

Second- and Third-Order Asymptotics of the Continuous-Time Poisson Channel

Yuta Sakai, *Member, IEEE*, Vincent Y. F. Tan, *Senior Member, IEEE*, and Mladen Kovačević, *Member, IEEE*,

Abstract

The paper derives the optimal second-order coding rate for the continuous-time Poisson channel. We also obtain bounds on the third-order coding rate. This is the first instance of a second-order result for a continuous-time channel. The converse proof hinges on a novel construction of an output distribution induced by Wyner's discretized channel and the construction of an appropriate ϵ -net of the input probability simplex. While the achievability proof follows the general program to prove the third-order term for non-singular discrete memoryless channels put forth by Polyanskiy, several non-standard techniques—such as new definitions and bounds on the probabilities of typical sets using logarithmic Sobolev inequalities—are employed to handle the continuous nature of the channel.

I. INTRODUCTION

This study explores fundamental limits in Poisson communication theory [2] from the perspective of fixed-error probability asymptotics [3]–[12]. The continuous-time Poisson channel—simply referred to as the *Poisson channel*—is a canonical optical direct-detection communication model [13], [14]. The output of the Poisson channel is a Poisson counting process whose intensity is determined by the sum of a *dark current noise* and an *input waveform* subject to peak and average power constraints; for more details refer to Section II of this paper. Kabanov [15] derived the capacity, i.e., the optimal first-order coding rate, of the Poisson channel in the absence of an average power constraint. Davis [16] generalized Kabanov's capacity formula with an average power constraint.

While Kabanov's [15] and Davis' [16] proofs involved martingale techniques, Wyner [17] provided an alternative proof based on a discretization technique. In particular, Wyner discretized the Poisson channel into a binary-input binary-output discrete memoryless channel. He then applied elementary information-theoretic techniques to analyze the capacity of this channel and related the capacity to that of the original Poisson channel. Using the same discretization argument, Wyner [17] derived the error exponent [18] of the Poisson channel for all rates below capacity.

Recently, to understand the finite blocklength performance of channel coding, refinements of asymptotic estimates on optimal coding rates with fixed error probability have gained increasing traction [3]–[8], [10]. In this paper, we derive the optimal second-order coding rate for the Poisson channel. We also show an upper and a lower bounds on the optimal third-order coding rate. This is the first instance of a conclusive second-order result in continuous-time communications in information theory.

While martingale-based techniques for Poisson channels enjoy several advantages [19], our proof techniques are inspired by Wyner's discretization argument [17]. In the converse part, particularly in the application of the meta-converse [5] to the discretized channel, we construct a somewhat artificial output distribution induced by Wyner's discretized channel and the construction of an appropriate ϵ -net of the input probability simplex. This construction differs from existing constructions in the literature [4], [7], [9] and appears to be essential in handling the continuous nature of the channel model. In the achievability part, we adapt Polyanskiy's technique to prove the third-order asymptotics for non-singular¹ discrete memoryless channels (DMCs) [6, Section 3.4.5] to our scenario. A straightforward generalization of the random coding union bound [5, Theorem 16] and a judicious choice of the input distribution inspired by the delta-convention [20, Convention 2.11] are proposed in view of the additive cost constraint imposed on the discretized channel. In addition, to bound a certain probability that results from the continuous nature of the Poisson channel and certain properties of its discretized version, a modified logarithmic Sobolev inequality (cf. [21, Chapter 6]) rather than Hoeffding's inequality is employed.

The rest of this paper is organized as follows: Section II introduces the formal definition of the Poisson channel, its classical channel capacity [15]–[17] is stated in Theorem 1, and our second-order asymptotics for the Poisson channel—i.e., the main result of this study—is presented in Theorem 2 together with certain bounds on the third-order coding rate. Section III describes

This paper was presented in part at the 2019 IEEE Information Theory Workshop (ITW2019), Visby, Gotland, Sweden [1].

¹A channel $W : \mathcal{X} \rightarrow \mathcal{Y}$ is said to be *singular* if $W(y | x)W(y | z) > 0$ implies that $W(y | x) = W(y | z)$ (cf. [8, Section 4.2.1]). A channel is said to be *non-singular* if it is not singular.

the proof of Theorem 2. This section is partitioned into various subsections. In Section III-A, we introduce the basic notations in the study of second- and third-order asymptotics. In Section III-B, we revisit Wyner's discretization argument [17]. The proofs of the converse and achievability parts of Theorem 2 are provided in Sections III-C and III-D, respectively. Section IV discusses technical novelties and contributions of our proofs; readers may benefit from reading through the discussion in Section IV before perusing the proofs.

II. CONTINUOUS-TIME POISSON CHANNEL AND ITS SECOND- AND THIRD-ORDER ASYMPTOTICS

We now introduce the mathematical model of the *continuous-time Poisson channel*. An input of the Poisson channel is an integrable function $\lambda : [0, \infty) \rightarrow [0, \infty)$ called a *waveform*. Given a waveform λ and a constant $\lambda_0 \geq 0$ called the *dark current*, the output of the Poisson channel is modeled by a Poisson counting process $\{v(t)\}_{t \geq 0}$ of intensity $\lambda(t) + \lambda_0$, i.e.,

$$\mathbb{P}\{v(0) = 0\} = 1, \quad (1)$$

$$\mathbb{P}\{v(t + \tau) - v(t) = k\} = \frac{e^{-\Lambda} \Lambda^k}{k!} \quad (2)$$

for every $0 \leq t, \tau < \infty$ and every $k \in \mathbb{N} \cup \{0\}$, where

$$\Lambda = \Lambda(\lambda, \lambda_0, t, \tau) := \int_t^{t+\tau} (\lambda(u) + \lambda_0) du. \quad (3)$$

Here, the Poisson counting process $\{v(t)\}_{t \geq 0}$ is defined as a random mapping $v : [0, \infty) \rightarrow \mathbb{N} \cup \{0\}$. For the sake of brevity, we denote the random mapping $v : [0, T] \rightarrow \mathbb{N} \cup \{0\}$ as v_0^T .

Let $T > 0$, $A > 0$, and $0 < \sigma \leq 1$ be three constants. Denote by $\mathcal{S}(T)$ the collection of non-decreasing functions $g : [0, T] \rightarrow \mathbb{N} \cup \{0\}$ satisfying $g(0) = 0$. In addition, denote by $\mathcal{W}(T, A, \sigma)$ the collection of waveforms $\lambda : [0, T] \rightarrow [0, A]$ satisfying the average power constraint

$$\frac{1}{T} \int_0^T \lambda(t) dt \leq \sigma A. \quad (4)$$

Then, a channel code for the Poisson channel with dark current λ_0 can be defined as follows:

Definition 1. Given an integer $M \geq 1$ and a real number $0 \leq \varepsilon \leq 1$, a pair of encoder $\phi : \{1, \dots, M\} \rightarrow \mathcal{W}(T, A, \sigma)$ and decoder $\psi : \mathcal{S}(T) \rightarrow \{1, \dots, M\}$ is called a $(T, M, A, \sigma, \varepsilon)_{\text{avg}}$ -code if

$$\frac{1}{M} \sum_{m=1}^M \mathbb{P}\{\psi(v_0^T) = m \mid \lambda = \phi(m)\} \geq 1 - \varepsilon. \quad (5)$$

Here, λ stands for the $\mathcal{W}(T, A, \sigma)$ -valued random variable (r.v.) induced by the encoder ϕ and the uniformly distributed messages on $\{1, \dots, M\}$.

For $0 < \varepsilon < 1$, denote by $M_{\text{avg}}^*(\lambda_0, T, A, \sigma, \varepsilon)$ the maximum integer M such that a $(T, M, A, \sigma, \varepsilon)_{\text{avg}}$ -code exists for the Poisson channel with dark current λ_0 . Assume throughout this paper that all logarithms are the natural logarithm.

Theorem 1 ([15]–[17]). *It holds that*

$$\log M_{\text{avg}}^*(\lambda_0, T, A, \sigma, \varepsilon) = T C^* + o(T) \quad (\text{as } T \rightarrow \infty), \quad (6)$$

where the Poisson channel capacity C^* is given by

$$C^* = C^*(\lambda_0, A, \sigma) := A \left((1 - p^*) s \log \frac{s}{p^* + s} + p^* (1 + s) \log \frac{1 + s}{p^* + s} \right), \quad (7)$$

and three numbers s , p^* , and p_0 are given by

$$s = s(\lambda_0, A) := \frac{\lambda_0}{A}, \quad (8)$$

$$p^* = p^*(\lambda_0, A, \sigma) := \min\{\sigma, p_0\}, \quad (9)$$

$$p_0 = p_0(\lambda_0, A) := \frac{(1 + s)^{1+s}}{s^s e} - s. \quad (10)$$

Our goal is to refine the $+o(T)$ term in (6). We do so via Wyner's discretization argument [17, Section II in Part I] and finite blocklength analyses. The following theorem exactly characterizes the optimal second-order coding rate of the Poisson channel together with bounds on the third-order coding rate.

Theorem 2. *It holds that*

$$\log M_{\text{avg}}^*(\lambda_0, T, A, \sigma, \varepsilon) = T C^* + \sqrt{TV^*} \Phi^{-1}(\varepsilon) + \rho_T, \quad (11)$$

where $\rho_T = O(\log T)$ as $T \rightarrow \infty$, the Poisson channel dispersion V^* is given by

$$\begin{aligned} V^* &= V^*(\lambda_0, A, \sigma) \\ &:= A \left((1 - p^*) s \log^2 \frac{s}{p^* + s} + p^* (1 + s) \log^2 \frac{1 + s}{p^* + s} \right), \end{aligned} \quad (12)$$

and $\Phi^{-1}(\cdot)$ stands for the inverse function of the standard Gaussian cumulative distribution function

$$\Phi(u) := \frac{1}{\sqrt{2\pi}} \int_{-\infty}^u e^{-t^2/2} dt. \quad (13)$$

More precisely, there exist positive constants c_1 and c_2 satisfying

$$\frac{1}{2} \log T - c_1 \leq \rho_T \leq \log T + c_2 \quad (14)$$

for sufficiently large T .

The converse and achievability parts of Theorem 2 are proved in Sections III-C and III-D, respectively. The technical contributions and novelties in the proofs of the converse and achievability parts will be discussed in detail in Sections IV-A and IV-B, respectively.

III. PROOF OF THEOREM 2

A. Notations for Second-Order Asymptotic Analysis

Given two discrete distributions P and Q on the same space, define the following four divergences:

$$D_s^\epsilon(P \parallel Q) := \sup \left\{ R \in \mathbb{R} \mid \mathbb{P} \left\{ \log \frac{P(Z)}{Q(Z)} \leq R \right\} \leq \epsilon \right\}, \quad (15)$$

$$D(P \parallel Q) := \mathbb{E} \left[\log \frac{P(Z)}{Q(Z)} \right], \quad (16)$$

$$V(P \parallel Q) := \mathbb{E} \left[\left(\log \frac{P(Z)}{Q(Z)} - D(P \parallel Q) \right)^2 \right], \quad (17)$$

$$\Xi(P \parallel Q) := \mathbb{E} \left[\left| \log \frac{P(Z)}{Q(Z)} - D(P \parallel Q) \right|^3 \right], \quad (18)$$

where Z is a r.v. satisfying² $\mathbb{P} \circ Z^{-1} = P$. Moreover, given countable alphabets \mathcal{X} and \mathcal{Y} , a distribution P on \mathcal{X} , a channel $W : \mathcal{X} \rightarrow \mathcal{Y}$, and a distribution Q on \mathcal{Y} , define the following three conditional divergences:

$$D(W \parallel Q \mid P) := \mathbb{E} \left[\log \frac{W(Y \mid X)}{Q(Y)} \right], \quad (19)$$

$$V(W \parallel Q \mid P) := \mathbb{E} \left[\left(\log \frac{W(Y \mid X)}{Q(Y)} - \mathbb{E} \left[\log \frac{W(Y \mid X)}{Q(Y)} \mid X \right] \right)^2 \right], \quad (20)$$

$$\Xi(W \parallel Q \mid P) := \mathbb{E} \left[\left| \log \frac{W(Y \mid X)}{Q(Y)} - \mathbb{E} \left[\log \frac{W(Y \mid X)}{Q(Y)} \mid X \right] \right|^3 \right], \quad (21)$$

where (X, Y) is a pair of r.v.'s satisfying $\mathbb{P} \circ (X, Y)^{-1} = P \times W$, and $P \times W$ stands for the joint distribution on $\mathcal{X} \times \mathcal{Y}$ defined as

$$(P \times W)(x, y) := P(x) W(y \mid x) \quad (22)$$

for each $(x, y) \in \mathcal{X} \times \mathcal{Y}$. In particular, we write

$$I(P, W) := D(W \parallel PW \mid P) = D(P \times W \parallel P \times PW), \quad (23)$$

$$V(P, W) := V(W \parallel PW \mid P), \quad (24)$$

$$\tilde{V}(P, W) := V(P \times W \parallel P \times PW), \quad (25)$$

$$\Xi(P, W) := \Xi(W \parallel PW \mid P), \quad (26)$$

$$\tilde{\Xi}(P, W) := \Xi(P \times W \parallel P \times PW) \quad (27)$$

²The notation $\mathbb{P} \circ Z^{-1}$ stands for the probability distribution induced by the r.v. Z .

for a distribution P on \mathcal{X} and a channel $W : \mathcal{X} \rightarrow \mathcal{Y}$, where PW stands for the output distribution on \mathcal{Y} defined as

$$PW(y) := \sum_{x' \in \mathcal{X}} (P \times W)(x', y) \quad (28)$$

for each $y \in \mathcal{Y}$.

B. Discretization of the Poisson Channel

Our analyses hinge on Wyner's *ad hoc* assumption [17, Section II in Part I]. At a high level, this assumption says that the performance of the original channel is roughly equivalent to a discretized version of the Poisson channel. We now introduce the discretized version of the Poisson channel as follows: For $\Delta > 0$, define the binary asymmetric channel $W_\Delta : \{0, 1\} \rightarrow \{0, 1\}$ by³

$$W_\Delta(1 | x) := \begin{cases} s A \Delta e^{-s A \Delta} & \text{if } x = 0, \\ (1 + s) A \Delta e^{-(1+s) A \Delta} & \text{if } x = 1, \end{cases} \quad (29)$$

where s is defined in (8). In particular, we define

$$W_n := W_{\Delta_n} \quad (30)$$

for each $n \geq 1$, where the number $\Delta_n > 0$ is given by

$$\Delta_n := \frac{T}{n}. \quad (31)$$

It is clear that $W_n(\cdot | 0)$ and $W_n(\cdot | 1)$ are Bernoulli distributions. We write these Bernoulli parameters as

$$a_n := W_n(1 | 0), \quad (32)$$

$$b_n := W_n(1 | 1). \quad (33)$$

Denote by $\mathcal{B}(n, \sigma)$ the set of n -length binary sequences $\mathbf{x} = (x_1, \dots, x_n) \in \{0, 1\}^n$ satisfying the weight constraint

$$\frac{1}{n} \sum_{i=1}^n x_i =: P_{\mathbf{x}}(1) \leq \sigma, \quad (34)$$

where $P_{\mathbf{x}}$ stands for the type or empirical distribution of the binary sequence $\mathbf{x} \in \{0, 1\}^n$ (see [20]). We define a channel code for the discretized channel W_n^n under the weight constraint σ as follows:

Definition 2. Given an integer $M \geq 1$ and a real $0 \leq \varepsilon \leq 1$, a pair of encoder $\phi : \{1, \dots, M\} \rightarrow \mathcal{B}(n, \sigma)$ and decoder $\psi : \{0, 1\}^n \rightarrow \{1, \dots, M\}$ is called an $(n, M, \sigma, \varepsilon)_{\text{avg}}$ -code for the discretized channel W_n^n if

$$\frac{1}{M} \sum_{m=1}^M W_n^n(\psi^{-1}(m) | \phi(m)) \geq 1 - \varepsilon, \quad (35)$$

where $W^n : \mathcal{X}^n \rightarrow \mathcal{Y}^n$ stands for the n -fold product channel of a DMC $W : \mathcal{X} \rightarrow \mathcal{Y}$, i.e.,

$$W^n(\mathbf{y} | \mathbf{x}) := \prod_{i=1}^n W(y_i | x_i) \quad (36)$$

for each $\mathbf{x} = (x_1, \dots, x_n) \in \mathcal{X}^n$ and $\mathbf{y} = (y_1, \dots, y_n) \in \mathcal{Y}^n$.

Wyner's *ad hoc* assumption [17, Section II in Part I] constrains a $(T, M, A, \sigma, \varepsilon)_{\text{avg}}$ -code for the Poisson channel in a certain way so that the resultant channel code is equivalent—in a sense to be made precise in Lemma 1—to an $(n, M, \sigma, \varepsilon)_{\text{avg}}$ -code for the discretized channel W_n^n . In fact, the Poisson channel and its discretized channel W_n^n can be compared via a certain channel ordering, as shown in the following proposition.

Proposition 1. The Poisson channel is better in the Shannon sense than its discretized channel W_n^n , where we say that a channel V_1 is better in the Shannon sense than another channel V_2 if for each $n \geq 1$ and each code for V_2^n , say C_2 , there exists a code for V_1^n , say C_1 , with the same message size and the average probability of error of C_2 is no larger than that for C_1 (cf. [20, Problem 6.17(a)], [22], [23]).

Proof of Proposition 1: See Appendix A. ■

³If the dark current of the Poisson channel is zero, i.e., $\lambda_0 = 0$, then the channel $W_\Delta : \{0, 1\} \rightarrow \{0, 1\}$ is a Z-channel.

Therefore, it is clear that a $(T, M, A, \sigma, \varepsilon)_{\text{avg}}$ -code exists for the Poisson channel, provided that an $(n, M, \sigma, \varepsilon)_{\text{avg}}$ -code exists for the discretized channel W_n^n . This implies that

$$M_n^*(\sigma, \varepsilon) \leq M_{\text{avg}}^*(\lambda_0, T, A, \sigma, \varepsilon), \quad (37)$$

where $M_n^*(\sigma, \varepsilon)$ stands for the maximum integer M such that an $(n, M, \sigma, \varepsilon)_{\text{avg}}$ -code exists for the discretized channel W_n^n . Moreover, Wyner [17, Theorem 2.1 in Part II] showed that this discretization error is negligible for n large enough. The following lemma is a direct consequence of [17, Theorem 2.1 in Part II].

Lemma 1. *There exist a sequence $\epsilon_n = o(1)$ satisfying $0 < \epsilon_n < 1 - \varepsilon$ and a subsequence $\{n_k\}_{k=1}^\infty$ such that*

$$M_{n_k}^*(\sigma, \varepsilon + \epsilon_{n_k}) = M_{\text{avg}}^*(\lambda_0, T, A, \sigma, \varepsilon) \quad (38)$$

for every $k \geq 1$.

C. Proof of Converse Part of Theorem 2

It follows from Lemma 1 that

$$\log M_{\text{avg}}^*(\lambda_0, T, A, \sigma, \varepsilon) \leq \limsup_{n \rightarrow \infty} \log M_n^*(\sigma, \varepsilon + \epsilon_n), \quad (39)$$

therefore, it suffices to prove the following lemma to assert the converse part of Theorem 2.

Lemma 2. *For every $0 < \varepsilon < 1$, it holds that*

$$\limsup_{n \rightarrow \infty} \log M_n^*(\sigma, \varepsilon + \epsilon_n) \leq T C^* + \sqrt{T V^*} \Phi^{-1}(\varepsilon) + \log T + O(1) \quad (40)$$

as $T \rightarrow \infty$.

Proof of Lemma 2: Let P^* be the capacity-achieving input distribution (CAID) for the Poisson channel, i.e., it is the Bernoulli distribution with parameter p^* , where p^* is defined in (9). By the definitions of p^* and p_0 in (9) and (10), respectively, we see that

$$\min \left\{ \sigma, \frac{1}{e} \right\} \leq p^* \leq \min \left\{ \sigma, \frac{1}{2} \right\}. \quad (41)$$

For each $-p^* \leq u \leq 1 - p^*$, we define the u -shifted distribution $P_{[u]}^*$ from the CAID P^* as the Bernoulli distribution

$$P_{[u]}^*(x) = \begin{cases} 1 - (p^* + u) & \text{if } x = 0, \\ p^* + u & \text{if } x = 1. \end{cases} \quad (42)$$

Now, construct the distribution $Q^{(n)}$ on $\{0, 1\}^n$ as follows:⁴

$$Q^{(n)}(\mathbf{y}) := \frac{1}{3} \prod_{i=1}^n P_{[-\kappa]}^* W_n(y_i) + \frac{1}{3} \prod_{i=1}^n P_{[\kappa]}^* W_n(y_i) + \frac{1}{3F} \sum_{\substack{m=-\infty; \\ 0 \leq p^* + m/T \leq 1}} e^{-\gamma m^2/T} \prod_{i=1}^n P_{[m/T]}^* W_n(y_i) \quad (43)$$

for each $n \geq 1$ and $\mathbf{y} = (y_1, \dots, y_n) \in \{0, 1\}^n$, where the constant $\kappa > 0$ is given by

$$\kappa := \frac{1}{2} \min \left\{ \sigma, \frac{1}{e} \right\}, \quad (44)$$

the constant $\gamma > 0$ will be specified later (specifically in (90) of Section III-C3), and F is the normalization constant ensuring that

$$\sum_{\mathbf{y} \in \{0, 1\}^n} Q^{(n)}(\mathbf{y}) = 1. \quad (45)$$

Note that the third component of $Q^{(n)}$ is a convex combination of a set of exponentially-weighted distributions indexed by an appropriately constructed ϵ -net in the input probability simplex. Also, we note that F is positive, and it follows by the Gaussian integral that

$$F < \sum_{m=-\infty}^{\infty} e^{-\gamma m^2/T} < 1 + \int_{-\infty}^{\infty} e^{-\gamma m^2/T} dm = 1 + \sqrt{\frac{\pi T}{\gamma}}. \quad (46)$$

⁴Throughout the proof of Lemma 2, we assume that T is large enough so that there exists at least one m satisfying the condition of the third sum in (43).

Let $\mathbb{N} := \{1, 2, \dots\}$ be the set of positive integers, and η chosen so that⁵

$$0 < \eta < 1 - \varepsilon - \max_{n \in \mathbb{N}} \epsilon_n, \quad (47)$$

where $\{\epsilon_n\}_{n=1}^\infty$ is given in Lemma 1. For each $n \geq 1$, choose a sequence $\mathbf{x}^{(n)} = (x_1^{(n)}, \dots, x_n^{(n)}) \in \{0, 1\}^n$ satisfying

$$\mathbf{x}^{(n)} \in \arg \max_{\mathbf{x} \in \{0, 1\}^n : P_{\mathbf{x}}(1) \leq \sigma} D_s^{\varepsilon + \epsilon_n + \eta}(W_n^n(\cdot | \mathbf{x}) \| Q^{(n)}). \quad (48)$$

For short, we write

$$P_n := P_{\mathbf{x}^{(n)}}, \quad (49)$$

$$p_n := P_n(1), \quad (50)$$

$$r_n := P_n W_n(1). \quad (51)$$

Now consider the partition $\{\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3\}$ of \mathbb{N} given by

$$\mathcal{I}_1 := \{n \in \mathbb{N} \mid p_n \geq p^* + \kappa\}, \quad (52)$$

$$\mathcal{I}_2 := \{n \in \mathbb{N} \mid p_n \leq p^* - \kappa\}, \quad (53)$$

$$\mathcal{I}_3 := \{n \in \mathbb{N} \mid |p_n - p^*| < \kappa\}. \quad (54)$$

Clearly, at least one of the subsets $\mathcal{I}_1, \mathcal{I}_2, \mathcal{I}_3 \subset \mathbb{N}$ must be countably infinite. We shall divide the proof of Lemma 2 into three subsequences: $\{p_n\}_{n \in \mathcal{I}_1}$, $\{p_n\}_{n \in \mathcal{I}_2}$, and $\{p_n\}_{n \in \mathcal{I}_3}$, since the limit superior is the supremum of the set of subsequential limits.

1) *When \mathcal{I}_1 is countably infinite:* Assuming that \mathcal{I}_1 is countably infinite, we now prove Lemma 2 for the subsequence $\{p_n\}_{n \in \mathcal{I}_1}$, where note from (48) that \mathcal{I}_1 is nonempty only if $p^* = p_0 < \sigma$. For simplicity, we shall write $\mathcal{I}_1 = \{n_k\}_{k=1}^\infty$ in this subsubsection. Firstly, it follows from the symbol-wise converse bound (cf. [7, Proposition 6] or [8, Proposition 4.4]) that

$$\log M_n^*(\sigma, \varepsilon + \epsilon_n) \leq D_s^{\varepsilon + \epsilon_n + \eta}(W_n^n(\cdot | \mathbf{x}^{(n)}) \| Q^{(n)}) + \log \frac{1}{\eta} \quad (55)$$

for every $n \geq 1$. Secondly, it follows by the sifting property of the information spectrum divergence from a convex combination $Q^{(n)}$ (cf. [7, Lemma 3] or [8, Lemma 2.2]) that

$$D_s^{\varepsilon + \epsilon_n + \eta}(W_n^n(\cdot | \mathbf{x}^{(n)}) \| Q^{(n)}) \leq D_s^{\varepsilon + \epsilon_n + \eta}(W_n^n(\cdot | \mathbf{x}^{(n)}) \| (P_{[\kappa]}^* W_n)^n) + \log 3 \quad (56)$$

where κ is given in (44). Thirdly, it follows by Chebyshev's inequality (cf. [7, Equation (5)] or [8, Proposition 2.2]) that

$$D_s^{\varepsilon + \epsilon_n + \eta}(W_n^n(\cdot | \mathbf{x}^{(n)}) \| (P_{[\kappa]}^* W_n)^n) \leq n D_n + \sqrt{\frac{n V_n}{1 - \varepsilon - \epsilon_n - \eta}}, \quad (57)$$

where D_n and V_n are given by

$$D_n = \frac{1}{n} \sum_{i=1}^n D(W_n(\cdot | x_i^{(n)}) \| P_{[\kappa]}^* W_n), \quad (58)$$

$$V_n = \frac{1}{n} \sum_{i=1}^n V(W_n(\cdot | x_i^{(n)}) \| P_{[\kappa]}^* W_n). \quad (59)$$

As P_n is the type of $\mathbf{x}^{(n)} = (x_1^{(n)}, \dots, x_n^{(n)})$ (see (48) and (49)), note that

$$D_n = D(W_n \| P_{[\kappa]}^* W_n | P_n), \quad (60)$$

$$V_n = V(W_n \| P_{[\kappa]}^* W_n | P_n). \quad (61)$$

As shown in Appendix B, it holds that

$$n D_n = T \tilde{C}(p_n) + o(1) \quad (62)$$

as $n \rightarrow \infty$, where the mapping $\tilde{C} : [0, \sigma] \rightarrow [0, \infty)$ is defined by

$$\tilde{C}(u) := A \left((p^* + \kappa - u) + (1 - u) s \log \frac{s}{p^* + \kappa + s} + u(1 + s) \log \frac{1 + s}{p^* + \kappa + s} \right). \quad (63)$$

⁵The maximum value of $\{\epsilon_n\}_{n=1}^\infty$ exists, because $\epsilon_n = o(1)$ as $n \rightarrow \infty$.

After some algebra, it follows from the definition of p_0 in (10) that

$$\begin{aligned}\tilde{C}(u) &= A \left((p^* + \kappa) - u \left(1 + s \log \frac{s}{p^* + \kappa + s} - (1 + s) \log \frac{1 + s}{p^* + \kappa + s} \right) + s \log \frac{s}{p^* + \kappa + s} \right) \\ &= A \left((p^* + \kappa) + u \log \frac{(1 + s)^{1+s}}{s^s e (p^* + \kappa + s)} + s \log \frac{s}{p^* + \kappa + s} \right) \\ &= A \left((p^* + \kappa) + u \log \frac{p_0 + s}{p^* + \kappa + s} + s \log \frac{s}{p^* + \kappa + s} \right),\end{aligned}\quad (64)$$

where the last equality follows by the definition of p_0 in (10). Since $p^* = p_0 < \sigma$, equality (64) implies that $\tilde{C} : [0, 1] \rightarrow \mathbb{R}$ is a strictly decreasing function on $[0, 1]$. Thus, since $p^* + \kappa \leq p_{n_k} \leq \sigma$ for every $k \geq 1$, we have

$$\limsup_{k \rightarrow \infty} \tilde{C}(p_{n_k}) \leq \tilde{C}(p^* + \kappa) < C^*, \quad (65)$$

where the second inequality is due to [17, Equation (2.11) in Part I]. On the other hand, as shown in Appendix C, it holds that

$$\limsup_{n \rightarrow \infty} n V_n \leq 8 A T (p^* + \kappa + s). \quad (66)$$

Combining (55)–(57), (62), (65), and (66), we obtain

$$\begin{aligned}\limsup_{k \rightarrow \infty} \log M_{n_k}^*(\sigma, \varepsilon + \epsilon_{n_k}) &< T \tilde{C}(p^* + \kappa) + 2 \sqrt{\frac{2 A T (p^* + \kappa + s)}{1 - \varepsilon - \eta}} + \log \frac{1}{\eta} + \log 3 \\ &= T \tilde{C}(p^* + \kappa) + O(\sqrt{T}) \\ &\leq T C^* + o(1)\end{aligned}\quad (67)$$

as $T \rightarrow \infty$. Therefore, Lemma 2 holds for the subsequence $\{n_k\}_{k=1}^\infty = \mathcal{I}_1$.

2) *When \mathcal{I}_2 is countably infinite:* The proof can be done in the same way as Section III-C1 by replacing the input distribution $P_{[\kappa]}^*$ by $P_{[-\kappa]}^*$ in (56). Then, replacing every occurrence of $p^* + \kappa$ by $p^* - \kappa$, we can verify that Lemma 2 holds for the subsequence $\{n_k\}_{k=1}^\infty = \mathcal{I}_2$, provided that \mathcal{I}_2 is countably infinite.

3) *When \mathcal{I}_3 is countably infinite:* Assuming that \mathcal{I}_3 is countably infinite, we now prove Lemma 2 for the subsequence $\{p_n\}_{n \in \mathcal{I}_3}$. For brevity, we shall write $\mathcal{I}_3 = \{n_k\}_{k=1}^\infty$ in this subsection. Define the integer m_k as

$$m_k := \min \left\{ m \in \mathbb{Z} \mid p_{n_k} \leq p^* + \frac{m}{T} \right\} \quad (68)$$

for each $k \geq 1$. Since $p_{n_k} < p^* + \kappa$ for every $k \geq 1$ (see (54)), it follows that

$$m_k \leq \tilde{m}_T := \min \left\{ m \in \mathbb{Z} \mid \kappa \leq \frac{m}{T} \right\}. \quad (69)$$

Moreover, since $\tilde{m}_T/T \rightarrow \kappa$ as $T \rightarrow \infty$, there exists a $T_0 > 0$ satisfying

$$\frac{m_k}{T} \leq 2 \kappa < 1 - p^* \quad (70)$$

for every $k \geq 1$ and $T \geq T_0$; henceforth, assume that $T \geq T_0$. Denote by

$$\tilde{P}_k := P_{\{m_k/T\}}^* \quad (71)$$

$$\tilde{p}_k := \tilde{P}_k(1) = p^* + \frac{m_k}{T}, \quad (72)$$

$$\tilde{r}_k := \tilde{P}_k W_{n_k}(1) \quad (73)$$

for each $k \geq 1$. By the definition of \tilde{p}_k in (72), it is clear that \tilde{p}_k is bounded away from zero for all $k \geq 1$. It follows by the sifting property of the information spectrum divergence from a convex combination $Q^{(n)}$ (cf. [7, Lemma 3] or [8, Lemma 2.2]) that

$$D_s^{\varepsilon + \epsilon_{n_k} + \eta}(W_{n_k}^{n_k}(\cdot \mid \mathbf{x}^{(n_k)}) \parallel Q^{(n_k)}) \leq D_s^{\varepsilon + \epsilon_{n_k} + \eta}(W_{n_k}^{n_k}(\cdot \mid \mathbf{x}^{(n_k)}) \parallel (\tilde{P}_k W_{n_k})^{n_k}) + \log 3 + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} + \frac{\gamma m_k^2}{T} \right). \quad (74)$$

By the definition of \tilde{m}_T in (69), it follows that

$$m_k \leq T |p_{n_k} - p^*| + 1; \quad (75)$$

that is, Inequality (74) can be relaxed as

$$D_s^{\varepsilon+\epsilon_{n_k}+\eta}(W_{n_k}^{n_k}(\cdot | \mathbf{x}^{(n_k)}) \| Q^{(n_k)}) \leq D_s^{\varepsilon+\epsilon_{n_k}+\eta}(W_{n_k}^{n_k}(\cdot | \mathbf{x}^{(n_k)}) \| (\tilde{P}_k W_{n_k})^{n_k}) + \log 3 \\ + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) + \gamma \left(T(p_{n_k} - p^*)^2 + 2|p_{n_k} - p^*| + \frac{1}{T} \right). \quad (76)$$

On the other hand, it follows by the Berry–Esseen theorem (cf. [7, Lemma 5] or [8, Proposition 2.2]) that

$$D_s^{\varepsilon+\epsilon_{n_k}+\eta}(W_{n_k}^{n_k}(\cdot | \mathbf{x}^{(n_k)}) \| (P^* W_{n_k})^{n_k}) \leq n_k D_k + \sqrt{n_k V_k} \Phi^{-1} \left(\varepsilon + \epsilon_{n_k} + \eta + \frac{6 \Xi_k}{\sqrt{n_k V_k^3}} \right), \quad (77)$$

where D_k , V_k , and Ξ_k are given by

$$D_k = \frac{1}{n_k} \sum_{i=1}^{n_k} D(W_{n_k}(\cdot | x_i^{(n_k)}) \| \tilde{P}_k W_{n_k}), \quad (78)$$

$$V_k = \frac{1}{n_k} \sum_{i=1}^{n_k} V(W_{n_k}(\cdot | x_i^{(n_k)}) \| \tilde{P}_k W_{n_k}), \quad (79)$$

$$\Xi_k = \frac{1}{n_k} \sum_{i=1}^{n_k} \Xi(W_{n_k}(\cdot | x_i^{(n_k)}) \| \tilde{P}_k W_{n_k}). \quad (80)$$

As P_n is the type of $\mathbf{x}^{(n)} = (x_1^{(n)}, \dots, x_n^{(n)})$ (see (48) and (49)), it follows that

$$D_k = D(W_{n_k} \| \tilde{P}_k W_{n_k} | P_{n_k}), \quad (81)$$

$$V_k = V(W_{n_k} \| \tilde{P}_k W_{n_k} | P_{n_k}), \quad (82)$$

$$\Xi_k = \Xi(W_{n_k} \| \tilde{P}_k W_{n_k} | P_{n_k}). \quad (83)$$

As shown in Appendix D, it holds that

$$n_k D_k \leq T C^* - T(p_{n_k} - p^*)^2 G_1 + A + o(1) \quad (84)$$

as $k \rightarrow \infty$, where the constant $G_1 > 0$ (whose positivity is asserted and proved in Appendix D) is given by

$$G_1 := A \left(\log \frac{p_0 + s}{p^* + s} + \frac{1}{2(p^* + s)} \left(1 - \frac{\kappa}{3(p^* + s)} \right) \right). \quad (85)$$

Moreover, as shown in Appendix E, by exploiting the Lipschitz properties of the information variances, there exist two constants $\beta_1, \beta_2 > 0$ satisfying

$$\left| \sqrt{n_k V_k} - \sqrt{T V^*} \right| \leq \frac{\beta_1}{\sqrt{T}} + \sqrt{T} |p_{n_k} - p^*| \beta_2 + o(1) \quad (86)$$

as $k \rightarrow \infty$. Furthermore, as shown in Appendix F, assuming that $\eta = 1/\sqrt{T}$, there exist a constant $G_2 > 0$ and a positive sequence $\delta_k = o(1)$ (as $k \rightarrow \infty$) such that

$$\Phi^{-1} \left(\varepsilon + \epsilon_{n_k} + \frac{1}{\sqrt{T}} + \frac{6 \Xi_k}{\sqrt{n_k V_k^3}} \right) \leq \Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k) + \frac{G_2}{\sqrt{T}} \quad (87)$$

for sufficiently large k and T .

Finally, we obtain

$$\begin{aligned}
\log M_{n_k}^*(\sigma, \varepsilon + \epsilon_{n_k}) &\stackrel{(a)}{\leq} D_s^{\varepsilon + \epsilon_{n_k} + (1/\sqrt{T})}(W_{n_k}^{n_k}(\cdot \mid \mathbf{x}^{(n_k)}) \parallel Q^{(n_k)}) + \frac{1}{2} \log T \\
&\stackrel{(b)}{\leq} D_s^{\varepsilon + \epsilon_{n_k} + (1/\sqrt{T})}(W_{n_k}^{n_k}(\cdot \mid \mathbf{x}^{(n_k)}) \parallel (\tilde{P}_k W_{n_k})^{n_k}) + \log 3 \\
&\quad + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) + \gamma \left(T(p_{n_k} - p^*)^2 + 2 + \frac{1}{T} \right) + \frac{1}{2} \log T \\
&\stackrel{(c)}{\leq} n_k D_k + \sqrt{n_k V_k} \Phi^{-1} \left(\varepsilon + \epsilon_{n_k} + \frac{1}{\sqrt{T}} + \frac{6 \Xi_k}{\sqrt{n_k V_k^3}} \right) + \log 3 \\
&\quad + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) + \gamma \left(T(p_{n_k} - p^*)^2 + 2 + \frac{1}{T} \right) + \frac{1}{2} \log T \\
&\stackrel{(d)}{\leq} n_k D_k + \sqrt{n_k V_k} \left(\Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k) + \frac{G_2}{\sqrt{T}} \right) + \log 3 \\
&\quad + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) + \gamma \left(T(p_{n_k} - p^*)^2 + 2 + \frac{1}{T} \right) + \frac{1}{2} \log T \\
&\stackrel{(e)}{\leq} (T C^* - T(p_{n_k} - p^*)^2 G_1 + A) + \sqrt{n_k V_k} \left(\Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k) + \frac{G_2}{\sqrt{T}} \right) + \log 3 \\
&\quad + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) + \gamma \left(T(p_{n_k} - p^*)^2 + 2 + \frac{1}{T} \right) + \frac{1}{2} \log T \\
&\stackrel{(f)}{\leq} T C^* - T(p_{n_k} - p^*)^2 G_1 + A + \sqrt{T V^*} \Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k) + G_2 \left(\sqrt{V^*} + \frac{\beta_1}{T} + \beta_2 \right) \\
&\quad + \left(\frac{\beta_1}{T} + \sqrt{T} |p_{n_k} - p^*| \beta_2 \right) |\Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k)| + \log 3 \\
&\quad + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) + \gamma \left(T(p_{n_k} - p^*)^2 + 2 + \frac{1}{T} \right) + \frac{1}{2} \log T + o(1) \\
&\stackrel{(g)}{\leq} T C^* + \sqrt{T V^*} \Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k) + \frac{1}{2} \log T + \log \left(1 + \sqrt{\frac{\pi T}{\gamma}} \right) \\
&\quad + f \left(\sqrt{T} |p_{n_k} - p^*| \right) + \frac{\beta_1 (|\Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k)| + G_2) + \gamma}{T} + o(1)
\end{aligned} \tag{88}$$

as $k \rightarrow \infty$ and for sufficiently large T , where

- (a) follows from (55),
- (b) follows from (76),
- (c) follows from (77),
- (d) follows from (87),
- (e) follows from (84),
- (f) follows from (86), and
- (g) follows by defining the function $f : \mathbb{R} \rightarrow \mathbb{R}$ as

$$f(u) := u^2 (\gamma - G_1) + u \beta_2 |\Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k)| + G_2 \left(\sqrt{V^*} + \beta_2 \right) + A + \log 3 + 2 \gamma. \tag{89}$$

By choosing the constant $\gamma > 0$ in (43) sufficiently small so that

$$\gamma < G_1, \tag{90}$$

it follows by the maximization of the quadratic function (89), which has a negative leading coefficient, that

$$f \left(\sqrt{T} |p_{n_k} - p^*| \right) \leq \frac{\beta_2^2 \Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k)^2}{4(G_1 - \gamma)} + G_2 \left(\sqrt{V^*} + \beta_2 \right) + A + \log 3 + 2 \gamma \tag{91}$$

for sufficiently large k and T . Combining (88) and (91), we have

$$\limsup_{k \rightarrow \infty} \log M_{n_k}^*(\sigma, \varepsilon + \epsilon_{n_k}) \leq T C^* + \sqrt{T V^*} \Phi^{-1}(\varepsilon) + \log T + O(1) \tag{92}$$

as $T \rightarrow \infty$, proving Lemma 2 for the subsequence $\{n_k\}_{k=1}^\infty = \mathcal{I}_3$. This completes the proof of Lemma 2 ■

D. Proof of Achievability Part of Theorem 2

As shown in Section III-B, a channel coding problem for the Poisson channel can be reduced to that of a certain discrete memoryless channel under an additive cost constraint. Now, define a channel code under an average cost-constraint as follows:

Definition 3. Given a cost function $\chi : \mathcal{X} \rightarrow \mathbb{R}$, a pair of encoder $f : \{1, \dots, M\} \rightarrow \mathcal{X}$ and decoder $g : \mathcal{Y} \rightarrow \{1, \dots, M\}$ is called an $(M, \varepsilon, \beta)_{\text{avg}}$ -code for a channel $W : \mathcal{X} \rightarrow \mathcal{Y}$ if

$$\frac{1}{M} \sum_{m=1}^M W(g^{-1}(m) | f(m)) \geq 1 - \varepsilon, \quad (93)$$

and

$$\max_{m \in \{1, \dots, M\}} \chi \circ f(m) \leq \beta. \quad (94)$$

The following lemma is a straightforward generalization of the random coding union bound [5, Theorem 16].

Lemma 3. Let M be a positive integer and β a real. For any distribution P on \mathcal{X} and any channel $W : \mathcal{X} \rightarrow \mathcal{Y}$, there exists an $(M, \varepsilon, \beta)_{\text{avg}}$ -code satisfying

$$\varepsilon \leq \mathbb{P}\{\chi(X) > \beta\} + \mathbb{E} \left[\min \left\{ 1, (M-1) \mathbb{P} \left\{ \log \frac{W(Y | \bar{X})}{PW(Y)} \geq \log \frac{W(Y | X)}{PW(Y)} \mid X, Y \right\} \right\} \right], \quad (95)$$

where the r.v.'s X , Y , and \bar{X} are defined so that $\mathbb{P} \circ (X, Y)^{-1} = P \times W$, $\mathbb{P} \circ \bar{X}^{-1} = P$, and $(X, Y) \perp\!\!\!\perp \bar{X}$.

Proof of Lemma 3: See Appendix G. ■

To ensure that $\Delta_n = o(1)$ as $T \rightarrow \infty$, assume throughout the achievability proof that⁶

$$n = \lceil T^2 \rceil, \quad (96)$$

where Δ_n is defined in (31), and $\lceil u \rceil := \min\{z \in \mathbb{Z} \mid z \geq u\}$ stands for the ceiling function. Recall that the u -shifted distribution $P_{[u]}^*$ from the CAID P^* is defined in (42). For each $n \geq 1$, define the Bernoulli distribution P_n by⁷

$$P_n := P_{[u_n]}^* \quad (\text{with } u_n = -p^* n^{-1/4}). \quad (97)$$

It is clear that P_n converges to P^* in the variational distance topology as $T \rightarrow \infty$. Denote by

$$p_n := P_n(1), \quad (98)$$

$$r_n := P_n W_n(1) \quad (99)$$

the Bernoulli parameters of P_n and $P_n W_n$, respectively. Now, we have the following lemma.

Lemma 4. For n satisfying (96), the following asymptotic estimates hold:

$$n I(P_n, W_n) = T C^* + o(1), \quad (100)$$

$$n \tilde{V}(P_n, W_n) = T V^* + o(1), \quad (101)$$

$$n \tilde{\Xi}(P_n, W_n) = T \Xi^* + o(1) \quad (102)$$

as $T \rightarrow \infty$, where C^* and V^* are defined in (7) and (12), respectively, and Ξ^* is defined as

$$\Xi^* := A \left(p^* (1+s) \log^3 \frac{1+s}{p^*+s} - (1-p^*) s \log^3 \frac{s}{p^*+s} \right). \quad (103)$$

Proof of Lemma 4: See Appendix H. ■

For each $n \geq 1$, denote by

$$(X_{n,1}, Y_{n,1}), (X_{n,2}, Y_{n,2}), \dots, (X_{n,n}, Y_{n,n}) \quad (104)$$

i.i.d. pairs of r.v.'s with generic distribution $P_n \times W_n$. For short, we write the random vectors

$$X^n = (X_{n,1}, X_{n,2}, \dots, X_{n,n}), \quad (105)$$

$$Y^n = (Y_{n,1}, Y_{n,2}, \dots, Y_{n,n}). \quad (106)$$

⁶As a matter of fact, it suffices to assume in the achievability proof that $n = \omega(T)$ as $T \rightarrow \infty$. We assume, however, here that (96) holds to give an explicit dependence between n and T . This dependence affects some constants that appear later in the proof.

⁷The choice of parameter $u_n = -p^* n^{-1/4}$ is inspired by the delta-convention [20, Convention 2.11].

Lemma 5. *It holds that*

$$\mathbb{P}\{N(1 \mid X^n) > n\sigma\} \leq e^{-2(p^*)^2 T} \quad (107)$$

for sufficiently large T , where $N(a \mid \mathbf{z})$ denotes the number of occurrences of an element $a \in \mathcal{A}$ in the sequence $\mathbf{z} = (z_1, \dots, z_m) \in \mathcal{A}^m$, i.e.,

$$N(a \mid \mathbf{z}) := \left| \left\{ 1 \leq i \leq m \mid z_i = a \right\} \right|. \quad (108)$$

Proof of Lemma 5: See Appendix I. ■

Given a constant $0 < \kappa < 1$, define the event

$$\mathcal{E}_T := \left\{ N(1 \mid Y^n) > \mathbb{E}[N(1 \mid Y^n)] - \kappa(p^* + s)AT \right\} \quad (109)$$

for each $T > 0$, where note that

$$\mathbb{E}[N(1 \mid Y^n)] = \mathbb{E}\left[\sum_{i=1}^n Y_{n,i}\right] = nr_n, \quad (110)$$

because $Y_{n,1}, \dots, Y_{n,n}$ are i.i.d. Bernoulli r.v.'s with the same parameter r_n . The following lemma asserts that (109) is a high probability set asymptotically in the sense that the probability of its complement decays exponentially fast in T .

Lemma 6. *There exists a positive constant $K_0 = K_0(\kappa, \lambda_0, A, \sigma)$ satisfying*

$$\mathbb{P}(\mathcal{E}_T^c) \leq e^{-K_0 T} \quad (111)$$

for sufficiently large T , where \mathcal{S}^c stands for the complement of the set \mathcal{S} .

Proof of Lemma 6: See Appendix J. ■

For each $n \geq 1$ and $\mathbf{x}, \mathbf{y} \in \{0, 1\}^n$, define the information density

$$\iota_n(\mathbf{x} \wedge \mathbf{y}) := \log \frac{W_n^n(\mathbf{y} \mid \mathbf{x})}{(P_n W_n)^n(\mathbf{y})}. \quad (112)$$

Then, the following two lemmas, which are analogous to [5, Lemma 47], hold.

Lemma 7. *There exists a positive constant $K_1 = K_1(\kappa, \lambda_0, A, \sigma)$ such that*

$$\mathbf{1}_{\mathcal{E}_T} \mathbb{E}\left[e^{-\iota_n(X^n \wedge Y^n)} \mathbf{1}_{\{\iota_n(X^n \wedge Y^n) \geq \gamma\}} \mid Y^n\right] \leq \frac{K_1 e^{-\gamma}}{\sqrt{T}} \quad (113)$$

almost surely for every real γ and for sufficiently large T , where $\mathbf{1}_{\mathcal{E}}$ stands for the indicator function of the event \mathcal{E} .

Proof of Lemma 7: See Appendix K. ■

Lemma 8. *There exists a positive constant $K_2 = K_2(\lambda_0, A, \sigma)$ satisfying*

$$\mathbb{E}\left[e^{-\iota_n(X^n \wedge Y^n)} \mathbf{1}_{\{\iota_n(X^n \wedge Y^n) > \gamma\}}\right] \leq \frac{K_2 e^{-\gamma}}{\sqrt{T}} \quad (114)$$

for every real γ and for sufficiently large T .

Proof of Lemma 8: See Appendix L. ■

The following lemma is a final tool to prove the achievability part of Theorem 2.

Lemma 9. *There exists a positive constant $K_3 = K_3(\lambda_0, A, \sigma)$ satisfying*

$$\mathbb{P}\{\iota_n(X^n \wedge Y^n) \leq \gamma\} \leq \Phi\left(\frac{\gamma - nI(P_n, W_n)}{\sqrt{n\tilde{V}(P_n, W_n)}}\right) + \frac{K_3}{\sqrt{T}} \quad (115)$$

for every real γ and for sufficiently large T .

Proof of Lemma 9: See Appendix M. ■

Now, for each $n \geq 1$, we define the following numbers:

$$M_n := \lceil \exp(S_n + G_n) \rceil, \quad (116)$$

$$S_n := nI(P_n, W_n) + \sqrt{n\tilde{V}(P_n, W_n)}\Phi^{-1}(\varepsilon_n), \quad (117)$$

$$G_n := \frac{1}{2} \log T - \log K_1, \quad (118)$$

$$\varepsilon_n := \varepsilon - \frac{K_2 + K_3}{\sqrt{T}} - e^{-2(p^*)^2 T} - e^{-K_0 T}, \quad (119)$$

where the constants K_0, K_1, K_2 , and K_3 are given in Lemmas 6–9, respectively. Then, it follows from Lemma 4 that

$$\begin{aligned} \log M_n &\geq n I(P_n, W_n) + \sqrt{n \tilde{V}(P_n, W_n)} \Phi^{-1}\left(\varepsilon - \frac{K_2 + K_3}{\sqrt{T}} - e^{-2(p^*)^2 T} - e^{-K_0 T}\right) + \frac{1}{2} \log T - \log K_1 \\ &\stackrel{(a)}{=} (T C^* + o(1)) + \sqrt{T V^* + o(1)} \left(\Phi^{-1}(\varepsilon) + O\left(\frac{1}{\sqrt{T}}\right)\right) + \frac{1}{2} \log T + O(1) \\ &= T C^* + \sqrt{T V^*} \Phi^{-1}(\varepsilon) + \frac{1}{2} \log T + O(1) \end{aligned} \quad (120)$$

as $T \rightarrow \infty$, where in (a), we have also applied a Taylor series expansion of $\Phi^{-1}(\cdot)$ around ε .

Let \bar{X}^n be a r.v. satisfying $\mathbb{P} \circ (\bar{X}^n)^{-1} = P_n^n$ and $\bar{X}^n \perp\!\!\!\perp (X^n, Y^n)$. It follows from Lemma 3 that there exists an $(n, M_n, \sigma, \varepsilon')$ _{avg}-code for the discretized channel W_n^n such that

$$\begin{aligned} \varepsilon' &\leq \mathbb{E} \left[\min \left\{ 1, (M_n - 1) \mathbb{P} \{ \iota_n(\bar{X}^n \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \mid X^n, Y^n \} \right\} \right] + \mathbb{P} \left\{ \frac{1}{n} \sum_{i=1}^n X_{n,i} > \sigma \right\} \\ &\stackrel{(a)}{\leq} \mathbb{E} \left[\min \left\{ 1, (M_n - 1) \mathbb{P} \{ \iota_n(\bar{X}^n \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \mid X^n, Y^n \} \right\} \right] + e^{-2(p^*)^2 T} \\ &= \mathbb{E} \left[\min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} P_{\bar{X}^n}(\bar{x}) \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] + e^{-2(p^*)^2 T} \\ &= \mathbb{E} \left[\min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} \mathbb{P} \{ X^n = \bar{x} \mid Y^n \} \frac{(P W_n)^n(Y^n)}{W_n^n(Y^n \mid \bar{x})} \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] + e^{-2(p^*)^2 T} \\ &= \mathbb{E} \left[\min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} \mathbb{P} \{ X^n = \bar{x} \mid Y^n \} \exp(-\iota_n(\bar{x} \wedge Y^n)) \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] + e^{-2(p^*)^2 T} \\ &= \mathbb{E} \left[\mathbf{1}_{\mathcal{E}_T} \min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} \mathbb{P} \{ X^n = \bar{x} \mid Y^n \} \exp(-\iota_n(\bar{x} \wedge Y^n)) \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] \\ &\quad + \mathbb{E} \left[\mathbf{1}_{\mathcal{E}_T^c} \min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} \mathbb{P} \{ X^n = \bar{x} \mid Y^n \} \exp(-\iota_n(\bar{x} \wedge Y^n)) \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] + e^{-2(p^*)^2 T} \\ &\leq \mathbb{E} \left[\mathbf{1}_{\mathcal{E}_T} \min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} \mathbb{P} \{ X^n = \bar{x} \mid Y^n \} \exp(-\iota_n(\bar{x} \wedge Y^n)) \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] + e^{-2(p^*)^2 T} + \mathbb{P}(\mathcal{E}_T^c) \\ &\stackrel{(b)}{\leq} \mathbb{E} \left[\mathbf{1}_{\mathcal{E}_T} \min \left\{ 1, (M_n - 1) \sum_{\bar{x} \in \{0,1\}^n} \mathbb{P} \{ X^n = \bar{x} \mid Y^n \} \exp(-\iota_n(\bar{x} \wedge Y^n)) \mathbf{1}_{\{ \iota_n(\bar{x} \wedge Y^n) \geq \iota_n(X^n \wedge Y^n) \}} \right\} \right] + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &\stackrel{(c)}{\leq} \mathbb{E} \left[\min \left\{ 1, \frac{K_1 (M_n - 1) \exp(-\iota_n(X^n \wedge Y^n))}{\sqrt{T}} \right\} \right] + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &= \mathbb{E} \left[\mathbf{1}_{\left\{ \iota_n(X^n \wedge Y^n) \leq \log \frac{K_1 (M_n - 1)}{\sqrt{T}} \right\}} \min \left\{ 1, \frac{K_1 (M_n - 1) \exp(-\iota_n(X^n \wedge Y^n))}{\sqrt{T}} \right\} \right] \\ &\quad + \mathbb{E} \left[\mathbf{1}_{\left\{ \iota_n(X^n \wedge Y^n) > \log \frac{K_1 (M_n - 1)}{\sqrt{T}} \right\}} \min \left\{ 1, \frac{K_1 (M_n - 1) \exp(-\iota_n(X^n \wedge Y^n))}{\sqrt{T}} \right\} \right] + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &\leq \mathbb{P} \left\{ \iota_n(X^n \wedge Y^n) \leq \log \frac{K_1 (M_n - 1)}{\sqrt{T}} \right\} + \frac{K_1 (M_n - 1)}{\sqrt{T}} \mathbb{E} \left[\mathbf{1}_{\left\{ \iota_n(X^n \wedge Y^n) > \log \frac{K_1 (M_n - 1)}{\sqrt{T}} \right\}} \exp(-\iota_n(X^n \wedge Y^n)) \right] \\ &\quad + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &\stackrel{(d)}{\leq} \mathbb{P} \left\{ \iota_n(X^n \wedge Y^n) \leq \log \frac{K_1 (M_n - 1)}{\sqrt{T}} \right\} + \frac{K_2}{\sqrt{T}} + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &\stackrel{(e)}{\leq} \Phi \left(\frac{\log(M_n - 1) + \log K_1 - (1/2) \log T - n I(P_n, W_n)}{\sqrt{n \tilde{V}(P_n, W_n)}} \right) + \frac{K_2 + K_3}{\sqrt{T}} + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &\stackrel{(f)}{\leq} \Phi \left(\frac{S_n + G_n + \log K_1 - (1/2) \log T - n I(P_n, W_n)}{\sqrt{n \tilde{V}(P_n, W_n)}} \right) + \frac{K_2 + K_3}{\sqrt{T}} + e^{-2(p^*)^2 T} + e^{-K_0 T} \\ &\stackrel{(g)}{=} \varepsilon \end{aligned} \quad (121)$$

for sufficiently large T , where

- (a) follows from Lemma 5,
- (b) follows from Lemma 6,
- (c) follows from Lemma 7,
- (d) follows from Lemma 8,
- (e) follows from Lemma 9,
- (f) follows by the definition of M_n in (116), and
- (g) follows by the definitions of S_n , G_n , and ε_n in (117)–(119), respectively.

Therefore, it follows from (37) and (120) that the achievability bound of Theorem 2 is satisfied, completing the proof. \blacksquare

IV. CONCLUDING REMARKS

We have derived the optimal second-order coding rate for the continuous-time Poisson channel. We have also obtained bounds on the third-order coding rate. This is the first instance of a second-order asymptotic result for continuous-time communication models in information theory. While the high-level proof ideas of Theorem 2 are based on Wyner’s discretization argument [17] and standard techniques in second-order asymptotics [3]–[8], several novel finite blocklength techniques have to be introduced in both the converse and achievability arguments in view of the continuous-time nature of the Poisson channel. In the following two subsections, we summarize these technical contributions, partitioning our discussion into the converse and achievability parts of Theorem 2.

A. Technical Contributions in Proving Converse Part of Theorem 2

In the proof of Lemma 2, we constructed a somewhat artificial output distribution $Q^{(n)}$ in (43) to be substituted into the ϵ -information spectrum divergence in (48). This construction of our choice of $Q^{(n)}$ is partly inspired by Tomamichel and Tan’s choice of the output distribution [7, Equation (6)], which was used to derive a tight third-order converse term for the fundamental limit of DMCs having positive channel dispersions [7, Proposition 8] (see also [8, Section 4.2.3]). Tomamichel and Tan’s choice is a hybrid between Hayashi’s choice of the output distribution used in [4, Section X-A] and another artificial output distribution based on the construction of an appropriate ϵ -net in the output probability simplex. Tomamichel and Tan’s and Hayashi’s choices cannot, however, be used to prove Lemma 2 even up to the second-order converse term $\sqrt{T} V^* \Phi^{-1}(\epsilon)$ in (40). This is because both choices require the application of the type counting lemma [20, Lemma 2.2] (see also [20, Problem 2.1]) in the approximation arguments. In contrast, due to the continuous nature of the Poisson channel and Wyner’s discretization argument, we have to take the limit superior in n on the left-hand side of (40). To ameliorate this problem, we constructed $Q^{(n)}$ in (43), whose third part consists of a convex combination of exponentially-weighted output distributions indexed by elements of an ϵ -net in the *input* probability simplex. This differs from Tomamichel and Tan’s work [7] in which they considered an ϵ -net for the *output* probability simplex. Moreover, while Tomamichel and Tan’s construction of the ϵ -net can yield a uniformly bounded normalization constant F , our construction in the third part of (43) cannot yield a uniformly bounded normalization constant F with respect to $T > 0$, but our construction yields an F that scaled as $O(\sqrt{T})$ as $T \rightarrow \infty$; see (46). This construction, and resulting unboundedness with respect to T , appears to be required to handle the continuous nature of Poisson channel. Because $F = O(\sqrt{T})$ as $T \rightarrow \infty$, our upper bound on the third-order coding rate, as shown in (14), is $\leq \log T + O(1)$ as $T \rightarrow \infty$, which differs slightly from the lower bound which reads $\geq (1/2) \log T + O(1)$ as $T \rightarrow \infty$.

B. Technical Contributions in Proving Achievability Part of Theorem 2

The proof of the achievability part of Theorem 2 is inspired by Polyanskiy’s technique to prove the second- and third-order asymptotics for non-singular DMCs (cf. [6, Section 3.4.5]). We note, however, that Polyanskiy’s proof [6, Section 3.4.5] holds for codes without a cost constraint. Moreover, although the (symbol-wise) discretized channel W_n is non-singular, it depends on n (see (29)–(31)). Thus, Polyanskiy’s technique cannot be adapted in a straightforward manner to yield the achievability part of Theorem 2. To adapt Polyanskiy’s technique to prove the third-order term for the Poisson channel, we first slightly generalize the random coding union bound so that it is amenable to handling cost constraints; this is stated in Lemma 3. By constructing an input distribution that is slightly perturbed from the CAID in (97) and using the concentration bound in Lemma 5, we were able to bound the probability that the cost constraint is violated. The choice of (97) and Lemma 5 are inspired by the delta-convention⁸ [20, Convention 2.11] and its consequent lemma [20, Lemma 2.12 or Problem 3.18(b)], respectively. Here, it is worth pointing out that if $p_0 < \sigma$, i.e., if the weight constraint in (34) is not tight, then it suffices to employ the CAID P^* (and not a perturbed version of it in (97)) to generate the random code. Next, we defined and analyzed a high-probability event \mathcal{E}_T of (109); this event replaces Polyanskiy’s choice in [6, Equation (3.318)]. In Lemma 6, the probability of \mathcal{E}_T^C was shown to be appropriately bounded by appealing to a modified logarithmic Sobolev inequality (see Remark 1 of Appendix J). We showed in Lemma 7 that conditioned on \mathcal{E}_T , each of the terms in the generalized random coding union bound can be appropriately bounded.

⁸The delta-convention is a technical assumption frequently used in the method of types [20] to assert that the strongly typical set is a high-probability set.

We note that there are other techniques to show that $+(1/2) \log n + O(1)$ is third-order achievable for certain channels sources; see, for example [9]–[12], [24]. For example, Tan and Tomamichel [10] showed that $+(1/2) \log n + O(1)$ is third-order achievable for the additive white Gaussian noise channel. However, while the key idea in [10] is to use Laplace's approximation to bound a certain probability, in the proof of Lemma 7 in Appendix K, we applied the Berry–Esseen theorem judiciously to bound the analogous probability.

APPENDIX A PROOF OF PROPOSITION 1

Given two channels $W_1 : \mathcal{X} \rightarrow \mathcal{Y}$ and $W_2 : \mathcal{Y} \rightarrow \mathcal{Z}$, denote by $W_1 W_2 : \mathcal{X} \rightarrow \mathcal{Z}$ the concatenation⁹ of W_1 and W_2 , i.e.,

$$(W_1 W_2)(z | x) := \mathbb{E}[W_2(z | Y_x)] \quad (122)$$

for each $(x, z) \in \mathcal{X} \times \mathcal{Z}$ with a certain r.v. Y_x satisfying $\mathbb{P} \circ Y_x^{-1} = W_1(\cdot | x)$. Let $W_{\lambda_0} : \mathcal{W}(T, A, \sigma) \rightarrow \mathcal{S}(T)$ be the Poisson channel defined in Section II. By the same argument as Wyner's *ad hoc* assumption [17, Section II in Part I], the discretized channel $W_n^n : \mathcal{B}(n, \sigma) \rightarrow \{0, 1\}^n$ defined in Section III-B can be seen as a concatenation of four channels

$$W_n^n = U W_{\lambda_0} V_1 V_2, \quad (123)$$

where the channel $U : \mathcal{B}(n, \sigma) \rightarrow \mathcal{W}(T, A, \sigma)$ is given by

$$U(\lambda | x_1, \dots, x_n) = \prod_{i=1}^n \mathbf{1}\{\lambda(t) = x_i A \quad \forall t \in ((i-1)\Delta_n, i\Delta_n]\}, \quad (124)$$

the channel $V_1 : \mathcal{S}(T) \rightarrow (\mathbb{N} \cup \{0\})^n$ is given by

$$V_1(\hat{y}_1, \dots, \hat{y}_n | v_0^T) = \prod_{i=1}^n \mathbf{1}\{\hat{y}_i = v(i\Delta_n) - v((i-1)\Delta_n)\}, \quad (125)$$

and the channel $V_2 : (\mathbb{N} \cup \{0\})^n \rightarrow \{0, 1\}^n$ is given by

$$V_2(y_1, \dots, y_n | \hat{y}_1, \dots, \hat{y}_n) = \prod_{i=1}^n (\mathbf{1}\{y_i = \hat{y}_i\} + \mathbf{1}\{y_i = 0 \text{ and } \hat{y}_i \geq 2\}). \quad (126)$$

Therefore, we can obtain Proposition 1 by considering appropriate stochastic encoder and decoder induced by U and $V_1 V_2$, respectively (cf. [20, Problem 6.17(b)], [22], [23]). This completes the proof of Proposition 1. ■

APPENDIX B PROOF OF (62)

Denote by

$$r'_n := P_{[\kappa]}^* W_n(1) = (1 - p^* - \kappa) a_n + (p^* + \kappa) b_n \quad (127)$$

the parameter of the Bernoulli distribution $P_{[\kappa]}^* W_n$, where a_n and b_n are defined in (32) and (33), respectively. Note that the following asymptotic equivalences hold:

$$a_n \sim \frac{s A T}{n}, \quad (128)$$

$$b_n \sim \frac{(1+s) A T}{n}, \quad (129)$$

$$r_n \sim \frac{(p_n + s) A T}{n}, \quad (130)$$

$$r'_n \sim \frac{(p^* + \kappa + s) A T}{n} \quad (131)$$

⁹Clearly, this concatenation operator is associative, as in the matrix multiplication.

as $n \rightarrow \infty$, where r_n is defined in (51). Then, we observe that

$$\begin{aligned}
D_n &\stackrel{(a)}{=} (1 - r_n) \log \frac{1}{1 - r_n^*} + r_n \log \frac{1}{r_n'} - (1 - p_n) h(a_n) - p_n h(b_n) \\
&\stackrel{(b)}{=} r_n' + r_n \log \frac{1}{r_n'} - (1 - p_n) h(a_n) - p_n h(b_n) + o(n^{-1}) \\
&\stackrel{(c)}{=} r_n' + r_n \log \frac{1}{r_n'} - (1 - p_n) a_n \log \frac{1}{a_n} - (1 - p_n) a_n - p_n b_n \log \frac{1}{b_n} - p_n b_n + o(n^{-1}) \\
&\stackrel{(d)}{=} (r_n' - r_n) + (1 - p_n) a_n \log \frac{a_n}{r_n'} - p_n b_n \log \frac{b_n}{r_n'} + o(n^{-1}) \\
&\stackrel{(e)}{=} \frac{AT}{n} \left((p^* + \kappa - p_n) + (1 - p_n) s \log \frac{s}{p^* + \kappa + s} + p_n (1 + s) \log \frac{1 + s}{p^* + \kappa + s} \right) + o(n^{-1})
\end{aligned} \tag{132}$$

as $n \rightarrow \infty$, where

- (a) follows by (60) and the definition of binary entropy function $h : u \mapsto -u \log u - (1 - u) \log(1 - u)$,
- (b) follows by the asymptotic equivalences as stated in (130)–(131) and $-\log(1 - u) \sim u$ as $u \rightarrow 0$,
- (c) follows by the asymptotic equivalences as stated in (128)–(129) and $-(1 - u) \log(1 - u) \sim u$ as $u \rightarrow 0$,
- (d) follows by the definition of $r_n := P_n W_n(1) = (1 - p_n) a_n + p_n b_n$ in (51), and
- (e) follows by the asymptotic equivalences as stated in (128)–(131).

Equation (132) indeed implies (62), as desired. ■

APPENDIX C PROOF OF (66)

Define the binary relative varentropy $v(p \| q)$ by

$$v(p \| q) := p \left(\log \frac{p}{q} - d(p \| q) \right)^2 + (1 - p) \left(\log \frac{1 - p}{1 - q} - d(p \| q) \right)^2, \tag{133}$$

for each $0 \leq p, q \leq 1$, where $d(p \| q)$ stands for the binary relative entropy defined by

$$d(p \| q) := p \log \frac{p}{q} + (1 - p) \log \frac{1 - p}{1 - q}. \tag{134}$$

After some algebra, we obtain

$$v(p \| q) = p(1 - p) \log^2 \left(\frac{p}{1 - p} \frac{1 - q}{q} \right). \tag{135}$$

Now, a direct calculation yields

$$\begin{aligned}
V_n &\stackrel{(a)}{=} (1 - p_n) v(a_n \| r_n') + p_n v(b_n \| r_n') \\
&\stackrel{(b)}{=} (1 - p_n) a_n \log^2 \left(\frac{a_n}{1 - a_n} \frac{1 - r_n'}{r_n'} \right) + p_n b_n (1 - b_n) \log^2 \left(\frac{b_n}{1 - b_n} \frac{1 - r_n'}{r_n'} \right) \\
&\stackrel{(c)}{=} \frac{AT}{n} \left((1 - p_n) s \log^2 \frac{s}{p^* + \kappa + s} + p_n (1 + s) \log^2 \frac{1 + s}{p^* + \kappa + s} \right) + o(n^{-1})
\end{aligned} \tag{136}$$

as $n \rightarrow \infty$, where

- (a) follows from (61) and the definition of r_n' in (127),
- (b) follows from (135), and
- (c) follows from the asymptotic equivalences as stated in (128)–(131).

We now employ the following inequality¹⁰.

Lemma 10 ([25, Lemma 1]). *For every $u > 0$ and $q > r$, it holds that $\ln_q u \leq \ln_r u$ with equality if and only if $u = 1$, where $\ln_q : (0, \infty) \rightarrow \mathbb{R}$ stands for the q -logarithm function [26] defined by*

$$\ln_q u := \begin{cases} \frac{u^{1-q} - 1}{1 - q} & \text{if } q \neq 1, \\ \log u & \text{if } q = 1. \end{cases} \tag{137}$$

It follows from Lemma 10 with $q = 1$ and $r = 1/2$ that

$$\log u \leq 2(\sqrt{u} - 1) < 2\sqrt{u} \tag{138}$$

¹⁰Lemma 10 is a generalization of the well-known information theoretic inequalities: $1 - x^{-1} \leq \log x \leq x - 1$.

for every $u > 0$. Now, we have

$$\begin{aligned}
\limsup_{n \rightarrow \infty} n V_n &\stackrel{(a)}{=} A T \limsup_{n \rightarrow \infty} \left((1 - p_n) s \log^2 \frac{s}{p^* + \kappa + s} + p_n (1 + s) \log^2 \frac{1 + s}{p^* + \kappa + s} \right) \\
&< A T \left(s \log^2 \frac{s}{p^* + \kappa + s} + (1 + s) \log^2 \frac{1 + s}{p^* + \kappa + s} \right) \\
&\stackrel{(b)}{<} 4 A T \left(s \left(\frac{p^* + \kappa + s}{s} \right) + (1 + s) \left(\frac{p^* + \kappa + s}{1 + s} \right) \right) \\
&= 8 A T (p^* + \kappa + s),
\end{aligned} \tag{139}$$

where

- (a) follows from (136), and
- (b) follows from (138).

This completes the proof of (66). ■

APPENDIX D PROOF OF (84)

After some algebra, we observe that

$$D(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k}) = I(P_{n_k}, W_{n_k}) + D(P_{n_k} W_{n_k} \parallel \tilde{P}_k W_{n_k}) \tag{140}$$

for each $k \geq 1$, and one has¹¹

$$\begin{aligned}
D(P_{n_k} W_{n_k} \parallel \tilde{P}_k W_{n_k}) &\stackrel{(a)}{=} r_{n_k} \log \frac{r_{n_k}}{\tilde{r}_k} + (1 - r_{n_k}) \log \frac{1 - r_{n_k}}{1 - \tilde{r}_k} \\
&\stackrel{(b)}{=} \frac{(p_{n_k} + s) A T}{n_k} \log \frac{p_{n_k} + s}{\tilde{p}_k + s} + (1 - r_{n_k}) \log \frac{1 - r_{n_k}}{1 - \tilde{r}_k} + o(n_k^{-1}) \\
&\stackrel{(c)}{\leq} (1 - r_{n_k}) \log \frac{1 - r_{n_k}}{1 - \tilde{r}_k} + o(n_k^{-1}) \\
&\leq \log \frac{1 - r_{n_k}}{1 - \tilde{r}_k} + o(n_k^{-1}) \\
&\stackrel{(d)}{=} \frac{A T}{n_k} (\tilde{p}_k - p_{n_k}) + o(n_k^{-1}) \\
&\stackrel{(e)}{=} \frac{A T}{n_k} \left(p^* + \frac{m_k}{T} - p_{n_k} \right) + o(n_k^{-1}) \\
&\stackrel{(f)}{\leq} \frac{A T}{n_k} \left(p^* + \frac{m_k}{T} - p^* - \frac{m_k - 1}{T} \right) + o(n_k^{-1}) \\
&= \frac{A}{n_k} + o(n_k^{-1})
\end{aligned} \tag{141}$$

as $k \rightarrow \infty$, where

- (a) follows from the definitions of r_{n_k} and \tilde{r}_k in (51) and (73), respectively,
- (b) follows from the facts that

$$r_n \sim \frac{(p_n + s) A T}{n} \quad (\text{as } n \rightarrow \infty), \tag{142}$$

$$\tilde{r}_k \sim \frac{(\tilde{p}_k + s) A T}{n_k} \quad (\text{as } k \rightarrow \infty), \tag{143}$$

- (c) follows from the definitions of \tilde{m}_T and \tilde{p}_k in (69) and (72), respectively, implying that $p_{n_k} \leq \tilde{p}_k$ or

$$\log \frac{p_{n_k} + s}{\tilde{p}_k + s} \leq 0, \tag{144}$$

- (d) follows from (196)–(143) and the fact that

$$\log(1 - u) \sim -u \quad (\text{as } u \rightarrow 0), \tag{145}$$

- (e) follows by the definition of \tilde{p}_k in (72), and

¹¹While Tomamichel and Tan [7, Property 4 of Lemma 7] gave an upper bound on the relative entropy $D(P \parallel Q)$ by the reverse Pinsker inequality $\leq |P - Q|^2 / Q_{\min}$ to prove [7, Proposition 8], we cannot get a useful upper bound by the reverse Pinsker inequality to prove the second-order converse of the Poisson channel, because for the Poisson channel, it holds that $Q_{\min} = \Theta(n_k^{-1})$ as $k \rightarrow \infty$.

- (f) follows by the definition of m_k in (69).

On the other hand, one can see in the same way as Appendix B that

$$I(P_{n_k}, W_{n_k}) = \frac{T}{n_k} g(p_{n_k}) + o(n_k^{-1}) \quad (146)$$

as $k \rightarrow \infty$, where the function $g : [0, 1] \rightarrow \mathbb{R}$ is defined by

$$g(u) := A \left((1-u)s \log \frac{s}{u+s} + u(1+s) \log \frac{1+s}{u+s} \right). \quad (147)$$

Direct calculations show

$$\begin{aligned} \frac{d}{du} g(u) &= A \left(s \left(-\log s + s \log(u+s) - \frac{1-u}{u+s} \right) + (1+s) \left(\log(1+s) - \log(u+s) - \frac{u}{u+s} \right) \right) \\ &= A \log \left(\frac{(1+s)^{1+s}}{s^s e} \frac{1}{u+s} \right) \\ &= A \log \frac{p_0 + s}{u+s}, \end{aligned} \quad (148)$$

$$\frac{d^2}{du^2} g(u) = -\frac{A}{u+s}, \quad (149)$$

$$\frac{d^3}{du^3} g(u) = \frac{A}{(u+s)^2}, \quad (150)$$

$$\frac{d^4}{du^4} g(u) = -\frac{2A}{(u+s)^3}, \quad (151)$$

where p_0 is defined in (10). Now, it follows from (9) that¹²

$$\left. \frac{d}{du} g(u) \right|_{u=p^*} = A \log \frac{p_0 + s}{p^* + s} = \begin{cases} = 0 & \text{if } p_0 \leq \sigma, \\ > 0 & \text{if } p_0 > \sigma, \end{cases} \quad (152)$$

and it follows from (10), (48), and (50) that $p_{n_k} < p^*$ if $p_0 > \sigma$. Therefore, it follows by Taylor's theorem applied to $g(\cdot)$ around p^* that there exists a real number \hat{p} between p^* and p_{n_k} such that¹³

$$\begin{aligned} g(p_{n_k}) &= g(p^*) + \left(\left. \frac{d}{du} g(u) \right|_{u=p^*} \right) (p_{n_k} - p^*) + \left(\left. \frac{d^2}{du^2} g(u) \right|_{u=p^*} \right) \frac{(p_{n_k} - p^*)^2}{2} \\ &\quad + \left(\left. \frac{d^3}{du^3} g(u) \right|_{u=p^*} \right) \frac{(p_{n_k} - p^*)^3}{6} + \left(\left. \frac{d^4}{du^4} g(u) \right|_{u=\hat{p}} \right) \frac{(p_{n_k} - p^*)^4}{24} \\ &= g(p^*) - |p_{n_k} - p^*| A \log \frac{p_0 + s}{p^* + s} - \frac{A (p_{n_k} - p^*)^2}{2 (p^* + s)} + \frac{A (p_{n_k} - p^*)^3}{6 (p^* + s)^2} - \frac{A (p_{n_k} - p^*)^4}{12 (\hat{p} + s)^3} \\ &\leq g(p^*) - |p_{n_k} - p^*| A \log \frac{p_0 + s}{p^* + s} - \frac{A (p_{n_k} - p^*)^2}{2 (p^* + s)} + \frac{A (p_{n_k} - p^*)^3}{6 (p^* + s)^2} \\ &= g(p^*) - |p_{n_k} - p^*| A \log \frac{p_0 + s}{p^* + s} - \frac{A (p_{n_k} - p^*)^2}{2 (p^* + s)} \left(1 - \frac{p_{n_k} - p^*}{3 (p^* + s)} \right) \\ &\stackrel{(a)}{\leq} g(p^*) - (p_{n_k} - p^*)^2 A \log \frac{p_0 + s}{p^* + s} - \frac{A (p_{n_k} - p^*)^2}{2 (p^* + s)} \left(1 - \frac{p_{n_k} - p^*}{3 (p^* + s)} \right) \\ &\stackrel{(b)}{\leq} g(p^*) - (p_{n_k} - p^*)^2 A \log \frac{p_0 + s}{p^* + s} - \frac{A (p_{n_k} - p^*)^2}{2 (p^* + s)} \left(1 - \frac{\kappa}{3 (p^* + s)} \right) \end{aligned} \quad (153)$$

for each $k \geq 1$, where

- (a) follows from (152) and the fact that

$$(p_{n_k} - p^*)^2 < |p_{n_k} - p^*| < 1, \quad (154)$$

and

- (b) follows by the definition of $\mathcal{I}_3 = \{n_k\}_{k=1}^\infty$ in (54).

¹²The first-order derivative in (152) is zero for the usual discrete memoryless channels (DMCs) without cost-constraint. However, the first-order derivative in (152) can be positive when there is a cost constraint on the codewords.

¹³The upper bound (153) is a counterpart of [7, Property 3 in Lemma 7].

Note from (152) that the second term

$$-(p_{n_k} - p^*)^2 A \log \frac{p_0 + s}{p^* + s} \quad (155)$$

in (153) is zero if $p_0 \leq \sigma$, and is negative if $p_0 > \sigma$. In any case, we have from (153) that $g(p_{n_k}) \leq g(p^*) - (\text{positive const.}) \times (p_{n_k} - p^*)^2$. By the definitions of C^* and $g(\cdot)$ in (7) and (147), respectively, it is clear that

$$g(p^*) = C^*. \quad (156)$$

Hence, we obtain

$$\begin{aligned} n_k D(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k}) & \\ & \stackrel{(a)}{=} n_k I(P_{n_k}, W_{n_k}) + n_k D(P_{n_k} W_{n_k} \parallel \tilde{P}_k W_{n_k}) \\ & \stackrel{(b)}{\leq} n_k I(P_{n_k}, W_{n_k}) + A + o(1) \\ & \stackrel{(c)}{\leq} T C^* - T (p_{n_k} - p^*)^2 A \left(\log \frac{p_0 + s}{p^* + s} + \frac{1}{2(p^* + s)} \left(1 - \frac{\kappa}{3(p^* + s)} \right) \right) + A + o(1) \end{aligned} \quad (157)$$

as $k \rightarrow \infty$, where

- (a) follows from (140),
- (b) follows from (141), and
- (c) follows from (146), (153), and (156).

Here, note that the terms in parentheses in the second term in (157) is strictly positive, i.e.,

$$\log \frac{p_0 + s}{p^* + s} + \frac{1}{2(p^* + s)} \left(1 - \frac{\kappa}{3(p^* + s)} \right) > 0, \quad (158)$$

because of (41), (44), and (152). This completes the proof of (84) with the identification of G_1 as the constant in (158). ■

APPENDIX E PROOF OF (86)

Similar to (136), we may observe that

$$n_k V(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k}) = T \tilde{v}(p_{n_k}, \tilde{p}_k) + o(1) \quad (159)$$

as $k \rightarrow \infty$, where the mapping $\tilde{v} : [0, 1] \times [0, 1] \rightarrow \mathbb{R}$ is defined by

$$\tilde{v}(t, u) := A \left((1-t) s \log^2 \frac{s}{u+s} + t(1+s) \log^2 \frac{1+s}{u+s} \right). \quad (160)$$

Since $\sqrt{\tilde{v}(t, u)}$ is a continuously differentiable function of $u \in (0, 1]$ for each fixed $t \in [0, 1]$, and since \tilde{p}_k and p_{n_k} are bounded away from zero for all $k \geq 1$, it follows by the Lipschitz continuity¹⁴ of $u \mapsto \sqrt{\tilde{v}(t, u)}$ that there exists a Lipschitz constant $\beta_1(t) > 0$ satisfying

$$\begin{aligned} \left| \sqrt{\tilde{v}(t, \tilde{p}_k)} - \sqrt{\tilde{v}(t, p_{n_k})} \right| & \leq \beta_1(t) |\tilde{p}_k - p_{n_k}| \\ & \stackrel{(b)}{=} \beta_1(t) \left(p^* + \frac{m_k}{T} - p_{n_k} \right) \\ & \stackrel{(c)}{\leq} \beta_1(t) \left(p^* + \frac{m_k}{T} - p^* - \frac{m_k - 1}{T} \right) \\ & = \frac{\beta_1(t)}{T} \end{aligned} \quad (161)$$

for every $k \geq 1$ and $0 \leq t \leq 1$, where

- (a) follows by the definition of \tilde{p}_k in (72), and
- (b) follows by the definition of m_k in (69).

Here, it can be verified by a direct calculation of the partial derivative of $u \mapsto \sqrt{\tilde{v}(t, u)}$ with fixed t that the Lipschitz constant $\beta_1(t)$ is continuous in $t \in [0, 1]$. Moreover, as p_{n_k} belongs to the closed interval $[p^* - \kappa, p^* + \kappa]$ (see (54)), inequality (161) can be uniformly relaxed as

$$\left| \sqrt{\tilde{v}(p_{n_k}, \tilde{p}_k)} - \sqrt{\tilde{v}(p_{n_k}, p_{n_k})} \right| \leq \frac{\beta_1}{T} \quad (162)$$

¹⁴Note that every continuously differentiable function is Lipschitz continuous and the Lipschitz constant can be taken to be the supremum of the absolute value of the first derivative (over its domain).

for every $k \geq 1$, where the absolute constant $\beta_1 > 0$ is given by

$$\beta_1 := \max_{t \in [p^* - \kappa, p^* + \kappa]} \beta_1(t). \quad (163)$$

Analogously, since $\sqrt{\tilde{v}(t, t)}$ is a continuously differentiable function of $t \in (0, 1]$, it follows by the Lipschitz continuity of $t \mapsto \sqrt{\tilde{v}(t, t)}$ that there exists an absolute constant $\beta_2 > 0$ satisfying

$$\left| \sqrt{\tilde{v}(p_{n_k}, p_{n_k})} - \sqrt{\tilde{v}(p^*, p^*)} \right| \leq \beta_2 |p_{n_k} - p^*| \quad (164)$$

for every $k \geq 1$. By the definitions of V^* and $\tilde{v}(\cdot, \cdot)$ in (12) and (160), respectively, it is clear that

$$\tilde{v}(p^*, p^*) = V^* \quad (165)$$

Combining (159), (161), (164), and (165), it follows by the triangle inequality that

$$\left| \sqrt{n_k V(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k})} - \sqrt{T V^*} \right| \leq \frac{\beta_1}{\sqrt{T}} + \sqrt{T} |p_{n_k} - p^*| \beta_2 + o(1) \quad (166)$$

as $k \rightarrow \infty$. This completes the proof of (86). \blacksquare

APPENDIX F PROOF OF (87)

Since $(t, u) \mapsto \sqrt{\tilde{v}(t, u)}$ is continuous and positive on $(0, 1) \times (0, 1)$, and since p_{n_k} and \tilde{p}_k are in the closed intervals $[p^* - \kappa, p^* + \kappa]$ and $[p^* - \kappa, p^* + 2\kappa]$, respectively (see (54), (69), (70), and (72)), it follows by the extreme value theorem that there exists a constant $v_{\min} > 0$ satisfying

$$\sqrt{v(p_{n_k}, \tilde{p}_k)} \geq v_{\min} \quad (167)$$

for every $k \geq 1$ yielding together with (159) that

$$n_k V(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k}) \geq T v_{\min} + \zeta_k \quad (168)$$

for some $\zeta = o(1)$ as $k \rightarrow \infty$.

Now, define the binary absolute and central third-moment divergence by

$$\xi(p \parallel q) := p \left| \log \frac{p}{q} - d(p \parallel q) \right|^3 + (1-p) \left| \log \frac{1-p}{1-q} - d(p \parallel q) \right|^3 \quad (169)$$

for each $0 \leq p, q \leq 1$ and where $d(p \parallel q)$ is defined in (134). Similar to (135), we see that

$$\xi(p \parallel q) = p(1-p)(p^2 + (1-p)^2) \left| \log^3 \left(\frac{p}{1-p} \frac{1-q}{q} \right) \right|. \quad (170)$$

Then, we obtain

$$\begin{aligned} \Xi_k &\stackrel{(a)}{=} (1-p_{n_k}) \xi(a_{n_k} \parallel \tilde{r}_k) + p_{n_k} \xi(b_{n_k} \parallel \tilde{r}_k) \\ &\stackrel{(b)}{=} (1-p_{n_k}) a_{n_k} (1-a_{n_k}) (a_{n_k}^2 + (1-a_{n_k})^2) \left| \log^3 \left(\frac{a_{n_k}}{1-a_{n_k}} \frac{1-\tilde{r}_k}{\tilde{r}_k} \right) \right| \\ &\quad + p_{n_k} b_{n_k} (1-b_{n_k}) (b_{n_k}^2 + (1-b_{n_k})^2) \left| \log^3 \left(\frac{b_{n_k}}{1-b_{n_k}} \frac{1-\tilde{r}_k}{\tilde{r}_k} \right) \right| \\ &\stackrel{(c)}{=} \frac{AT}{n_k} \left(-(1-p_{n_k}) s \log^3 \frac{s}{\tilde{p}_k + s} + p_{n_k} (1+s) \log^3 \frac{1+s}{\tilde{p}_k + s} \right) + o(n_k^{-1}) \end{aligned} \quad (171)$$

as $k \rightarrow \infty$, where

- (a) follows from (83),
- (b) follows from (170), and
- (c) follows from the asymptotic equivalences as stated in (128)–(130) and (143).

Similar to (168), it follows by the extreme value theorem that there exists a constant $\xi_{\max} > 0$ satisfying

$$n_k \Xi(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k}) \leq T \xi_{\max} + o(1) \quad (172)$$

as $k \rightarrow \infty$. Combining (168) and (172), there exists a positive sequence $\delta_k = o(1)$ (as $k \rightarrow \infty$) satisfying

$$\frac{6 \Xi(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k})}{\sqrt{n_k V(W_{n_k} \parallel \tilde{P}_k W_{n_k} \mid P_{n_k})}} \leq \frac{6 \xi_{\max}}{\sqrt{T} v_{\min}^3} + \delta_k. \quad (173)$$

Supposing that $\eta = 1/\sqrt{T}$, since

$$\epsilon_{n_k} + \delta_k + \frac{1}{\sqrt{T}} + \frac{6\xi_{\max}}{\sqrt{T}v_{\min}^3} < \frac{1-\varepsilon}{2} \quad (174)$$

for sufficiently large k and T , it follows from a Taylor series expansion of $\Phi^{-1}(\cdot)$ around $\varepsilon + \epsilon_{n_k} + \delta_k$ that

$$\Phi^{-1}\left(\varepsilon + \epsilon_{n_k} + \delta_k + \frac{1}{\sqrt{T}} + \frac{6\xi_{\max}}{\sqrt{T}v_{\min}^3}\right) \leq \Phi^{-1}(\varepsilon + \epsilon_{n_k} + \delta_k) + \frac{v_{\min}^{3/2} + 6\xi_{\max}}{v_{\min}^{3/2}\sqrt{T}} \tilde{G}_2 \quad (175)$$

for sufficiently large k and T , where the positive constant \tilde{G}_2 is given as

$$\tilde{G}_2 = \sqrt{2\pi} \max \left\{ \exp\left(\frac{1}{2}\Phi^{-1}(\varepsilon)^2\right), \exp\left(\frac{1}{2}\Phi^{-1}\left(\frac{1+\varepsilon}{2}\right)^2\right) \right\} \quad (176)$$

depending only on the tolerated probability of error $0 < \varepsilon < 1$. This completes the proof of (87). \blacksquare

APPENDIX G PROOF OF LEMMA 3

Let X_1, X_2, \dots, X_M be i.i.d. r.v.'s with generic distribution P . Consider a maximum-likelihood decoder $g_{\text{ML}} : \mathcal{Y} \rightarrow \mathcal{X}$ satisfying

$$g_{\text{ML}}(Y) \in \arg \max_{m \in \{1, \dots, M\}} W(Y | X_m) \quad (177)$$

with probability 1. Then, the error probability averaged over the ensemble of random codes $\{X_m\}_{m=1}^M$ is given by

$$\begin{aligned} \mathbb{E} \left[\frac{1}{M} \sum_{m=1}^M \mathbb{P}\{\chi(X) > \beta \text{ or } g_{\text{ML}}(Y) \neq X \mid X = X_m\} \right] &\leq \mathbb{E} \left[\frac{1}{M} \sum_{m=1}^M \mathbb{P}\{\chi(X) > \beta \mid X = X_m\} + \frac{1}{M} \sum_{m=1}^M \mathbb{P}\{g_{\text{ML}}(Y) \neq X \mid X = X_m\} \right] \\ &= \mathbb{P}\{\chi(X) > \beta\} + \mathbb{E}[\mathbb{P}\{g_{\text{ML}}(Y) \neq X \mid X = X_1\}]. \end{aligned} \quad (178)$$

By the standard argument of the random coding union bound (see the proof of [5, Theorem 16]), the last term in the right-hand side on (178) can be bounded from above by

$$\mathbb{E}[\mathbb{P}\{g_{\text{ML}}(Y) \neq X \mid X = X_1\}] \leq \mathbb{E} \left[\min \left\{ 1, (M-1) \mathbb{P} \left\{ \log \frac{W(Y | \tilde{X})}{PW(Y)} \geq \log \frac{W(Y | X)}{PW(Y)} \mid X, Y \right\} \right\} \right], \quad (179)$$

which asserts Lemma 3 together with (178). \blacksquare

APPENDIX H PROOF OF LEMMA 4

Since $n = \omega(T)$ as $T \rightarrow \infty$ (see (96)), it follows that $a_n = o(1)$ and $b_n = o(1)$ as $T \rightarrow \infty$. We readily see that

$$\begin{aligned} I(P_n, W_n) &= h(r_n) - (1-p_n)h(a_n) - p_nb_nh(b_n) \\ &\stackrel{(a)}{=} r_n \log \frac{1}{r_n} - (1-p_n)a_n \log \frac{1}{a_n} - p_nb_n \log \frac{1}{b_n} + o(n^{-1}) \\ &\stackrel{(b)}{=} (1-p_n)a_n \log \frac{a_n}{r_n} + p_nb_n \log \frac{b_n}{r_n} + o(n^{-1}) \\ &\stackrel{(c)}{=} (1-p^*)a_n \log \frac{s}{p^*+s} + p^*b_n \log \frac{1+s}{p^*+s} + o(n^{-1}) \\ &\stackrel{(d)}{=} \frac{AT}{n} \left((1-p^*)s \log \frac{s}{p^*+s} + p^*(1+s) \log \frac{1+s}{p^*+s} \right) + o(n^{-1}) \\ &= \frac{TC^*}{n} + o(n^{-1}) \end{aligned} \quad (180)$$

as $T \rightarrow \infty$, where

- (a) follows from the fact that $-(1-u)\log(1-u) \sim u$ as $u \rightarrow 0$,
- (b) follows by the definition of $r_n = (1-p_n)a_n + p_nb_n$ in (99),

- (c) follows from the facts that

$$\lim_{T \rightarrow \infty} p_n = p^*, \quad (181)$$

$$\lim_{T \rightarrow \infty} \frac{a_n}{r_n} = \frac{s}{p^* + s}, \quad (182)$$

$$\lim_{T \rightarrow \infty} \frac{b_n}{r_n} = \frac{1 + s}{p^* + s}, \quad (183)$$

and

- (d) follows from the asymptotic equivalences as stated in (128)–(129).

Equation (180) implies (100) of Lemma 4.

We shall next verify (101) of Lemma 4. Noting the asymptotic equivalences stated in (128)–(129) and

$$n r_n \sim (p^* + s) A T \quad (\text{as } T \rightarrow \infty), \quad (184)$$

$$u \sim -\log(1 - u) \quad (\text{as } u \rightarrow 0), \quad (185)$$

it follows from (180) that

$$\left(\log \frac{1 - a_n}{1 - r_n} - I(P_n, W_n) \right)^2 = O(n^{-2}), \quad (186)$$

$$\left(\log \frac{1 - b_n}{1 - r_n} - I(P_n, W_n) \right)^2 = O(n^{-2}), \quad (187)$$

$$\left(\log \frac{a_n}{r_n} - I(P_n, W_n) \right)^2 = \log^2 \frac{s}{p^* + s} + O(n^{-1}), \quad (188)$$

$$\left(\log \frac{b_n}{r_n} - I(P_n, W_n) \right)^2 = \log^2 \frac{1 + s}{p^* + s} + O(n^{-1}) \quad (189)$$

as $T \rightarrow \infty$. Therefore, we obtain

$$\begin{aligned} \tilde{V}(P_n, W_n) &= (1 - p_n)(1 - a_n) \left(\log \frac{1 - a_n}{1 - r_n} - I(P_n, W_n) \right)^2 + (1 - p_n) a_n \left(\log \frac{a_n}{r_n} - I(P_n, W_n) \right)^2 \\ &\quad + p_n(1 - b_n) \left(\log \frac{1 - b_n}{1 - r_n} - I(P_n, W_n) \right)^2 + (1 - p_n) b_n \left(\log \frac{b_n}{r_n} - I(P_n, W_n) \right)^2 \\ &= (1 - p_n) a_n \log^2 \frac{s}{p^* + s} + p_n b_n \log^2 \frac{1 + s}{p^* + s} + o(n^{-1}) \\ &= \frac{A T}{n} \left((1 - p^*) s \log^2 \frac{s}{p^* + s} + p^* (1 + s) \log^2 \frac{1 + s}{p^* + s} \right) + o(n^{-1}) \\ &= \frac{T V^*}{n} + o(n^{-1}) \end{aligned} \quad (190)$$

as $T \rightarrow \infty$, implying (101) of Lemma 4. Finally, Equation (102) of Lemma 4 can be verified in the same way as (190). This completes the proof of Lemma 4. \blacksquare

APPENDIX I PROOF OF LEMMA 5

We observe that

$$\begin{aligned} \mathbb{P}\{N(1 | X^n) > n \sigma\} &\stackrel{(a)}{=} \mathbb{P}\{N(1 | X^n) - \mathbb{E}[N(1 | X^n)] > n(\sigma - p^*(1 - n^{-1/4}))\} \\ &\stackrel{(b)}{\leq} \mathbb{P}\{N(1 | X^n) - \mathbb{E}[N(1 | X^n)] > p^* n^{3/4}\} \\ &\stackrel{(c)}{\leq} \exp(-2(p^*)^2 \sqrt{n}) \end{aligned} \quad (191)$$

where

- (a) follows from the fact that $\mathbb{E}[N(1 | X^n)] = n p^* (1 - n^{-1/4})$,
- (b) follows by the definition of p^* in (9), and
- (c) follows by Hoeffding's inequality (cf. [21, Theorem 2.8]).

This completes the proof of Lemma 5 together with the hypothesis in (96) that $n = \lceil T^2 \rceil$. \blacksquare

APPENDIX J
PROOF OF LEMMA 6

In this proof, we employ the following lemma, which is an application of the modified logarithmic Sobolev inequality (cf. [21, Chapter 6]).

Lemma 11 ([21, Theorem 6.12]). *Let Z_1, \dots, Z_n be independent \mathcal{A} -valued r.v.'s. Consider a Borel-measurable mapping $f : \mathcal{A}^n \rightarrow \mathbb{R}$ satisfying the self-bounding property: for each $i = 1, \dots, n$, there exists a Borel-measurable mapping $f_i : \mathcal{A}^{n-1} \rightarrow \mathbb{R}$ such that*

$$0 \leq f(z_1, \dots, z_n) - f_i(z_1, \dots, z_{i-1}, z_{i+1}, \dots, z_n) \leq 1 \quad (192)$$

and

$$\sum_{i=1}^n \left(f(z_1, \dots, z_n) - f_i(z_1, \dots, z_{i-1}, z_{i+1}, \dots, z_n) \right) \leq f(z_1, \dots, z_n) \quad (193)$$

for every $(z_1, \dots, z_n) \in \mathcal{A}^n$. Then, it holds that

$$\mathbb{P} \left\{ f(Z_1, \dots, Z_n) \leq \mathbb{E}[f(Z_1, \dots, Z_n)] - t \right\} \leq \exp \left(- \frac{t^2}{2 \mathbb{E}[f(Z_1, \dots, Z_n)]} \right) \quad (194)$$

for every $0 < t \leq \mathbb{E}[f(Z_1, \dots, Z_n)]$.

The following example shows a special case of Lemma 11.

Example 1. *If Z_1, \dots, Z_n are independent Bernoulli r.v.'s, then the mapping*

$$f(Z_1, \dots, Z_n) = \sum_{i=1}^n Z_i, \quad (195)$$

which follows a binomial distribution, satisfies the self-bounding property.

Recall that $n = \lceil T^2 \rceil$ (see (96)). By the asymptotic equivalence

$$n r_n \sim (p^* + s) A T \quad (\text{as } T \rightarrow \infty), \quad (196)$$

it follows from the choice of constant $0 < \kappa < 1$ that there exists a $T_0 = T_0(\kappa, \lambda_0, A, \sigma) > 0$ satisfying

$$\kappa (p^* + s) A T \leq n r_n \leq (1 + \kappa) (p^* + s) A T \quad (197)$$

for every $T \geq T_0$. Now, we observe that

$$\begin{aligned} \mathbb{P}(\mathcal{E}_T^c) &= \mathbb{P} \left\{ \sum_{i=1}^n Y_{n,i} \leq \mathbb{E} \left[\sum_{i=1}^n Y_{n,i} \right] - \kappa (p^* + s) A T \right\} \\ &\stackrel{(a)}{\leq} \exp \left(- \frac{\kappa^2 (p^* + s)^2 A^2 T^2}{2 n r_n} \right) \\ &\stackrel{(b)}{\leq} \exp \left(- \frac{\kappa^2 (p^* + s) A T}{2 (1 + \kappa)} \right) \\ &\stackrel{(c)}{\leq} \exp(-K_0 T), \end{aligned} \quad (198)$$

where

- (a) holds for every $T \geq T_0$, because it follows from (110), the left-hand inequality of (197), and Lemma 11,
- (b) holds for every $T \geq T_0$, because of the right-hand inequality of (197), and
- (c) follows by choosing the constant

$$K_0 = K_0(\kappa, \lambda_0, A, \sigma) = \frac{\kappa^2 (p^* + s) A}{2 (1 + \kappa)}. \quad (199)$$

This completes the proof of Lemma 6. ■

Remark 1. *While Lemma 5 is proved using Hoeffding's inequality, the same inequality cannot be used to show Lemma 6. This is because the Bernoulli parameter r_n given in (99) approaches to zero as T goes to infinity, but Hoeffding's inequality is independent of (the rate of decay of) r_n . We have avoided this issue via the modified logarithmic Sobolev inequality as stated in Lemma 11.*

APPENDIX K
PROOF OF LEMMA 7

For each $n \geq 1$, let $B_{n,1}, B_{n,2}, \dots, B_{n,n}$ be i.i.d. Bernoulli r.v.'s with parameter

$$\mathbb{P}\{B_{n,i} = 1\} = \frac{p_n b_n}{r_n} \quad \text{for } i = 1, \dots, n. \quad (200)$$

For short, we write $B_n^m = (B_{n,1}, \dots, B_{n,m})$. Lemma 6 tells us that there exists a $T_0 > 0$ such that $\mathbb{E}[N(1 | Y^n)] > \kappa(p^* + s)AT$ for every $T \geq T_0$. With probability one, for any reals α and β and for all $T \geq T_0$, we have

$$\begin{aligned} & \mathbf{1}_{\mathcal{E}_T} \mathbb{P} \left\{ \alpha \leq \log \frac{W_n^n(Y^n | X^n)}{(P_n W_n)^n(Y^n)} \leq \alpha + \beta \mid Y^n \right\} \\ &= \mathbf{1}_{\mathcal{E}_T} \sum_{\mathbf{x} \in \{0,1\}^n} \frac{P_n^n(\mathbf{x}) W_n^n(Y^n | \mathbf{x})}{P_n W_n(Y^n)} \mathbf{1} \left\{ \alpha \leq \log \frac{W_n^n(Y^n | \mathbf{x})}{(P_n W_n)^n(Y^n)} \leq \alpha + \beta \right\} \\ &= \mathbf{1}_{\mathcal{E}_T} \sum_{\mathbf{x} \in \{0,1\}^n} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0,0|\mathbf{x},Y^n)} \left(\frac{(1-p_n)a_n}{r_n} \right)^{N(0,1|\mathbf{x},Y^n)} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{N(1,0|\mathbf{x},Y^n)} \left(\frac{p_n b_n}{r_n} \right)^{N(1,1|\mathbf{x},Y^n)} \\ & \quad \times \mathbf{1} \left\{ \alpha \leq \log \left(\left(\frac{1-a_n}{1-r_n} \right)^{N(0,0|\mathbf{x},Y^n)} \left(\frac{a_n}{r_n} \right)^{N(0,1|\mathbf{x},Y^n)} \left(\frac{1-b_n}{1-r_n} \right)^{N(1,0|\mathbf{x},Y^n)} \left(\frac{b_n}{r_n} \right)^{N(1,1|\mathbf{x},Y^n)} \right) \leq \alpha + \beta \right\} \\ &= \mathbf{1}_{\mathcal{E}_T} \sum_{k_0=0}^{N(0|Y^n)} \sum_{k_1=0}^{N(1|Y^n)} \binom{N(0|Y^n)}{k_0} \binom{N(1|Y^n)}{k_1} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0|Y^n)-k_0} \left(\frac{(1-p_n)a_n}{r_n} \right)^{N(1|Y^n)-k_1} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{k_0} \left(\frac{p_n b_n}{r_n} \right)^{k_1} \\ & \quad \times \mathbf{1} \left\{ \alpha \leq \log \left(\left(\frac{1-a_n}{1-r_n} \right)^{N(0|Y^n)-k_0} \left(\frac{a_n}{r_n} \right)^{N(1|Y^n)-k_1} \left(\frac{1-b_n}{1-r_n} \right)^{k_0} \left(\frac{b_n}{r_n} \right)^{k_1} \right) \leq \alpha + \beta \right\} \\ &= \mathbf{1}_{\mathcal{E}_T} \sum_{k_0=0}^{N(0|Y^n)} \sum_{k_1=0}^{N(1|Y^n)} \binom{N(0|Y^n)}{k_0} \binom{N(1|Y^n)}{k_1} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0|Y^n)-k_0} \left(\frac{(1-p_n)a_n}{r_n} \right)^{N(1|Y^n)-k_1} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{k_0} \left(\frac{p_n b_n}{r_n} \right)^{k_1} \\ & \quad \times \mathbf{1} \left\{ \alpha \leq N(0|Y^n) \log \frac{1-a_n}{1-r_n} + N(1|Y^n) \log \frac{a_n}{r_n} + k_0 \log \frac{1-b_n}{1-r_n} + k_1 \log \frac{b_n}{a_n} \leq \alpha + \beta \right\} \\ &\stackrel{(a)}{=} \mathbf{1}_{\mathcal{E}_T} \sum_{k_0=0}^{N(0|Y^n)} \binom{N(0|Y^n)}{k_0} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{k_0} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0|Y^n)-k_0} \\ & \quad \times \sum_{k_1=0}^{N(1|Y^n)} \binom{N(1|Y^n)}{k_1} \left(\frac{p_n b_n}{r_n} \right)^{k_1} \left(\frac{(1-p_n)a_n}{r_n} \right)^{N(1|Y^n)-k_1} \mathbf{1} \left\{ \alpha(n, k_0, Y^n) \leq k_1 \log \frac{b_n}{a_n} \leq \alpha(n, k_0, Y^n) + \beta \right\} \\ &\stackrel{(b)}{=} \mathbf{1}_{\mathcal{E}_T} \sum_{k_0=0}^{N(0|Y^n)} \binom{N(0|Y^n)}{k_0} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{k_0} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0|Y^n)-k_0} \mathbb{P} \left\{ \alpha(n, k_0, Y^n) \leq N(1 | B_n^{N(1|Y^n)}) \log \frac{b_n}{a_n} \leq \alpha(n, k_0, Y^n) + \beta \right\} \\ &\stackrel{(c)}{\leq} \mathbf{1}_{\mathcal{E}_T} \sum_{k_0=0}^{N(0|Y^n)} \binom{N(0|Y^n)}{k_0} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{k_0} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0|Y^n)-k_0} \left(\Phi \left(\frac{\alpha(n, k_0, Y^n) + \beta}{\log(b_n/a_n)} \right) - \Phi \left(\frac{\alpha(n, k_0, Y^n)}{\log(b_n/a_n)} \right) + \frac{12 \xi_n}{\sigma_n^2} \right) \\ & \quad \times \frac{1}{\sqrt{N(1|Y^n) \sigma_n^2}} \\ &\leq \underbrace{\mathbf{1}_{\mathcal{E}_T} \sum_{k_0=0}^{N(0|Y^n)} \binom{N(0|Y^n)}{k_0} \left(\frac{p_n(1-b_n)}{1-r_n} \right)^{k_0} \left(\frac{(1-p_n)(1-a_n)}{1-r_n} \right)^{N(0|Y^n)-k_0}}_{=1} \left(\frac{\beta}{(\log(b_n/a_n))\sqrt{2\pi}} + \frac{12 \xi_n}{\sigma_n^2} \right) \frac{1}{\sigma_n \sqrt{N(1|Y^n)}} \\ &= \mathbf{1}_{\mathcal{E}_T} \left(\frac{\beta}{(\log(b_n/a_n))\sqrt{2\pi}} + \frac{12 \xi_n}{\sigma_n^2} \right) \frac{1}{\sigma_n \sqrt{N(1|Y^n)}} \\ &\stackrel{(d)}{\leq} \mathbf{1}_{\mathcal{E}_T} \left(\frac{\beta}{(\log(b_n/a_n))\sqrt{2\pi}} + \frac{12 \xi_n}{\sigma_n^2} \right) \frac{1}{\sigma_n \sqrt{\mathbb{E}[N(1|Y^n)] - \kappa(p^* + s)AT}} \\ &\leq \left(\frac{\beta}{(\log(b_n/a_n))\sqrt{2\pi}} + \frac{12 \xi_n}{\sigma_n^2} \right) \frac{1}{\sigma_n \sqrt{\mathbb{E}[N(1|Y^n)] - \kappa(p^* + s)AT}} \end{aligned}$$

$$\begin{aligned}
&\stackrel{(e)}{=} \left(\frac{\beta}{(\log(b_n/a_n))\sqrt{2\pi}} + \frac{12\xi_n}{\sigma_n^2} \right) \frac{1}{\sigma_n \sqrt{n r_n - \kappa(p^* + s) A T}} \\
&= \left(\frac{\beta}{(\log(b_n/a_n))\sqrt{2\pi}} + \frac{12\xi_n}{\sigma_n^2} \right) \frac{1}{\sigma_n \sqrt{T}} \sqrt{\frac{T}{n r_n - \kappa(p^* + s) A T}},
\end{aligned} \tag{201}$$

where

- (a) follows by defining the r.v. $\alpha(n, k_0, Y^n)$ so that

$$\alpha(n, k_0, Y^n) := \alpha - N(0 | Y^n) \log \frac{1 - a_n}{1 - r_n} - N(1 | Y^n) \log \frac{a_n}{r_n} - k_0 \log \frac{1 - b_n}{1 - a_n}, \tag{202}$$

- (b) follows from the fact that the r.v.

$$N(1 | B_n^{N(1|Y^n)}) = \sum_{i=1}^{N(1|Y^n)} B_{n,i} \tag{203}$$

follows the binomial distribution with parameters $N(1 | Y^n)$ and $p_n b_n / r_n$,

- (c) follows from the Berry–Esseen theorem with the identities:

$$\begin{aligned}
\sigma_n^2 &:= \mathbb{E}[(B_{n,1} - \mathbb{E}[B_{n,1}])^2] \\
&= \frac{p_n(1 - p_n) a_n b_n}{r_n^2},
\end{aligned} \tag{204}$$

$$\begin{aligned}
\xi_n &:= \mathbb{E}[|B_{n,1} - \mathbb{E}[B_{n,1}]|^3] \\
&= \frac{(1 - p_n) a_n}{r_n} \left(\frac{p_n b_n}{r_n} \right)^3 + \frac{p_n b_n}{r_n} \left(1 - \frac{p_n b_n}{r_n} \right)^3,
\end{aligned} \tag{205}$$

- (d) follows by the definition of \mathcal{E}_T in (109), and
- (e) follows from (110).

Recall that $n = \omega(T)$ as $T \rightarrow \infty$. By the asymptotic equivalences

$$n a_n \sim s A T, \tag{206}$$

$$n b_n \sim (1 + s) A T, \tag{207}$$

$$n r_n \sim (p^* + s) A T \tag{208}$$

as $T \rightarrow \infty$, we see that

$$\lim_{T \rightarrow \infty} \log \frac{b_n}{a_n} = \log \frac{1 + s}{s}, \tag{209}$$

$$\lim_{T \rightarrow \infty} \sigma_n^2 = \frac{p^*(1 - p^*) s (1 + s)}{(p^* + s)^2}, \tag{210}$$

$$\lim_{T \rightarrow \infty} \xi_n = \frac{(1 - p^*) s}{p^* + s} \left(\frac{p^*(1 + s)}{p^* + s} \right)^3 + \frac{p^*(1 + s)}{p^* + s} \left(1 - \frac{p^*(1 + s)}{p^* + s} \right)^3, \tag{211}$$

and

$$\lim_{T \rightarrow \infty} \sqrt{\frac{T}{n r_n - \kappa(p^* + s) A T}} = \frac{1}{\sqrt{(1 - \kappa)(p^* + s) A}}. \tag{212}$$

Therefore, it follows from (201) that there exist $K_1 = K_1(\kappa, \lambda_0, A, \sigma) > 0$ and $T_1 = T_1(\kappa, \lambda_0, A, \sigma) > 0$ satisfying

$$\mathbf{1}_{\mathcal{E}_T} \mathbb{P} \left\{ \alpha \leq \log \frac{W_n^n(Y^n | X^n)}{(P_n W_n)^n(Y^n)} \leq \alpha + \beta \mid Y^n \right\} \leq \frac{K_1}{2\sqrt{T}} \tag{213}$$

almost surely for every reals α and β and every $T \geq T_1$. Now, as in [5, Equation (474)], it follows from (213) that

$$\begin{aligned}
&\mathbf{1}_{\mathcal{E}_T} \mathbb{E} \left[e^{-\iota_n(X^n \wedge Y^n)} \mathbf{1}_{\{\iota_n(X^n \wedge Y^n) \geq \gamma\}} \mid Y^n \right] \\
&\leq \sum_{l=0}^{\infty} \exp(-\gamma - l \log 2) \mathbf{1}_{\mathcal{E}_T} \mathbb{P} \left\{ \gamma + l \log 2 \leq \log \frac{W_n^n(Y^n | X^n)}{(P_n W_n)^n(Y^n)} < \gamma + (1 + l) \log 2 \mid Y^n \right\} \\
&\leq \frac{K_1 \exp(-\gamma)}{2\sqrt{T}} \sum_{l=0}^{\infty} 2^{-l} \\
&= \frac{K_1 \exp(-\gamma)}{\sqrt{T}}
\end{aligned} \tag{214}$$

almost surely for every $T \geq T_1$. This completes the proof of Lemma 7. \blacksquare

APPENDIX L PROOF OF LEMMA 8

It follows from [5, Lemma 47] (see also [8, Theorem 1.7]) that

$$\mathbb{E} \left[\mathbf{1}_{\{\iota_n(X^n \wedge Y^n) > \gamma\}} \exp(-\iota_n(X^n \wedge Y^n)) \right] \leq 2 \left(\frac{\log 2}{\sqrt{2} \pi} + \frac{\tilde{\Xi}(P_n, W_n)}{\tilde{V}(P_n, W_n)} \right) \frac{\exp(-\gamma)}{\sqrt{n \tilde{V}(P_n, W_n)}}, \quad (215)$$

where note that

$$\iota_n(X^n \wedge Y^n) = \sum_{i=1}^n \log \frac{W_n(Y_{n,i} | X_{n,i})}{P_n W_n(Y_{n,i})} \quad (216)$$

and

$$\mathbb{E} \left[\log \frac{W_n(Y_{n,1} | X_{n,1})}{P_n W_n(Y_{n,1})} \right] = I(P_n, W_n), \quad (217)$$

$$\mathbb{E} \left[\left(\log \frac{W_n(Y_{n,1} | X_{n,1})}{P_n W_n(Y_{n,1})} - I(P_n, W_n) \right)^2 \right] = \tilde{V}(P_n, W_n), \quad (218)$$

$$\mathbb{E} \left[\left| \log \frac{W_n(Y_{n,1} | X_{n,1})}{P_n W_n(Y_{n,1})} - I(P_n, W_n) \right|^3 \right] = \tilde{\Xi}(P_n, W_n). \quad (219)$$

Therefore, Lemma 4 yields Lemma 8. \blacksquare

APPENDIX M PROOF OF LEMMA 9

It follows from the Berry–Esseen theorem (cf. [8, Theorem 1.6]) that

$$\mathbb{P} \left\{ \iota_n(X^n \wedge Y^n) \leq \gamma \right\} \leq \Phi \left(\frac{\gamma - n I(P_n, W_n)}{\sqrt{n \tilde{V}(P_n, W_n)}} \right) + \frac{6 \tilde{\Xi}(P_n, W_n)}{\sqrt{n \tilde{V}(P_n, W_n)}^3}. \quad (220)$$

The existence of the constant $K_3 = K_3(\lambda_0, A, \sigma) > 0$ can be verified by Lemma 4. This completes the proof of Lemma 9. \blacksquare

Yuta Sakai (S'16-M'19) was born in Japan in 1992. He is currently a Research Fellow in the Department of Electrical and Computer Engineering at the National University of Singapore (NUS). He received the B.E. and M.E. degrees in the Department of Information Science from the University of Fukui in 2014 and 2016, respectively, and the Ph.D. degree in the Advanced Interdisciplinary Science and Technology from the University of Fukui in 2018. His research interests include information theory and coding theory.

Vincent Y. F. Tan (S'07-M'11-SM'15) was born in Singapore in 1981. He is currently a Dean's Chair Associate Professor in the Department of Electrical and Computer Engineering and the Department of Mathematics at the National University of Singapore (NUS). He received the B.A. and M.Eng. degrees in Electrical and Information Sciences from Cambridge University in 2005 and the Ph.D. degree in Electrical Engineering and Computer Science (EECS) from the Massachusetts Institute of Technology (MIT) in 2011. His research interests include information theory, machine learning, and statistical signal processing.

Dr. Tan received the MIT EECS Jin-Au Kong outstanding doctoral thesis prize in 2011, the NUS Young Investigator Award in 2014, the Singapore National Research Foundation (NRF) Fellowship (Class of 2018) and the NUS Young Researcher Award in 2019. He was also an IEEE Information Theory Society Distinguished Lecturer for 2018/9. He is currently serving as an Associate Editor of the IEEE Transactions on Signal Processing and an Associate Editor of Machine Learning for the IEEE Transactions on Information Theory.

Mladen Kovačević was born in Sarajevo, Bosnia and Herzegovina, in 1984. He received the Dipl.Ing. (2007) and Ph.D. (2014) degrees in Electrical and Computer Engineering from the University of Novi Sad, Serbia, where he also currently works as an Assistant Professor. In the period from Oct. 2015 to May 2018 he worked at the National University of Singapore, as a Research Fellow in the group of Vincent Y. F. Tan. His research interests include information theory, coding theory, and discrete mathematics.
