent studies adopt new variants of synchronous parallel SGD algorithms (see Hazan and Kale [2014], Johnson and Zhang [2013], Smith et al. [2016], Zhang et al. [2016], Loshchilov and Hutter [2016], Chen et al. [2016], Wang et al. [2017], Zhou and Cong [2018]). Zhou and Cong [2018] analyzed a $K$ step averaging SGD ($K$-AVG) algorithm, and their analysis shows that synchronous parallel SGD with less frequent global averaging can sometimes provide faster training speed and can constantly result in better test accuracies. Since then a number of variants of $K$-AVG have
been proposed and studied, see [Lin et al., 2018], [Wang and Joshi, 2018] and references therein.

Although \textit{K-AVG} demonstrates better scaling behavior than ASGD implementations, the communication cost of global reductions for \textit{K-AVG} may not be amortized by the local SGD steps when the number of learners is very large. For this reason, we propose a new generic distributed, hierarchical averaging SGD algorithm (\textit{Hier-AVG}) which can reproduce several popular parallel SGD variants by adjusting its parameters. As \textit{Hier-AVG} is bulk-synchronous, it allows for infrequent global gradient averaging among learners to effectively minimize communication overhead just like \textit{K-AVG}. Instead of using a parameter server, the learners in \textit{Hier-AVG} communicate their learned gradients with their local neighbors at regular intervals for several rounds before global averaging. The staleness of gradients which can result in divergence of ASGD methods, can be precisely controlled in \textit{Hier-AVG}. Meanwhile, it maps well to current and future large distributed platforms since a single node typically employ multiple GPUs. \textit{Hier-AVG} intersperse global averaging with local ones to manage the staleness of gradients and utilize the natural communication hierarchy in the distributed platforms effectively.

The main contributions of this article are summarized as follows: 1. In section 3.2, we derive several non-asymptotic bounds on the expected average squared gradient norms for \textit{Hier-AVG} under different metrics. We show that \textit{Hier-AVG} with infrequent global averaging can still achieve standard convergence rate for non-convex optimization problems. As a byproduct of parallelization, \textit{Hier-AVG} can deploy larger step size schedule. 2. In section 3.3, we analytically show that \textit{Hier-AVG} with less frequent global averaging can sometimes have faster training convergence and can constantly have better test accuracy. 3. In section 3.4, by analyzing the bounds we derived, we show that the training speed of \textit{Hier-AVG} can be improved by deploying more frequent local averaging with more participants. 4. In section 3.5, We compare \textit{Hier-AVG} with \textit{K-AVG} and show that local averaging can be used to reduce global averaging frequency without deterioating traning speed and test accuracy.

The experimental results used to validate our analysis are presented in section 4 on various popular deep neural nets. To sum up, our analysis and experiments suggest that \textit{Hier-AVG} with
local averaging deployed can use infrequent global reduction, which sheds light on an alternative way
to effectively reduce communication overhead without deteriorating training speed, and oftentimes
provide better test accuracy.

2 Preliminaries and Notations

In this section, we introduce some standard assumptions used in the analysis of non-convex op-
timization algorithms and key notations frequently used throughout this paper. We use $\| \cdot \|_2$ to
denote the $\ell_2$ norm of a vector in $\mathbb{R}^d$; $\langle \cdot \rangle$ to denote the general inner product in $\mathbb{R}^d$. For the key
parameters we use:

- $P$ denotes the total number of learners for global averaging.
- $S$ denotes the number of learners in a local node for local averaging; we further assume that $S|P$ and $S \geq 1$.
- $K_2$ denotes the length of global averaging interval;
- $K_1$ denotes the length of local averaging interval and $1 \leq K_1 \leq K_2$.
- $B_n$ or $B$ denotes the size of mini-batch for the $n$-th global update;
- $\gamma_n$ or $\gamma$ denotes the learning rate (step size) for the $n$-th global update;
- $\xi^j_{k,s}$ with $j = 1, ..., P$, $k = 1, ..., K_2$, and $s = 1, ..., B$. are i.i.d. realizations of a random
  variable $\xi$ generated by the algorithm by different learners and in different iterations.

We study the following optimization problem:

$$\min_{w \in \mathcal{X}} F(w)$$ \hfill (2.1)

where objective function $F : \mathbb{R}^d \to \mathbb{R}$ is continuously differentiable but not necessarily convex
over $\mathcal{X}$, and $\mathcal{X} \subset \mathbb{R}^d$ is a non-empty open subset. Since our analysis is in a very general setting,
$F$ can be understood as both the expected risk $F(w) = \mathbb{E} f(w; \xi)$ or the empirical risk $F(w) = n^{-1} \sum_{i=1}^n f_i(w)$. The following assumptions (see Bottou et al. [2018]) are standard to analyze such problems.

**Assumption 1.** The objective function $F : \mathbb{R}^d \to \mathbb{R}$ is continuously differentiable and the gradient function of $F$ is Lipschitz continuous with Lipschitz constant $L > 0$, i.e.

$$\| \nabla F(w) - \nabla F(\tilde{w}) \|_2 \leq L \| w - \tilde{w} \|_2$$

for all $w, \tilde{w} \in \mathbb{R}^d$.

This assumption is essential to convergence analysis of our algorithm as well as most gradient based ones. Under such an assumption, the gradient of $F$ serves as a good indicator for how far to move to decrease $F$.

**Assumption 2.** The sequence of iterates $\{w_j\}$ is contained in an open set over which $F$ is bounded below by a scalar $F^\star$.

Assumption 2 requires that objective function to be bounded from below, which guarantees the problem we study is well defined.

**Assumption 3.** For any fixed parameter $w$, the stochastic gradient $\nabla F(w; \xi)$ is an unbiased estimator of the true gradient corresponding to the parameter $w$, namely,

$$\mathbb{E}_\xi \nabla F(w; \xi) = \nabla F(w).$$

One should notice that the unbiasedness assumption here can be replaced by a weaker version which is called the First Limit Assumption (see Bottou et al. [2018]) that can still be applied to our analysis. For simplicity, we just assume that the stochastic gradient is an unbiased estimator of the true one.
Assumption 4. There exist scalars $M \geq 0$ such that,

$$\mathbb{E}_\xi \| \nabla F(w; \xi) \|^2_2 - \| \mathbb{E}_\xi \nabla F(w; \xi) \|^2_2 \leq M.$$ 

Assumption 4 characterizes the variance of the stochastic gradients.

Assumption 5. There exist scalars $M_G \geq 0$ such that,

$$\mathbb{E}_\xi \| \nabla F(w; \xi) \|^2_2 \leq M_G.$$ 

Assumption 5 defines a uniform bound on the second order moment of the stochastic gradients.

3 Main Results

In this section, firstly we present Hier-AVG as Algorithm 1. Hier-AVG works as follows: each local worker individually runs $K_1$ steps of local SGD; then each group of $S$ workers locally average and synchronize their updated parameter; after each local worker runs a total count of $K_2$ local SGD steps, all $P$ workers globally average and synchronize their parameters and repeat this cycle until convergence. Then we establish the standard convergence results of Hier-AVG and analyze the impact of $K_2$, $S$ and $K_1$ on convergence. Finally, we compare Hier-AVG with K-AVG and show that local averaging can be used to reduce global averaging frequency to achieve communication overhead reduction without deteriorating training speed and test accuracy.

3.1 Hier-AVG Algorithm

Assume that $K_2 = K_1 \ast \beta$ with $\beta \geq 1$. For simplicity of analysis and presentation, we assume that $\beta$ is an integer, which means that the length of global averaging interval is multiple of the length of the local one. In practice, it can be implemented at the practitioner’s will rather than using $\beta$ as an integer. The performance and results should be consistent with our analysis in this work. One should notice that Algorithm 1 is a very general synchronous parallel SGD algorithm. By setting
Algorithm 1: Hier-AVG

initialize the global parameter $\tilde{w}_1$;

for $n = 1, \ldots, N$ (global averaging) do

Processor $P_j$, $j = 1, \ldots, P$ do concurrently:

Synchronize the parameter on each local learner $w^j_n = \tilde{w}_n$;

for $b = 0, \ldots, \beta - 1$ (local averaging) do

for $k = 1, \ldots, K_1$ (local SGD) do

randomly sample a mini-batch of size $B_n$ and update:

$w^j_{n+b*K_1+k} = w^j_{n+b*K_1+k-1} - \frac{\gamma_n}{B_n} \sum_{s=1}^{B_n} \nabla F (w^j_{n+b*K_1+k-1}; x^j_{n+b*K_1+k,s})$

end

Locally average and synchronize the parameters of each worker $P_{jt}$ within each local cluster:

$w^j_{n+(b+1)*K_1} = \frac{1}{S} \sum_{t=1}^{S} w^j_{n+(b+1)*K_1}$

end

Globally average and synchronize $\tilde{w}_{n+1} = \frac{1}{P} \sum_{j=1}^{P} w^j_{n+\beta*K_1}$;

end

different values of $K_2$, $K_1$ and $S$, it can reproduce various commonly adopted SGD variants. For instance, Hier-AVG with $K_2 = 1$, $K_1 = 1$ and $S = 1$ is equivalent to synchronous parallel SGD Zinkevich et al. [2010]; Hier-AVG with $K_1 = 1$ and $S = 1$ or simply $K_2 = K_1$ is equivalent to $K$-AVG Zhou and Cong [2018].

3.2 On the Convergence of Hier-AVG

In this section, we prove the convergence results for Algorithm 1 under two different metrics: one is $T^{-1} \sum_{t=0}^{T-1} \mathbb{E} \| \nabla F(\tilde{w}_t) \|^2_2$, where $\tilde{w}_t = P^{-1} \sum_{j=1}^{P} w^j_t$ denotes the average weight across all workers at each SGD step. Especially, when $t \equiv 0 \mod K_2$, $\tilde{w}_t = \tilde{w}_n$ with $n = t/K_2$. Such a metric was used to analyze the convergence behavior of $K$-AVG for strongly convex Stich [2018] and nonconvex Yu et al. [2018] optimization problems. The other metric we use is $N^{-1} \sum_{n=1}^{N} \mathbb{E} \| \nabla F(\tilde{w}_n) \|^2_2$ which only measures the averaged gradient norms at each global update. The former is used to analyze
the convergence rate of Hier-AVG and study the impact of global parameter $K_2$ while the latter has a clearer characterization of the impact of local parameters $K_1$ and $S$ with a more delicate analysis of the local behavior of Hier-AVG. We derive non-asymptotic upper bounds on the expected average squared gradient norms under constant step size and batch size setting, which serves as a cornerstone of our analysis. Bounds under such a setting are very meaningful and reflects the convergence behavior in real world applications because in practice models are typically trained with only finite many samples, and step size is set as constants during each iteration phase on large distributed platforms.

**Theorem 3.1** (fixed step size and fixed batch size). Assume that Assumption 1-5 hold, and Algorithm 1 is run with constant step size $\gamma$ and constant batch size $B$ such that

$$0 < L\gamma \leq 1. \quad (3.1)$$

Then for all $T \in \mathbb{N}^*$

$$\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E}\left\| \nabla F(\bar{w}_t) \right\|_2^2 \leq \frac{2(F(\bar{w}_0) - F^*)}{\gamma T} + 4L^2\gamma^2K^2_2M^2_2G + \frac{L\gamma M}{PB}. \quad (3.2)$$

Especially, by taking

$$\gamma = \frac{1}{\sqrt{PB/T}}, \text{ and } K_2 = T^{1/4}/(PB)^{3/4}, \quad (3.3)$$

we get

$$\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E}\left\| \nabla F(\bar{w}_t) \right\|_2^2 \leq \frac{2(F(\bar{w}_0) - F^*)}{\sqrt{PBT}} + \frac{4L^2M^2_2G}{\sqrt{PBT}} + \frac{LM}{\sqrt{PBT}}. \quad (3.4)$$

Proof of Theorem 3.1 can be found in section 6.1. When there are $T$ overall updates, globally and locally, a total number of $PBT$ data samples are processed. Theorem 3.1 indicates that Hier-AVG can achieve an iteration complexity of $O(1/\sqrt{PBT})$ which is the standard convergence rate for nonconvex optimization, see Ghadimi and Lan [2013]. Theorem 3.1 has two more important implications: 1. to achieve the standard convergence rate, one can use larger step size. From (3.3), we can see that the step size $\gamma = O(\sqrt{PB/T})$ is scaled up by the number of workers $P$ as a benefit
of parallelization. This result is consistent with the previous analysis of K-AVG in Zhou and Cong [2018].

2. The length of global averaging interval can be large, namely $K_2 = O(T^{1/4}/(PB)^{3/4})$, which indicates that it is unnecessary to use too frequent global averaging. Similar phenomena have been observed for K-AVG and studied by several recent works Zhou and Cong [2018], Yu et al. [2018], Stich [2018]. We will have a more detailed discussion on the behavior of $K_2$ in section 3.3.

Although Theorem 3.1 characterized the convergence rate of Hier-AVG and the impact of global parameter $K_2$, it doesn’t capture the behavior of local averaging, namely the impact of local parameters $K_1$ and $S$ on convergence. In the following theorem, we relax Assumption 5 and derive a new upper bound measured by a different metric with a more detailed characterization of $K_1$ and $S$.

**Theorem 3.2** (fixed step size and fixed batch size). Assume that Assumption 1-4 hold and Algorithm 1 is run with constant step size $\gamma$ and fixed batch size $B$ with the parameters satisfying

\[
1 - L^2\gamma^2 \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta \nabla F, w \right) - L\gamma K_2 \geq 0, \tag{3.5}
\]

Then for all $N \in \mathbb{N}^+$

\[
\frac{1}{N} \sum_{n=1}^{N} \mathbb{E} \left\| \nabla F(\tilde{w}_n) \right\|_2 \leq \frac{2\mathbb{E}[F(\tilde{w}_1) - F^*]}{N(K_2 - \delta)\gamma} + \frac{L\gamma MK_2^2}{PB(K_2 - \delta)} + \frac{L^2\gamma^2 MK_2}{12B(K_2 - \delta)} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) \tag{3.6}
\]

where $\delta := L^2\gamma^2(1 + \delta \nabla F, w) \in (0, 1)$ and $0 < \delta \nabla F, w \leq (K_2 - 1)K_2/2 - 1$ is a constant depending on the intermediate gradient norms between each global update.

The proof of Theorem 3.2 can be found in section 6.2. Expected (weighted) average squared gradient norms is used as a typical metric to show convergence for nonconvex optimization problems, see Ghadimi and Lan [2013]. This bound is generic and one can use it to derive classical bounds for different synchronous parallel SGD algorithms by plugging in specific values of $K_2$, $K_1$ and $S$. 
For example, by plugging in $K_1 = 1$ and $S = 1$ (or simply $K_2 = K_1$, in both cases, $K_2$ is $K$ in $K$-AVG), (3.6) reproduce the same bound for $K$-AVG as in Zhou and Cong [2018].

As we can see, by only scheduling a constant step size, it converges to some nonzero constant as $N \to \infty$. To make it converge to zero, diminishing step size schedule is needed. Intuitively, more frequent (larger $K_1$) and larger scale (larger $S$) local averaging should lead to faster convergence. Bound (3.6) justified this intuition for $S$. The impact length of local averaging interval $K_1$ and global averaging interval $K_2$ are more complicated. We will have a more detailed discussion in later sections.

In the following theorem, we show that by scheduling diminishing step size and/or dynamic batch sizes, $Hier$-AVG converges.

**Theorem 3.3** (diminishing step size and dynamic batch size). Assume that Algorithm 1 is run with diminishing step size $\gamma_j$ and growing batch size $B_j$ satisfying

$$1 - L^2 \gamma_j^2 \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_F \|w\| \right) - L \gamma_j K_2 \geq 0, \quad (3.7)$$

Then for all $N \in \mathbb{N}^*$

$$\mathbb{E} \sum_{j=1}^{N} \frac{\gamma_j}{\sum_{j=1}^{N} \gamma_j} \|\nabla F(\tilde{w}_j)\|_2^2 \leq \frac{2\mathbb{E}[F(\tilde{w}_1) - F^*]}{(K_2 - 1) \sum_{j=1}^{N} \gamma_j} + \sum_{j=1}^{N} \frac{L M K_2^2 \gamma_j^2}{PB_j(K_2 - 1) \sum_{j=1}^{N} \gamma_j} \quad (3.8)$$

$$+ \sum_{j=1}^{N} \frac{L^2 M K_2 \gamma_j^3}{12 B_j(K_2 - 1) \sum_{j=1}^{N} \gamma_j} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} \right)$$

$$+ (K_1 - 1)(3K_2 + K_1 - 2)).$$

Especially, if

$$\lim_{N \to \infty} \sum_{j=1}^{N} \gamma_j = \infty, \quad \lim_{N \to \infty} \sum_{j=1}^{N} \frac{\gamma_j^2}{PB_j} < \infty, \quad \lim_{N \to \infty} \sum_{j=1}^{N} \frac{\gamma_j^3}{B_j} < \infty, \quad (3.9)$$

10
Then
\[ \mathbb{E} \sum_{j=1}^{N} \frac{\gamma_j}{\sum_{j=1}^{N} \gamma_j} \| \nabla F(\tilde{w}_j) \|_2^2 \to 0, \text{ as } N \to \infty. \] (3.10)

The proof of Theorem 3.3 can be found in section 6.3. (3.9) also indicates that \textit{Hier-AVG} can use larger step size schedule than ASGD which requires \( \sum_{j=1}^{\infty} \gamma_j = \infty \), \( \sum_{j=1}^{\infty} \gamma_j^2 < \infty \) in general. This result is consistent with our previous analysis in Theorem 3.1.

### 3.3 Larger Value of \( K_2 \) Can Sometimes Lead to Faster Training Speed

As we have shown in Theorem 3.1, to achieve the standard convergence rate \( O(1/\sqrt{PBT}) \), the length of global averaging interval \( K_2 \) can be as large as \( T^{1/4}/(PB)^{3/4} \). In this section, we study the impact of \( K_2 \) on convergence through the non-asymptotic bound (3.6). We show that sometimes larger \( K_2 \) can even lead to faster training convergence. The result also implies that adaptive choice of \( K_2 \) may be better for convergence.

We consider a situation where \( T = N \ast K_2 \) is a constant, which means a fixed amount of data is processed or a fixed number of epochs is run. \( K_2 \) denotes the length of global averaging interval, or in other words, \( K_2 \) controls the frequency of global averaging under such setting. Larger \( K_2 \) means less frequent global averaging thus less frequent updates on parameter \( w \).

In the following theorem, we analytically show that under certain conditions larger value of \( K_2 \) can make training process converge faster. This is quite counter intuitive. Since one might think that smaller \( K_2 \) (or more frequent global averaging equivalently) should lead to better convergence performance. Especially, when \( K_2 = 1 \), \textit{Hier-AVG} is equivalent to sequential SGD with a large mini-batch size. However, it has been shown both analytically and experimentally by several recent works that \cite{Zhou2018, Zhang2016, Lin2018, Yu2018, Wang2018, Joshi2018, Stich2018} that \textit{K-AVG} with less frequent global averaging sometimes leads to faster convergence and better test accuracy simultaneously.

**Theorem 3.4.** Let \( T = N \ast K_2 \) be a constant. Suppose that Algorithm 1 is run under the condition
of Theorem 3.2 with fixed $K_1$ and $S$. If

$$\frac{\delta(F(\tilde{w}_1) - F^*)}{T\gamma(1 - \delta)} > \frac{2L\gamma M}{PB} + \frac{L^2\gamma^2 M}{BS},$$

(3.11)

Then Hier-AVG with some $K_2 > 1$ can have faster training speed than $K_2 = 1$.

The proof of Theorem 3.4 can found in section 6.4. It essentially says sometimes frequent global averaging is unnecessary for Hier-AVG to gain faster training speed. This is very meaningful for training large scale machine learning applications. Because global synchronization can cause expensive communication overhead on large platforms. As a consequence, the real run time of training can be severely slower when too frequent global reduction is deployed. Moreover, empirical observations have constantly shown that less frequent global averaging leads to better test accuracy.

To better understand Theorem 3.4 condition (3.11) implies that larger value of $(F(\tilde{w}_1) - F^*)$ requires some $K_2 > 1$ thus longer delay to minimize the bound in (3.6). The intuition is that if the initial guess is too far away from $F^*$, then less frequent synchronizations can lead to faster convergence for training. Less frequent averaging implies higher variance of the stochastic gradient in general. It is quite reasonable to think that if it is still far away from the solution, a stochastic gradient with larger variance may be preferred. As we mentioned in the proof, the optimal value of $K_2^*$ depends on quantities such as $L, M$, and $(F(\tilde{w}_1) - F^*)$ which are unknown to us in practice. Therefore, to obtain a concrete $K_2^*$ in practice is not so realistic.

Corresponding experimental results to validate our analysis are shown in section 4.1. In that section, we also empirically show that larger $K_2$ can constantly provide better test accuracies on various models.

3.4 Small $K_1$ and Large $S$ can Accelerate Training

In this section, we study the behavior of two local parameters $K_1$ and $S$, which control the frequency and the scope of local averaging respectively. Apparently, smaller $K_1$ means more frequent local averaging, and larger $S$ means more number of learners involved in local averaging. In the following
theorem, we show that when $K_2$ is fixed, smaller $K_1$ and larger $S$ can lead to faster training convergence for Hier-AVG.

**Theorem 3.5.** Suppose that Algorithm 1 is run under the same condition as in Theorem 3.2 or Theorem 3.3 with fixed $K_2$. Then both bounds in (3.6) and (3.8): 1. are monotone increasing with respect to $K_1$; 2. are monotone decreasing with respect to $S$.

The proof of Theorem 3.5 can be found in section 6.5. The behaviors of $K_1$ and $S$ are quite expected. It means that more frequent local averaging and/or more participants in local averaging can lead to faster convergence for training. Modern high performance computing (HPC) architectures typically employ multiple GPUs per node and the communication bandwidth within a node is much bigger. Thus the communication cost raised by local averaging can be much less costly than that of global averaging.

To better understand the impact of local averaging on convergence, we take a closer look at both bounds (3.6) and (3.8). Both $S$ and $K_1$ appear in the third term on the right hand side. When the first part in the third term is dominant, $S$ acts as a scaling factor in $(K_2 - K_1)(4K_2 + K_1 - 3)/S$, which can be understood as local averaging with more participants amortizes the cost introduced by global averaging represented by $K_2$; when the second term is dominant, one can simply set $K_1 = 1$ to cancel off this term. These shed light on an alternative way to speed up training by deploying local averaging. Meanwhile, another lesson we learned here is that one can trade less costly local averaging for global averaging given that less frequent global reduction oftentimes provides better test accuracy and less communication overhead. We will have a more detailed discussion on this in the next section. The experimental results that validate our analysis are presented in section 4.2.

### 3.5 Using Local Averaging to Reduce Global Averaging Frequency

From last section, a meaningful lesson we learned about Hier-AVG is that we can use more local averaging to speed up convergence in the sacrifice of less costly local communications. In this section, we compare Hier-AVG with $K$-AVG, and show that Hier-AVG with less frequent global reduction by deploying local averaging can converge faster than $K$-AVG while has less communication cost
when the number of workers $P$ is large. We consider $Hier-AVG$ and $K-AVG$ in a non-asymptotic scenario where $K-AVG$ is run with $K$ and $Hier-AVG$ with $K_2 = (1 + a)K$ with some $0 < a < 1$ and $K_1 = 1$ and $S = 4$. Typically, a single node is equipped with 4 or more GPUs. Local communication at such a scale is almost negligible. Apparently, after processing the same amount of data, $Hier-AVG$ has much less communication cost than $K-AVG$ due to less frequent global averaging involved.

**Theorem 3.6.** Under the conditions of Theorem 3.4, let $Hier-AVG$ be run with $K_2 = (1 + a)K$ with $a \in [0, 0.6]$, $K_1 = 1$ and $S = 4$. Suppose that $L_\gamma P \gg 1$. Then $Hier-AVG$ can converge faster than $K-AVG$ after processing the same amount of data.

The proof of Theorem 3.6 can be found in section 6.6. The result of Theorem 3.6 has two meaningful consequences: 1. From the point view of parallel computing, even with comparable convergence rate, $Hier-AVG$ with less global averaging whose communication overhead are reduced can have some real run time reduction in the training phase when $P$ is large; 2. As our experimental results show in section 4.3, less frequent global averaging can often lead to better test accuracy. As a consequence, compared with $K-AVG$, $Hier-AVG$ can serve as a better alternative algorithm to gain comparable or faster training speed while achieving better test accuracy. As our experiments show in section 4.3, we constantly observe that $Hier-AVG$ has better performance than $K-AVG$ even when $a = 1$ and $K_1 > 1$.

### 4 Experimental results

In this section, we present experimental results to validate our analysis of $Hier-AVG$. All SGD methods are implemented with Pytorch, and the communication is implemented using CUDA-aware openMPI 2.0. All implementations use the cuDNN library 7.0 for forward and backward propagations. Our experiments are implemented on a cluster of 32 IBM Minsky nodes interconnected with Infiniband. Each node is an IBM S822LC system containing 2 Power8 CPUs with 10 cores each, and 4 NVIDIA Tesla P100 GPUs.
We evaluate our algorithm on four state-of-the-art neural network models. They are ResNet-18 [He et al. 2016], GoogLeNet [Szegedy et al. 2015], MobileNet [Howard et al. 2017], and VGG19 [Simonyan and Zisserman 2014]. They represent some of the most advanced neural network architectures used in current large scale machine learning tasks. Most of our experiments are done on the dataset CIFAR-10 [Krizhevsky and Hinton 2009]. In addition, we also demonstrate the superior performance of Hier-AVG over K-AVG using the ImageNet-1K [Deng et al. 2009] dataset which has a much larger size. Unless noted, the batchsize we use is 64, and the total amount of data we train is 200 epochs. The initial learning rate is 0.1, and decreases to 0.01 after 150 epochs.

4.1 Impact of $K_2$ on convergence

Theorem 3.4 shows that the optimal $K_2$ for convergence is not necessarily 1, and larger $K_2$ can sometimes lead to faster convergence than a smaller one. Fig. 1a, 1b, 1c and 1d show the impact of $K_2$ on convergence for ResNet-18, GoogLeNet, MobileNet, and VGG19 respectively. Within each figure, the training accuracies for $K_2 = 8, 16, \text{ and } 32$ between epoch 170 to epoch 200 are shown. We use $P = 32$ learners and set $K_1 = 4, S = 4$.

For ResNet-18 and GoogLeNet, the training accuracies with three different $K_2$ are similar. In fact, the best training accuracy for GoogLeNet is achieved with $K_2 = 32$. For MobileNet and VGG19, the best training accuracies are achieved with $K_2 = 8$, and the training accuracy with $K_2 = 32$ is higher than with $K_2 = 16$. Above all, there is no clue that more frequent global averaging (smaller $K_2$) leads to faster convergence.

Modern neural networks are typically fairly deep and have a large number of weights. Without
mitigation, overfitting can plague generalization performance. Thus, we also investigate the impact of $K_2$ on test accuracy.

Fig. 2a, 2b, 2c and 2d show test accuracies with the same setup for ResNet-18, GoogLeNet, MobileNet, and VGG19 respectively. For ResNet-18, the best test accuracy is achieved with $K_2 = 16$, about 0.3% higher than with $K_2 = 8$. For GoogLeNet, the best test accuracy is achieved with $K_2 = 32$, although at epoch 200 all three runs show similar test accuracy. For MobileNet, $K_2 = 8, 16, and 32$ have similar test performance. For VGG19, $K_2 = 8$ has the best test accuracy at epoch 200.

It is clear that increasing $K_2$ does not necessarily reduce convergence speed for training, but obviously it reduces the frequency of costly global reduction when $P$ increases. For example, the best test accuracy for GoogLeNet is achieved with $K_2 = 32$. In comparison with $K_2 = 8$, 4 times fewer global reductions are used. As a result, the real run time for training can be effectively reduced due to much less communication overhead.

4.2 Impact of $K_1$ and $S$ on Convergence

In section 3.4, Theorem 3.5 claims that reducing $K_1$ and increasing $S$ can speed up training convergence. In practice, with a limited budget in terms of the amount of data samples processed (e.g., a fixed number of training epochs), we can adjust $K_1$ and $S$ to accelerate training. Recall that $K_1$ and $S$ determine local communication behavior. They provide deterministic means, at least in theory, for practitioners to fine tune training to achieve the best results within their computational budget and time constraint.
Fig. 3a, 3b, 3c and 3d show the impact of $K_1$ on convergence. As all networks achieve high training accuracy, we show the evolution of training loss from epoch 170 to epoch 200. In each figure we show the training loss for $K_1 = 4$ and 8, and we set $K_2 = 32$, $S = 4$, and $P = 16$. As we can see, for all networks it is clear that a lower training loss is achieved with $K_1 = 4$ than with $K_1 = 8$.

Fig. 4a, 4b, 4c and 4d show the impact of $S$ on convergence. Again we show the evolution of training loss from epoch 170 to epoch 200. In each figure we plot the training loss for $S = 2$ and 4, and we set $K_2 = 32$, $K_1 = 4$, and $P = 16$. In all figures lower training loss is achieved with $S = 4$ than with $S = 2$.

4.3 Comparison with $K$-AVG

As we have mentioned, one of the biggest challenges of distributed training is the communication overhead. In $K$-AVG, $K$ determines the frequency of global reduction. It is shown by Zhou and Cong 2018, from the perspective of convergence, large $P$ may require small $K$ for faster convergence. We explained in section 3.5 that Hier-AVG provides the option to reduce global reduction frequency by using local averaging. Since modern architectures typically employ multiple...

Table 1: Comparison of Hier-AVG and $K$-AVG

GPUs per node, and the intra-node communication bandwidth is much higher than inter-node bandwidth, Hier-AVG is a perfect match for such systems.

We evaluate the performance of Hier-AVG by setting $K_2 = 2K_{opt}$ and $S = 4$, where $K_{opt}$ is the fine tuned value of $K$ for $K$-AVG implementation. The experimental results is summarized in Table 1. We experiment with $P = 16$, 32, and 64 learners on ResNet-18. With 16 learners, $K_{opt} = 32$ for $K$-AVG. Then we set $K_2 = 64$ for Hier-AVG, and experiment with $K_1 = 2$, 4, and 16. The corresponding validation accuracies are 94.01%, 94.11%, and 94.08% respectively. They are all higher than the best accuracy achieved by $K$-AVG at 94.0%. With 32 and 64 learners, $K_{opt} = 4$ for $K$-AVG. We set $K_2 = 8$ for Hier-AVG, the accuracies achieved are 93.90% and 93.17% at $K_1 = 4$, $S = 8$ and $K_1 = 1$ $S = 4$, respectively. The best accuracies achieved by $K$-AVG with 32 and 64 learners are 93.7% and 92.5% respectively.

In our experiments, while reducing the global reduction frequency by half, Hier-AVG still achieves validation accuracy comparable to $K$-AVG. Note that we do not show the actual wall-clock time per epoch because Pytorch implementations do not support GPU-direct communication yet on our target architecture. For all reductions, the data is copied from GPU to CPU first. It is clear though once GPU-direct communication is implemented, Hier-AVG can effectively reduce communication time.
4.4 Performance of Hier-AVG on ImageNet

In this section, we further investigate the performance of Hier-AVG with the ImageNet-1K dataset which is much larger than CIFAR-10 and it contains 1.28 million training images split across 1000 classes, and 50,000 validation images.

During training, a crop of random size (of 0.08 to 1.5) of the original size and a random aspect ratio (of 3/4 to 4/3) of the original aspect ratio is made. This crop is then resized to $224 \times 224$. Random color jittering with a ratio of 0.4 to the brightness, contrast and saturation of an image is then applied. Next a random horizontal flip is applied to the input, and the input is then normalized with mean (0.485, 0.456, 0.406) and standard deviation (0.229, 0.224, 0.225) for the (R, G, B) channels respectively. For $K$-AVG we set $K = 43$, and for Hier-AVG we set $K_2 = 43$, $K_1 = 20$, and $S = 4$.

Fig. 5a shows the training accuracies comparison between $K$-AVG and Hier-AVG with 16 learners. Clearly, Hier-AVG achieves higher training accuracy than $K$-AVG since the first epoch. After the first 5 epochs, Hier-AVG achieved 6% higher training accuracy than $K$-AVG, and at the 46-th epoch, Hier-AVG achieved 17.33% higher training accuracy than $K$-AVG. At the 90-th epoch, the training accuracy of Hier-AVG is 1.15% higher than $K$-AVG.

Fig. 5b shows the test accuracies comparison between $K$-AVG and Hier-AVG with 16 learners. As we can see, Hier-AVG also achieves higher validation accuracy than $K$-AVG since the first epoch. At epoch 5, Hier-AVG achieved 12% higher accuracy than $K$-AVG, and at the 90-th epoch, Hier-AVG achieved 0.51% higher accuracy than $K$-AVG.

5 Conclusion

We proposed a two stage hierarchical averaging SGD algorithm to effectively reduce communication overhead while not deterioate training and test performance for distributed machine learning. We established the convergence results for Hier-AVG for non-convex optimization problems and show that Hier-AVG with infrequent global reduction can still achieve the expected convergence rate,
while oftentimes provides faster training speed and better test accuracy. By introducing local averaging, we show that it can be used to accelerate training. Moreover, we show analytically and experimentally that local averaging can serve as an alternative remedy to reduce global reduction frequency without doing harm to the convergence rate for training and generalization performance for testing. As a result, Hier-AVG provides an alternative method for practitioners to train large scale machine learning applications on distributed platforms.

6 Proofs

6.1 Proof of Theorem 3.1

Proof. We denote by

\[ \bar{\mathbf{w}}_t = \frac{1}{P} \sum_{j=1}^{P} \mathbf{w}_t^j \]  

(6.1)

as the global average of local iterates over all P workers. A quick observation is that when \( t \equiv 0 \mod K_2 \), then \( \mathbf{w}_t = \bar{\mathbf{w}}_i \) with \( i = t/K_2 \). In the following theorem, we derive an upper bound on the convergence measured by \( T^{-1} \sum_{t=1}^{T} \mathbb{E}\|\nabla F(\bar{\mathbf{w}}_{t-1})\|^2 \). It is easy to see that

\[ \mathbf{w}_{t+1} - \mathbf{w}_t = -\frac{\gamma}{PB} \sum_{j=1}^{P} \sum_{s=1}^{B} \nabla F(\mathbf{w}_{t}^j; \xi_{t+1,s}^j). \]  

(6.2)
Consider

\[
E\left[F(\bar{w}_{t+1}) - F(\bar{w}_t)\right] \leq E\left(\nabla F(\bar{w}_t), \bar{w}_{t+1} - \bar{w}_t\right) + \frac{L}{2} E\left\|\bar{w}_{t+1} - \bar{w}_t\right\|^2_2 \tag{6.3}
\]

\[
\leq -\gamma E\left[\left(\nabla F(\bar{w}_t), \frac{1}{P} \sum_{j=1}^P \nabla F(w^j_t)\right)\right] \tag{6.4}
\]

\[
+ \frac{L\gamma^2}{2P^2 B^2} E\left\|\sum_{j=1}^P \sum_{s=1}^B \nabla F(w^j_t; \xi^j_{t+1,s})\right\|^2_2. \tag{6.5}
\]

where (6.4) is due to the fact that random variables \(\nabla F(w^j_t; \xi^j_{t+1,s})\) are i.i.d. over \(s\) for fixed \(t\) and \(j\) conditioning on previous steps. In the following, we will bound (6.4) and (6.5) respectively.

For (6.4), some simple algebra implies that

\[
-\gamma E\left[\left(\nabla F(\bar{w}_t), \frac{1}{P} \sum_{j=1}^P \nabla F(w^j_t)\right)\right] = -\frac{\gamma}{2} E\left[\|\nabla F(\bar{w}_t)\|^2_2 + \|\frac{1}{P} \sum_{j=1}^P \nabla F(w^j_t)\|^2_2 - \|\nabla F(\bar{w}_t) - \frac{1}{P} \sum_{j=1}^P \nabla F(w^j_t)\|^2_2\right]. \tag{6.6}
\]

For term \(\|\nabla F(\bar{w}_t) - \frac{1}{P} \sum_{j=1}^P \nabla F(w^j_t)\|^2_2\), we have

\[
E\left\|\nabla F(\bar{w}_t) - \frac{1}{P} \sum_{j=1}^P \nabla F(w^j_t)\right\|^2_2 = \frac{1}{P^2} \sum_{j=1}^P \left\|\nabla F(\bar{w}_t) - \nabla F(w^j_t)\right\|^2_2 \leq \frac{1}{P} \sum_{j=1}^P E\left\|\nabla F(\bar{w}_t) - \nabla F(w^j_t)\right\|^2_2 \tag{6.7}
\]

\[
\leq \frac{L^2}{P} \sum_{j=1}^P E\left\|\bar{w}_t - w^j_t\right\|^2_2.
\]

To bound \(E\left\|\bar{w}_t - w^j_t\right\|^2_2\), we first set \(t_0\) to be the largest integer such that \(t_0 \equiv 0 \mod K_2\) and \(t_0 \leq t\). In other words, \(t_0\) is the latest iteration number that is less than \(t\) when global averaging happens. Then we can write

\[
w^j_t = \bar{w}_{t_0} - \frac{\gamma}{B} \sum_{\tau=t_0+1}^t \sum_{s=1}^B \nabla F(w^j_{\tau-1}, \xi^j_{\tau,s}) \tag{6.8}
\]
and
\[ \mathbf{w}_t = \mathbf{w}_{t_0} - \frac{\gamma}{P B} \sum_{j=1}^{P} \sum_{\tau=t_0+1}^{t} \sum_{s=1}^{B} \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j). \] (6.9)

Plug (6.8) and (6.9) in \( \mathbb{E}\|\mathbf{w}_t - \mathbf{w}_t^j\|_2^2 \), we get
\[
\mathbb{E}\|\mathbf{w}_t - \mathbf{w}_t^j\|_2^2 = \gamma^2 \mathbb{E}\left[ \sum_{\tau=t_0+1}^{t} \left( \frac{1}{P B} \sum_{j=1}^{P} \sum_{s=1}^{B} \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j) - \frac{1}{B} \sum_{s=1}^{B} \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j) \right) \right]^2
\leq 2\gamma^2 \mathbb{E}\left[ \sum_{\tau=t_0+1}^{t} \frac{1}{P B} \sum_{j=1}^{P} \sum_{s=1}^{B} \| \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j) \|_2^2 + \sum_{\tau=t_0+1}^{t} \frac{1}{B} \sum_{s=1}^{B} \| \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j) \|_2^2 \right]
\leq 2\gamma^2 (t - t_0)^2 \sum_{\tau=t_0+1}^{t} \sum_{s=1}^{B} \left( \frac{1}{P B} \sum_{j=1}^{P} \mathbb{E}\| \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j) \|_2^2 + \frac{1}{B} \mathbb{E}\| \nabla F(\mathbf{w}_{\tau-1}^j, \xi_{\tau,s}^j) \|_2^2 \right)
\leq 4\gamma^2 (t - t_0)^2 M_G^2
\leq 4\gamma^2 K_G^2 M_G^2. \] (6.10)

Plug (6.10) back into (6.7), we get
\[
\mathbb{E}\|\nabla F(\mathbf{w}_t) - \frac{1}{P} \sum_{j=1}^{P} \nabla F(\mathbf{w}_t^j) \|_2^2 \leq 4L^2 \gamma^2 K_G^2 M_G^2. \] (6.11)

Then we get the bound on (6.4) as
\[
-\gamma \mathbb{E}\left[ \left( \nabla F(\mathbf{w}_t), \frac{1}{P} \sum_{j=1}^{P} \nabla F(\mathbf{w}_t^j) \right) \right] \leq -\frac{\gamma}{2} \mathbb{E}\left[ \| \nabla F(\mathbf{w}_t) \|_2^2 + \| \frac{1}{P} \sum_{j=1}^{P} \nabla F(\mathbf{w}_t^j) \|_2^2 \right] + 2L^2 \gamma^3 K_G^2 M_G^2. \] (6.12)

On the other hand, for (6.5) we have
\[
\frac{L\gamma^2}{2} \mathbb{E}\| \frac{1}{P B} \sum_{j=1}^{P} \sum_{s=1}^{B} \nabla F(\mathbf{w}_t^j; \xi_{t+1,s}^j) \|_2^2 \leq \frac{L\gamma^2}{2} \mathbb{E}\| \frac{1}{P B} \sum_{j=1}^{P} \sum_{s=1}^{B} (\nabla F(\mathbf{w}_t^j; \xi_{t+1,s}^j) - \nabla F(\mathbf{w}_t^j; \nabla F(\mathbf{w}_t^j)) \|_2^2
\leq \frac{L\gamma^2}{2} \mathbb{E}\| \frac{1}{P B} \sum_{j=1}^{P} \sum_{s=1}^{B} (\nabla F(\mathbf{w}_t^j; \xi_{t+1,s}^j) - \nabla F(\mathbf{w}_t^j)) \|_2^2 + \frac{L\gamma^2}{2} \mathbb{E}\| \frac{1}{P} \sum_{j=1}^{P} \nabla F(\mathbf{w}_t^j) \|_2^2 \] (6.13)
\begin{align}
& \leq \frac{L\gamma^2}{2P^2B^2} \sum_{j=1}^{P} \sum_{s=1}^{B} \mathbb{E} \left\| \nabla F(w_t^j; \xi_{t+1,s}) - \nabla F(w_t^j) \right\|_2^2 + \frac{L\gamma^2}{2P} \mathbb{E} \left\| \frac{1}{P} \sum_{j=1}^{P} \nabla F(w_t^j) \right\|_2^2 \\
& \leq \frac{L\gamma^2 M}{2PB} + \frac{L\gamma^2}{2P} \mathbb{E} \left\| \frac{1}{P} \sum_{j=1}^{P} \nabla F(w_t^j) \right\|_2^2
\end{align}
(6.16)

where (6.15) is due to $P^{-1} \sum_{j=1}^{P} \left( \nabla F(w_t^j; \xi_{t+1,s}) - \nabla F(w_t^j) \right) = 0$ condition on $w_t^j$ and the independence over $s$. (6.16) is due to the same trick and conditional independence over $j$ and $s$.

Combine (6.12) and (6.17), we get

$$
\mathbb{E} \left[ F(\bar{w}_{t+1}) - F(\bar{w}_t) \right] \leq -\frac{\gamma}{2} \mathbb{E} \left\| \nabla F(\bar{w}_t) \right\|_2^2 - \frac{\gamma(1 - L\gamma)}{2} \left\| \frac{1}{P} \sum_{j=1}^{P} \nabla F(w_t^j) \right\|_2^2 + 2L^2 \gamma^3 K_2^2 M_G^2 + \frac{L\gamma^2 M}{2PB}.
$$

Take the summation over $t$, under the assumption $0 < L\gamma \leq 1$ we get

$$
\frac{\gamma}{2} \sum_{t=0}^{T-1} \mathbb{E} \left\| \nabla F(\bar{w}_t) \right\|_2^2 \leq \left[ F(\bar{w}_0) - \mathbb{E} F(\bar{w}_T) \right] + 2L^2 \gamma^3 K_2^2 M_G^2 + \frac{L\gamma^2 M}{2PB},
$$
(6.18)

which leads to

$$
\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E} \left\| \nabla F(\bar{w}_t) \right\|_2^2 \leq \frac{2(F(\bar{w}_0) - \mathbb{E} F(\bar{w}_T))}{\gamma T} + 4L^2 \gamma^2 K_2^2 M_G^2 + \frac{L\gamma M}{PB}
$$
(6.19)

By setting $\gamma = \sqrt{PB/T}$ and $K_2 = T^{1/4}/(PB)^{3/4}$, we get

$$
\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E} \left\| \nabla F(\bar{w}_t) \right\|_2^2 \leq \frac{2(F(\bar{w}_0) - F^*)}{\sqrt{PBT}} + 4L^2 M_G^2 + \frac{LM}{\sqrt{PBT}}.
$$
(6.20)
6.2 Proof of Theorem 3.2

Proof. We denote $\tilde{w}_n$ as the $n$-th global update in Hier-AVG, denote $\bar{w}^j_{n+kK_1+t}$ as $t$-th local update on learner $j$ after $k$ times local averaging. By the algorithm,

$$\tilde{w}_{n+1} - \tilde{w}_n = -\gamma \frac{PB}{P\beta - 1} \sum_{j=1}^P \sum_{k=0}^{\beta - 1} \sum_{t=0}^{K_1 - 1} \sum_{s=1}^B \nabla F(\bar{w}^j_{n+kK_1+t}; \xi^j_{kK_1+t,s}).$$

By the definition of SGD, the random variables $\xi^j_{kK_1+t,s}$ are i.i.d. for all $t = 0, ..., K_1 - 1$, $s = 1, ..., B$, $j = 1, ..., P$ and $k = 0, ..., \beta - 1$.

Consider

$$E \left[ F(\tilde{w}_{n+1}) - F(\tilde{w}_n) \right] \leq E \left[ \nabla F(\tilde{w}_n), \tilde{w}_{n+1} - \tilde{w}_n \right] + \frac{L}{2} E \left[ \| \tilde{w}_{n+1} - \tilde{w}_n \|^2 \right] \quad (6.21)$$

$$\leq -\gamma \left( \nabla F(\tilde{w}_n), E \sum_{k=0}^{\beta - 1} \sum_{t=0}^{K_1 - 1} \sum_{s=1}^B \nabla F(\bar{w}^j_{n+kK_1+t}) \right) \quad (6.22)$$

$$+ \frac{L\gamma^2}{2P^2B^2} E \left\| \sum_{j=1}^P \sum_{k=0}^{\beta - 1} \sum_{t=0}^{K_1 - 1} \sum_{s=1}^B \nabla F(\bar{w}^j_{n+kK_1+t}; \xi^j_{kK_1+t,s}) \right\|^2 \quad (6.23)$$

Note that here we abused the expectation notation $E$ a little bit. Throughout this proof, $E$ always means taking the overall expectation. For each fixed $k$ and $t$, the random variables $\nabla F(\bar{w}^j_{n+kK_1+t}; \xi^j_{kK_1+t,s})$ are i.i.d. for all $j$ and $s$ conditioning on previous steps. As a result, we can drop the summation over $j$ and $s$ in (6.22) due to the averaging factors $B$ and $P$ in the dominator. To be more specific, under the unbiasedness Assumption 3, by taking the overall expectation we can immediately get

$$E \left[ F(\tilde{w}_{n+1}) - F(\tilde{w}_n) \right] \leq E \left[ \nabla F(\tilde{w}_n), \tilde{w}_{n+1} - \tilde{w}_n \right] + \frac{L}{2} E \left[ \| \tilde{w}_{n+1} - \tilde{w}_n \|^2 \right] \quad (6.21)$$

$$\leq -\gamma \left( \nabla F(\tilde{w}_n), E \sum_{k=0}^{\beta - 1} \sum_{t=0}^{K_1 - 1} \sum_{s=1}^B \nabla F(\bar{w}^j_{n+kK_1+t}) \right) \quad (6.22)$$

$$+ \frac{L\gamma^2}{2P^2B^2} E \left\| \sum_{j=1}^P \sum_{k=0}^{\beta - 1} \sum_{t=0}^{K_1 - 1} \sum_{s=1}^B \nabla F(\bar{w}^j_{n+kK_1+t}; \xi^j_{kK_1+t,s}) \right\|^2 \quad (6.23)$$

for fixed $j$ and $t$. Next, we show how to get rid of the summation over $j$. Recall that $\bar{w}^j_{\alpha+1} = \bar{w}_\alpha - \frac{\gamma}{B} \sum_{s=1}^B \nabla F(\bar{w}_\alpha; \xi_{\alpha,s}^j)$. Obviously, $\bar{w}^j_{\alpha+1}$, $j = 1, ..., P$ are i.i.d. conditioning on $\bar{w}_\alpha$ because $\xi_{0,s}^j$, $j = 1, ..., P$, $s = 1, ..., B$ are i.i.d. Similarly, $\bar{w}^j_{\alpha+2} = \bar{w}^j_{\alpha+1} - \frac{\gamma}{B} \sum_{s=1}^B \nabla F(\bar{w}^j_{\alpha+1}; \xi_{1,s}^j)$, $j = 1, ..., P$. 
are i.i.d. due to the fact that \( \mathbf{w}_j^{\alpha+t} \)'s are i.i.d., \( \xi_j^{t,s} \)'s are i.i.d., and \( \bar{\mathbf{w}}_j^{\alpha+t} \)'s are independent from \( \xi_j^{t,s} \)'s. By induction, one can easily show that for each fixed \( t, \mathbf{w}_j^{\alpha+t} \), \( j = 1, ..., P \) are i.i.d. Thus for each fixed \( t \)

\[
\frac{1}{P} \sum_{j=1}^{P} \mathbb{E} \nabla F(\mathbf{w}_j^{\alpha+t}) = \mathbb{E} \nabla F(\mathbf{w}_j^{\alpha+t}).
\]

We can therefore get rid of the summation over \( j \) as well. We will frequently use the above iterative conditional expectation trick in the following analysis.

Next, we will bound (6.22) and (6.23) respectively. For (6.23), we have

\[
\frac{L_{\gamma}^2 K_1 \beta}{2P^2 B^2} \mathbb{E} \sum_{k=0}^{\beta-1} K_{1-1} \sum_{t=0}^{P} \sum_{j=1}^{B} \left\| \sum_{j=1}^{B} \nabla F(\mathbf{w}_{n+kK_1+t}; \xi_j^{t,s}) \right\|_2^2
\]

\[
= \frac{L_{\gamma}^2 K_1 \beta}{2P^2 B^2} \mathbb{E} \sum_{k=0}^{\beta-1} K_{1-1} \sum_{t=0}^{P} \sum_{j=1}^{B} \left( \nabla F(\mathbf{w}_{n+kK_1+t}; \xi_j^{t,s}) - \nabla F(\bar{\mathbf{w}}_{n+kK_1+t}) \right) \right\|_2^2
\]

\[
+ \frac{L_{\gamma}^2 K_1 \beta}{2P^2 B^2} \mathbb{E} \sum_{k=0}^{\beta-1} K_{1-1} \sum_{t=0}^{P} \sum_{j=1}^{B} \left( \nabla F(\mathbf{w}_{n+kK_1+t}; \xi_j^{t,s}) - \nabla F(\bar{\mathbf{w}}_{n+kK_1+t}) \right) \right\|_2^2
\]

\[
+ \frac{L_{\gamma}^2 K_1 \beta}{2P^2 B^2} \sum_{k=0}^{\beta-1} K_{1-1} \sum_{t=0}^{P} \sum_{j=1}^{B} \nabla F(\bar{\mathbf{w}}_{n+kK_1+t}) \right\|_2^2
\]

where in the last equation, we used the fact that for fixed \( t \) and \( k \) and conditioning on \( \nabla F(\bar{\mathbf{w}}_{n+kK_1+t}), \sum_{j=1}^{B} \mathbb{E} (\nabla F(\bar{\mathbf{w}}_{n+kK_1+t}; \xi_j^{t,s}) - \nabla F(\bar{\mathbf{w}}_{n+kK_1+t})) = 0 \) under unbiasedness Assumption 3. Further, under the bounded variance Assumption 4, we have

\[
\frac{L_{\gamma}^2 K_1 \beta}{2P^2 B^2} \sum_{k=0}^{\beta-1} K_{1-1} \sum_{t=0}^{P} \sum_{j=1}^{B} \nabla F(\bar{\mathbf{w}}_{n+kK_1+t}; \xi_j^{t,s}) \right\|_2^2
\]

\[25\]
Note that in the first equity we can change the summation over \( j \) and \( s \) out of the squared norms without introducing an extra \( PB \) factor is due to the fact that conditioning on \( \tilde{w}^j_{n+kK_1+t} \), \( \nabla F(\tilde{w}^j_{n+kK_1+t}; \xi^j_{kK_1+t,s}) \) are all independent with respect to different \( j \) and \( s \). In the following, we will use this trick over and over again without further explanation.

For (6.22), we have

\[
-\gamma \left\langle F(\tilde{w}_n), \mathbb{E} \sum_{k=0}^{\beta-1} \sum_{t=0}^{K_1-1} \nabla F(\tilde{w}^j_{n+kK_1+t}) \right\rangle
\]

\[
= -\frac{\gamma}{2} \sum_{k=0}^{\beta-1} \sum_{t=0}^{K_1-1} \left( \mathbb{E}\|\nabla F(\tilde{w}_n)\|^2 + \mathbb{E}\|\nabla F(\tilde{w}^j_{n+kK_1+t})\|^2 \right) + \frac{\gamma}{2} \sum_{k=0}^{\beta-1} \sum_{t=0}^{K_1-1} \mathbb{E}\|\nabla F(\tilde{w}^j_{n+kK_1+t}) - \nabla F(\tilde{w}_n)\|^2
\]

\[
\leq -\frac{\gamma \beta K_1}{2} \mathbb{E}\|\nabla F(\tilde{w}_n)\|^2 - \frac{\gamma}{2} \sum_{k=0}^{\beta-1} \sum_{t=0}^{K_1-1} \mathbb{E}\|\nabla F(\tilde{w}^j_{n+kK_1+t})\|^2 + \frac{\gamma L^2}{2} \sum_{k=0}^{\beta-1} \sum_{t=0}^{K_1-1} \mathbb{E}\|\tilde{w}^j_{n+kK_1+t} - \tilde{w}_n\|^2,
\]

(6.24)

where we used the Lipschitz Assumption 1 in the last inequality.

In the following lemma, we derive a general bound on \( \mathbb{E}\|\tilde{w}^j_{n+kK_1+t} - \tilde{w}_n\|^2 \).
Lemma 1. For any $t \in \{0, 1, 2, ..., K_1 - 1\}$ and $\eta \in \{0, 1, 2, ..., \beta - 1\}$, we have

\[
\mathbb{E}\|\tilde{w}_n^j + K_{1+t} - \tilde{w}_n\|^2 \leq \frac{\gamma^2 M}{B} (K_1 \eta + t \left( t + \frac{K_1 S}{B} \right) + \gamma^2 (K_1 \eta + t) \sum_{k=0}^{K_1+t} \mathbb{E}\|\nabla F(\tilde{w}_n^j)^2 \|^2
\] (6.25)

Proof. Recall that for any $P_j$ in a local cluster $P_{lc}$ with $|P_{lc}| = S$,

\[
\begin{align*}
\tilde{w}_n^j &\equiv \sum_{j \in P_{lc}} \sum_{\eta = 0}^{\eta} \sum_{i=0}^{t} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) + \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{k=0}^{K_1+t} \sum_{r=0}^{B} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}).
\end{align*}
\]

Therefore,

\[
\begin{align*}
\mathbb{E}\|\tilde{w}_n^j \eta K_1 + t - \tilde{w}_n\|^2
\end{align*}
\] (6.26)

\[
\begin{align*}
= \mathbb{E}\left( \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{i=0}^{t} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) + \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{k=0}^{K_1+t} \sum_{r=0}^{B} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \right) \| \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \|^2
\end{align*}
\] (6.27)

\[
\leq \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{i=0}^{t} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \|^2
\] (6.28)

\[
\begin{align*}
+ \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{i=0}^{t} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \|^2
\end{align*}
\] (6.29)

For term (6.28)

\[
\frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{i=0}^{t} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \|^2
\] (6.30)

\[
= \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{i=0}^{t} \sum_{s=1}^{B} \left( \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) - \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \right) \|^2
\] (6.31)

\[
\leq \frac{t-1}{B} \sum_{j \in P_{lc}} \sum_{i=0}^{t} \sum_{s=1}^{B} \nabla F(\tilde{w}_n^j \eta K_1 + r; \xi_{\eta K_1 + i, s}) \|^2
\] (6.32)
Similarly, for term (6.29) we have

\[ \gamma^2 M \frac{B}{S^2} (K_1 \eta + t) t + \gamma^2 (K_1 \eta + t) \sum_{i=0}^{t-1} E \left\| \nabla F (\bar{w}^j_{n+\eta K_1+i}) \right\|_2^2. \] (6.34)

Therefore, using the result of Lemma 1

\[ \frac{\gamma^2 L^2 \beta-1 K_1-1}{2} \sum_{\eta=0}^{t-1} \sum_{t=0}^{t-1} \mathbb{E} \left\| \bar{w}^j_{n+\eta K_1+t} - \bar{w}_n \right\|_2^2 \]

\[ \leq \frac{L^2 \gamma^2 M}{2B} \sum_{\eta=0}^{t-1} \sum_{t=0}^{t-1} (K_1 \eta + t) \left( t + \frac{K_1 \eta}{S} \right) + \frac{L^2 \gamma^2 M}{2} \sum_{\eta=0}^{t-1} \sum_{t=0}^{t-1} \mathbb{E} \left\| \nabla F (\bar{w}^j_{n+\eta K_1+t}) \right\|_2^2 \]

\[ = \frac{L^2 \gamma^2 M \eta}{2B} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) \]

\[ + \frac{L^2 \gamma^2 M K_2 (K_2 - 1)}{2B} \mathbb{E} \left\| \nabla F (\bar{w}_n) \right\|_2^2 \]

\[ + \frac{L^2 \gamma^2 M}{2} \sum_{\eta=0}^{t-1} \sum_{t=0}^{t-1} (K_1 \eta + t) \mathbb{1}\{K_1 \eta + t - 1 \geq 1\} \sum_{k=1}^{K_1 \eta+t-1} \mathbb{E} \left\| \nabla F (\bar{w}^j_{n+k}) \right\|_2^2. \]

Then we will have an upper bound on

\[ \sum_{\eta=0}^{t-1} \sum_{t=0}^{t-1} (K_1 \eta + t) \mathbb{1}\{K_1 \eta + t - 1 \geq 1\} \sum_{k=1}^{K_1 \eta+t-1} \mathbb{E} \left\| \nabla F (\bar{w}^j_{n+k}) \right\|_2^2. \]
Lemma 2.

\[
\beta - 1 \sum_{\eta=0}^{K_1-1} (K_1\eta + t)1\{K_1\eta + t - 1 \geq 1\} \leq \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_{\nabla F, w}\right) \sum_{k=1}^{K_2-1} \mathbb{E}\left\| \nabla F(\bar{w}_{n+k}^j) \right\|_2^2,
\]

(6.37)

where \(\delta \in (0, K_2(K_2-3)/2)\) is a constant depending on the immediate gradient norms \(\|\nabla F(\bar{w}_{n+k}^j)\|_2^2\), \(k = 1, ..., K_2 - 1\).

Proof. Obviously, \(\mathbb{E}\left\| \nabla F(\bar{w}_{n+1}^j) \right\|_2^2\) has the most copies, we will derive an upper bound on the number of \(\mathbb{E}\left\| \nabla F(\bar{w}_{n+1}^j) \right\|_2^2\) and then use this bound to uniformly bound the number of terms for \(\mathbb{E}\left\| \nabla F(\bar{w}_{n+k}^j) \right\|_2^2\), \(k = 1, ..., K_2 - 2\).

\[
\sum_{\eta=0}^{K_1-1} \sum_{t=0}^{K_1-1} (K_1\eta + t)1\{K_1\eta + t - 1 \geq 1\} \leq \sum_{t=0}^{K_1-1} t1\{t \geq 2\}1\{K_1 \geq 3\} + \sum_{t=0}^{K_1-1} (K_1 + t)1\{K_1 + t \geq 2\}1\{K_1 \geq 2\}
\]

\[
+ \sum_{\eta=2}^{K_1-1} \sum_{t=0}^{K_1-1} (K_1\eta + t)1\{K_1\eta + t \geq 2\}
\]

\[
= \frac{(K_1 - 2)(K_1 + 1)}{2}1\{K_1 \geq 3\} + \frac{K_1(3K_1 - 1)}{2}1\{K_1 \geq 2\} + \frac{(K_2 - 2K_1)(K_2 + 2K_1 - 1)}{2}
\]

\[
\leq \frac{K_2(K_2 - 1)}{2} - 1.
\]

\[\square\]
Following Lemma 2, we get

\[
\frac{\gamma L^2}{2} \sum_{\eta=0}^{\beta-1} \sum_{t=0}^{K_1-1} \mathbb{E} \| \mathbf{w}_{n+\eta K_1+t} - \mathbf{w}_n \|^2_2 \\
< \frac{L^2 \gamma^2 M K_2}{24B} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) \\
+ \frac{L^2 \gamma^2 M K_2}{2} \mathbb{E} \left\| \nabla F(\mathbf{w}_n) \right\|^2_2 \\
+ \frac{L^2 \gamma^3 M K_2}{2} \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_{\nabla F,w} \right) \sum_{k=1}^{K_2-1} \mathbb{E} \left\| \nabla F(\mathbf{w}_{n+k}) \right\|^2_2. 
\]  
(6.38)

Plug (6.38) into (6.24), we have

\[
\begin{align*}
-\gamma \left( \mathbb{E} \sum_{k=0}^{\beta-1} \sum_{t=0}^{K_1-1} \nabla F(\mathbf{w}_{n+k K_1+t}) \right) \\
\leq -\frac{\gamma (K_2 + 1)}{2} \left[ 1 - \frac{L^2 \gamma^2 K_2(K_2 - 1)}{2(K_2 + 1)} \right] \mathbb{E} \left\| \nabla F(\mathbf{w}_n) \right\|^2_2 \\
- \frac{\gamma}{2} \left( 1 - L^2 \gamma^2 \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_{\nabla F,w} \right) \right) \sum_{k=1}^{K_2-1} \mathbb{E} \left\| \nabla F(\mathbf{w}_{n+k}) \right\|^2_2 \\
+ \frac{L^2 \gamma^3 M K_2}{24B} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right)
\end{align*}
\]  
(6.39)

Plug (6.23) and (6.39) back into \( \mathbb{E} \left[ F(\mathbf{w}_{n+1}) - F(\mathbf{w}_n) \right] \), we get

\[
\mathbb{E} \left[ F(\mathbf{w}_{n+1}) - F(\mathbf{w}_n) \right] \\
\leq -\frac{\gamma (K_2 + 1)}{2} \left[ 1 - \frac{L^2 \gamma^2 K_2(K_2 - 1)}{2(K_2 + 1)} - \frac{L \gamma K_2}{K_2 + 1} \right] \mathbb{E} \left\| \nabla F(\mathbf{w}_n) \right\|^2_2 \\
- \frac{\gamma}{2} \left( 1 - L^2 \gamma^2 \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_{\nabla F,w} - L \gamma K_2 \right) \right) \sum_{k=1}^{K_2-1} \mathbb{E} \left\| \nabla F(\mathbf{w}_{n+k}) \right\|^2_2 \\
+ \frac{L^2 \gamma^3 M K_2}{24B} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) + \frac{L \gamma^2 K_2^2 M}{2PB}
\]  
(6.40)

Under the condition,

\[
1 - L^2 \gamma^2 \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_{\nabla F,w} \right) - L \gamma K_2 \geq 0,
\]

30
we have
\[
\frac{\gamma(K_2 + 1)}{2} \left[ 1 - \frac{L^2 \gamma^2(K_2 - 1)K_2}{2(K_2 + 1)} - \frac{L \gamma K_2}{K_2 + 1} \right] \geq \frac{\gamma}{2} \left( K_2 - L^2 \gamma^2(1 + \delta_{\nabla F,w}) \right).
\]

We can therefore drop the second term on the right hand side in (6.40) and take the summation over \( n \) to get
\[
\mathbb{E} \left[ F(\tilde{\mathbf{w}}_N) - F(\tilde{\mathbf{w}}_1) \right] \\
\leq -\frac{\gamma}{2} \left( K_2 - L^2 \gamma^2(1 + \delta_{\nabla F,w}) \right) \sum_{n=1}^{N} \mathbb{E} \| \nabla F(\tilde{\mathbf{w}}_n) \|^2_2
\]
\[
+ \frac{L^2 \gamma^3 M K_2}{2AB} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) + \frac{L \gamma^2 K_2^2 M}{2PB}
\]

Under Assumption 2, we have
\[
F^* - F(\tilde{\mathbf{w}}_1) \leq F(\tilde{\mathbf{w}}_N) - F(\tilde{\mathbf{w}}_1).
\]

As a result,
\[
\frac{\gamma}{2} \left( K_2 - L^2 \gamma^2(1 + \delta_{\nabla F,w}) \right) \sum_{n=1}^{N} \mathbb{E} \| \nabla F(\tilde{\mathbf{w}}_n) \|^2_2 \\
\leq \mathbb{E} \left[ F(\tilde{\mathbf{w}}_1) - F^* \right] + \frac{L^2 \gamma^3 M K_2}{2AB} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) + \frac{L \gamma^2 K_2^2 M}{2PB}
\]

Thus we have
\[
\frac{1}{N} \sum_{n=1}^{N} \mathbb{E} \| \nabla F(\tilde{\mathbf{w}}_n) \|^2_2 \leq \frac{2\mathbb{E} [F(\tilde{\mathbf{w}}_1) - F^*]}{N[K_2 - L^2 \gamma^2(1 + \delta_{\nabla F,w})] \gamma} + \frac{L \gamma M K_2^2}{PB[K_2 - L^2 \gamma^2(1 + \delta_{\nabla F,w})]} \\
+ \frac{L^2 \gamma^2 M K_2}{12B[K_2 - L^2 \gamma^2(1 + \delta_{\nabla F,w})]} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right).
\]
6.3 Proof of Theorem 3.3

Proof. The proof of Theorem 3.3 is similar to that of Theorem 3.2. Indeed, under the condition (3.5),

\[1 - L^2 \gamma_j^2 \left( \frac{K_2(K_2 - 1)}{2} - 1 - \delta_{F,w} \right) - L \gamma_j K_2 \geq 0,\]

we have

\[
\frac{\gamma_j(K_2 + 1)}{2} \left[ 1 - \frac{L^2 \gamma_j^2 K_2(K_2 - 1)}{2(K_2 + 1)} - \frac{L \gamma_j K_2}{K_2 + 1} \right] \geq \frac{\gamma_j}{2} \left( K_2 - L^2 \gamma_j^2 (1 + \delta_{F,w}) \right). \tag{6.43}
\]

Meanwhile, from (6.3), we have

\[L^2 \gamma_j^2(1 + \delta_{F,w}) \leq L^2 \gamma_j^2 K_2^2/2 \leq 1,\]

thus \(K_2 - L^2 \gamma_j^2(1 + \delta_{F,w}) \geq K_2 - 1\). By replacing \(\gamma\) with \(\gamma_j\) in (6.40) together with (6.43), we have

\[
\gamma_j(K_2 + 1) E \left\| \nabla F(\tilde{w}_j) \right\|_2^2 \leq \frac{2}{(K_2 - 1) \sum_{j=1}^N \gamma_j} \left[ F(\tilde{w}_{j+1}) - F(\tilde{w}_j) \right] + \frac{L \gamma_M K_2^2}{2PB} + \frac{L^2 \gamma_j^3 MK_2^2}{24B} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right). \tag{6.44}
\]

Taking the summation over \(j\), and divide both sides by \(\sum_{j=1}^N \gamma_j\), we got

\[
\sum_{j=1}^N \frac{\gamma_j}{\sum_{j=1}^N \gamma_j} E \left\| \nabla F(\tilde{w}_j) \right\|_2^2 \leq \frac{2}{(K_2 - 1) \sum_{j=1}^N \gamma_j} \left[ F(\tilde{w}_{1}) - F^* \right] + \frac{LMK_2^2 \gamma_j^2}{PB(K_2 - 1) \sum_{j=1}^N \gamma_j} + \frac{L^2 \gamma_j^3 MK_2^2}{12B(K_2 - 1) \sum_{j=1}^N \gamma_j} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right).
\]

\[\square\]

6.4 Proof of Theorem 3.4

Proof. Under the assumption \(T = N \times K_2\), we can rewrite the bound (3.6) as

\[
\frac{1}{N} \sum_{n=1}^N \frac{1}{\gamma_n} E \left\| \nabla F(\tilde{w}_n) \right\|_2^2 \leq \frac{2}{T(K_2 - \delta) \gamma} \left[ F(\tilde{w}_{1}) - F^* \right] K_2 + \frac{L \gamma_M K_2^2}{PB(K_2 - \delta)}
\]

\[
+ \frac{L^2 \gamma_j^2 MK_2^2}{12B(K_2 - \delta)} \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right)
\]

32
To move on, we set

\[ B(K_2) := f(K_2) \ast g(K_2) \]

where

\[ f(K_2) := \left( \alpha + \beta K_2 + \eta \left( \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2) \right) \right) \]

and

\[ g(K_2) := \left( \frac{K_2}{K_2 - \delta} \right), \quad \alpha = \frac{2(EF(\tilde{w}_1) - F^*)}{T\gamma}, \quad \beta = \frac{L\gamma M}{PB}, \quad \eta = \frac{L^2\gamma^2 M}{12B}. \]

To minimize the right hand side of (3.6), it is equivalent to solve the following integer program

\[ K_2^* = \min_{K_2 \in \mathbb{N}^+} B(K_2), \]

which can be very hard. Meanwhile, one should notice that \( K_2^* \) depends on some unknown quantities such as \( L, M \) and \( (F(\tilde{w}_1) - F^*) \). Instead, we investigate the monotonicity of \( B(K_2) \). Firstly, we show that \( f(K_2) \) is non-decreasing.

**Lemma 3.** Given \( K_2 \geq K_1 \geq 1 \), \( f(K_2) \) is non-decreasing.

**Proof.** The key is to show that \((K_2 - K_1)(4K_2 + K_1 - 3)/S\) is non-decreasing with respect to \( K_2 \). It is easy to see that the quadratic function \((K_2 - K_1)(4K_2 + K_1 - 3)/S\) is non-decreasing with respect to \( K_2 \) when \( K_2 \geq 3(K_1 + 1)/8 \), which is always true given \( K_2 \geq K_1 \geq 1 \). Thus, \((K_2 - K_1)(4K_2 + K_1 - 3)/S\) is monotone increasing, so is \( f(K_2) \). \( \square \)

On the other hand, \( g(K_2) \) is monotone decreasing for \( K_2 \geq 1 \). Therefore, \( B(K_2) \) is a multiplication of an increasing function and a decreasing one. Thus, a sufficient condition for \( K_2^* > 1 \) is that \( B(2) < B(1) \), which is equivalent to

\[ \frac{\delta \alpha}{1 - \delta} > 2\beta + \frac{12\eta}{S}. \]
6.5 Proof of Theorem 3.5

Proof. The proof of part 2 is obvious, so we omit it here. For part 1, With $K_2$ fixed, it is sufficient to consider the monotonicity of $(K_2 - K_1)(4K_2 + K_1 - 3)/S + (K_1 - 1)(3K_2 + K_1 - 2)$ for both bounds in (3.6) and (3.8). Set

$$f(K_1) = \frac{(K_2 - K_1)(4K_2 + K_1 - 3)}{S} + (K_1 - 1)(3K_2 + K_1 - 2). \tag{6.45}$$

Then

$$f'(K_1) = \frac{(S - 1)(3K_2 + 2K_1 - 3)}{S}.$$ 

Apparently, $f(K_1)$ is monotone increasing with respect to $K_1$ when $K_1 \geq 2$ given $S > 1$ and $K_2 \geq K_1$. \qed

6.6 Proof of Theorem 3.6

Proof. When $P$ is large enough such that $L\gamma P \gg 1$, the second term in bound (3.6) is dominated by the third term. We omit the second term in (3.6) and denote it by $\mathcal{H}(K)$ and get

$$\mathcal{H}(K) := f_1(K) * g_1(K)$$

where

$$f_1(K) := \left(\alpha + \eta\left(\frac{(1 + a)K - 1}{4}\right)\right)$$

and

$$g_1(K) := \left(\frac{(1 + a)K}{(1 + a)K - \delta}\right), \quad \alpha = \frac{2[E F(\tilde{w}_1) - F^*]}{T\gamma}, \quad \eta = \frac{L^2\gamma^2M}{6B}.$$
On the other hand, we denote the similar bound of $K$-AVG as $\chi(K)$ by plugging in $K_2 = K$, $K_1 = 1$, $S = 1$ in (3.2) (also see Zhou and Cong [2018]), which is

$$\chi(K) := f_2(K) * g_2(K),$$

(6.46)

where

$$f_2(K) := \alpha + \eta(K - 1)(2K - 1), \quad g_2(K) := \left(\frac{K}{K - \delta}\right).$$

In the following, we show that $H(K) < \chi(K)$ uniformly for all $K \geq 2$ and $a \in [0, 0.443]$. It is easy to see that $0 < g_1(K) < g_2(K)$ for all $K \geq 2$. Next, we show that $f_1(K) < f_2(K)$ for all $K \geq 2$ and $a \in [0, 0.443]$. Set

$$F(K) := f_1(K) - f_2(K).$$

(6.47)

Then $F(K)$ is a quadratic function of $K$,

$$F'(K) = ((1 + a)^2 - 4)K + 3 - \frac{3(1 + a)}{4},$$

(6.48)

Then it is easy to see that for all $a \in [0, 0.779]$ and $F'(K) \leq 0$ for all $K \geq 2$. Meanwhile,

$$F(2) = 2(1 + a)^2 - \frac{3}{2}(1 + a) - \frac{11}{4},$$

(6.49)

and it is easy to check that $F(2) < 0$ for all $a \in [0, 0.606]$. As a result, $F(K) < 0$ for all $K \geq 2$ and $a \in [0, 0.606]$. This implies that $H(K) < \chi(K)$ for all $K \geq 2$ and all $a \in [0, 0.606]$.
