I. INTRODUCTION

The impossibility of decoupling an open quantum system from its surrounding environment has motivated the development of methods to minimize the harmful non-unitary effects on a quantum evolution [1]. In general, such effects can be smoothened for slowly driven Hamiltonians, which are governed by the adiabatic theorem [2–4]. Adiabatic evolutions have been extensively used in a number of applications, such as geometric phases [5, 6], quantum computation [7–11], quantum thermodynamics [12–16], quantum game theory [17], among others [18–20]. For closed systems, adiabaticity is associated with a decoupled dynamics of eigenspaces corresponding to distinct energy eigenvalues in the spectrum of a quantum Hamiltonian. In particular, assuming no level crossings in the energy spectrum along the evolution, if a quantum state is prepared in an instantaneous non-degenerate eigenstate of a sufficiently slowly varying Hamiltonian \( H(t) \) at an initial time then it will evolve to the corresponding instantaneous eigenstate at later times. Remarkably, this picture has been challenged for quantum systems driven by highly oscillating fields under resonant conditions [21], which may imply in the failure of the expected adiabatic behavior. In particular, this issue has been experimentally investigated in a nuclear magnetic resonance setup [22], where it has been shown that many previously introduced quantitative adiabatic conditions [23–25] may fail at resonance. As an alternative to deal with this problem, a validation mechanism for adiabaticity has been recently introduced and experimentally realized via ion traps [26]. In this approach, adiabatic conditions may be consistently verified by adopting non-inertial reference frames.

Concerning open quantum systems, a generalization of the adiabatic theorem can be directly achieved for non-unitary evolution under time-local master equations governed by a Lindbladian super-operator \( \mathcal{L} \) (see, e.g., Refs. [27–30]). In this case, as originally derived in Ref. [27], open-system adiabaticity can be defined by replacing the concept of decoupled evolution of eigenspaces of a Hamiltonian \( H(t) \) for the decoupled evolution of Jordan blocks [31] of a Lindbladian \( \mathcal{L} \). The open-system adiabatic behavior reduces to the closed case as decoherence vanishes and implies, in general, in a finite optimal time for Jordan block decoupling, since there is a competition between the adiabatic time scale (requiring slow evolution) and the relaxation time scale (requiring fast evolution) [28]. This is rather different from the traditional closed-system case, where adiabaticity is favored by long evolution times, being exact at the infinite time limit.

In this work, we introduce a realization of the open-system adiabatic theorem, investigating the adiabatic behavior in a decohering environment both at resonance and off-resonance. The experimental setup is based on a hyperfine quantum bit (qubit) built upon a single trapped Ytterbium ion \(^{171}\text{Yb}^+\), where the ion hyperfine energy levels are used as degrees of freedom of a two-level system (see, e.g., Refs. [26, 32]). As illustrations of our approach, we implement an oscillating Landau-Zener Hamiltonian, specifically introduced to investigate the effects of resonance, and the adiabatic quantum algorithm for the Deutsch problem, where fidelities can be interpreted in terms of computation outcomes. Moreover, for both cases, we provide a class of density operators for which the open-system adiabaticity occurs at the infinite time limit, circumventing the usual competition between the adiabatic and relaxation time scales. As a by-product, this is shown to simplify the general quantitative condition obtained Ref. [27] for a class of initial quantum states.

II. ADIABATIC APPROXIMATION FOR OPEN QUANTUM SYSTEMS

Let us consider a discrete $D$-dimensional open quantum system described by a density operator $\rho(t)$. The non-unitary evolution of the system is assumed to be driven by a time-local master equation given by

$$\dot{\rho}(t) = L_t[\rho(t)],$$

where $L_t[\bullet]$ is the Lindbladian operator and the subscript $t$ denotes that $L_t[\bullet]$ may be time-dependent. As in Ref. [27], the open-system adiabatic dynamics is conveniently derived by adopting the superoperator formalism [33]. In this formalism, Eq. (1) can be rewritten as

$$|\rho(t)\rangle = \mathbb{L}(t)|\rho(t)\rangle,$$

where $|\rho(t)\rangle$ is the $D^2$-dimensional coherence vector and $\mathbb{L}(t)$ is a $(D^2 \times D^2)$-dimensional matrix. The components $\mathbb{L}_r(t)$ of the vector $|\rho(t)\rangle$ are obtained from $\mathbb{L}_r(t) = \text{Tr}[\sigma^r \mathbb{L}(t)]$ and the elements $\mathbb{L}_{nm}(t)$ of $\mathbb{L}(t)$ are written as $\mathbb{L}_{nm}(t) = (1/D)\text{Tr}[\sigma^m \mathbb{L}_n(t)]$, where $\{\sigma_n\}$ is a matrix basis obeying $\text{Tr}[\sigma^m \sigma^n] = D \delta_{mn}$ [43]. Here, we will consider the particular case a superoperator $\mathbb{L}(t)$ whose Jordan decomposition [31] admits one-dimensional Jordan blocks only, which will be individually associated with distinct non-crossing-time-dependent eigenvalues $\lambda_n(t)$. As provided in Appendix A, the adiabatic behavior will follow from the adiabatic quantum condition (AQC)

$$\max_{n\in[0,D]} \xi_{\beta\alpha}(t) \ll 1,$$

where $\xi_{\beta\alpha}(t)$ is the adiabatic parameter, reading

$$\xi_{\beta\alpha}(t) = \left| e^{\int_{0}^{t} \Re[\lambda_n(t') - \lambda_{n'}(t')] dt'} \langle \langle \mathbb{E}_{n}(t)|\mathbb{D}_{n'}(t) \rangle \rangle \right|,$$

with $\langle |\mathbb{D}_{n}(t)\rangle \rangle$ and $\langle \langle \mathbb{E}_{n}(t) \rangle \rangle$ denoting the right and left eigengroups of $\mathbb{L}(t)$ with eigenvalues $\lambda_n(t)$, respectively, and $\Re[z]$ representing the real part of $z \in \mathbb{C}$. Eq. (3) ensures decoupled evolution of Jordan-Lindblad eigenspaces [27]. The energy scale $|\lambda_n(t) - \lambda_{n'}(t)|$ takes into account both the Hamiltonian spectrum and the decohering rates. The coherence vector for an arbitrary time $t$ can be expanded as

$$|\rho(t)\rangle = \sum_{m=0}^{D} c_m(t)e^{\int_{0}^{t} \Re[\lambda_m(t') - \lambda_{m'}(t')] dt'}|\mathbb{D}_{m}(t)\rangle,$$

where $c_m(t)$ are complex functions of time associated with the right eigenbasis of $\mathbb{L}(t)$. It is important to highlight that, unlike the closed-system case [23–25, 34, 35], the adiabatic parameter in Eq. (4) is such that $\xi_{\beta\alpha}(t) = \xi_{\beta\alpha}(0)$ due to the presence of the factor $\eta_{\beta\alpha}(t) \equiv e^{\int_{0}^{t} \Re[\lambda_m(t') - \lambda_{m'}(t')] dt'}$. This means that, if we have $\max_{n\in[0,D]} \xi_{\beta\alpha}(t) \ll \xi_{\beta\alpha}(0)$, then the dynamics of $\rho(t)$ is decoupled from the coefficient $c_m(t)$, but it does not mean that $c_m(t)$ is decoupled of $\eta_{\beta\alpha}(t)$. Moreover, the real exponential in the factor $\eta_{\beta\alpha}(t)$ is responsible for the general finite optimal time for the adiabatic behavior in open systems [27]. However, we can show that, under decoherence, adiabaticity may still occur in the infinite time limit, as it happens for closed systems, for a class of initial quantum states. Indeed, let $\mathbb{L}(t)$ be a Lindblad superoperator that admits one-dimensional Jordan blocks with distinct eigenvalues $\lambda_n(t)$. Assume that the initial state of the system can be written as a superposition of two independent eigenvectors of $\mathbb{L}(0)$ and that there are no eigenvalue crossings in the spectrum of $\mathbb{L}(t)$. Then, the adiabatic dynamics in open system is achieved for slowly-varying Lindblad superoperators $\mathbb{L}(t)$, with decoupling of Jordan blocks of $\mathbb{L}(t)$ increasing as $t \rightarrow \infty$. See Appendix B for a detailed proof of this statement.

III. OPEN SYSTEM AQC FOR HIGHLY OSCILLATING DRIVEN FIELDS

A. Landau-Zener model under dephasing

In order to investigate the adiabatic behavior of open systems in a controllable experimental realization, let us consider, as our first example, the single-qubit Landau-Zener Hamiltonian, which is given by

$$H(t) = (\omega_0/2)\sigma_z + (\omega_z/2) \sin(\omega t)\sigma_x .$$

This Hamiltonian presents a resonant configuration when $\omega_0 \approx \omega_z$, as shown in Appendix C. Indeed, it can be used to illustrate the fact that, due to resonance, several quantitative adiabatic conditions designed for closed systems [22–25, 34, 35] are neither necessary nor sufficient to describe the adiabatic behavior in the model if the analysis is performed in the traditional inertial reference frame [26]. Concerning decoherence, we consider that the qubit is coupled to a dephasing reservoir evolving under a Lindblad master equation

$$\dot{\rho}(t) = -i[H(t), \rho(t)] + \gamma [\sigma_0 \rho(t) \sigma_z - \rho(t)],$$

with $\gamma$ denoting a time-independent dephasing rate. By rewriting Eq. (6) in the superoperator formalism we obtain a $4 \times 4$ dimensional superoperator $\mathbb{L}(t)$ whose elements are $\mathbb{L}_{nm}(t) = (1/2)\text{Tr}[-i\sigma_n[H(t), \sigma_m] + \gamma \sigma_n \sigma_z \sigma_m - \sigma_m]$. So, we have

$$\mathbb{L}(t) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & -2\gamma & -\omega_0 & \omega_0 \sin(\omega t) \tan \theta \\ 0 & \omega_0 & -2\gamma & 0 \\ 0 & -\omega_0 \sin(\omega t) \tan \theta & 0 & 0 \end{bmatrix} .$$

The system is initialized in the ground state of $H(0)$, which is given by $\rho(0) = |1\rangle\langle 1|$. Then, the coherence initial vector $|\rho(0)\rangle$ is written as $|\rho(0)\rangle = |D_0(0)\rangle - |D_1(0)\rangle$, where the eigenvectors of the driving super-operator are $|D_0(t)\rangle = [1 \ 0 \ 0 \ 0]^T$ and $|D_1(t)\rangle = [0 \ 0 \ 0 \ \sin(\omega t) \tan \theta]^T$, which are associated with eigenvalues $\lambda_0 = 0$ and $\lambda_1 = -2\gamma$, respectively, with $\theta = \arctan(\omega_0/\omega_z)$. The other eigenvalues of $\mathbb{L}(t)$ are $\lambda_2 = -\gamma - \Delta(t) \sec \theta/2$ and $\lambda_3 = -\gamma - \Delta(t) \sec \theta/2 - 2\gamma^2 + \omega_0^2(2\cos(2\omega t) \sin^2(\theta) - 3) + (2\gamma^2 - \omega_0^2) \cos(2\theta)$. Thus, adiabatic dynamics is such that it inhibits transitions from eigenvectors $|D_0(t)\rangle$ and $|D_1(t)\rangle$ to other eigenstates of $\mathbb{L}(t)$. See Appendix C for a complete characterization of the eigenstates of $\mathbb{L}(t)$.
B. Experimental implementation

We explore the adiabatic behavior of the resonant Landau-Zener Hamiltonian in a decohering environment both from a theoretical and an experimental point of view. In order to experimentally realize the model, we use a trapped Ytterbium ion ($^{171}$Yb$^+$) to implement the dynamics in Eq. (6), with the experimental setup shown in Fig. 1. We encode the qubit into two hyperfine energy levels of the $^2S_{1/2}$ ground state, which is denoted by $|0\rangle \equiv \frac{1}{\sqrt{2}} |S_{1/2}\rangle |F = 0, m_F = 0\rangle$ and $|1\rangle \equiv \frac{1}{\sqrt{2}} |S_{1/2}\rangle |F = 1, m_F = 0\rangle$. Using microwave manipulation, we can implement the target Hamiltonian and mimic the desired dephasing channel. A detailed description of the experimental architecture can be found in Ref. [32].

By using the arbitrary waveform generator (AWG), we coherently drive the hyperfine qubit to implement the target Hamiltonian. This is a well-established experimental procedure. However, there is no a universal way to control the two-level system interacting with an environment. Instead, we have introduced a new approach, which is based on a Gaussian noise working as environment. (b) The relevant energy spectrum of the $^{171}$Yb$^+$ ion and the six needle trap.

To verify the effectiveness of the adiabatic condition for open systems, we use the fidelity as a figure of merit. Fidelity can be used as a distinguishability measure between two density matrices $\rho_1$ and $\rho_2$, being defined by $F(t) = \mathcal{A}[\rho_1, \rho_2]$, where $\mathcal{A}[\rho_1, \rho_2] = \text{Tr}[\rho_1^{1/2} \rho_2 \rho_1^{1/2}]^{1/2}$. The experimental output data and the theoretical predictions are shown in Fig. 2, where theoretical and experimental process fidelity are, respectively, given by $F_{\text{Theo}}(t) = \mathcal{A}[\rho_{\text{ad}}(t), \rho_{\text{Theo}}(t)]$ and $F_{\text{Exp}}(t) = \mathcal{A}[\rho_{\text{ad}}(t), \rho_{\text{Exp}}(t)]$, where $\rho_{\text{Theo}}(t)$ is the numerical solution of Eq. (6) and $\rho_{\text{Exp}}(t)$ is obtained from the standard quantum state tomography. Remarkably, experimental fidelity is measured as 99.4% in our system [32].

Concerning the expected adiabatic behavior, we note first that, once the eigenvector $|D_0(t)\rangle = |D_0\rangle$ is time-independent, its dual left eigenstate $\langle \langle E_0(t) | = \langle \langle E_0 |$ is also time-independent, so that we can use the relation $\langle \langle E_0 | D_0(t) \rangle \rangle = -\langle \langle E_0 | D_0(t) \rangle \rangle$ to conclude that $\xi_{00} = \xi_{e0} = 0$. Thus, we do not have transitions from $|D_0\rangle$ to any other state. In addition, as detailed in Appendix B, $\xi_{e0} = 0$ is always valid for any open quantum system. On the other hand, $\xi_{e2}$ is nonvanishing. Its behavior is shown in the inset plot in Fig. 2., which allows us to conclude that the adiabatic approximation shown in Eq. (4) is indeed satisfied for the range of values for the parameters chosen in the experiment. Since the coefficients $\xi_{e2}$ are small and decay as a function of time, it is then expected that the fidelities increase approaching the value one as time $t \to \infty$. Indeed, the adiabatic evolved state can be written as

$$\rho_{\text{ad}}(t) = \frac{1}{2} \left[ 1 - \frac{1}{2} e^{-2\gamma t} \sin(\omega t) \cos(\theta) \sigma_y - e^{-2\gamma t} \sigma_z \right].$$

From Fig. 2, notice that fidelities with respect to the adiabatic density operator $\rho_{\text{ad}}(t)$ tend to increase for long evolution times but they undergo strong oscillations at an intermediate time scale. This is a consequence of the resonance phenomenon. If evolution is not long enough, the qubit approximately evolves as a closed system, since decoherence effects do not considerably drive the system through a non-unitary evolution. Indeed, it is known that, in this situation, resonance limits the applicability of the adiabatic theorem. In order to provide correct adiabatic predictions in closed systems, it would be required, for instance, the change for a non-inertial frame viewpoint [26]. Remarkably, as time increases in an open-system scenario, decoherence plays a relevant role, driving the system with high fidelities to the adiabatic evolution predicted by the adiabatic approximation established by Eq. (3). This is rather different for closed systems, where resonance challenges the applicability of the adiabatic theorem for an arbitrary time scale [21, 22, 26].
where the relevant eigenvalues of $\Pi(t)$ are given by $\lambda_0 = 0$ and $\lambda_1 = -2\gamma$, with their corresponding eigenvectors reading $|D_0(s)\rangle = [1 \ 0 \ 0 \ 0 \ 0]^T$ and $|D_1(s)\rangle = [0 \ \cos(Fs) \ -\sin(Fs) \ 0 \ 1]^T$, where $s = t/\tau \in [0, 1]$ is the normalized evolution time. The other eigenvalues are $\lambda_2 = -(\gamma + \Delta)$ and $\lambda_3 = -(\gamma - \Delta)$, where $\Delta^2 = \gamma^2 - \omega^2$. Therefore, from this set of eigenvectors, we can identify the initial state $|\psi(0)\rangle$ of the protocol as given by the superposition $|\psi(0)\rangle = |D_0(0)\rangle + |D_1(0)\rangle$ and the evolved adiabatic matrix density is obtained as (see Appendix D)

$$\rho_{DA}(s) = \frac{1}{2} \left[ \mathbb{1} + e^{-2\gamma s} (-1)^{f(0)+f(1)} \sigma_x \right]. \tag{11}$$

The above adiabatic solution provides the target state of the algorithm at $s = 1$ under the action of the decohering environment. The dynamics of the system and its distance with respect to $\rho_{DA}(s)$ (as measured by the fidelity) are provided in Fig. 3, where without loss of generality, we consider the implementation of the algorithm for a balanced function $f(0) = f(1) = 0$. As before, the theoretical and experimental fidelities of achieving the adiabatic open-system dynamics are defined by $F_{\text{th}}(\tau) = A[|\rho_{DA}^{\text{th}}(0), \rho_{\text{N-sol}}(s)|$ and $F_{\text{Exp}}(\tau) = A[|\rho_{DA}^{\text{th}}(1), \rho_{\text{Exp}}(s)|$, respectively, with $\rho_{\text{N-sol}}(s)$ given by the numerical solution of Eq. (6) for the Hamiltonian $H_{DA}(t)$ and $\rho_{\text{Exp}}(t)$ obtained via quantum tomography.

Remarkably, by looking at the adiabatic decohering dynamics of the Deutsch algorithm, it is argued in Ref. [27] that there should be an optimal time for the adiabatic approximation. While this is true in general, as a consequence of the competition between the adiabatic and the decoherence time scales, here fidelity increases to its maximum as $\tau \to \infty$. Indeed, as proved in Appendix B, this is because the initial density operator is a superposition of two blocks of $\Pi(0)$, given that $\Pi(t)$ admits one-dimensional Jordan blocks and does not show eigenvalue crossings.
B. Experimental investigation of an optimal adiabatic time window

A challenge in the implementation of adiabatic quantum algorithms under decoherence is to obtain a favorable trade-off between the necessary time to achieve the adiabatic regime and the (restrictive) time scale of decohering effects. As previously illustrated, the oscillatory behavior of the fidelity is a common phenomenon in the adiabatic evolution of both closed and open quantum systems. In particular, it is possible to identify the first maximum of the fidelity near to one in different adiabatic protocols and systems [32, 39–42]. To investigate how useful the fidelity maxima can be, we show in Fig. 4 the fidelity of achieving the desired target state of the Deutsch algorithm, which is the expected output of the algorithm. In this case, the desired output for a balanced function f is the pure state |−⟩, which can be represented by the density operator

\[ ρ_{DA}^{out}(1) = (1/2)(\mathbb{1} - σ_x). \]  

Observe that, since we are evolving under decoherence, the target state provided by Eq. (12) is distinct of the adiabatic solution given in Eq. (11), with the adiabatic solution reducing to the target state in the limit of vanishing decoherence. In order to quantify the success of the algorithm under decoherence, we define the fidelity of the real dynamics with respect to the target output density operator. The theoretical values are provided as \( F_{Exp}^{Cas}(τ) = \mathcal{A}[ρ_{DA}^{out}(1), ρ_{N-sol}(τ)] \), while their experimental counterparts are \( F_{Exp}^{Cas}(τ) = \mathcal{A}[ρ_{DA}^{out}(1), ρ_{Exp}(τ)] \).

Notice that the fidelity with respect to the pure target state in Fig. 4 decays for long times as the decoherence rate increases. This is in contrast with the fidelity with respect to the mixed-state adiabatic evolution for the pure system in Fig. 3, which goes to one as \( t \to \infty \). This is because adiabaticity in open systems is related to decoupling of Jordan blocks in a non-unitary evolution, which is only approximately equivalent (in the weak coupling regime) to achieving a pure target state after a computation process. Therefore, by focusing on pure target states, it is possible to see a preferred time-window exhibiting maximum fidelity. In Fig. 4, we show two windows with high fidelities, which are highlighted in light green color. Notice that these windows also correspond to high fidelities in Fig. 3, which means that adiabaticity in open systems is indeed able to provide the target state of the Deutsch algorithm with high fidelity for convenient measurement times.

V. CONCLUSIONS

In this paper we have addressed, both from a theoretical and an experimental point of view, the resonance sensitivity and the time optimality of the adiabatic approximation in open systems. First, we have shown that, distinctly from the closed case, the validity conditions for adiabaticity under decoherence may be robust against resonant phenomena. Second, we have implemented an adiabatic version of the Deutsch algorithm, analyzing its run-time optimality in open systems. In contrast with the general picture previously derived in the literature [27, 28], we have shown that the adiabatic approximation for open systems holds in the asymptotic time limit \( t \to \infty \) in the Deutsch algorithm, which is an arbitrarily valid consequence of the one-dimensional Jordan decomposition of the Lindblad superoperator \( \mathbb{L}_{DA}(t) \), the absence of level crossings, and the initialization of the system as a superposition of only two eigenstates of \( \mathbb{L}_{DA}(t) \). It is worth mentioning that, if we are interested in maximizing the probability of measuring the target (pure) state as the outcome of the algorithm, instead of the open-system adiabatic mixed-state density operator, then there is an optimal time window for the system measurement.

Concerning the experimental results, we have reported, to the best of our knowledge, the first experimental investigation of the adiabatic approximation in a fully controllable open system, where the decoherence rates can be freely set to verify the quantitative validity conditions for the adiabatic behavior. By using a hyperfine qubit encoded in ground-state energy levels of a trapped Ytterbium ion, all of the theoretical predictions highlighted above have been successfully realized. In this context, this work generalizes to the open-system scenario the experimental analysis of adiabaticity under resonance implemented for closed systems in Ref. [22]. Moreover, it also provided a framework to exploit the experimental realization of adiabaticity in quantum computing under decoherence, tackling features such as optimal run-time of an algorithm, asymptotic time behavior, competition between adiabatic and relaxation time-scales, outcome fidelities, among others. Scalability and more general features of open systems, such as non-Markovianity, are left as future challenges.

Appendix A: Adiabatic approximation: proof of Eqs. (3) and (4)

The adiabatic approximation in open quantum systems can be appropriately described by the super-operator formalism [27]. To begin with, let us consider a time-local non-unitary dynamics for a D-dimensional quantum system, which reads

$$\dot{\rho}(t) = \mathcal{L}[\rho(t)],$$  
(A1)

where $\mathcal{L}[\bullet]$ is the dynamical generator. In particular, such equation can be rewritten as

$$|\dot{\rho}(t)\rangle = \mathbb{L}(t)|\rho(t)\rangle,$$  
(A2)

where the double ket $|\rho(t)\rangle$ denotes a super-vector (or coherence vector, in case of a single qubit) and $\mathbb{L}(t)$ will be referred as the Lindblad super-operator. The prefix super is due to the dimensions of $|\rho(t)\rangle$ and $\mathbb{L}(t)$, namely, $\mathbb{L}(t)$ can be represented by a $D^2 \times D^2$ matrix and $|\rho(t)\rangle$ by a vector with $D^2$ components, where $D$ is the dimension of the Hilbert space associated with the quantum system. The components $\mathcal{L}_\alpha(t)$ of the vector $|\rho(t)\rangle$ are obtained from $\mathcal{L}_\alpha(t) = \text{Tr}[\rho(t)\sigma_\alpha]$, and the elements $\mathbb{L}_{nm}(t)$ of $\mathbb{L}(t)$ are written as $\mathbb{L}_{nm}(t) = (1/D)\text{Tr}[\sigma_m \mathcal{L}_n], \text{ where } [\sigma_m]$ is a matrix basis obeying $\text{Tr}[\sigma_m \sigma_n] = D\delta_{mn}$. From these definitions, the inner product between two elements $|\rho(t)\rangle$ and $|\mathcal{L}(t)\rangle$ is identified as $\langle \mathcal{L}(t)|\rho(t)\rangle = D\text{Tr}(\rho(t)\mathcal{L}(t))$. In particular, for a single qubit, we get $\mathbb{L}(t)$ as a $4 \times 4$ matrix and $|\rho(t)\rangle$ as a four-vector (vector with 4 components). By writing the density matrix $\rho(t)$ of a single qubit in terms of the components $\mathcal{L}_\alpha(t)$, we obtain

$$\rho(t) = \frac{1}{2} \left[ 1 + \mathcal{L}_\alpha(t) \sigma_\alpha + \mathcal{L}_\beta(t) \sigma_\beta + \mathcal{L}_\gamma(t) \sigma_\gamma \right].$$  
(A3)

In general $\mathbb{L}(t)$ does not admit a diagonal form, but it can be decomposed in the Jordan block-diagonal form. To this end, we define the set of right (quasi-) eigenvectors $\{ |D_{nm}^\alpha(t)\rangle \}$ and its left counterpart $\{ \langle D_{nm}^\alpha(t) | \}$, with $\alpha$ denoting a Jordan block with eigenvalue $\lambda_n(t)$ and $m_n$ denoting a (possible) degenerate (quasi-) eigenvector. The (quasi-) eigenvalue equations are written as $[27]$

$$\mathbb{L}(t)|D_{nm}^\alpha(t)\rangle = \lambda_n(t)|D_{nm}^\alpha(t)\rangle + |D_{nm}^{\alpha,-1}(t)\rangle,$$  
(A4)

$$\langle D_{nm}^\alpha(t) | \mathbb{L}(t) = \lambda_n(t) \langle D_{nm}^\alpha(t) | + \langle D_{nm}^{\alpha,-1}(t) | .$$  
(A5)

If the superoperator $\mathbb{L}(t)$ admits an one-dimensional Jordan block decomposition, we can simplify the above equations as

$$\mathbb{L}(t)|D_{nm}(t)\rangle = \lambda_n(t)|D_{nm}(t)\rangle,$$  
(A6)

$$\langle D_{nm}(t) | \mathbb{L}(t) = \lambda_n(t) \langle D_{nm}(t) | .$$  
(A7)

We will assume superoperators $\mathbb{L}(t)$ that admit the Jordan decomposition given by Eqs. (A6) and (A7). Thus, the solution of Eq. (A2) can be represented as

$$|\rho(t)\rangle = \sum \alpha c_\alpha(t)e^{\int_0^t \lambda_n(s)ds} |D_{\alpha}(t)\rangle,$$  
(A8)

where $c_\alpha(t)$ are coefficients to be determined. Now, using the above ansatz in Eq. (A2), we find

$$\sum \alpha c_\alpha(t)e^{\int_0^t \lambda_n(s)ds} |D_{\alpha}(t)\rangle = \sum \alpha \dot{c}_\alpha(t)e^{\int_0^t \lambda_n(s)ds} |D_{\alpha}(t)\rangle + \sum \alpha c_\alpha(t)e^{\int_0^t \lambda_n(s)ds} |D_{\alpha}(t)\rangle,$$

so that each $c_\alpha(t)$ evolves as

$$\dot{c}_\alpha(t)e^{\int_0^t \lambda_n(s)ds} |D_{\alpha}(t)\rangle = c_\alpha(t)\langle \mathcal{E}_\alpha(t)| |D_{\alpha}(t)\rangle e^{\int_0^t \lambda_n(s)ds},$$  
(A9)

We can rewrite Eq. (A9) as

$$\frac{d}{dt} \left[ c_\alpha(t)e^{\int_0^t \lambda_n(s)ds} |D_{\alpha}(t)\rangle \right] = \sum \alpha c_\alpha(t) \mathcal{E}_\alpha(t) e^{\int_0^t \lambda_n(s)ds},$$  
(A10)

where we defined $\mathcal{E}_\alpha(t) = \langle \mathcal{E}_\alpha(t)| |D_{\alpha}(t)\rangle$. Thus, to achieve the adiabatic behavior, the right-hand-side of Eq. (A10) must vanish, so that we get

$$c_\alpha(t) \approx c_\alpha(0) e^{\int_0^t \lambda_n(s)ds}.$$  
(A11)

Thus, a sufficient condition to obtain such result arises by imposing

$$\max_{\mathcal{E} \in [0,\tau]} \left| \frac{\int_0^t \mathcal{E}_\alpha(t) e^{\int_0^t \lambda_n(s)ds} dt}{\lambda_{\beta}(t) - \lambda_{\alpha}(t)} \right| < 1,$$  
(A12)

where the eigenvalue gap $|\lambda_{\beta}(t) - \lambda_{\alpha}(t)|$ appears as a natural energy scale to set the adiabatic behavior of the system. In general, since $\mathbb{L}(t)$ is not Hermitian, each eigenvalue $\lambda_n(t)$ can be decomposed as $\lambda_n(t) = \Re \lambda_n(t) + i \Im \lambda_n(t)$. Then, Eq. (A12) becomes

$$\max_{\mathcal{E} \in [0,\tau]} \left| \frac{\int_0^t \mathcal{E}_\alpha(t) e^{\int_0^t \lambda_n(s)ds} dt}{\lambda_{\beta}(t) - \lambda_{\alpha}(t)} \right| < 1 .$$  
(A13)

Hence, Eq. (A13) leads to the adiabatic coefficient in Eq. (4), which reads

$$\xi_{\beta}(t) = \frac{\int_0^t \mathcal{E}_\alpha(t) e^{\int_0^t \lambda_n(s)ds} dt}{\lambda_{\beta}(t) - \lambda_{\alpha}(t)} ,$$  
(A14)

Appendix B: Asymptotic adiabatic dynamics for open systems

By using the master equation (A1), it follows that the superoperator $\mathcal{L}[\bullet]$ satisfies $\text{Tr}[\mathcal{L}[\rho(t)]] = 0$, since $\text{Tr}[\rho(t)] = 0$. Thus, if we consider the basis $[\sigma_n]$, with $\sigma_0 = I$, the first row of the matrix representation of $\mathbb{L}(t)$ is vanishing. In fact, by adopting that the matrix elements of $\mathbb{L}(t)$ are written as $\mathbb{L}_{0n}(t) = (1/D)\text{Tr}[\sigma_m \mathcal{L}_n(\sigma_m)]$, we have

$$\mathbb{L}_{0n}(t) = \frac{1}{D} \text{Tr}[\mathcal{L}_n(\sigma_m)] = 0 .$$  
(B1)
Then $\mathbb{L}(t)$ has at least one eigenvalue zero with eigenvector constant. We further assume that $\mathbb{L}(t)$ admits one-dimensional Jordan decomposition and that there are no eigenvalue crossings in the spectrum of $\mathbb{L}(t)$. If we suitably order the basis so that the first eigenvalue is $\lambda_0 = 0$, we get the associated eigenvector as

$$|\mathcal{D}_0\rangle = \begin{bmatrix} 1 & 0 & 0 \cdots & 0 \end{bmatrix}^T.$$  \hspace{1cm} (B2)

As an immediate result, it follows that $\langle \mathcal{E}_0 | = |\mathcal{D}_0\rangle^\dagger$. In addition, such vector is associated with the maximally mixed state $(1/D)|\mathbb{1}\rangle$. In fact, the elements $q_n(t)$ of $|\rho(t)\rangle$ are given by $q_n(t) = \text{Tr}[\sigma^+_n \rho(t)]$, so that in the basis $\{|1, \sigma_n\rangle\}$ we have

$$q_n(t) = \frac{1}{D} \text{Tr}[\sigma^+_n |\mathcal{D}_0\rangle \langle |\mathcal{D}_0\rangle |\mathcal{D}_0\rangle \langle |\mathcal{D}_0\rangle] = \delta_{n0}.$$  \hspace{1cm} (B3)

where we use that $\text{Tr}[\sigma^+_n \sigma_n] = D\delta_{n0}$ and $\text{Tr}[\sigma_n] = D\delta_{n0}$. Therefore, by writing the density matrix as

$$\rho(t) = \frac{1}{D} \left[ \mathbb{1} + \sum_{n=1}^{D-1} q_n(t) \sigma_n \right],$$  \hspace{1cm} (B4)

it is possible to conclude that any physical initial state $|\rho(0)\rangle$ must be written as a combination of $|\mathcal{D}_0\rangle$ and other vectors $|\mathcal{D}_{\neq0}(t)\rangle$. Hence, the initial state can be generally written as

$$|\rho(0)\rangle = c_0(0)|\mathcal{D}_0\rangle + \sum_{\beta \neq 0} c_\beta(0)|\mathcal{D}_\beta(t)\rangle,$$  \hspace{1cm} (B5)

where $c_0(0) = 1$ and $c_\beta(0)$ are general complex coefficients.

The dynamics of the vanishing eigenvalue subspace can be studied from Eq. (A9). Indeed, let us write

$$\dot{c}_0(t) = \sum_{\beta \neq 0} c_\beta(t) \langle \mathcal{E}_\alpha | \mathcal{D}_\beta(t) \rangle e^{\frac{i}{\hbar} \lambda_0(t) \sigma_\alpha}.$$  \hspace{1cm} (B6)

where we already used $\lambda_0(t) = 0$ and $\langle \mathcal{E}_\alpha | \mathcal{D}_\beta(t) \rangle = 0$. Now, using that the superoperators $|\mathcal{D}_\beta(t)\rangle$ and $|\mathcal{E}_\alpha(t)\rangle$ satisfies $\langle \mathcal{E}_\alpha(t) | \mathcal{D}_\beta(t) \rangle = \delta_{\alpha\beta}$ for any $\beta$ and $\alpha$, we have

$$\frac{d}{dt} \langle \mathcal{E}_\alpha(t) | \mathcal{D}_\beta(t) \rangle = \langle \dot{\mathcal{E}}_\alpha(t) | \mathcal{D}_\beta(t) \rangle + \langle \mathcal{E}_\alpha(t) | \dot{\mathcal{D}}_\beta(t) \rangle = 0,$$  \hspace{1cm} (B7)

and consequently we conclude that

$$\langle \dot{\mathcal{E}}_\alpha(t) | \mathcal{D}_\beta(t) \rangle = \langle \mathcal{E}_\alpha(t) | \dot{\mathcal{D}}_\beta(t) \rangle.$$  \hspace{1cm} (B8)

By using this result in Eq. (B6), we get $\dot{c}_0(t) = 0$, which then implies in $c_0(t) = 1$, $\forall t$.

Concerning the dynamics of the remaining eigenstates of $\mathbb{L}(t)$, let us assume that the initial state is such that a single Jordan block is populated in addition to the block associated with $\lambda_n(t)$, i.e., $c_\beta(0) \neq 0$ for a single $\eta \in [1, D^2 - 1]$. We then start by looking at the adiabatic condition in Eq. (A14). The parameter $\xi_{\beta\eta}(t)$ tells us whether or not $\beta$ can evolve decoupled from $\eta$, but it does not provides any information whether $\alpha$ can evolve decoupled from $\beta$. Assume that $\max_{\alpha \in [0,N]} \xi_{\beta\eta}(t) \ll 1$ asymptotically in time ($t \to \infty$), due to the fact that $\Re \left[ \lambda_0(t) - \lambda_\beta(t) \right] < 0$, $\forall \alpha, \beta, t$. Provided the absence of level crossings as a function of time, this condition selects the largest eigenvalue $\lambda_\beta(t)$. Then, we write $\dot{c}_\beta(t) = b(t)c_\eta(t)$, with $b(t)$ denoting a complex coefficient. The solution reads $c_\beta(t) = c_\beta(0)e^{\frac{i}{\hbar} \int_{0}^{t} b(t') dt'}$. On the other hand, once the parameter $\xi_{\beta\eta}(t)$ does not necessarily satisfy $\max_{\alpha \in [0,N]} \xi_{\beta\eta}(t) \ll 1$, we generically write $\dot{c}_\beta(t) = \sum_{\alpha \neq \beta} \xi_{\alpha\beta}(t)c_\alpha(t) + \delta_\beta(t)c_\eta(t)$, with $\alpha, \beta$ and $\eta$ complex coefficients. However, by imposing $\xi_{\alpha\beta}(0) = 0$, it yields $c_\beta(0) = 0$ and consequently $c_\beta(t) = \sum_{\alpha \neq \beta} \delta_{\alpha\eta}(t)c_\alpha(t)$. By iteratively applying this argument after decoupling $\lambda_\beta(t)$, we finally obtain that $\dot{c}_\beta(t) = \delta_\beta(t)c_\eta(t)$, stopping as $\lambda_\eta(t)$ becomes the largest eigenvalue of the remaining set. Thus, by assuming a single $c_\eta(0) \neq 0$ in the initial state, which is equivalent to assuming an initial superposition of only two Jordan blocks, an adiabatic dynamics for $t \to \infty$ is always achieved, reading

$$|\rho(t)\rangle = |\mathcal{D}_\eta\rangle + c_\eta(t)|\mathcal{D}_\eta(t)\rangle.$$  \hspace{1cm} (B8)

### Appendix C: Open system AQC for highly oscillating driven fields

Let us consider a Landau-Zener type Hamiltonian given by

$$H(t) = \frac{\omega_0}{2} \sigma_z + \frac{\omega}{2} \sin(\omega t)\sigma_x.$$  \hspace{1cm} (C1)

We can rewrite Eq. (C1) as

$$H(t) = \frac{\omega_0}{2} \left[ \sigma_z + \tan \theta \sin(\omega t)\sigma_x \right],$$  \hspace{1cm} (C2)

where $\theta = \arctan[\omega_x/\omega_0]$. It is not obvious that the Hamiltonian $H(t)$ in Eq. (C2) exhibits a resonant behavior. In order to see this fact, let us define an time-dependent oscillating frame $R(t) = e^{i\frac{\omega_0}{2} t \sigma_y}$. In this oscillating frame, the Hamiltonian is given by

$$H_R(t) = R(t)H(t)R^\dagger(t) + iR(t)\dot{R}^\dagger(t) = \frac{\omega_0 - \omega}{2} \sigma_z + \frac{\omega}{2} \sigma_y,$$  \hspace{1cm} (C3)

where $f(t) = e^{i\omega_0 t \sigma_y} \sin(\omega t) \tan \theta$. Notice then that we can get a resonant situation if we choose $\omega_0 \approx \omega$. Concerning the Lindblad superoperator in the superoperator formalism, Eq. (6) of the main text implies that

$$\Xi(t) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & -2\gamma & -\omega_0 \sin(\omega t) \tan \theta & 0 \\ 0 & -\omega_0 \sin(\omega t) \tan \theta & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$  \hspace{1cm} (C4)

whose eigenvectors are given by

$$|\mathcal{D}_0(t)\rangle = \begin{bmatrix} 1 & 0 & 0 & 0 \end{bmatrix}^T,$$  \hspace{1cm} (C5a)

$$|\mathcal{D}_1(t)\rangle = \begin{bmatrix} 0 & 0 & \sin(\omega t) \tan \theta & 1 \end{bmatrix}^T,$$  \hspace{1cm} (C5b)

$$|\mathcal{D}_2(t)\rangle = \begin{bmatrix} 0 & -\lambda_2(t)\omega_0 & 1 - \sin(\omega t) \tan \theta & 1 \end{bmatrix}^T,$$  \hspace{1cm} (C5c)

$$|\mathcal{D}_3(t)\rangle = \begin{bmatrix} 0 & -\lambda_3(t)\omega_0 & 1 - \sin(\omega t) \tan \theta & 1 \end{bmatrix}^T.$$  \hspace{1cm} (C5d)

The eigenvectors above are associated with the eigenvalues $\lambda_0(t) = 0$, $\lambda_1(t) = -\gamma$, $\lambda_2(t) = -\gamma - \Delta(t) \sec(\theta)/2$, and $\lambda_3(t) = -\gamma + \Delta(t) \tan(\theta)/2$.
Δ(t) sec(θ)/2, respectively, where we have defined Δt(θ) = 2γ2 + ω0[2cos(2ω0t) sin2(θ) − 3] + (2γ2 − ω0) cos(2θ). The system is initialized in the ground state of H(0) as |1⟩ so that, in terms of the Pauli matrices, the initial state is given by

$$\rho(0) = |1\rangle\langle 1| = \frac{1}{2} [1 - \sigma_z]. \quad (C6)$$

The initial state in the superoperator formalism is then [ρ(0)] = [ 1 0 0 1 ]T. Therefore, from Eqs. (C5), we get

$$\rho(0) = [\mathcal{D}(0)] - [\mathcal{D}(1)]. \quad (C7)$$

By imposing now an adiabatic evolution under $\mathcal{L}(t)$ we obtain that the evolved state is

$$\rho(t) = [\mathcal{D}(0)] - e^{i\mathcal{H}(t)}[\mathcal{A}^{\rho(0)}][\mathcal{D}(1)]^{-1} e^{-i\mathcal{H}(t)} \quad (C8)$$

From Eq. (C8), the adiabatic density matrix can then be written as

$$\rho(t) = \frac{1}{2} \left[ 1 - e^{-2\gamma t} \cos(\omega t) \sigma_z - e^{-2\gamma t} \sigma_z \right]. \quad (C9)$$

**Appendix D: Adiabatic Deutsch algorithm under dephasing channel**

As it has been discussed in Ref. [28], an adiabatic Hamiltonian capable of implementing the Deutsch algorithm can be written as

$$H(t) = -\omega \cos\left(\frac{\pi F t}{2\tau}\right) \sigma_x - \omega \sin\left(\frac{\pi F t}{2\tau}\right) \sigma_y, \quad (D1)$$

where $\pi$ is the total evolution time and $F = (-1)^{f(0)} - (-1)^{f(1)}$. Thus, if we drive the system by Eq. (D1), the system is initialized in the state $|\psi(0)\rangle = |+\rangle$ and it adiabatically evolves to $|\psi(t)\rangle = |+\rangle (|\psi(t)\rangle = |-\rangle)$ when $f$ is constant (balanced). Again, we will study the dynamics given by the master equation (6) of the main text. In order to analyze the adiabatic behavior of the system, we then consider the Lindblad equation in the superoperator formalism [27]. By writing the density operator $\rho(t)$ in terms of its components $\varrho_n(t)$, we obtain

$$\rho(t) = \frac{1}{2} [1 + \varrho_1(t)\sigma_x + \varrho_2(t)\sigma_y + \varrho_3(t)\sigma_z]. \quad (D2)$$

Then, we can write $|\rho(t)\rangle = [1 \varrho_1(t) \varrho_2(t) \varrho_3(t)\sigma_z]^{-T}$ as the cohering supervector, whose components are $\varrho_n(t) = \text{Tr}[\rho(t)\sigma_n]$. The Lindblad superoperator $\mathcal{L}(t)$ has elements computed from $\mathcal{L}_{nm}(t) = \frac{1}{2}\text{Tr}[-i\sigma_n[H(t),\sigma_m] + \gamma_n \sigma_n [\sigma_m \sigma_n - \sigma_n \sigma_m]]$. Thus

$$\mathcal{L}(t) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & -2\gamma & 0 & q(t) \\ 0 & 0 & -2\gamma & -r(t) \\ 0 & -q(t) & r(t) & 0 \end{bmatrix}, \quad (D3)$$

where $r(t) = -\cos(\pi F s/2)$ and $q(t) = \sin(\pi F s/2)$. The set of eigenvalues of $\mathcal{L}(t)$ are $\lambda_0 = 0, \lambda_1 = -2\gamma, \lambda_2 = -(\gamma - \Delta)$ and $\lambda_3 = -(\gamma + \Delta)$, where $\Delta = \sqrt{\gamma^2 - \omega^2}$. Therefore, $\mathcal{L}(t)$ is composed by one-dimensional Jordan blocks. In addition, the eigenvectors of $\mathcal{L}(t)$ are

$$\mathcal{L}(t) \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & \cos\left(\frac{\pi F t}{2}\right) & -\sin\left(\frac{\pi F t}{2}\right) & 0 \\ 0 & \sin\left(\frac{\pi F t}{2}\right) & \cos\left(\frac{\pi F t}{2}\right) & 1 \\ 0 & -\sin\left(\frac{\pi F t}{2}\right) & \sin\left(\frac{\pi F t}{2}\right) & 1 \end{bmatrix},$$

where we have defined $\eta_3 = -\lambda_1/\omega$ and $s = t/\tau$. Therefore, in this formalism, the initial state $\rho(0) = (1 + \sigma_x)/2$ is represented by the cohering supervector $|\rho(0)\rangle = [1 1 0 0]T$. It is important to highlight that, from the set of eigenvectors of $\mathcal{L}(t)$, we can see that the initial state can be written as

$$|\rho(0)\rangle = c_0(0)|\mathcal{D}(0)\rangle + c_1(0)|\mathcal{D}(1)\rangle, \quad (D8)$$

where $c_0(0) = c_1(0) = 1$. Therefore, the adiabatic approximation for open systems [27] states that our system will undergo an adiabatic dynamics given by

$$|\psi(s)\rangle = c_0(0)e^{\theta_0(s)}|\mathcal{D}(0)\rangle + c_1(0)e^{\theta_1(s)}|\mathcal{D}(1)\rangle, \quad (D9)$$

where $\theta_0(s) = 0$ and $\theta_1(s) = -2\gamma t$. Thus, from the above equation and by using that $\cos(F \pi/2) = (-1)^{f(0)+f(1)}$, the density matrix associated with the output state reads

$$\rho(1) = \frac{1}{2} [1 + e^{-2\gamma t}(-1)^{f(0)+f(1)} \sigma_z]. \quad (D10)$$

**References**

From these definitions, one identifies the inner product between two elements $|\rho(t)\rangle$ and $|\lambda(t)\rangle$ as $\langle\lambda(t)|\rho(t)\rangle = DTr\{\rho(t)\lambda^\dagger(t)\}$.
