The Log-Concave Maximum Likelihood Estimator is Optimal in High Dimensions

Yuval Dagan∗  Gil Kur†

Abstract

We study the problem of learning a \(d\)-dimensional log-concave distribution from \(n\) i.i.d. samples with respect to both the squared Hellinger and the total variation distances. We show that for all \(d \geq 4\) the maximum likelihood estimator achieves an optimal risk (up to a logarithmic factor) of \(O(d(n^{-2/(d+1)} \log(n)))\) in terms of squared Hellinger distance. Previously, the optimality of the MLE was known only for \(d \leq 3\). Additionally, we show that the metric plays a key role, by proving that the minimax risk is at least \(\Omega(d(n^{-2/(d+4)}))\) in terms of the total variation. Finally, we significantly improve the dimensional constant in the best known lower bound on the risk with respect to the squared Hellinger distance, improving the bound from \(2^{-d} n^{-2/(d+1)}\) to \(\Omega(n^{-2/(d+1)})\). This implies that estimating a log-concave density up to a fixed accuracy requires a number of samples which is exponential in the dimension.

1 Introduction

Density estimation of a probability distribution is one of the classical and fundamental problems in statistics [Scott, 2015, Silverman, 2018]. This task has been well studied over the non-parametric family of log-concave distributions (see, for example, the recent survey of Samworth [2018]). This rich family has a key role in statistics [Bagnoli and Bergstrom, 2005], pure mathematics [Brazitikos et al., 2014, Stanley, 1984], computer science [Balcan and Long, 2013, Lovász and Vempala, 2007] and economics [An, 1997]. It includes the Gaussian, exponential, uniform over convex bodies, logistic, Gamma, Laplace, Weibull, Chi and Chi-Squared, Beta distributions and more.

Traditionally, the study was focused on low dimensions [Kim et al., 2018, Dümbgen and Rufibach, 2011, Balabdaoui et al., 2009, Doss and Wellner, 2016, Diakonikolas et al., 2016]. In recent years, statisticians and computer scientists have been studying density estimation of \(d\)-dimensional log-concave distributions [Diakonikolas et al., 2017, Dümbgen et al., 2011, Kim and Samworth, 2016, Cule et al., 2010, Cule and Samworth, 2010, Carpenter et al., 2018, Dümbgen and Rufibach, 2009, Diakonikolas et al., 2018b]. More generally, there is an on going research over a variety of non-parametric families in high dimensions [De et al., 2018, Diakonikolas et al., 2017, 2018b, Acharya et al., 2017, Carpenter et al., 2018, Diakonikolas et al., 2018b, Dümbgen et al., 2011, Schuhmacher and Dümbgen, 2010, Balcan and Long, 2013, Chan et al., 2014].

In statistics, the accuracy of estimators is commonly measured with respect to the Hellinger and total variation distances. This work regards the risk of learning \(d\)-dimensional log-concave densities in both metrics. The first to study this task are [Kim and Samworth, 2010]. One of their main results is a lower bound on the risk of any log-concave density estimator, with respect to the squared Hellinger distance, denoted by \(h^2(\cdot, \cdot)\):

\[
\inf_{\hat{f} \in \hat{F}_d} \mathcal{R}_{h^2}(\hat{f}) \geq \begin{cases} 
  cn^{-\frac{1}{2}} & \text{if } d = 1 \\
  e^{-cd} n^{-\frac{1}{2(d+1)}} & \text{if } d \geq 2 
\end{cases}
\]

where \(\hat{F}_d\) is the set of log-concave estimators, \(F_d\) is the set of log-concave distributions over \(\mathbb{R}^d\) and \(\mathcal{R}_{h^2}(f) = \sup_{\hat{f} \in \hat{F}_d} \mathbb{E}[h^2(f, \hat{f})]\). In order to upper bound the risk, it is natural to consider the
the maximum likelihood estimator (MLE). The log-concave MLE, denoted by \( \hat{f} \), is widely investigated \cite{Cule2010, Cule2011, Dumbgen2011, Dumbgen2009, Schuhmacher2010, Chen2013, Carpenter2018, Robeva2017, Wellner2016, Balabdaoui2009, Feng2018, Kim2018}. Its sample complexity for low-dimensional multivariate distributions was first studied by \cite{Kim2016}. They showed the following upper bound:

\[
R_{h^2}(\hat{f}) \leq \begin{cases} 
Cn^{-\frac{4}{d+1}} \log(n) & d = 1 \\
Cn^{-\frac{2}{d+1}} \log(n) & d = 2, 3
\end{cases}
\]  

(2)

By Eq. (1), this risk is optimal up to a logarithmic factor. In higher dimensions, a recent paper of Carpenter et al. \cite{Carpenter2018} showed that

\[
R_{h^2}(\hat{f}) \leq O_d\left(n^{-\frac{2}{d+1}} \log^3(n)\right) \text{ for } d \geq 4.
\]  

(3)

This estimate is sub optimal, and it strengthened the conjecture of Samworth \cite{Samworth2018} that the MLE has suboptimal-risk when \( d \geq 4 \). Our result shows that their conjecture is false: the MLE achieves an optimal risk (up to a logarithmic factor) when \( d \geq 4 \). Specifically, we prove the following:

**Theorem 1.** Assume that \( d \geq 4 \). Then the maximum log–likelihood estimator, \( \hat{f} \), achieves a risk of

\[
R_{h^2}(\hat{f}) \leq C(d)n^{-\frac{2}{d+1}} \log(n).
\]

Based on our analysis, we strongly believe that the logarithmic factor is redundant.

In the rest of the paper, we provide lower bounds on the minimax risk with respect to both the total variation and the squared Hellinger metrics. Their difference is significant in some cases, while the following is guaranteed: \( h^2 \leq \text{dTV} \leq \sqrt{2h^2} \). Hence, it is natural to ask whether in this task, the minimax risk is different with respect to the total variation distance.

In terms of the total variation, the minimax risk is only known for univariate log concave distributions \cite{Chan2013, Devroye2012, Diakonikolas2016} and equals \( \Theta(n^{-2/5}) \). However, in Hellinger squared the risk is different and equals \( \Theta(n^{-4/5}) \). In high dimensions, a difference between the minimax risks was not known, and the best lower bound in both metrics was \( \Omega(d(n^{-2/(d+1)}) \), as already presented in Eq. (1). In this paper, we derive a stronger lower bound on the risk of any estimator in terms of the total variation distance. Specifically, we prove the following:

**Theorem 2.** There exists a universal constant \( c > 0 \), such that for all \( d \geq 1 \):

\[
\inf_{\bar{f} \in \bar{F}_d} \mathcal{R}_{\text{TV}}(\bar{f}) \geq e^{-cd} n^{-\frac{2}{d+1}}.
\]  

(4)

This bound is almost tight: \cite{Diakonikolas2017} showed that the risk is upper bounded by \( O_d(n^{-2/(d+4)} \log(n))^{4/(d+4)} \). In the aforementioned paper, the authors conjecture that the risk is \( O_d(n^{-2/(d+4)}) \). Based on our results, we strongly support their conjecture. Therefore, we conclude that the metric has a key role in log-concave density estimation.

In our last result, we significantly improve the dimensional constant in the lower bound in terms of the squared Hellinger distance (see Eq. (1)). We remove the negative exponent \( e^{-cd} \) appearing in Eq. (1) and replace it with an absolute constant.

**Theorem 3.** There exists a universal constant \( c > 0 \), such that for all \( d \geq 2 \):

\[
\inf_{\bar{f} \in \bar{F}_d} \mathcal{R}_{h^2}(\bar{f}) \geq cn^{-\frac{2}{d+1}}.
\]  

(5)

This Theorem implies that estimating a \( d \)-dimensional log-concave density up to a fixed accuracy requires exponentially in the dimension many samples. Moreover, our proof shows that this bound even holds for a subset of this family: uniform distributions over the convex bodies.
Comparison to learning convex bodies. The problem of estimating a convex body from the convex hull of random samples is extensively studied in the high dimensional geometry literature (see, for example, the books by Schneider and Weil [2008] and Chiu et al. [2013]). It is well-known that if the points are drawn uniformly, then with high probability the convex hull is $cdn^{-2/(d+1)}$-close to the original set in symmetric volume difference. The latter implies that the risk of learning uniform distributions over convex bodies is $O(d)n^{-2/(d+1)}$, with respect to both the Hellinger squared and the total variation. Observe that the aforementioned family is a small subset of the multivariate log-concave distributions. Remarkably, our first result implies that the log-concave MLE achieves the same risk with respect to the squared Hellinger distance (up to a logarithmic factor). In contrast, our second result shows that with respect to the total variation distance, learning a log-concave density is harder than a convex set.

Finally, we note that there are other works in statistics on learning convex sets in various settings. For example, see the works of Guntuboyina [2012] and Rademacher and Goyal [2009].

Notations

Constants

The notation $c, C, c', c_1$ etc. denotes absolute constants which do not depend on the problem parameters. $c(d), C(d), c_d, \ldots$ are constants that depends only on the dimension of samples. Uppercase $C$ is used for constants greater than 1 and lowercase $c$ for constants less than 1.

Geometry notations

The notations are listed below:

- The volume (or a surface area) of a set is denoted by $\text{vol}(\cdot)$.
- The centered $d$-dimensional Euclidean ball with radius 1 is denoted by $B_d$ and $\partial B_d$ denotes its surface area. The Euclidean ball with center $x$ and radius $r$ is denoted by $B_d(x, r)$, and $B_d(r)$ denotes a centered ball with radius $r$.
- The squared Hellinger distance is denoted by $h^2$, and the total variation distance is denoted by $d_{TV}$.

Probability and Statistics notations

Notations are listed below:

- Let $\mathcal{F}_d$ and $\mathcal{C}_d$ denote the family of log-concave distributions and uniform distributions over convex bodies in $\mathbb{R}^d$, respectively.
- Denote by $n$ the number of sampled points and the dimension by $d$.
- denote by $\hat{f}_d$ the family of log-concave density estimators. Additionally, $\hat{f}$ denotes to be maximum likelihood estimator (MLE).
- The risk of an estimator with respect to some family of distributions is denoted by $\mathcal{R}(\cdot)$.

2 Main Results

We present a summary of our main results, as presented in Section 1. Our main theorem shows that the risk of the log-concave maximum likelihood estimator, in the terms squared Hellinger distance, achieve the minimax risk (up to a factor of $O_d(\log(n))$) when the dimension is $d \geq 4$.

Theorem 1. Assume that $d \geq 4$. Then the maximum log-likelihood estimator, $\hat{f}$, achieves a risk of

$$\mathcal{R}_{h^2}(\hat{f}) \leq C(d)n^{-\frac{1}{d+1}} \log(n).$$

For $d \leq 3$, Kim and Samworth [2016] showed that the MLE achieves the minimax up to a logarithmic factor, hence it is optimal in all dimensions.

Our next result gives a lower bound on the minimax risk in terms of the total variation distance.
The Hausdorff distance between two convex bodies $K_1, K_2$ in $\mathbb{R}^d$ is defined as
\[
d_H(K_1, K_2) = \max_{p_1 \in K_1} d(K_2, p_1), \max_{p_2 \in K_2} d(K_1, p_2).
\]

A convex body is a closed convex set $K \subseteq \mathbb{R}^d$ with non-empty interior. The collection of all convex bodies contained in $\mathbb{R}^d$ is denoted by $\mathcal{K}_d$, and $\mathcal{K}_d^{(1)}$ denotes the collection of bodies contained in $B_d$.

Given a convex body $K$ and $r > 0$, denote $K_r = \{x \in \mathbb{R}^d : d(K, x) \leq r\}$, namely, the inflation of $K$ by a radius of $r$. Denote $K_{-r} = \{x \in K: d(x, \partial K) \geq r\}$. The following is a known statement:

Claim 1. If $K, K'$ are convex bodies with $d_H(K, K') \leq r$, then the following holds:
- $K_{-r} \subseteq K'_{-r}$.
- If $K \subseteq B_d$, then $\text{vol}(K_r \setminus K) \leq \text{vol}((1 + r)B_d) - \text{vol}(B_d) = \text{vol}(B_d)((1 + r)^d - 1)$.
- If $K \subseteq B_d$, then $\text{vol}(K \setminus K_{-r}) \leq r\text{vol}(\partial K) = rd\text{vol}(B_d)$.

3 Preliminaries

3.1 Covering numbers with bracketing

Let $(\mathcal{X}, d)$ be a metric space, fix $\delta > 0$ and let $S \subseteq \mathcal{X}$ be a finite subset. We provide three definitions:
- We say that $S$ is a $\delta$-net if for any $x \in \mathcal{X}$ there exists $y \in S$ such that $d(x, y) \leq \delta$. Define the $\delta$-covering number, $N_{\delta,d}(\mathcal{X})$, as the smallest cardinality of a $\delta$-net.
- Given a partial ordering $\preceq$ over $\mathcal{X}$, we say that $S$ is a $\delta$-net with bracketing if for any $x \in \mathcal{X}$ three exist $\overline{x}, \underline{x} \in S$ such that $d(\overline{x}, \underline{x}) \leq \delta$ and $\underline{x} \preceq x \preceq \overline{x}$. Define the $\delta$-covering number with bracketing, $N_{\overline{\delta},\underline{\delta},d}(\mathcal{X})$, as the smallest cardinality of a $\delta$-net with bracketing.
- We say that $S$ is a $\delta$-packing if for any $x, x' \in S$, $d(x, x') > \delta$. Define the packing number, $M_{\delta,d}(\mathcal{X})$, as the smallest cardinality of a $\delta$-packing.

The following relations hold: $N_{\delta,d}(\mathcal{X}) \leq N_{\overline{\delta},\underline{\delta},d}(\mathcal{X})$ and $M_{2\delta,d}(\mathcal{X}) \leq N_{\delta,d}(\mathcal{X}) \leq M_{\delta,d}(\mathcal{X})$. When $\mathcal{X}$ is a family of sets, we define the bracketing numbers with respect to the order of containment, namely, for any $S, S' \subseteq S$, $S \preceq S'$ if $S \subseteq S'$.

3.2 Geometry

Let $B_d$ denote the centered unit ball in $\mathbb{R}^d$ of radius 1. For a point $p \in \mathbb{R}^d$ and a measurable set $K \subseteq \mathbb{R}^d$, define $d(K, p) = \inf_{u \in K} \|p - u\|_2$.

Definition 1. The Hausdorff distance between two convex bodies $K_1$ and $K_2$ in $\mathbb{R}^d$ is defined as
\[
d_H(K_1, K_2) = \max_{p_1 \in K_1} d(K_2, p_1), \max_{p_2 \in K_2} d(K_1, p_2).
\]

Finally, we drastically improve the dimensional constant of the best known lower bound on the minimax risk in terms of the squared Hellinger distance presented in Eq. (1) [Kim and Samworth, 2010].

Theorem 3. There exists a universal constant $c > 0$ such that for all $d \geq 2$:
\[
\inf_{f \in \mathcal{F}_d} \mathcal{R}_{h^2}(\hat{f}) \geq c n^{-\frac{1}{2d}},
\]

This Theorem shows that in order to approximate a log-concave distribution up to a fixed accuracy, the number required samples is exponential in the dimension. Moreover, our proof shows that this bound even holds for a subset of this family: the uniform distributions over convex bodies.
Lemma 3.1. The following holds:
\[
\text{vol}(B_d) = \frac{\pi \frac{d}{2}}{\Gamma\left(\frac{d}{2} + 1\right)} = (1 + O(d^{-1}))(\pi d)^{-0.5} \left(\frac{2\pi e}{d}\right)^{\frac{d}{2}}.
\]

Therefore, the radius of a ball with volume one is \( (1 + O\left(\frac{\ln(d)}{d}\right))\sqrt{\frac{d}{2\pi e}} \). Additionally, the following identities hold:
1. For all \( r \in (1, \infty) \), \( \text{vol}(B_d(\sqrt{rd})) \leq c_1 \cdot r^d \text{vol}(B_d) \).
2. \( c\sqrt{d} \leq \frac{\text{vol}(B_d)}{\text{vol}(B_{d-1})} \leq C\sqrt{d} \).
3. \( \text{vol}(\partial B_d) = d\text{vol}(B_d) \).

The following presents bounds on the packing numbers of the unit sphere \( M_{\epsilon,l_2}(B_d) \). It appears in the book by Artstein-Avidan et al. [2015].

Lemma 3.2. Let \( \epsilon < c \), for some universal constant \( c \), and let \( l_2 \) be the Euclidean distance. Then,
\[
c_2^{d-1}\delta^{-d} \leq M_{\epsilon,l_2}(B_d) \leq c_1^{d-1}\delta^{-d}
\]

The following is a bound by Bronshtein [1976] on the covering numbers of \( K^{(1)}_d \) under the Hausdorff metric.

Lemma 3.3 (Bronshtein [1976], Theorem 2.). There exists a dimensional constant \( c(d) \) such that for any \( 0 < \epsilon < 1 \),
\[
\log N_{\epsilon,d_H}\left(K^{(1)}_d\right) \leq C(d)\left(\frac{1}{\epsilon}\right)^{(d-1)/2}.
\]

3.3 Isotropic log-concave densities

There are many fascinating developments on isotropic log-concave distributions. An excellent source is the book by Brazitikos et al. [2014].

Definition 2 (log concave random vector). A \( d \)-dimensional density function \( f \) is log-concave if the following holds for all \( x, y \in \mathbb{R}^d \) and \( \lambda \in (0, 1) \):
\[
f(\lambda x + (1 - \lambda)y) \geq f(x)^\lambda f(y)^{1-\lambda}.
\]

Equivalently, \( f(x) = e^{-U(x)} \) where \( U : \mathbb{R}^p \to \mathbb{R} \cup \{\infty\} \) is convex. We say that \( f \) is an isotropic log-concave density if it has a zero mean and identity covariance.

The following is a simple and basic property:

Claim 2. Let \( X \) be random vectors over \( \mathbb{R}^d \) with log–concave density. Then, \( AX + b \) has a log–concave density, and for any \( d \times d \) real matrix \( A \) and \( b \in \mathbb{R}^d \).

Finally:

Lemma 3.4 (Kim and Samworth [2016]). Let \( f \) be an isotropic log-concave density on \( \mathbb{R}^d \). Then \( f \) can be bounded by
\[
f(x) \leq e^{-c_A(d)\|x\|_2 + C_B(d)},
\]
for positive dimensional constants \( c_A(d) \) and \( C_B(d) \).

3.4 Other inequalities

The following is a variant of Assoud’s Cube Lemma [Van der Vaart, 2000, Tsybakov, 2003].

Lemma 3.5 (Assoud’s lemma). Let \( \mathcal{F} \) denote a family of functions. Fix \( K \in \mathbb{N} \), and suppose that the family \( \{f_\alpha \in \mathcal{F} : \alpha \in \{0, 1\}^K\} \) has the following two properties:
1. \( h^2(f_\alpha, f_\beta) \geq \gamma \|\alpha - \beta\|_0 \) for all \( \alpha, \beta \in \{0, 1\}^K \), where \( \|\alpha - \beta\|_0 \) denotes the Hamming distance between \( \alpha \) and \( \beta \).
2. There exists \( c \in (0, 1) \) such that for every \( \alpha, \beta \in \{0, 1\}^K \) satisfying \( \|\alpha - \beta\|_0 = 1 \), we have

\[
h^2(f_\alpha, f_\beta) \leq \frac{c}{n}.
\]

Then

\[
\inf_{f \in F} \mathcal{R}_K(f) \geq \frac{K}{8} \cdot (1 - \sqrt{c}) \cdot \gamma.
\]

Next, we present McDiarmid’s inequality:

**Lemma 3.6** (McDiarmid’s inequality). Let \( X_1, \ldots, X_n \) be i.i.d random variables drawn from some distribution \( P \) over a domain \( \Omega \), let \( \varphi : \Omega^n \rightarrow \mathbb{R} \) be a function and let \( \lambda_1, \ldots, \lambda_n \in \mathbb{R}_+ \). Assume that for any \( x = (x_1, \ldots, x_n) \) and \( x' = (x'_1, \ldots, x'_n) \in \Omega^n \),

\[
|\varphi(x) - \varphi(x')| \leq \sum_{i=1}^n \mathbb{I}_{x_i \neq x'_i}.
\]

Then, for any \( t > 0 \),

\[
\Pr_{X \sim P^n} [|\varphi(X) - E\varphi(X)| \geq t] \leq 2 \exp \left( -\frac{2t^2}{\sum_{i=1}^n \lambda_i^2} \right).
\]

## 4 Proof of Theorem 1

The heart of the proof is to show that with high probability, for any convex set \( K \), the difference between the empirical (i.e. the number of samples inside \( K \)) and the expected measure is at most \( O_d(n^{-\frac{d}{2d+3}}) \).

Formally, let \( X_1, \ldots, X_n \) denote \( n \) samples drawn i.i.d. from some distribution. Given a measurable set \( S \subseteq \mathbb{R}^d \), let \( Z_S(X) := \sum_{i=1}^n \mathbb{I}_{X_i \in S} \) (we will sometimes write \( Z_S \) instead).

**Theorem 4.** Let \( X_1, \ldots, X_n \sim P \), where \( P \) has log-concave density. Then, for any \( t > 0 \),

\[
\Pr \left[ \sup_{K \in K_d} |Z_K(X) - E\varphi(X)|/n > C(d)n^{-\frac{d}{2d+3}} + \frac{t}{\sqrt{n}} \right] \leq 2e^{-2t^2}.
\]

Throughout the proof, we will use the following definition: given a measure \( \mu \) over \( \mathbb{R}^d \), the distance \( d_\mu \) between two measurable sets \( S, S' \) is defined as the measure of their symmetric difference, \( d_\mu(S, S') = \mu(S \triangle S') + \mu(S' \triangle S) \). In Section 4.1, we present a general chaining bound. Then, in Section 4.2 we bound the covering numbers of \( K_d \) with respect to \( d_\mu \) for a log-concave distribution \( P \), and apply the chaining lemma, to prove Theorem 1. Finally, in Section 4.3 we show how to derive Theorem 1 from Theorem 4.

### 4.1 Chaining on empirical processes

In this section, we present a uniform bound on empirical processes. In particular, we prove the following:

**Lemma 4.1.** Let \( P \) be a probability measure over \( \mathbb{R}^d \) and let \( X_1, \ldots, X_n \sim P \). Let \( \mathcal{A} \) be a family of measurable subsets of \( \mathbb{R}^d \), let \( r_o \) be the smallest integer \( i \) such that \( 2^{-i} < \text{vol}(\bigcup \mathcal{A}) \) and let \( r \geq r_o \) be an integer. Assume that \( \log N_{[2^{-r}, d_\mu]}(\mathcal{A}) \leq 2^{-r}n/3 \). Then,

\[
E \left[ \sup_{S \in \mathcal{A}} |Z_S(X) - E\varphi(X)|/n \right] \leq 2^{-r} + C \sum_{i=r_o}^r \sqrt{2^{-i} \log N_{[2^{-i}, d_\mu]}(\mathcal{A})/n}.
\]

**Remark 1.** This bound is proved by the chaining method, relying on deviation bounds on the differences \( Z_S - Z_{S'} = Z_{S \cap S'} - Z_{S' \cap S} \). We note that each such difference has a variance of \( np \), where \( p = \text{vol}(S \triangle S') \). If it was a sub-Gaussian random variable with constant \( np \), then one could use Dudley’s integral to obtain Lemma 4.1. However, its sub-Gaussian constant is \( n \), which is not sufficient to derive this bound. Instead we use the fact that it is sub-Exponential with the suitable constants. In this setting, if the covering numbers of \( d_\mu \) are not too large, then we can also derive a similar bound.

Let \( \text{Bin}(n, p) \) denote the binomial distribution with parameters \( n \) and \( p \). The following is a standard concentration inequality:

\[
\Pr\left[ |X - E(X)| \geq t \right] \leq 2 \exp\left( -\frac{t^2}{\text{Var}(X)} \right).
\]
Lemma 4.2. Let $Y \sim \text{Bin}(n, p)$. Then:
\[
\Pr \left[ Y/n \geq p(1 + \delta) \right] \leq \begin{cases} 
 e^{-\delta^2 np/3} & 0 \leq \delta \leq 1 \\
 e^{-\delta np/3} & \delta \geq 1 
\end{cases},
\]
and for all $0 \leq \delta \leq 1$,
\[
\Pr \left[ Y/n \leq p(1 - \delta) \right] \leq e^{-\delta^2 np/2}.
\]

We shall use the following simple corollary of Lemma 4.2.

Corollary 1. Let $Y \sim \text{Bin}(n, p)$. Then, for any $t \geq 0$ and $\alpha \leq \min(p, t)$,
\[
\Pr \left[ |Y/n - p| \geq t \right] \leq 2e^{-\alpha t n/(3p)}.
\]

It is well known that the expected maximum of $k$ $\sigma^2$-sub-Gaussian variables is $O(\sqrt{\log k} \sigma)$. The binomial distribution is sub-Gaussian with a non-optimal constant when $p$ is small, namely, it is too far from the variance. In order to prove the theorem, we want to prove a similar result for the binomial distribution, which is sub-exponential with $\sigma^2 = np$ (Lemma 4.2). If we restrict the maximum to be taken over $k \leq e^{np/3}$ variables, we derive the following:

Lemma 4.3. Fix $0 < p < 1$ and $n, k$ are positive integers. Assume that $Y_1, \ldots, Y_k$ are random variables such that $Y_i \sim \text{Bin}(n, p_i)$ for $p_i \leq p$. Then, if $k \geq 2$ and $\log k \leq np/3$, then
\[
E \left[ \sup_{1 \leq i \leq k} |Y_i/n - p_i| \right] \leq C \left( \frac{p \log k}{n} \right),
\]

Proof. For any $t' \geq 1$, we apply Corollary 1 with $t = t' \sqrt{3p_i \log k/n}$ and $\alpha = \sqrt{3p_i \log k/n}$,
\[
\Pr \left[ \sup_{1 \leq i \leq k} \left| Y_i/n - p_i \right| > t' \sqrt{3p_i \log k/n} \right] \leq \sum_{i=1}^k \Pr \left[ \left| Y_i/n - p_i \right| > t' \sqrt{3p_i \log k/n} \right]
\]

By change of variables, we conclude that
\[
E \left[ \sup_{1 \leq i \leq k} |Y_i/n - p_i| \right] \leq \int_{t=0}^\infty \Pr \left[ \sup_{1 \leq i \leq k} \left| Y_i/n - p_i \right| > t \right] dt
\]

Using Lemma 4.3, we prove Lemma 4.1.

Proof of Lemma 4.1. For any $i = r_0 - 1, r_0, r_0 + 1, \ldots, r_0 - 1$, let $N_i$ be a $2^{-i}$-net for $A$ with respect to $d_P$, such that $|N_i| = N_{2^{-i}, d_P}(A) \leq N_{\|2^{-i}, d_P}(A)$. We may assume that $N_{r_0-1} = \{\emptyset\}$. Let $N_r$ be a $2^{-r}$-net with bracketing with respect to $d_P$, of size $|N_r| = N_{\|2^{-r}, d_P}(A)$. For any $S \in A$ and $r_0 - 1 \leq i \leq r$, let $q_i(S) = \arg \min_{S' \in A_i} d(S, S')$. Set $Z'_S = Z_2 - EZ_S$ for all $S \in A$ and note that $Z'_{q_0-1(S)} = Z'_S = 0$, hence $Z'_2 = \sum_{i=r_0}^r (Z'_{q_i(S)} - Z'_{q_{i-1}(S)})$.

We start by bounding the maximal deviation with respect to $S \in N_r$, and then extend to $S \in A$:
\[
E \left[ \max_{S \in N_r} |Z'_S| \right] = E \left[ \max_{S \in N_r} \sum_{i=r_0}^r |Z'_{q_i(S)} - Z'_{q_{i-1}(S)}| \right]
\]

\[
\leq \sum_{i=r_0}^r E \left[ \max_{S \in N_r} |Z'_{q_i(S)} - Z'_{q_{i-1}(S)}| \right] + \sum_{i=r_0}^r E \left[ \max_{S \in N_r} |Z'_{q_i(S)} - Z'_{q_{i-1}(S)}| \right].
\]
We now upper bound the first term in the right hand side of Eq. (8). The second term can be bounded in the same way. For any \( i = r_0, \ldots, r \) and \( S \in \mathcal{A} \), define
\[
p_{i,s} := P(q_i(S) \setminus q_{i-1}(S)) \leq d_P(d_i(S), q_{i-1}(S)) \leq d_P(q_i(S), S) + d_P(S, q_{i-1}(S)) \leq 2^{-i} + 2^{-i+1} = 3 \cdot 2^{-i}.
\]
Observe that \( Z_{q_i(S) \setminus q_{i-1}(S)} \sim \text{Bin}(n, p_{i,s}) \), and that for any fixed \( i \), the maximum is over at most \( N_{i,2^{-i},d_P}(A)N_{i,2^{-i+1},d_P}(A) \) elements. We apply Lemma 4.3 with \( p = 3 \cdot 2^{-i} \) and \( k \leq N_{i,2^{-i},d_P}(A)N_{i,2^{-i+1},d_P}(A) \). Note that Lemma 4.3 requires that \( \log k \leq np/3 \). Indeed, recall that
\[
\log N_{i,2^{-i},d_P}(A) \leq \log N_{i,2^{-i},d_P}(A) \leq 2^{-r} n/3 \leq 2^{-i} n/3.
\]
Hence, the following holds
\[
\log k \leq \log N_{i,2^{-i},d_P}(A) + \log N_{i,2^{-i+1},d_P}(A) \leq 2 \cdot n 2^{-i}/3 \leq np/3.
\]
Applying Lemma 4.3 one obtains that for all \( i = r_0, \ldots, r \),
\[
E \left[ \max_{S \in \mathcal{N}_r} |Z'_{q_i(S) \setminus q_{i-1}(S)}| \right] \leq C \sqrt{2^{-i} N_{i,2^{-i},d_P}(A)}.
\]
Similarly, for the second term in Eq. (8) we obtain
\[
E \left[ \max_{S \in \mathcal{N}_r} |Z'_{q_{i-1}(S) \setminus q_i(S)}| \right] \leq C \sqrt{2^{-i} N_{i,2^{-i},d_P}(A)}.
\]
We sum over \( i = r_0, \ldots, r \) and conclude that
\[
E \left[ \max_{S \in \mathcal{N}_r} |Z_S| \right] \leq \sum_{i=r_0}^r 2C \sqrt{2^{-i} N_{i,2^{-i},d_P}(A)}.
\]
Finally, we extend from the maximum over \( \mathcal{N}_r \) to the supremum over all sets in \( \mathcal{A} \). The lemma will follow, if we show that
\[
E \left[ \max_{S \in \mathcal{A}} |Z_S|/n \right] \leq E \left[ \max_{S \in \mathcal{N}_r} |Z_S|/n \right] + 2^{-r}.
\]
Fix some \( S \in \mathcal{A} \) and let \( \overline{S}, \underline{S} \in \mathcal{N}_r \) be elements such that \( \underline{S} \subseteq S \subseteq \overline{S} \) and \( P(\overline{S} \setminus \underline{S}) \leq 2^{-r} \). Then, the following holds
\[
(Z_S - EZ_S)/n \leq (Z_{\overline{S}} - EZ_{\overline{S}})/n + (EZ_S - EZ_{\underline{S}})/n \leq E \left[ \max_{S \in \mathcal{N}_r} |Z_S|/n \right] + 2^{-r}.
\]
Similarly:
\[
(EZ_S - Z_S)/n \leq (EZ_{\overline{S}} - EZ_{\overline{S}})/n + (EZ_{\underline{S}} - Z_{\underline{S}})/n \leq E \left[ \max_{S \in \mathcal{N}_r} |Z_S|/n \right] + 2^{-r}.
\]
Thus, the Lemma follows. \( \square \)

Finally, we prove the following almost trivial lemma.

**Lemma 4.4.** Let \( \mathcal{A} \) be a family of measurable subsets of \( \mathbb{R}^d \), and let \( n \in \mathbb{N} \) be a positive integer. Then,
\[
E \left[ \sup_{S \in \mathcal{A}} |Z_S - EZ_S|/n \right] \leq 2P(\bigcup \mathcal{A}).
\]

**Proof.** The following holds:
\[
E \left[ \sup_{S \in \mathcal{A}} \frac{|Z_S - EZ_S|}{n} \right] \leq E \left[ \sup_{S \in \mathcal{A}} |Z_S|/n \right] + E \left[ \sup_{S \in \mathcal{A}} |EZ_S|/n \right] \leq 2E \left[ Z_{\cup \mathcal{A}}/n \right] = 2P(\bigcup \mathcal{A}).
\]
\( \square \)

\(^1\) Note that Lemma 4.3 requires that \( k \geq 2 \). However, since, \( N_{i,\epsilon,d_P}(A) \geq 2 \) for all \( \epsilon \), this lemma can be applied.
4.2 The covering numbers of collections of convex sets

We start with a simple observation:

**Lemma 4.5.** For any $K \in \mathcal{K}_d^{(1)}$, and $0 < r \leq 1/d$, it holds that $\text{vol}(K_r \setminus K_{-r}) \leq 3rd\text{vol}(B_d)$.

**Proof.** Using the inequality $e^x \leq 1 + 2x$ for $0 \leq x \leq 1$ and using Claim 1, the following holds:

$$\text{vol}(K_r \setminus K_{-r}) = \text{vol}(K_r \setminus K) + \text{vol}(K \setminus K_{-r}) \leq \left((1 + r)d - 1\right)\text{vol}(B_d) + rd\text{vol}(B_d) \leq \left(e^{rd} - 1 + rd\right)\text{vol}(B_d) \leq 3rd\text{vol}(B_d).$$

\[ \square \]

Let $U$ denote the uniform distribution over $B_d$, and let $d_U$ denote the corresponding distance as defined above: for any $A, B \subseteq \mathcal{K}_d^{(1)}$, $d_U(A, B) = (\text{vol}(A \setminus B) + \text{vol}(B \setminus A)) / \text{vol}(B_d)$. We start by bounding the bracketing numbers of $\mathcal{K}_d^{(1)}$ with respect to $d_U$:

**Lemma 4.6.** Fix $0 < \epsilon \leq 1$. Then, $N_{\epsilon, d_U}(\mathcal{K}_d^{(1)}) \leq 2N_{\epsilon/(3d), d_U}(\mathcal{K}_d^{(1)})$.

**Proof.** Let $r = \epsilon/(3d)$. Let $\mathcal{N}$ be an $r$-covering of $\mathcal{K}_d^{(1)}$ with respect to the Hausdorff distance, of size $|\mathcal{N}| = N_{d, d_U}(\mathcal{K}_d^{(1)})$. Define the set $\mathcal{N}' := \{K_{r' - r} : K \in \mathcal{N} \} \cup \{K_r : K \in \mathcal{N}\}$, and we will show that it is an $\epsilon$-bracketing of $\mathcal{K}_d^{(1)}$ with respect to $d_U$. Fix $K' \in \mathcal{K}_d^{(1)}$, and let $K$ be an element of $\mathcal{N}$ satisfying $d_U(K, K') \leq r$. From Claim 1, $K_{r'} \subseteq K' \subseteq K_r$. Note that $K_r, K_{r'} \in \mathcal{N}'$, and Lemma 4.3 implies that $d_U(K_r, K_{r'}) \leq r$. \[ \square \]

Note that Lemma 4.6 and Lemma 4.3 imply that $N_{\epsilon, d_U}(\mathcal{K}_d^{(1)}) \leq c(d)\epsilon^{-(d-1)/2}$ for all $0 < \epsilon \leq 1$.

Next, we use Lemma 4.4 to obtain the following bound:

**Lemma 4.7.** Let $P$ be a distribution with a density function $p$, let $X_1, \ldots, X_n \sim P$ be i.i.d. samples. Let $A$ be a bounded measurable set, and let $R = \sup_{x \in A}\|a\|_2$. Let $m = \sup_{a \in A} R^d p(a) / \text{vol}(B_d)$. Let $C_N(d)$ be the dimensional constant such that $\log N_{\epsilon, d_U}(\mathcal{K}_d^{(1)}) \leq C_N(d)\epsilon^{-(d-1)/2}$ for all $0 < \epsilon \leq 1$. Then, the following holds:

$$\mathbb{E}_P \left[ \sup_{K \in \mathcal{K}_d} |Z_{K \cap A}(X) - EZ_{K \cap A}(X)| / n \right] \leq C \left( \frac{C_N(d)}{n} \right)^{\frac{d-1}{d}} m^{\frac{d-1}{d}}. \quad (9)$$

**Proof.** First, we may assume that $R = 1$. Indeed,

$$\sup_{K \in \mathcal{K}_d} |Z_{K \cap A}(X) - EZ_{K \cap A}(X)| = \sup_{K \in \mathcal{K}_d} \left| Z_{(K \cap A)/R}(X/R) - EZ_{(K \cap A)/R}(X/R) \right| = \sup_{K' \in \mathcal{K}_d} \left| Z_{K' \cap (A/R)}(X/R) - EZ_{K' \cap (A/R)}(X/R) \right|. \quad (10)$$

Denote by $p'$ the density of each $X_i/R$, and note that $\sup_{a \in A} R^d p(a) / \text{vol}(B_d) = \sup_{a \in A/R} p'(a) / \text{vol}(B_d)$. Hence, the definition of $m$ implies that if the lemma is correct for $R = 1$, it is correct for all $R > 0$.

Since $A \subseteq B_d$, we define $A = \{ A \cap K : K \in \mathcal{K}_d^{(1)} \}$, and bound $\sup_{S \in A} |Z_S - EZ_S|$. Let $r$ be the integer such that

$$2^{-r-1} < \left( \frac{3C_N(d)}{n} \right)^{\frac{d-1}{d}} m^{\frac{d-1}{d}} \leq 2^{-r}.$$

Let $r_0$ be the smallest integer $i$ such that $2^{-i} < P(\bigcup A) = P(A)$. If $r < r_0$ then $2^{-r} \geq P(\bigcup A)$. Lemma 4.4 concludes that the left hand size of Eq. 10 is bounded by $2P(\bigcup A) \leq 2^{-r+1}$, and the proof follows by definition of $r$.

Assume for the rest of the proof that $r \geq r_0$. We apply Lemma 4.4 with the same values of $r$, $r_0$ and $A$. Using the bound on the bracketing numbers, we obtain that for any $0 < \epsilon \leq m$,

$$\log N_{\epsilon, d_U}(A) \leq \log N_{\epsilon, m, d_U}(\mathcal{K}_d^{(1)}) \leq C_N(d) \left( \frac{m}{\epsilon} \right)^{\frac{d-1}{d}}.$$
In particularly, this holds for any $0 < \epsilon \leq 2^{-r_0}$, since $2^{-r_0} \leq P(\bigcup A) \leq m$. This last inequality and the definition of $r$ implies that

$$\log N_{2^{-r},d,p} \leq n2^{-r}/3.$$ 

Applying Lemma 4.11 and recalling that $d \geq 4$, one obtains that

$$E \left[ \sup_{S \in A} |Z_S - EZ_S| / n \right] \leq 2^{-r} + C \sum_{i=1}^{\infty} \sqrt{2^{-i}C_N(d)(m/2^{-i})^{d+1}/n}$$

$$\leq 2^{-r} + C'2^{-r}\sqrt{C_N(d)(1/2^{-r})^{d+1}m^{d+1}/n}$$

$$\leq 2^{-r} + C'2^{-r}\sqrt{C_N(d)m^{d+1}/n},$$

as required.

Next, we extend the supremum from $K \in K_d \cap A$ to $K \in K_d$, by a successive approximation.

**Lemma 4.8.** Let $P$ be a log-concave distribution. Then,

$$E \left[ \sup_{K \in K_d} |Z_K - EZ_K| / n \right] \leq C(d)n^{-\frac{2}{d+1}}.$$

**Proof.** First, recall from Claim 2 that linear transformations preserve log-concavity, hence we may assume that $P$ is isotropic. For any $i = 0, 1, 2, \ldots$, let $A_i = \{ x \in \mathbb{R}^d : i < |x|_2 < i + 1 \}$. The following holds:

$$E \left[ \sup_{K \in K_d} |Z_K - EZ_K| / n \right] \leq \sum_{i=0}^{\infty} E \left[ \sup_{K \in K_d} |Z_{K \cap A_i} - EZ_{K \cap A_i}| / n \right].$$

(10)

For any integer $i \geq 0$, let $m_i = \sup_{x \in A_i} (i+1)^{d}p_0(x)/\text{vol}(B_d)$. Lemma 4.7 implies that

$$E \left[ \sup_{K \in K_d} |Z_{K \cap A_i} - EZ_{K \cap A_i}| / n \right] \leq C \left( \frac{C_N(d)}{n} \right)^{\frac{2}{d+1}} m_i^{d+1}.$$

From Lemma 5.8 it follows that for all $i \geq 0$, $m_i \leq (i+1)^{d}e^{-cA(d)+c\mu(d)/\text{vol}(B_d)}$. Summing over $i = 0, 1, \ldots$, the right hand side of Eq. (1) is bounded by

$$C \left( \frac{C_N(d)}{n} \right)^{\frac{2}{d+1}} \left( \frac{1}{\text{vol}(B_d)} \right)^{\frac{2}{d+1}} e^{-cA(d)+c\mu(d)/\text{vol}(B_d)} \sum_{i=0}^{\infty} \left( e^{-cA(d)+c\mu(d)/\text{vol}(B_d)} \right)^i (i+1)^{d(d+1)}.$$ 

The series converges, and the claim follows.

Applying McDiarmid’s inequality, one obtains the main theorem:

**Proof of Theorem 4** Define a function $\varphi : (\mathbb{R}^d)^n \rightarrow \mathbb{R}$, by $\varphi(X_1, \ldots, X_n) = \sup_{K \in K_d} |Z_K(X_1, \ldots, X_n) - EZ_K| / n$. Note that Lemma 4.8 bounds the expectation of $\varphi$. Applying Lemma 5.9 with $\varphi$ and $\lambda_1 = \cdots = \lambda_n = 1$, one obtains a tail bound on $\varphi$, and the result follows.

4.3 Deriving Theorem 1

Carpenter et al. 2018 essentially proved in Section 3 that the MLE minimax risk is upper bounded by

$$R_{\text{MLE}}(\hat{f}) \leq C(d) \cdot \log(n) \cdot E \left[ \sup_{K \in K_d} |Z_K(X) - EZ_K(X)| / n \right].$$

Their main result is an analogous Theorem (Lemma 10), which states that with high probability

$$\sup_{K \in K_d} |Z_K(X) - EZ_K(X)| / n = O_d(n^{-2/(d+3)} \log^2 n).$$
Therefore, they concluded in Theorem 7 that 
\[ R_{h_2}(\hat{f}) \leq O_d \left( n^{-2/(d+3)} \log^3 n \right). \]

Theorem 4 follows from the proof of Theorem 7 [Carpenter et al., 2018], by replacing their main lemma (Lemma 10) with Theorem 4 from this paper.

We note that Carpenter et al. [2018] used a different technique in their main lemma: they utilized the VC dimension of polytopes, while we bound the covering numbers under the Hausdorff distance, and apply chaining techniques.

5 Proof of Theorem 2

5.1 Outline of the proof

The main idea is to create a family of log-concave distributions
\[ \mathcal{F}_{\{0,1\}^K} := \{ f_\alpha : \alpha \in \{0,1\}^K \}, \]
where \( K = \Theta_d(n^{\frac{d}{d+3}}) \). Its members are perturbations of the Gaussian distribution. By definition, its of size \( 2^{\Theta_d(n^{\frac{d}{d+3}})} \).

These perturbations are negligible Hellinger squared, but not in the total variation metric. In more details, the Hellinger squared distance between a couple of distributions \( f_\alpha, f_\beta \) where \( \alpha, \beta \in \{0,1\}^K \), is
\[ O_d \left( \|\alpha - \beta\|_0 \cdot n^{-1} \right). \]
while in total variation it is
\[ O_d \left( \|\alpha - \beta\|_0 n^{\frac{d}{d+3}} \cdot n^{-1} \right). \] (11)

A variant of the Assouad’s Lemma (Lemma 3.5) implies that the risk with respect to the squared Hellinger is at least
\[ O_d \left( n^{-2/(d+3)} \log^3 n \right). \]
By Eq. (11), switching from Hellinger to total variation, we get an extra factor of \( n^{2/d+3} \). Thus,
\[ \inf_{\hat{f} \in \mathcal{F}_{\text{TV}}} \mathcal{R}_{d_{\text{TV}}} (\hat{f}) \geq O_d(n^{-\frac{2}{d+3}}). \]

5.2 Proof

Denote by \( \gamma(x) \) the Gaussian density of \( \mathbb{R}^d \). For our Theorem, we may assume that \( \delta \in (0,e^{-Cd}) \) and define \( g_{x_0,\delta}(x) \) as follows, for all \( x_0 \in \mathbb{R}^d \):
\[ g_{x_0,\delta}(x) = \begin{cases} \frac{1}{4}(\delta - \|x - x_0\|_2)^2 & \|x - x_0\|_2 \leq \delta \\ 0 & \|x - x_0\|_2 > \delta. \end{cases} \] (12)

Using \( g_{x,\delta} \), we can construct log-concave functions:

**Lemma 5.1.** Let \( x_1, \ldots, x_l \in \mathbb{R}^d \), such that \( \|x_i - x_j\| > 2\delta \) for all \( i \neq j \). Then, the function
\[ f(x) = \prod_{i=1}^l e^{g_{x_i,\delta}}(x) \gamma(x) = \begin{cases} e^{g_{x_i,\delta}}(x) \gamma(x) & \exists i \text{ such that } \|x - x_i\|_2 < \delta \\ \gamma(x) & \text{otherwise} \end{cases} \] is log-concave.

The proof of this lemma is deferred to Section 5.2.1. For an intuition, note that \( \log \gamma(x) + g_{x,\delta} \) is concave due to the fact that the Hessian of \( \gamma(x) \) equals \(-I\), while the largest singular value in the Hessian of \( g_{x,\delta} \) is bounded by \( 1/2 \), hence the sum of Hessians is negative semi-definite.

For any \( \|x - x_0\|_2 < \frac{\delta}{2} \), the following holds:
\[ e^{g_{x_0,\delta}}(x) \in \left( 1 + \frac{1}{16}\delta^2, 1 + \frac{1}{3}\delta^2 \right), \] (13)
where we used \( 1 + x \leq e^x \leq 1 + 2x \), when \( x \) is small enough. We use the following lemma, which is proved in Section 5.2.2.
Proof. Indeed, we can check the normalization factor for \( C \) and \( \delta \) importantly, the normalization factor is negligible, as stated below:

\[ \delta \]

Lemma 5.4. \( \delta \)

Let \( K \) be the number \( N \) from this lemma, and we create a finite set of log-concave distributions \( F^{\{0,1\}}_K := \{ f_\alpha : \alpha \in \{0,1\}^K, f_\alpha \in F_d \} \), where

\[ f_\alpha(x) := C_{d,\delta}^{-1} \gamma(x) e \cdot \exp \left( \sum_{i=1}^K \alpha_i g_{x_i,\delta}(x) + \sum_{i=1}^K (1 - \alpha_i) g_{-x_i,\delta}(x) \right), \tag{14} \]

where \( C_{d,\delta} \) is the normalization factor. Due to the Gaussian symmetry, i.e. \( \gamma(x) = \gamma(-x) \) for all \( x \in \mathbb{R}^d \), and from the definition of \( f_\alpha \), the normalization constants are identical for all \( \alpha \in \{0,1\}^K \). Most importantly, the normalization factor is negligible, as stated below:

**Lemma 5.3.** It holds that \( C_{d,\delta} \leq (1,1 + e^{-Cd}) \).

**Proof.** Indeed, we can check the normalization factor for \( \alpha = (1, \ldots, 1) \) by Eq. (12),

\[ \int_{\mathbb{R}^d} f_\alpha(x)dx - 1 = \sum_{i=1}^K \int_{B_d(x_i, \delta)} (e^{g_{x_i,\delta}}(x) - 1) \gamma(x)dx \]

\[ \leq C \cdot K \cdot \delta^2 \int_{B_d(\delta)} \gamma(x)dx \]

\[ \leq C \cdot K \cdot \delta^2 \max_{x \in \mathbb{R}^d} \gamma(x) \]

\[ \leq C \cdot \| \gamma \|_{TV} \delta^2 \leq e^{-Cd}, \]

where we used the facts that \( \delta \leq e^{-Cd} \), Lemma 5.4 and Eq. (14). This derives that \( C_{d,\delta} \leq 1 + e^{-cd} \), and \( C_{d,\delta} \geq 1 \) since \( e^{\gamma_0(x)} \geq 1 \).

Next, we bound the distances between densities in this class.

**Lemma 5.4.** For any \( \alpha, \beta \in \{0,1\}^K \),

\[ c_1^{-d} \| \alpha - \beta \|_{TV} \leq d_{TV}(f_\alpha, f_\beta) \leq c_2^{-d} \| \alpha - \beta \|_{TV} \]

and

\[ c_3^{-d} \| \alpha - \beta \|_{TV} \leq d_{TV}(f_\alpha, f_\beta) \leq c_4^{-d} \| \alpha - \beta \|_{TV} \]

In particular,

\[ c_5^{-d} d_{TV}(f_\alpha, f_\beta) \leq d_{TV}(f_\alpha, f_\beta) \leq c_6^{-d} d_{TV}(f_\alpha, f_\beta). \tag{15} \]

**Proof.** Observe that \( f_\alpha \) and \( f_\beta \) differ only on the balls corresponding to indices where they differ. Clearly, there are \( 2 \| \alpha - \beta \|_0 \) such balls. Define

\[ A_{\alpha, \beta} := \bigcup_{1 \leq i \leq K : \alpha_i \neq \beta_i} (B_d(x_i, \delta) \cup B_d(-x_i, \delta)) \]

We bound \( d_{TV}(f_\alpha, f_\beta) \) as follows:

\[ d_{TV}(f_\alpha, f_\beta) = \int_{\mathbb{R}^d} |f_\alpha(x) - f_\beta(x)|dx \]

\[ \geq C_{d,\delta}^{-1} \int_{A_{\alpha, \beta}} \left( \prod_{i=1}^K e^{\alpha_i - \beta_i g_{x_i,\delta}(x)} - 1 \right) \gamma(x)dx \]

\[ \geq C \min_{y \in B_d(\sqrt{2d})} \gamma(y) \int_{A_{\alpha, \beta}} \left( \prod_{i=1}^K e^{\alpha_i - \beta_i g_{x_i,\delta}(x)} - 1 \right)dx \]

\[ \geq c_4^{-d} \| \alpha - \beta \|_0 \int_{B_d(\delta/2)} (e^{\gamma_0,\delta}(x) - 1) dx \]

\[ \geq c_4^{-d} \| \alpha - \beta \|_0 \int_{B_d(\delta/2)} \frac{\delta^2}{16} dx \]

\[ \geq c_4^{-d} \| \alpha - \beta \|_0 \delta^{d+2} \| \gamma \|_{TV} \]

\[ \geq c_1^{-d} \| \alpha - \beta \|_0 \delta^{d+2} \| \gamma \|_{TV} \]
Similarly, one can lower bound the Hellinger squared. This concludes the proof.

By Eqs. (15), (16) we conclude that
\[
\delta^4 \geq \frac{1}{n} \text{vol}(B_d) \cdot \text{vol}(B_d) \cdot \frac{1}{n} \text{vol}(B_d).
\]

where we used the identity \( \sqrt{1 + x} \leq 1 + \frac{1}{2} x \) when \( x \) is small enough and that \( e^{\delta x} \leq 1 + \frac{1}{2} \delta^2 \).

Similarly, one can lower bound the Hellinger squared. This concludes the proof. \( \square \)

We apply Assouad’s Lemma (Lemma 3.5), to bound the squared Hellinger minimax risk of any estimator. The first requirement in this lemma follows by Lemma 5.4 for
\[
\gamma = c^d \delta^{d+4} \text{vol}(B_d).
\]

For the second requirement, observe that for \( \|\alpha - \beta\|_0 = 1 \). We know by Lemma 5.4 that
\[
h^2(f_\alpha, f_\beta) \leq c^d d^{d+4} \text{vol}(B_d).
\]

Therefore, we set \( \delta \) such that
\[
c^d d^{d+4} \text{vol}(B_d) = \frac{0.5}{n},
\]

or equivalently
\[
\delta = c^d \text{vol}(B_d)^{\frac{1}{d+1}} \frac{n^{-\frac{1}{d+1}}}{\text{vol}(B_d)} = c^d (d) \sqrt{n} n^{-\frac{1}{d+1}}.
\]

where \( c(4) \in (c_1, C_1) \). Finally, apply Assouad’s Lemma with the value \( K \) defined above, namely
\[K = c^d d^{d+4} \frac{\text{vol}(B_d)^{\frac{1}{d+1}}}{\text{vol}(B_d)} \text{vol}(B_d)\text{vol}(B_d)\]
and \( \gamma = c^d d^{d+4} \text{vol}(B_d) \) and \( c = 1/2 \). We get that
\[
\inf_{f \in \mathcal{F}_d} \mathcal{R}_{h^2}(\bar{f}) \geq \sqrt{1 - (1/2)^2} \cdot K \cdot \gamma \geq c^d \delta^4 \geq c^d n^{-\frac{1}{d+1}}.
\]

where we used Lemma 5.4. Now, we restrict ourselves to a subset of log-concave estimators that output distributions from \( \mathcal{F}_{(0,1)^k} \), namely
\[
\tilde{\mathcal{F}}_d := \{ f : (\mathbb{R}^d)^n \to \mathcal{F}_{(0,1)^k} \}.
\]

By Eqs. (13), (14) we conclude that
\[
\inf_{f \in \tilde{\mathcal{F}}_d} \mathcal{R}_{d_{TV}}(\bar{f}) \geq c^d n^{-\frac{1}{d+1}} \inf_{f \in \tilde{\mathcal{F}}_d} \mathcal{R}_{h^2}(\bar{f}) \geq c^d n^{-\frac{1}{d+1}} \inf_{f \in \tilde{\mathcal{F}}_d} \mathcal{R}_{h^2}(\bar{f}) \geq c^d n^{-\frac{1}{d+1}}.
\]

To conclude the proof, we show the following:

**Lemma 5.5.** The following holds: \( \inf_{f \in \tilde{\mathcal{F}}_d} \mathcal{R}_{d_{TV}}(\bar{f}) \geq \inf_{f \in \tilde{\mathcal{F}}_d} \mathcal{R}_{d_{TV}}(\bar{f}) \) / 2.

**Proof.** Choose the log-concave estimator from \( \tilde{\mathcal{F}}_d \) that minimizes the risk, denoted by \( \bar{f} \). Then, project it to \( \tilde{\mathcal{F}}_d \) namely, for every \( n \) samples, we define the projection as follows
\[
\bar{f}(x_1, \ldots, x_n) := \arg \min_{f \in \tilde{\mathcal{F}}_d} d_{TV}(\bar{f}(x_1, \ldots, x_n), f_\alpha).
\]

Now, we use the triangle inequality

\[\]
Claim 5. A function \( \phi \) is concave if and only if for any \( x_0 \in \mathbb{R}^d \) and any \( v \in S^{d-1} \), the function \( \psi : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( \psi(t) = \phi(x_0 + tv) \) is concave.

Clearly a univariate function is concave if and only if for any \( x \in \mathbb{R} \) there exists a neighborhood where it is concave. Formally:

Claim 4. A function \( \psi : \mathbb{R} \rightarrow \mathbb{R} \) is concave if and only if for any \( x \in \mathbb{R} \) there exists \( \epsilon_x > 0 \) such that \( \psi \) is concave on \( (x-\epsilon_x, x+\epsilon_x) \).

Combining these two claims, we obtain the following equivalence:

Claim 5. A function \( \phi : \mathbb{R}^d \rightarrow \mathbb{R} \) is concave if and only if for any \( x_0 \in \mathbb{R}^d \) and any \( v \in S^{d-1} \) there exists \( \epsilon > 0 \) such that the function \( \psi_{x_0, v, \epsilon} : (-\epsilon, \epsilon) \rightarrow \mathbb{R} \) defined by \( \psi_{x_0, v, \epsilon}(t) = \phi(x_0 + tv) \) is concave.

Using Claim 5, we will prove that \( \log f \) is concave. Pick \( x \in \mathbb{R}^d \), and divide into cases:

- If \( \|x - x_i\| > \delta \) for all \( 1 \leq i \leq \ell \), then \( \log f = \log \gamma(x) \) in a neighborhood of \( f \), where \( \log \gamma(x) \) is a concave function. In particular, \( \psi_{x,v,\epsilon} \) is concave for any \( v \in S^{d-1} \) and a sufficiently small \( \epsilon > 0 \).

- If \( \|x - x_i\| < \delta \) for some \( 1 \leq i \leq \ell \), then \( \log f(x) \) equals \( \log \gamma(x) + \log g_{x_i,\delta}(x) \) in some neighborhood of \( x \). Thus,

\[
\log f(x) = \log \gamma(x) + \log g_{x_i,\delta}(x) = \frac{d}{2} \log(2\pi) + \frac{1}{4}(\delta - \|x - x_i\|)^2 - \|x\|^2/2,
\]

which is a concave function as required.

- If \( \|x - x_i\| = \delta \), then for any \( v \in S^{d-1} \), there exists \( \epsilon > 0 \) such that \( \psi_{x,v,\epsilon}(t) := \log(f(x + tv)) \) has non-increasing derivative, hence it is concave. The key observation is that \( \psi_{x,v,\epsilon}(y) \) is differentiable at \( y = 0 \), while the monotonicity of the derivative for \( y \in (-\epsilon, \epsilon) \setminus \{0\} \) follows from the fact that \( \psi_{x,v,\epsilon} \) is concave and differentiable there.

### 5.2.2 Proof of Lemma 5.2

Proof. Using a standard packing argument (Lemma 3.2), we can find a set of disjoint balls with radius \( \delta \) in \( B_d(\sqrt{2d}) \) of size

\[
\epsilon^d \frac{B_d(\sqrt{2d})}{B_d(\delta)}.
\] (17)

Now we take two antipodal caps with height \( 1 - 2\delta \), namely,

\[
S^{1,\delta} := C(x_0, 1 - 2\delta) \quad \text{and} \quad S^{-1,\delta} := C(-x_0, 1 - 2\delta).
\]

Since \( \delta < e^{-Cd} \), by standard volume considerations we know \( \text{vol}(S^{1,\delta} \cup S^{-1,\delta}) > (1 - (c')^d)\text{vol}(B_d(\sqrt{2d})) \), for a sufficiently small \( c' \). Thus by Eq. (17) we must have a cap that contains

\[
(0.5c)^d \frac{B_d(\sqrt{2d})}{B_d(\delta)}.
\]

of the disjoint ball, then we return this set and its antipodal, namely we take each ball in this set and also its antipodal. And the claim follows.
6 Proof of Theorem

Before we prove the theorem, we note that the proof builds upon the proof of Theorem 1 part (ii) in the paper by Kim and Samworth [2016]. Their proof relies on a packing argument of the unit sphere, to generate a hard family of log-concave distributions. Any packing of the unit sphere can cover at most \( e^{-cd} \) of its surface area, this caused their proof to suffer from a similar factor in the risk. The main insight is that we can replace the packing with an approximate-packing which covers a constant fraction of the sphere. For this purpose, We utilize a lemma appearing in a recent paper in high dimensional geometry by Kur [2019], where the main result is how to find an optimal polytope that approximates the Euclidean ball in the symmetric volume difference.

First, we define a cap (of a ball):

**Definition 3.** A cap (of a ball) with height \( h \in (0, 1) \) and a center \( x_0 \in \partial B_d \) is defined as

\[
C(x_0, h) := \{ x \in B_d : x_0 \cdot x \geq 1 - h \}.
\]

In order to simplify the proof, we first show how the following main lemma derives the theorem, and then we prove the lemma.

**Lemma 6.1.** Let \( N \geq 10^d \). There exists \( c \in (0, 1) \), \( t_{d,N} \in (0.5, 1) \) and \( c_{d,N} \in (c_1, C_1) \) such that the following holds: There is a set of caps \( C(x_1, t_{d,N}), \ldots, C(x_N, t_{d,N}) \) that defines a body

\[
P_{d,N} := B_d \setminus \bigcup_{i=1}^{cN} C(x_i, t_{d,N})
\]

with volume

\[
\text{vol}(P_{d,N}) \geq \left( 1 - c_{d,N} N^{-\frac{1}{d+1}} \right) \text{vol}(B_d).
\] (18)

Moreover, for \( 1 \leq i \leq cN \), each cap \( C(x_i, t_{d,N}) \) has an equal volume of \( C_{d,N} N^{-(1+\frac{1}{d+1})} \text{vol}(B_d) \) and satisfies the following property:

\[
\text{vol} \left( C(x_i, t_{d,N}) \setminus \bigcup_{j=1, i \neq j}^{cN} C(x_j, t_{d,N}) \right) \geq c_3 C(x_i, t_{d,N})
\] (19)

where \( C_{d,N} \in (c_4, C_4) \).

Observe that the last equation implies that the overlap between the caps is not too large.

The value of \( N \) will be defined later, and we set \( K := cN \), where \( c \) is the constant in Lemma 6.1. Denote by \( C_d \) the family of uniform distributions over convex bodies. Define

\[
\mathcal{F}_{\{0,1\}^K} := \left\{ f_\alpha \in C_d : \alpha \in \{0,1\}^K \right\},
\]

where \( f_\alpha \) is defined as follows:

\[
f_\alpha(x) := \frac{\mathbb{1}_{P_{d,N}}(x) + \sum_{i=1}^{K} \mathbb{1}_{C(x_i, t_{d,N})}(x) \cdot \mathbb{1}_{\alpha_i = 1}}{\text{vol}(B_d)(1 - C_\alpha)}.
\]

where \( \text{vol}(B_d)(1 - C_\alpha) \) is the normalization factor, i.e. \( \text{vol}(B_d)(1 - C_\alpha) = \text{vol}(\bigcup_{i=1}^{K} C(x_i, t_{d,N}) \mathbb{1}_{\alpha_i = 1} \cup P_{d,N}) \). Clearly, the normalization factors may be different for different \( \alpha \). However, by Lemma 6.1 we know that \( \text{vol}(\bigcup_{i=1}^{K} C(x_i, t_{d,N})) \leq C_4 N^{-\frac{2}{d+1}} \text{vol}(B_d) \). Therefore,

\[
0 \leq C_\alpha \leq \text{vol} \left( \bigcup_{i=1}^{K} C(x_i, t_{d,N}) \right) \leq C_4 N^{-\frac{2}{d+1}}.
\] (20)
We apply Assoud’s Lemma (Lemma 3.5), hence we prove that both of its requirements are satisfied. For the first requirement: for any $\alpha, \beta \in \{0, 1\}^K$,

$$h^2(f_\alpha, f_\beta) = \int_{\mathbb{R}^d} \left( \sqrt{f_\alpha(x)} - \sqrt{f_\beta(x)} \right)^2 \, dx \geq \int_{B_d \setminus P_{d,N}} \left( \sqrt{f_\alpha(x)} - \sqrt{f_\beta(x)} \right)^2 \, dx$$

$$\geq \int_{\text{supp} f_\alpha \setminus \text{supp} f_\beta} \left( (1 - C_\alpha) \text{vol}(B_d) \right)^{-1} \, dx + \int_{\text{supp} f_\beta \setminus \text{supp} f_\alpha} \left( (1 - C_\beta) \text{vol}(B_d) \right)^{-1} \, dx$$

$$\geq \left( 1 - CN^{-\frac{2}{d+2}} \right) \text{vol}(B_d)^{-1} \left( \text{vol}(\text{supp} f_\alpha \setminus \text{supp} f_\beta) + \text{vol}(\text{supp} f_\beta \setminus \text{supp} f_\alpha) \right) \quad (21)$$

$$\geq c_2 \|\alpha - \beta\|_0 N^{-\left(1 + \frac{2}{d+2}\right)},$$

where we used Eq. (19), and supp denotes the support. Therefore, we may set $\gamma = c_3 N^{-\left(1 + \frac{2}{d+2}\right)}$, and the requirement holds.

For the second requirement of Assoud’s Lemma, observe that when $\|\alpha - \beta\|_0 = 1$, the distributions differ by two caps. Using similar considerations as in Eq. (21) we derive that

$$h^2(f_\alpha, f_\beta) \leq CN^{-\left(1 + \frac{2}{d+2}\right)}.$$ 

In order for $CN^{-\left(1 + \frac{2}{d+2}\right)} \leq \frac{\alpha}{m}$ to hold, we set $N = c_1 n^{\frac{d+2}{d+1}}$. Then, we apply Assoud’s Lemma with the previous value of $K$, namely, $K = c_2 n^{\frac{d+2}{d+1}}$ and $\gamma = cn^{-1}$. Thus,

$$\inf_{f \in F_d} R_{h^2}(f) \geq c_4 \cdot K \cdot \gamma \geq c_4 \cdot cn^{-1} \cdot c_2 n^{\frac{d+2}{d+1}} = c_3 n^{-\frac{2}{d+2}},$$

and the claim follows. Lastly, we prove Lemma 6.1.

**Proof of Lemma 6.1** First we use a lemma proven by Kur (2019) (substituting $\gamma = 1$). This lemma was created to show that there is a polytope with $N \geq 10^d$ facets that gives an optimal approximation in the symmetric volume difference of the Euclidean ball up to a universal constant.

**Lemma 6.2** (Kur (2019), Corollary of Lemma 3.1). Let $N \geq 10^d$ and $t_{d,N} := \sqrt{1 - \frac{\text{vol}(\partial B_d)}{N \text{vol}(B_{d-1})}}$. There is a set of $x_1, \ldots, x_N$ points on the unit $d$-dimensional sphere, that define a body

$$\widehat{P}_{d,N} := B_d \setminus \bigcup_{i=1}^N C(x_i, t_{d,N}).$$

that satisfies the following:

$$\text{vol}(P_{d,N}) = \left( 1 - c_{d,N} N^{-\frac{2}{d+2}} \right) \text{vol}(B_d)$$

(22)

where $c_{d,N} \in (c_1, C_1)$.

In order to prove Lemma 6.1 we first need to estimate the volume of a cap $C(x, t_{d,N})$. Using a standard result (see for example, Lemma 5.2 by Kur (2019)) the volume of each cap equals:

$$\text{vol}(C(x, t_{d,N})) = \text{vol}(B_{d-1}) \frac{(1 - t_{d,N}^2)^{\frac{d+1}{d}}}{t_{d,N} (d-1)} + O \left( \frac{\text{vol}(C(x, t_{d,N}))}{d} \right).$$

This expression is at most

$$C_1 \text{vol}(B_{d-1}) \frac{(1 - t_{d,N}^2)^{\frac{d+1}{d}}}{t_{d,N} (d-1)} \cdot \frac{1 + t_{d,N}}{t_{d,N}}$$

$$\leq C_2 \text{vol}(B_{d-1}) \frac{(1 - t_{d,N}^2)^{\frac{d+1}{d}}}{t_{d,N} (d-1)} \cdot (1 - t_{d,N}) = C_2 N^{-1} (1 - t_{d,N}) \text{vol}(\partial B_d)$$

$$= C_2 N^{-1} (1 - t_{d,N}) \text{vol}(B_d) \leq C_3 N^{-\left(1 + \frac{2}{d+2}\right)} \text{vol}(B_d).$$

(23)
where we used the definition of \( t_{d,N} = \sqrt{1 - \left( \frac{\text{vol}(\partial B_d)}{\text{vol}(B_{d-1})} \right)^{2/d}} \) ≥ 1 − \( CN^{-\frac{2}{d}} \) and Lemma 3.1. Using similar considerations it is easy to show that \( \text{vol}(C(x, t_{d,N})) \geq c_{1}N^{-(1+\frac{2}{d})}\text{vol}(B_d) \). Thus we derive that the volume of each cap is at most \( \tilde{C}_{d,N}N^{-(1+\frac{2}{d})}\text{vol}(B_d) \) where \( \tilde{C}_{d,N} \in (c_{1}, C_{1}) \). We utilize the following lemma:

**Lemma 6.3.** Let \( A = \{ S_{1}, \ldots, S_{N} \} \) be a collection of measurable sets in \( \mathbb{R}^{d} \), each of the same volume \( v \). Additionally, we also assume that \( \text{vol} \left( \bigcup_{i=1}^{N} S_{i} \right) = cNv \), for some constant \( 0 < c < 1 \). Then, there exists a subset \( A' \subseteq A \) of size at least \( Nc/2 \), such that the following holds:

\[ \forall S \in A': \text{vol} \left( S \setminus \bigcup_{S' \in A', S' \neq S} S' \right) \geq vc/2. \]

**Proof.** In order to return a set that satisfies Lemma 6.1 we perform the following greedy algorithm: We initialize a list \( L \leftarrow \{1, \ldots, N\} \): For each \( i \in \{1, \ldots, N\} \), in an increasing order, we check if \( \text{vol} \left( S_{i} \setminus \bigcup_{S' \in L, S' \neq S_{i}} S' \right) < vc/2. \)

If the answer is positive, we remove \( S_{i} \) from \( L \), and set \( L \leftarrow L \setminus \{S_{i}\} \). Otherwise, we do not change \( L \). Then, we continue with \( i + 1 \).

In the end of the algorithm, we are guaranteed to have \( \text{vol}(\bigcup L) \geq Nvc/2 \), since each removal decreases the volume of \( \bigcup L \) by at most \( vc/2 \). Additionally, since element is of volume \( v \), there are at least \( cN/2 \) remaining elements. The proof follows with \( A' = L \).

We apply Lemma 6.3 with \( A = \{C(x_{1}, t_{d,N}), \ldots, C(x_{N}, t_{d,N})\} \), \( v = \tilde{C}_{d,N}N^{-(1+\frac{2}{d})}\text{vol}(B_d) \), and \( c = c_{d,N} \). The lemma concludes by returning the set of caps \( A' \). \( \square \)
