QUANTUM DIFFERENTIALS ON CROSS PRODUCT HOPF ALGEBRAS

RYAN AZIZ AND SHAHN MAJID

Abstract. We construct canonical strongly bicovariant differential graded algebra structures on all four flavours of cross product Hopf algebras, namely double cross products $A \hookrightarrow A \triangleright H \hookleftarrow H$, double cross coproducts $A \rightarrow A \triangleright H \rightarrow H$, biproducts $A\leftarrow A \triangleright B$ and bicrossproducts $A \hookrightarrow A \triangleright H \hookleftarrow H$ on the assumption that the factors have strongly bicovariant calculi $\Omega(A), \Omega(H)$ (or a braided version $\Omega(B)$). We use super versions of each of the constructions. Moreover, the latter three quantum groups all coact canonically on one of their factors and we show that this coaction is differentiable. In the case of the Drinfeld double $D(A, H) = A \triangleright \triangleright H$ (where $A$ is dually paired to $H$), we show that its canonical actions on $A, H$ are differentiable. Other applications are a canonical $\Omega(C_q(GL_2 \ltimes \mathbb{C}^2))$ for the quantum group of affine transformations of the quantum plane and $\Omega(C_\lambda[\text{Poinc}_1,1])$ for the bicrossproduct Poincaré quantum group in 2 dimensions.

1. Introduction

A modern ‘quantum groups’ approach to noncommutative geometry starts with differential structures on quantum groups or Hopf algebras and associated comodule algebras, expressed in the form of a differential graded algebra (DGA), see [9,3] and an extensive literature. In general, there will be many such DGAs on a given Hopf algebra even if we demand left and right translation invariance (i.e., bicovariance). The most general result here is an immediate consequence of the Hopf module lemma first pointed out by Woronowicz [25], is that bicovariant calculi at first order correspond to (say) right ideals of the augmentation ideal that are stable under the right adjoint coaction. This, however, only translates the problem to finding such ideals. If the Hopf algebra is coquasitriangular and essentially factorisable then a general classification was obtained in [15] and later in [2] in terms of the irreducible corepresentations, but for other types of Hopf algebras there are no such general results. Of particular interest are inhomogeneous quantum groups, normally some form of cross product of ‘translations’ and ‘rotations’ coacting on another copy of the former. This is needed in physics for a quantum Poincaré group coordinate algebra coacting on quantum spacetime, but until now there has generally been no canonical choice of differential structure needed further to develop the geometry of such inhomogeneous quantum groups.

Here we solve this problem for all main flavours of inhomogeneous quantum groups in a way which, rather than classifying all bicovariant calculi, selects out a canonical calculus for given calculi on the factors, with the property that the inhomogeneous quantum group coacts differentiably on its canonically associated comodule algebra. This applies to biproduct Hopf algebras $A \triangleright B$ where $A$ acts and coacts on a braided-Hopf algebra $B$ from the same side [23,12,8] and the biproduct coacts on $B$, bicrossproducts $A \triangleright H$ where $H$ acts on $A$ and $A$ coacts on $H$ [10,8] and the

LPDP Indonesian Endowment Fund For Education No. 1571072104910081.
bicrossproduct coacts on $H$, and double cross coproducts $A\sqtriangleleft H$ where each factor coacts on the other and the double cross product coacts on each factor. The fourth flavour is in principle the double cross product $A\times H$ where each factor acts on the other and the double acts canonically on $A^*, H^*$, but differentiability would need us to have calculi on $A^*, H^*$ which is further data that would need to be supplied. The special case of the Drinfeld double $D(A, H) = A^{op} \bowtie H$ in the generalised form for dually paired Hopf algebras $A, H$ (as introduced by the 2nd author\[10, 8\]), however, has a canonical action on $H, A$ and these we show are differentiable as actions. This is a slightly unusual concept for a noncommutative geometer if we think of our algebras as ‘coordinate algebras’, but arises naturally here. We also note that first order differential calculi on finite group bicrossproducts $\mathbb{C}(M)\bowtie CG$, where a finite group factorises into $G, M$, were classified in \[21\] if one wants the full moduli of these in isolation.

Our approach starts with the notion of a strongly bico covariant exterior algebra $\Omega(A)$ introduced in \[20\]. Here an exterior algebra means $\Omega(A) = \oplus_0 \Omega^i$ is a graded algebra with a graded derivation $d$ with $d^2 = 0$ (a DGA) which is generated by $\Omega^0 = A$ and $\Omega^1 = AdA$. This is strongly bico covariant if $\Omega(A)$ is a super-Hopf algebra with coproduct $\Delta_*$ (say) where $\Delta_*|_A = \Delta$, the coproduct of $A$, in degree zero and $d$ is a graded coderivation in the sense

$$\Delta_* d = (d \otimes \text{id} + (-1)^{|d|} \otimes d) \Delta_* ,$$

where $(-1)^{|\omega} = (-1)^{|\omega|}$ for $\omega$ of degree $|\omega|$. It was shown in \[20\] that the canonical exterior algebra due to Woronowicz\[23\] of a first order bivariant calculus is strongly bico covariant with $\Delta_*|_\Omega = \Delta_L + \Delta_R$ in terms of the coactions on $\Omega^i$ induced by $\Delta$ (that the Woronowicz construction gives a super-Hopf algebra here was already known\[4\] while the supercoderivation property was new). Conversely, if $\Omega(A)$ is strongly bico covariant then $\Delta_*|_\Omega \subseteq (A \otimes \Omega^0) \oplus \cdots \oplus (\Omega^i \otimes A)$ recovers the left and right coactions on each $\Omega^i$ as the outer components, making $\Omega(A)$ bivariant as a left and right comodule algebra, but contains a lot more information in the intermediate components. One can add to this the idea that an algebra $B$ with a right coaction $\Delta_R : B \to B \otimes A$ has an exterior algebra $\Omega(B)$ such that $\Delta_R$ extends to $\Delta_{R,B} : \Omega(B) \to \Omega(B) \bowtie \Omega(A)$ as a super comodule algebra. Then $\Delta_{R,B}$ is said to be differentiable. This is used in \[3\] in a different context from the present paper, namely in the theory of quantum principal bundles and fibrations. Exact definitions and any further conditions are provided in the preliminaries Section \[2\].

Our canonical construction in this context will be to construct the required exterior algebra as a super extension of the same flavour of cross (co)product. Thus we define $\Omega(A\bowtie H) := \Omega(A)\bowtie \Omega(H)$ and $\Omega(A\bullet H) := \Omega(A)\bullet \Omega(H)$ in Section \[5\] $\Omega(A\bowtie B) := \Omega(A)\bowtie \Omega(B)$ in Section \[4\] and $\Omega(A\bullet H) := \Omega(A)\bullet \Omega(H)$ in Section \[5\] using the obvious super-Hopf versions of the cross products. In each case, the new part is to check that the exterior derivative $d$ extends correctly so that the result is strongly bico covariant, and that the canonical (co)actions where applicable are differentiable.

We will see that this approach is remarkably effective. Thus, bivariant calculi on the Sweedler-Taft algebra $U_q(b_+)$ (a sub-Hopf algebra of $U_q(sl_2)$) were studied in \[22\] and our construction lands on the most natural one in the classification there, albeit in the dual language of $\mathbb{C}_q[B_+] = \mathbb{C}[t, t^{-1}] \bowtie \mathbb{C}[x]$ where $\mathbb{C}[x]$ is developed as a braided-line in the category or $\mathbb{Z}$-graded spaces of $\mathbb{C}[t, t^{-1}]$-comodules. The exterior algebra $\Omega(\mathbb{C}_q[B_+])$ is in Proposition \[13\] as a warm-up to Proposition \[11\] for $\Omega(\mathbb{C}_q[GL_2] \bowtie \mathbb{C}^{\mathbb{C}_q}_q)$, where the quantum plane $\mathbb{C}^{\mathbb{C}_q}_q$ is viewed as a braided Hopf algebra in the category of $\mathbb{C}_q[GL_2]$ comodules. Moreover, our general construction
ensures that the canonical coaction of $\mathbb{C}_q[B_+]$ on $\mathbb{C}[x]$ and the canonical coaction of $\mathbb{C}_q[GL_2] \bowtie \mathbb{C}_q^2$ on $\mathbb{C}_q^2$ are both differentiable for their natural $q$-differential calculus. Similarly, one of the simplest bicrossproducts beyond finite groups is the Planck-scale Hopf algebra $\mathbb{C}_q[g, g^{-1}] \bowtie \mathbb{C}[p]$ and Proposition 5.4 recovers a known exterior algebra $\Omega(\mathbb{C}_q[g, g^{-1}] \bowtie \mathbb{C}[p])$ in [19] but now uniquely determined by the Hopf algebra coacting differentiably on $\mathbb{C}[x]$ with its unique finite-difference form of bicovariant calculus. This is a warm-up for the simplest Poincaré quantum group $\mathbb{C}_\lambda[\text{Poinc}_{1,1}] = U(b_+) \bowtie \mathbb{C}[SO_{1,1}]$ in a family of models of quantum spacetime [16]. We show in Proposition 5.5 that this has a unique exterior algebra $\Omega(\mathbb{C}_\lambda[\text{Poinc}_{1,1}])$ such that the natural coaction of the Poincaré quantum group on the associated quantum spacetime $U(b_+)$ is differentiable. Here $U(b_+)$ with primitive generators $x, t$ and relations $[x, t] = \lambda x$ is regarded as the algebra of spacetime coordinates in 1+1 dimensions, equipped with its unique Poincaré covariant calculus from [24].

The larger picture that emerges in this work is that we should not choose differential structures independently on each algebra but in a coherent manner such that that natural maps between them are differentiable.

Meanwhile, the calculus $\Omega(D(A, H)) := \Omega(A)^{op} \bowtie \Omega(H)$ is in Proposition 5.8 is computed for the simplest case of $\mathbb{C}[SU_2] \bowtie \mathbb{C}[SU_2]$ of interest in 3D quantum gravity, but the significance of a differential calculus on it is not clear. By contrast on the codouble side, $U_q(su_2)^{cop} \bowtie \mathbb{C}[SU_2]$ can be seen as some version of $\mathbb{C}_q[SO_{1,3}]$ and the latter can be seen both as a cobosonisation and as a double cross product $\mathbb{C}_q[SU_2] \bowtie \mathbb{C}_q[SU_2]$ with a canonical coaction on $q$-Minkowski space, see [8]. Although we will not study applications of this here, our results provide a canonical $\Omega(\mathbb{C}_q[SO_{1,3}])$ such that this coaction is differentiable at least on the unit $q$-hyperboloid $\mathbb{C}_q[SU_2]$ with its calculus obtained in [17] by a super version of transmutation. The general Hopf algebraic picture which concerns us is that if $A$ is any coquasitriangular Hopf algebra then the coquasitriangular structure provides a (skew) pairing of $A$ with itself and hence a canonical ‘double’ coquasitriangular Hopf algebra $D(A, A) = A \bowtie A$, so we have a canonical calculus $\Omega(A \bowtie A) := \Omega(A) \bowtie \Omega(A)$ in Section 5.9. We then have an isomorphism $A \bowtie A \cong A \bowtie A$ where $A$ is the transmutation of $A$, see [8], so we can also view this as $\Omega(A) \bowtie \Omega(A)$. This provides the motivating construction to lead from Section 5 to Section 4.

2. Preliminaries on strongly bicovariant differential calculi

Here we recall what is meant by a strongly bicovariant differential calculus on a bialgebra or Hopf algebra, following [20], and what it means for a coaction by it to be differentiable. We also look at what it means for an action to be differentiable. The section includes some first lemmas that will be needed later as well the example of the FRT bialgebra $A(R)$ in the $q$-Hecke case coacting differentiably on the associated quantum plane.

2.1. Super, braided and super-braided Hopf algebras. Let $k$ be a field. We recall that a Hopf algebra $A$ is a unital algebra together with algebra maps coproduct $\Delta : A \rightarrow A \otimes A$ and counit $\epsilon : A \rightarrow k$ forming a coalgebra, and equipped with an antipode map $S : A \rightarrow A$ defined by $(Sa_{(1)})a_{(2)} = ea = a_{(1)}Sa_{(2)}$ for all $a \in A$, where we use the Sweedler notation $a_{(1)} \otimes a_{(2)}$ (summation understood). More generally, a super-Hopf algebra is a $\mathbb{Z}_2$-graded Hopf algebra $A$, where $A = A_0 \oplus A_1$, with grade $|a| = i$ for $a \in A_i$, where $i = 0, 1$. Here the coproduct $\Delta : A \rightarrow A \otimes A$ respects the total grades and is an algebra map to the super tensor product algebra

$$(a \otimes b)(c \otimes d) = (-1)^{|b||c|}(ac \otimes bd)$$
for $a, b, c, d \in A$. The counit also respects the grade and hence $\epsilon |_{A_0} = 0$ if we work over a field $k$. If $A$ is a super-Hopf algebra then $A \otimes A$ is also a super-Hopf algebra, with

$$\Delta(a \otimes b) = (-1)^{|a||b|} a_{(1)} \otimes b_{(1)} \otimes a_{(2)} \otimes b_{(2)}$$

where $|a|$ is the degree of $a$.

The notions of action and coaction under a Hopf algebra similarly have super version, namely respecting the total degree. Thus $V = V_0 \oplus V_1$ is a super right $A$-module algebra if $V$ is a super right $A$-module by $\triangleright : V \otimes A \to A$ and additionally

$$(vw) \triangleright a = (-1)^{|v||a|} (v \triangleright a)(w \triangleright a),$$

and a super right $A$-module coalgebra if additionally

$$\Delta(v \triangleright a) = (-1)^{|v||a|} v_{(1)} \triangleright a_{(1)} \otimes v_{(2)} \otimes a_{(2)}$$

for all homogeneous $v, w \in V$ and $a \in A$. Similarly, $V$ is a super right $A$-comodule algebra if $V$ is a super right $A$-comodule by $\Delta_R : V \to V \otimes A$, denoted by $\Delta_R v = v^\overrightarrow{m} \otimes v^\overrightarrow{m}$ (summation understood) and additionally

$$\Delta_R(vw) = (-1)^{|w||v|} (v^\overrightarrow{m} \otimes w^\overrightarrow{m}) \otimes v^\overrightarrow{m} w^\overrightarrow{m},$$

and a super right $A$-comodule coalgebra if additionally

$$(\Delta \otimes \text{id}) \Delta_R v = (-1)^{|v||w|} (v^\overrightarrow{m} \otimes w^\overrightarrow{m}) \otimes v^\overrightarrow{m} w^\overrightarrow{m},$$

for all homogeneous $v, w \in V$ and $a \in A$. There is also an equivalently well left-handed version of super $A$-(co)module (co)algebra.

The usual notion of crossed or Drinfeld-Radford-Yetter modules (c.f. [11, 12, 23]) also has a super version: $V$ is a super right $A$-crossed module over a super-Hopf algebra $A$ if $V$ is both a super right $A$-module and a super right $A$-comodule, such that

$$\Delta_R(v \triangleright a) = (-1)^{|v||a|} (v^\overrightarrow{m} \otimes w^\overrightarrow{m}) \otimes v^\overrightarrow{m} w^\overrightarrow{m}$$

and $\Psi(a) = (S_{A_{(1)}}) v^\overrightarrow{m} a_{(2)} \otimes (S_{A_{(1)}}) v^\overrightarrow{m} a_{(3)}$ for all homogeneous $v \in V$ and $a \in A$. The category $\mathcal{M}_A^A$ of super right $A$-crossed modules is a prebraided category with the braiding $\Psi : V \otimes W \to W \otimes V$ given by

$$\Psi(v \otimes w) = (-1)^{|v||w|} (v^\overrightarrow{m} \otimes w^\overrightarrow{m}) \otimes (v \triangleright w^\overrightarrow{m})$$

and braided if $A$ has invertible antipode, which we will assume throughout.

Next we recall that a braided Hopf algebra (or ‘braided group’) $B$ as introduced and studied in [11, 14] is a Hopf algebra in a braided category $C$, where we view the unit element as morphism $\eta : \mathbf{1} \to B$, and the product, coproduct, counit $\epsilon : B \to \mathbf{1}$ and antipode are morphisms. In a concrete setting, we denote a coproduct for braided Hopf algebra as $\Delta b = b_{(1)} \otimes b_{(2)}$ (summation understood) where $\Delta$ is an algebra morphism to the braided tensor product algebra so that $\Delta(ab) = b_{(1)} \Psi(b_{(2)} \otimes c_{(1)}) c_{(2)}$, with the braiding $\Psi$ of the category on $B \otimes B$. In the category of super or $\mathbb{Z}_2$-graded vector spaces, this just means a super-Hopf algebra since the categorical braiding on $B$ is $\Psi(b \otimes c) = (-1)^{|b||c|} c \otimes b$. We will also need the notion of super braided-Hopf algebra satisfies the same axioms as braided-Hopf algebra but $\mathbb{Z}_2$-graded and with an extra factor $(-1)^{|a||b|}$ in every braiding. This assumes direct sums in the category and can be viewed as a braided Hopf algebra in a super version of the braided category where objects are of the form $V_0 \oplus V_1$ and the braiding has the additional signs according to the degree.

When $A$ is an ordinary Hopf algebra and $B$ is a braided-Hopf algebra in $\mathcal{M}_A^A$ a category of right $A$-crossed modules, there is an ordinary Hopf algebra $A \bowtie B$, the
bosonisation cf [13] or biproduct[23, 12] of $B$ built on $A \otimes B$ with product and coproduct

$$(a \otimes b)(c \otimes d) = ac(1) \otimes (bc(2))d$$

$$\Delta(a \otimes b) = a(1) \otimes b(1) \otimes \alpha a(2)b(2) \otimes b(3).$$

This structure was found in [23] from a study of Hopf algebras with projection (they are of this form) prior to the theory of braided-Hopf algebras, while the above formulation is due to the second author in [12]. If $A$ is (co)quasitriangular then a functor from $A$-(co)modules to $A$-crossed modules leads to special cases of (co)bosonisation in the more strict original sense of [13]. There is also an equivalently well left-handed version for braided-Hopf algebra $B$ in category of left $A$-crossed modules $\mathcal{M}_A$ which gives a bosonisation $B >\bowtie A$.

2.2. Differentials on Hopf algebras. A differential calculus on an algebra $A$ is an $A$-$A$-bimodule $\Omega^1 = \text{span}\{a db\}$ where $d : A \rightarrow \Omega^1$ is a linear map obeying Leibniz rule $d(ab) = (da)b + adb$. The calculus $\Omega^1$ is said to be inner if there is an element $\theta \in \Omega^1$ such that $d = [\theta, \ ]$. If, moreover, $A$ is a Hopf algebra then $\Omega^1$ is said to be left-covariant if $\Omega^1$ is a left $A$-comodule with left coaction $\Delta_L : \Omega^1 \rightarrow A \otimes \Omega^1$ such that $\Delta_L d = (id \otimes d)\Delta$. It is said to be right covariant if $\Omega^1$ is an right $A$-comodule with right action $\Delta_R : \Omega^1 \rightarrow \Omega^1 \otimes A$ such that $\Delta_R d = (d \otimes id)\Delta$. If $\Omega^1$ is both left and right covariant, it is said to be bicovariant.

By exterior algebra on $A$, we will mean that, $A, \Omega^1$ as above extends to a differential graded algebra $\Omega = \oplus_{n \geq 0} \Omega^n$ generated by $A = \Omega^0, \Omega^1$ and $d$ extends to $d : \Omega^n \rightarrow \Omega^{n+1}$ by the graded Leibniz rule $d(\omega \eta) = (d\omega)\eta + (-1)^{\omega}\omega d\eta$ holds for all $\omega, \eta \in \Omega$. Here $|\omega|$ denotes the degree of $\omega$. Again, when $A$ is a Hopf algebra, $\Omega$ is left covariant if it is a left $A$-comodule algebra with graded $\Delta_L$ commuting with $d$, and similarly for the right covariant case and bicovariant cases. Finally, an exterior algebra $\Omega$ is strongly bicovariant[20] if it is a super-Hopf algebra with super-degree given by the grade mod 2, the super-coproduct $\Delta_*$ is grade preserving and restricts to the coproduct of $A$, and $d$ is a super-coderivation in the sense

$$\Delta_* d\omega = (d \otimes id + (-1)^{|\omega|}|id \otimes d)\Delta_*\omega$$

as discussed in the introduction. It is proved in [20] that any strongly bicovariant exterior algebra is bicovariant, justifying the terminology, with $\Delta_L,\Delta_R$ on $\Omega^1$ extracted from the relevant grade component of $\Delta_*|_{\Omega^1}$. For example, $\Delta_*|_{\Omega^1} = \Delta_L + \Delta_R$ for the coactions on $\Omega^1$.

Given $(A, \Omega^1, d)$, one has the maximal prolongation exterior algebra $\Omega_{\text{max}}$ where we impose the quadratic relation $\sum_i db_i dc_i + \sum_j dr_j ds_j = 0$ whenever $\sum_i db_i, c_i - \sum_j r_j s_j = 0$ is a relation in $\Omega^1$, where $b_i, c_i, r_i, s_i \in A$. In the bicovariant case on a Hopf algebra an exterior algebra one has a canonical exterior algebra $\Omega_{\text{wor}}$ in [25], see [18] for a modern treatment. If $(A, \Omega^1, d)$ is bicovariant, both $\Omega_{\text{max}}$ and $\Omega_{\text{wor}}$ are strongly bicovariant, see [18] and [3] respectively.

Finally, in the strongly bicovariant case it follows[20] by a super version of the Radford-Majid biproduct theorem[23, 12] that $\Omega \cong A \bowtie \Lambda^*$ is super-bosonisation, where $\Lambda = \oplus_{i \geq 1} \Lambda^i$ is the subalgebra of left-invariant differential forms and forms a super braided-Hopf algebra in category of right $A$-crossed modules $\mathcal{M}_A$.

**Lemma 2.1.** Let $A, H$ be Hopf algebras, and let $\Omega(A), \Omega(H)$ be strongly bicovariant exterior algebras. Then $\Omega(A \otimes H) := \Omega(A) \otimes \Omega(H)$ is a strongly bicovariant exterior
algebra with super tensor product algebra and super tensor coproduct coalgebra, and differential
\[ d(\omega \otimes \eta) = d_A \omega \otimes \eta + (-1)^{|\omega|} \omega \otimes d_H \eta, \]
for all \( \omega, \tau \in \Omega(A) \) and \( \eta, \xi \in \Omega(H) \). Furthermore, it is isomorphic to \((A \otimes H) \otimes (A \otimes H)\).

**Definition 2.2.** Differentiable coactions and actions.

It is easy to see that \( \Omega^1(A \otimes H) = \text{span}\{(a \otimes h)\text{d}(b \otimes g)\} = \text{span}\{a \text{d}_A b \otimes f + c \otimes \text{d}_H g\} = \Omega^1(A) \otimes H \otimes A \otimes \Omega(H) \) since
\[ (c \otimes h)\text{d}(1 \otimes g) = c \otimes \text{d}_H g, \]
for all \( a, b, c \in A \) and \( h, g, f \in H \). The graded Leibniz-rule hold since \( d(\omega) = d_A \omega \) and \( d(\eta) = d_H \eta \) for all \( \omega \in \Omega(A) \) and \( \eta \in \Omega(H) \), and the algebra is just a super tensor product algebra. The new part is that \( d \) is a super-coderivation:
\[ \Delta_d d(\omega \eta) = \Delta_d ((d \omega) \eta + (-1)^{|\omega|} \omega d \eta) \]
\[ = (\Delta_d (d \omega) \eta + (-1)^{|\omega|}\Delta_d \omega (d \eta) \eta) \]
\[ = (\Delta_d (d \omega) \eta + (-1)^{|\omega|}\Delta_d \omega (d \eta) \eta) \]
\[ + (-1)^{|\omega|}\eta (\Delta_d (\omega \eta)) \]
\[ = (\Delta_d (d \omega) \eta + (-1)^{|\omega|}\Delta_d \omega (d \eta) \eta) \]
\[ + (-1)^{|\omega|}\eta (\Delta_d (\omega \eta)) \]
\[ = (d \omega) \eta + (-1)^{|\omega|} \omega d \eta. \]

Furthermore, \( A \otimes H \) acts and coacts on \( \Lambda_A \otimes \Lambda_H \) by \( (v \otimes w) \delta(a \otimes h) = v \otimes w \delta h \) and \( \Delta_R (v \otimes w) = v^{\text{even}} \otimes w^{\text{even}} + v^{\text{odd}} \otimes w^{\text{odd}} \) for all \( a \in A \), \( h \in H \) and \( v \in \Lambda_A \), \( w \in \Lambda_H \), making \( \Lambda_A \otimes \Lambda_H \) an \( A \otimes H \)-crossed module since
\[ \Delta_R ((v \otimes w) \delta(a \otimes h)) = (v^{\text{even}} \otimes w^{\text{even}}) \delta(a_{(2)} \otimes h_{(2)})) \otimes (S(a_{(1)} \otimes h_{(1)}))((v^{\text{odd}} \otimes w^{\text{odd}})(a_{(3)} \otimes h_{(3)}) \]
\[ = (v^{\text{even}} \otimes w^{\text{even}}) \delta((a_{(2)} \otimes h_{(2)})) \otimes (S(a_{(1)}))v^{\text{odd}} \otimes a_{(2)} \otimes h_{(3)}(v_{(2)} \otimes w^{\text{odd}}). \]

Thus there is a bosonisation \((A \otimes H) \otimes (A \otimes H) \otimes (A \otimes H) \otimes (A \otimes H) \) and it is easy to show that \( \Omega(A) \otimes \Omega(H) \cong A \otimes H \otimes A \otimes H \cong (A \otimes H) \otimes (A \otimes H) \) by \( a \otimes v \otimes h \otimes w \mapsto a \otimes h \otimes v \otimes w \).

### 2.3. Differentiable coactions and actions

Let \( A \) be a Hopf algebra or bialgebra, and let \( B \) be an algebra. We first recall the concept of differentiable coaction. (This is also discussed in [3] Chapter 4.2.)

**Definition 2.2.** Let \( B \) be a right \( A \)-comodule algebra with coaction \( \Delta_R b = b^{\text{even}} \otimes b^{\text{odd}} \) equipped with \( \Omega(B) \) which is a right \( A \)-comodule algebra with right coaction \( \Delta_R \eta = \eta^{\text{even}} \otimes \eta^{\text{odd}} \) on each degree such that \( d \) is a comodule map. The coaction \( \Delta_R \) is called **differentiable** if it extends to a degree-preserving map \( \Delta_{R*} : \Omega(B) \rightarrow \Omega(B) \otimes \Omega(A) \) of differential exterior algebras, where we take the graded tensor product, and \( \Delta_{R*} \) respects \( d \) of \( \Omega(B) \otimes \Omega(A) \) in the sense that \( \Delta_{R*} \circ d = d \Delta_{R*} \), or explicitly
\[ \Delta_{R*} \circ d = d \Delta_{R*} = d \eta^{\text{even}} \otimes \eta^{\text{odd}} + (-1)^{|\eta|} \eta^{\text{even}} \otimes d_A \eta^{\text{odd}}, \]
where we denote \( \Delta_{R*} \eta = \eta^{\text{even}} \otimes \eta^{\text{odd}} \in \Omega(B) \otimes \Omega(A) \) for all \( \eta \in \Omega(B) \).
If $\Delta_{R*}$ exists then it is uniquely determined from $\Delta_R$. For instance on $\Omega^1(B)$, we would need
\begin{equation}
\Delta_{R*}(bd_{BC}) = b^\overline{m}d_{BC}^\overline{m} \otimes b^\overline{m}c^\overline{m} + b^\overline{m}c^\overline{m} \otimes b^\overline{m}d_{BC}^\overline{m}.
\end{equation}
where the first term is the coaction $\Delta_R : \Omega^1(B) \to \Omega^1(B) \otimes A$ and the second term is the map
\[
\delta_R(bd_{BC}) = b^\overline{m}c^\overline{m} \otimes b^\overline{m}d_{BC}^\overline{m}, \quad \delta_R : \Omega^1(B) \to B \otimes \Omega^1(A),
\]
which we require to be well-defined.

**Lemma 2.3.** \cite{3} For $\Omega(B)$ an $A$-covariant calculus, if the map $\Delta_{R*} : \Omega^1(B) \to (\Omega^1(B) \otimes A) \otimes (B \otimes \Omega^1(A))$ in (2.3) is well-defined and $\Omega(B)$ is the maximal prolongation of $\Omega^1(B)$ then $\Delta_{R*}$ extends to all degrees and the coaction $\Delta_R$ is differentiable.

**Proof.** This is in \cite{3} but to be self-contained, we give our own short proof. In fact, it suffices to prove that $\Delta_{R*}$ extends to $\Omega^2(B)$ since the maximal prolongation is quadratic. So we need to check that $\Delta_{R*}(\xi \eta) = \Delta_{R*}(\xi)\Delta_{R*}(\eta)$ is well-defined for $\xi, \eta \in \Omega^1(B)$. Suppose we have the relation $bd_{BC} = 0$ in $\Omega^1(B)$ (sum of such terms understood) which implies that $d_Bbd_{BC} = 0 \in \Omega^2(B)$. Applying $\Delta_{R*}$ to the relation in $\Omega^1(B)$ we have
\[
b^\overline{m}d_{BC}^\overline{m} \otimes b^\overline{m}c^\overline{m} = 0, \quad b^\overline{m}c^\overline{m} \otimes b^\overline{m}d_{BC}^\overline{m} = 0.
\]
Applying $\text{id} \otimes d_A$ to the first equation and $d_B \otimes \text{id}$ to the second equation then subtracting them gives us
\[
b^\overline{m}d_{BC}^\overline{m} \otimes (d_Ab^\overline{m})c^\overline{m} - (d_Bb^\overline{m})c^\overline{m} \otimes b^\overline{m}d_{BC}^\overline{m} = 0,
\]
which is the $\Omega^1(B) \otimes \Omega^1(A)$ part of $\Delta_{R*}(d_Bbd_{BC})$. Applying $d_B \otimes \text{id}$ to the first equation gives
\[
d_Bb^\overline{m}d_{BC}^\overline{m} \otimes b^\overline{m}c^\overline{m} = 0
\]
which is the $\Omega^2(B) \otimes \text{id}$ part. Finally, applying $\text{id} \otimes d_A$ to the second equation gives
\[
b^\overline{m}c^\overline{m} \otimes d_Ab^\overline{m}d_{BC}^\overline{m} = 0,
\]
which is the $B \otimes \Omega^2(A)$ part. Since all relations in the maximal prolongation are sent to zero then $\Delta_{R*}$ extends to $\Omega^2(B)$, which completes the proof. \hfill $\square$

There is an equally good left-handed definition of differentiable coaction, where the left coaction $\Delta_L : B \to A \otimes B$ extends to degree preserving map $\Delta_{L*} : \Omega(B) \to \Omega(A) \otimes \Omega(B)$ of exterior algebra. We also need a concept of differentiable action, which we introduce now

**Definition 2.4.** Let $B$ be a right $A$-module algebra with action $\triangleleft : B \otimes A \to A$, equipped with an $A$-covariant exterior algebra $\Omega(B)$ in the sense of an $A$-module algebra with $\text{d}$ an $A$-module map. The action is called differentiable if it extends to a degree-preserving map $\triangleleft : \Omega(B) \otimes \Omega(A) \to \Omega(B)$, making $\Omega(B)$ a super $\Omega(A)$-module algebra, and $\triangleleft$ respects $\text{d}$ of $\Omega(B) \otimes \Omega(A)$ in the sense that $d_B\triangleleft = \triangleleft d_A$, or explicitly
\begin{equation}
\text{d}_B(\eta \triangleleft \omega) = (\text{d}_B\eta)\triangleleft \omega + (-1)^{|\eta|}\eta \triangleleft (\text{d}_A\omega).
\end{equation}
If the action is differentiable, then it is uniquely determined. For instance, on $\Omega^1(B)$ and $\Omega^2(B)$, we have
\[
d_B(b \triangleleft a) = (\text{d}_Bb) \triangleleft a + b \triangleleft (\text{d}_Aa), \quad d_B((\text{d}_Bb) \triangleleft a) = -(\text{d}_Bb) \triangleleft (\text{d}_Aa)
\]
where the \((d_B b)\ast a\) is given as is \(d_B (b\ast a)\), hence \(b\ast d_A a\) is determined, and hence also \(a \triangleright B \otimes \Omega^1(A) \rightarrow \Omega^2(B)\). Similarly the second equation specifies \(a \triangleright \Omega^2(B) \otimes \Omega^1(A) \rightarrow \Omega^3(B)\). The action also obeys module algebra axiom, for example

\[
(\eta \xi) \triangleright a = (\eta \triangleright a) (\xi \triangleright d_A a) + (-1)^{[\xi]} (\eta \triangleright d_A a) (\xi \triangleright a),
\]

for all \(\eta, \xi \in \Omega(B)\) and \(a \in A\), hence \(\Omega(B) \otimes \Omega^1(A) \rightarrow \Omega(B)\) is specified.

**Lemma 2.5.** Let \(B\) be an \(A\)-module algebra with an exterior algebra \(\Omega(B)\) which is also an \(A\)-module algebra and \(\Omega(A)\) is the maximal prolongation of \(\Omega^1(A)\). If \(\triangleright : \Omega(B) \otimes \Omega^1(A) \rightarrow \Omega(B)\) is well-defined by

\[
\eta \triangleright (d_A a) c := (\eta \triangleright d_A a) \ast c, \quad \eta \triangleright d_A a := (-1)^{[\eta]} (d_B (\eta \ast a) - (d_B \eta) \ast a)
\]

for all \(\eta \in \Omega(A)\) and \(a, c \in A\) then \(\triangleright\) extends to \(\triangleright : \Omega(B) \otimes \Omega(A) \rightarrow \Omega(B)\) as differentiable action.

**Proof.** First we check that \(\triangleright : \Omega(B) \otimes \Omega^1(A) \rightarrow \Omega(B)\) if defined as above gives an action of \(\Omega^1(A)\) in the sense

\[
\eta \triangleright (ad_A c) = \eta \triangleright (d_A (ac) - (d_A a)c) = (-1)^{[\eta]} d_B (\eta \ast ac) - (-1)^{[\eta]} (d_B \eta) \ast ac - (\eta \ast d_A a) \ast c
\]

\[
= (-1)^{[\eta]} (d_B (\eta \ast a) \ast c) - (-1)^{[\eta]} ((d_B \eta) \ast a) \ast c - (\eta \ast d_A a) \ast c
\]

\[
= (-1)^{[\eta]} ((d_B \eta) \ast a) \ast c + (\eta \ast d_A a) \ast c - (\eta \ast d_A a) \ast c
\]

\[
= (-1)^{[\eta]} ((d_B \eta) \ast a) \ast c + (\eta \ast d_A a) \ast c - (\eta \ast d_A a) \ast c
\]

\[
= (-1)^{[\eta]} (d_B (\eta \ast a) \ast c) - ((d_B \eta) \ast a) \ast c
\]

We now suppose that \(\Omega(A)\) is the maximal prolongation of \(\Omega^1(A)\) and show that we can extend the above to a right action of \(\Omega(A)\) of all degrees. The higher relations are quadratic of the form \(d_A ad_A c = 0\) for \(ad_A c = 0\) (a sum of such terms understood) and we check that

\[
0 = d_B (\eta \triangleright (ad_A c)) = (d_B \eta) \triangleright (ad_A c) + (-1)^{[\eta]} \eta \triangleright (d_A ad_A c) = (-1)^{[\eta]} \eta \triangleright (d_A ad_A c)
\]

as required. Indeed this gives an action of \(\Omega^2(A)\) in the sense

\[
\eta \ast d_A ad_A c = \eta \ast d_A (ad_A c) = (-1)^{[\eta]} (d_B (\eta \ast ad_A c) - (d_B \eta) \ast ad_A c)
\]

\[
= (-1)^{[\eta]} ((d_B (\eta \ast a) \ast c) - ((d_B \eta) \ast a) \ast c
\]

and since \(\Omega(A)\) is the maximal prolongation of \(\Omega^1(A)\), then there is no new relations in higher degree and thus \(\ast\) can be extended further to be an action of \(\Omega(A)\) of all degrees, making \(\Omega(H)\) a super right \(\Omega(A)\)-module.

Next we check that \(\Omega(B)\) is a super right \(\Omega(A)\)-module algebra with regard to the action of \(\Omega^1(A)\),

\[
(\eta \xi) \triangleright a = (-1)^{[\eta] + [\xi]} (d_B (\eta \xi \ast a)) - d_B (\eta \xi) \ast a
\]

\[
= (-1)^{[\eta] + [\xi]} (d_B (\eta a) (\xi \ast a)) - (d_B \eta \xi) \ast a - (-1)^{[\eta]} (d_B \eta \xi) \ast a
\]

\[
= (-1)^{[\eta] + [\xi]} (d_B (\eta a) (\xi \ast a)) + (-1)^{[\xi]} (\eta a) d_B (\xi \ast a) - (-1)^{[\eta] + [\xi]} ((d_B \eta) \xi) \ast a
\]

\[
= (-1)^{[\eta] + [\xi]} (d_B \eta) \ast (\xi \ast a) + (-1)^{[\xi]} (\eta a) d_B (\xi \ast a) + (-1)^{[\xi]} (\eta a) ((d_B \xi) \ast a)
\]

\[
= (\eta a) ((d_A a) \ast a) + (-1)^{[\xi]} (\eta a) ((d_B \xi) \ast a)
\]

\[
= (\eta a) ((d_A a) \ast a) + (-1)^{[\xi]} (\eta a) ((d_B \xi) \ast a)
\]
where we see the coproduct \( \Delta_a(d_Aa) = a_{(1)} \otimes d_Aa_{(2)} + d_Aa_{(1)} \otimes a_{(2)} \) of \( \Omega(A) \). As a direct consequence, one can find that

\[
(\eta\xi)\circ(\text{id}d_Ac) = (\eta\circ(a_{(1)}c_{(1)}))((\xi\circ(d_{Aa_{(1)}})c_{(2)})) + (-1)^{|\xi|}|(\eta\circ(a_{(2)}c_{(1)}))((\xi\circ(a_{(1)}c_{(2)}))
\]

as required for the action of general elements of \( \Omega^1(A) \). Since \( \Omega(A) \) is the maximal prolongation of \( \Omega^1(A) \), then by taking \( ad_Ac = 0 \), one can check that

\[
0 = d_B((\eta\xi)\circ(\text{id}d_Ac)) = (d_B(\eta\xi))\circ(\text{id}d_Ac) + (-1)^{|\eta|+|\xi|}(\eta\xi)\circ(d_Aa_{(1)}d_Aa_{(2)})
\]

implying \((\eta\xi)\circ(\text{id}d_Ac) = 0\), making \( \Omega(B) \) a super right \( \Omega(A) \)-module algebra.  

There is an equally good left-handed definition of differentiable action, where the left action \( \triangleright : A \otimes B \rightarrow B \) extends to \( \triangleright : \Omega(A) \otimes B \rightarrow B \), making \( \Omega(B) \) a super left \( \Omega(A) \)-module algebra.

### 2.4. Differentials on the FRT bialgebra

We recall that the FRT-bialgebra\(^7\) \( A(R) \) is generated by \( t = (t^i_j) \) such that

\[
Rt_it_j = t_jt_iR, \quad \Delta t = t \otimes t, \quad \epsilon t = \text{id}
\]

where \( R = (R^i_j) \in M_n(C) \otimes M_n(C) \) where \((i,j)\) label the first copy and \((k,l)\) the second. In the compact notation the numerical suffices indicate the position in the tensor matrix product, e.g. \( t_1 = t \otimes \text{id} \), \( t_2 = \text{id} \otimes t \), \( R_{23} = \text{id} \otimes R \) etc. We ask for \( R \) to satisfy the Yang-Baxter equation \( R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12} \) (equivalent to the braid relation) and for the present purpose to be \( q \)-Hecke, which means that it satisfies

\[
(PR - q)(PR + q^{-1}) = 0,
\]

where \( P = (P^i_j) \) is a permutation matrix with \( P^i_j = \delta_i^j\delta^k_l \) in terms of the Kronecker delta or identity matrix. The \( q \)-Hecke condition is equivalent to \( R_{23}R = \text{id} + (q-q^{-1})PR \) where \( R_{23} \) has the tensor factors swapped.

It is already proven in \(^S\) Prop. 10.5.1 that \( A(R) \) in the \( q \)-Hecke case is an additive braided Hopf algebra in the braided category of \( A(R)^{\text{cop}} \otimes A(R) \)-right comodules (or \( A(R) \)-bicomodules) with coproduct \( \Delta t = t \otimes 1 + 1 \otimes t \), or in a compact notation \( t'' = t' + t \) where \( t' \) is a second copy of \( t \), and \( t'' \) obeys FRT-bialgebra relation provided \( t'_1t_2 = R_{21}t_2t'_1R \). This expresses the braided Hopf algebra homomorphism property of the coproduct with respect to the relevant braiding \( \Psi(t_1 \otimes t_2) = R_{21}t_2 \otimes t_1R \), see \(^S\) for details. As a consequence, as for any additive braided-Hopf algebra, it followed that \( A(R) \) has a bicovariant exterior algebra \( \Omega(A(R)) \) generated by \( t \) and \( dt \) with bimodule relations as in the next lemma. The new part is that this makes \( \Omega(A(R)) \) strongly bicovariant.

**Lemma 2.6.** Let \( A(R) \) be the FRT-bialgebra with \( R \) \( q \)-Hecke. The exterior algebra \( \Omega(A(R)) \) with bimodule and exterior algebra relations \((dt_1)t_2 = R_{21}t_2dt_1R \) and \( dt_1dt_2 = -R_{21}dt_2dt_1R \) as in \(^S\) is strongly bicovariant with \( \Delta t = dt \otimes t + t \otimes dt \).

**Proof.** The exterior algebra was already constructed in \(^S\), but we provide a short check of the Leibniz rule so as to be self-contained. Thus, on generators,

\[
\begin{align*}
\text{d}(t_2t_1R) &= R((dt_1)t_2 + t_1dt_2) = RR_{21}t_2dt_1R + R_{21}t_2dt_2 \\
&= (dt_2)t_1R + (q-q^{-1})R_{21}t_2dt_1R + R_{21}t_2dt_2 \quad \text{(id + (q-q^{-1})PR \text{ on } t_2dt_1R} \\
&= (dt_2)t_1R + t_2dt_1R = R_{21}t_2dt_2R + t_2dt_1R \quad \text{d(t_2t_1R)}
\end{align*}
\]
where we used $R_{21} = R^{-1} + (q-q^{-1})P$ for the 2nd equality and $t_1 dt_2 P = Pt_2 dt_1$ for the 3rd. Applying $d$ once more to the stated bimodule relation on degree 1 gives the stated relations in degree 2 and there are no further relations in higher degree, which means that $\Omega(A(R))$ is the maximal prolongation of $\Omega^1(A(R))$.

The new part is the super-coproduct $\Delta_\ast$, which is uniquely determined by the super-coderivation property but we need to check that it is well-defined. Thus,

$$\Delta_\ast((dt_1)_{t_2}) = (dt_1)_{t_2} t_1 t_2 + t_1 t_2 \otimes dt_1 t_2 = R_{21} t_2 dt_1 R \otimes t_1 t_2 + t_1 t_2 \otimes R_{21} t_2 dt_1 R$$

$$= R_{21} t_2 dt_1 \otimes t_2 t_1 R + R_{21} t_2 t_1 \otimes t_2 dt_1 R = \Delta_\ast(R_{21} t_2 dt_1 R)$$

on $\Omega^1(A(R))$. Since $\Omega(A(R))$ is the maximal prolongation, we do not in principle need to check the relations in higher degrees due to arguments similar to the proof of Lemma 2.3. In practice, however, we check the degree 2 relations explicitly. Thus

$$\Delta_\ast(R_{21} t_2 dt_1 R) = R_{21} (dt_1 t_2 \otimes t_1 t_2 + t_2 dt_1 \otimes t_1 t_2 - t_2 dt_1 \otimes t_1 t_2 + t_1 t_2 \otimes dt_1 t_2) R$$

$$= R_{21} dt_1 t_2 R \otimes t_1 t_2 - R_{21} t_2 dt_1 R \otimes t_1 t_2 + t_1 t_2 \otimes R_{21} t_2 dt_1 R$$

$$= R_{21} t_2 dt_1 \otimes t_2 t_1 R - R_{21} t_2 dt_1 R \otimes t_2 t_1 + t_1 t_2 \otimes R_{21} t_2 dt_1 + R_{21} t_2 t_1 \otimes dt_1 t_2 R$$

$$= R_{21} t_2 dt_1 \otimes t_2 t_1 R + (id + (q-q^{-1})P) t_1 dt_2 R_{21} \otimes t_2 dt_1 R$$

$$= R_{21} t_2 dt_1 \otimes R t_1 dt_2 (id + (q-q^{-1})P) + R_{21} t_2 t_1 \otimes dt_1 t_2 R$$

$$= R_{21} t_2 dt_1 \otimes t_2 t_1 R + (id + (q-q^{-1})P) R t_1 dt_2 R_{21} \otimes t_2 dt_1 R + (q-q^{-1}) P R t_1 dt_2 R_{21} \otimes t_2 dt_1 R$$

$$- R_{21} t_2 dt_1 \otimes R t_1 dt_2 - (q-q^{-1}) R_{21} t_2 dt_1 \otimes R t_1 dt_2 PR + R_{21} t_2 t_1 \otimes dt_2 dt_1 R.$$

The two expressions are equal since

$$PR t_1 dt_2 R_{21} \otimes t_2 dt_1 R = R_{21} P t_1 dt_2 \otimes dt_1 t_2 = R_{21} t_2 dt_1 \otimes P dt_1 t_2 = R_{21} t_2 dt_1 \otimes dt_2 t_1 P$$

$$= R_{21} t_2 dt_1 \otimes R t_1 dt_2 R_{21} P = R_{21} t_2 dt_1 \otimes R t_1 dt_2 PR.$$

so that $(q-q^{-1})(PR t_1 dt_2 R_{21} \otimes t_2 dt_1 R - R_{21} t_2 dt_1 \otimes R t_1 dt_2 PR)$ vanishes. \hfill $\square$

Now consider additive braided-Hopf algebras $V(R)$ on which $A(R)$ right coacts. These are the $q$-Hecke case of the general construction in [8 Prop. 10.2.8] and are generated by $x = (x_i)$ regarded as a vector row with relations $q x_i x_j = x_j x_i R$ with coaction $\Delta_R x = x \otimes t$. The braided Hopf algebra structure (due to the 2nd author) is expressed in [8 Thm. 10.2.6] as braided addition $x'' = x' + x$ where $x''$ obeys the relation of $V(R)$ provided $x'_i x'_j = x'_j x'_i q R$ (the latter expresses the braiding $\Psi(x_1 \otimes x_2) = x_2 \otimes x_1 q R$ induced by the coquasitriangular structure $K(t_1 \otimes t_2) = q R$). As before, the additive braided-Hopf algebra theory implies the maximal prolongation exterior algebra $\Omega(V(R))$ given at the end of [8 Chapter 10.4] with the relations shown in the next lemma. A more formal treatment of the exterior algebras on an additive braided Hopf algebra, which underlies both $\Omega(A(R))$ and $\Omega(V(R))$, recently appeared in [13 Prop. 2.9]. The new part is that $\Delta_R$ is differentiable.

**Lemma 2.7.** Let $V(R)$ be the right $A(R)$-covariant braided plane with $R$ q-Hecke. The exterior algebra $\Omega(V(R))$ with bimodule and exterior algebra relations $(dx_1) x_2 = x_2 dx_1 q R$ and $-dx_1 dx_2 = dx_2 dx_1 q R$ as in [8] has differentiable right coaction with $\Delta_R dx = dx \otimes t + x \otimes dt$. 
Proof. That $\Delta_{R^\ast}$ is well-defined on degree 1 is

$$\Delta_{R^\ast}((dx_1|x_2) = (dx_1)x_2 \otimes t_1t_2 + x_1x_2 \otimes (dt_1)t_2 = x_2dx_1qR \otimes t_1t_2 + x_1x_2 \otimes R_{22}t_2dt_1R$$

$$= x_2dx_1 \otimes qRt_2t_2 + x_1x_2R_{22} \otimes t_2dt_1R = x_2dx_1 \otimes t_2t_2qR + x_2x_1 \otimes t_2dt_1qR$$

$$= \Delta_{R^\ast}(x_2dx_1qR).$$

This is sufficient by Lemma 2.3 since $\Omega(V(R))$ is the maximal prolongation of $\Omega^2(V(R))$. If one wants to see it explicitly on degree 2, this is

$$\Delta_{R^\ast}(-dx_1dx_2) = -dx_1dx_2 \otimes t_2t_2 - (dx_1)x_2 \otimes t_1dt_2 + x_1x_2 \otimes (dt_1)t_2 - x_1x_2 \otimes dt_1dt_2$$

$$= dx_2dx_1qR \otimes t_1t_2 - qdx_2x_1 \otimes (id + (q - q^{-1})PR) + x_1x_2 \otimes dt_2dt_1qR$$

which simplifies to the first expression.

We will suppose later that $A(R)$ has a central grouplike element $D$ such that $A = A(R)[D^{-1}]$ is a Hopf algebra. For the standard $C_q[GL_n]$ $R$-matrix, this is just the $q$-determinant allowing $S$ to be constructed as $D^{-1}$ times a $q$-matrix of cofactors. (Another approach, which we will not take, is to assume that $R$ is ‘bi-invertible’ and define a Hopf algebra by reconstruction from a rigid braided category defined by $R$.) It is easy to see that $\Omega(A(R))$ extends to a strongly bicovariant exterior algebra $\Omega(A)$ with $dD^{-1} = -D^{-1}(dD)D^{-1}$.

3. DIFFERENTIALS ON DOUBLE (CO)CROSS PRODUCTS

Here we briefly cover the quantum group construction $\otimes\otimes$ from [10] and its dual $\triangleright\triangleright$ in the notation of [5]. The former includes the Drinfeld double of a Hopf as generalised in [10] to the case of dually paired Hopf algebras.

3.1. Exterior algebras by super double cross product. Let $A$ and $H$ be two bialgebras or Hopf algebras with $H$ is a right $A$-module coalgebra by $\cdot : H \otimes A \to H$, and $A$ is a left $H$-module coalgebra by $\triangleright : H \otimes A \to A$. We suppose that $\otimes$ and $\triangleright$ are compatible as in [10] $\triangleright$ such that they form a double cross product Hopf algebra $A\triangleleft H$.

Now let $\Omega(A)$ and $\Omega(H)$ be strongly bicovariant exterior algebras, and let $\otimes$ and $\triangleright$ extend to $< : \Omega(H) \otimes\otimes\Omega(A) \to \Omega(H)$ and $\triangleright : \Omega(H) \triangleright\triangleright\Omega(A) \to \Omega(A)$ as module coalgebras such that

$$d_H(\eta \omega) = (d_H \eta) \omega + (-1)^{\eta} \eta d_A \omega$$

$$d_A(\eta \omega) = (d_H \eta) \triangleright \omega + (-1)^{\eta} \eta d_A \omega.$$
finite-dimensional case with case, the product becomes \((a \triangleleft \triangleleft H) \otimes (\eta_1, \eta_2) \triangleleft \triangleleft \triangleleft \omega_1 \triangleleft \triangleleft \triangleleft \omega_2)\) then we have a super double cross product bialgebra or Hopf algebra \(\Omega(A) \otimes \Omega(H)\) with super tensor product coalgebra and product
\[
(\omega \otimes \eta)(\tau \otimes \xi) = (-1)^{|\eta_2||\tau_1|} (\omega(\eta_1) \triangleright \tau_1) \otimes (\eta_2 \triangleleft \triangleleft \tau_2) \xi
\]
for all \(\eta, \xi \in \Omega(H)\) and \(\omega, \tau \in \Omega(A)\). We omit the proof that \(\Omega(A) \otimes \Omega(H)\) is a super Hopf algebra since this is similar to the usual version \cite{Ho} with extra signs.

**Theorem 3.1.** Let \(A, H\) be bialgebras or Hopf algebras forming a double cross product \(A \otimes H\) and let \(\Omega(A)\) and \(\Omega(H)\) be strongly bicovariant with \(\triangleleft, \triangleright\) obeying (3.1)–(3.6). Then \(\Omega(A \otimes H) := \Omega(A) \otimes \Omega(H)\) is a strongly bicovariant exterior algebra on \(A \otimes H\) with differential
\[
d(\omega \otimes \eta) = \text{ad}_A \omega \otimes \eta + (-1)^{|\omega|} \omega \otimes \text{ad}_H \eta
\]

**Proof.** First note that \(\Omega^1(A \otimes H) = \text{span}\{(a \otimes h) \text{ad}(b \otimes g)\} = \text{span}\{ad_A(b \otimes f + c \otimes \text{hd}_H g)\} = \Omega^1(A) \otimes H \oplus A \otimes \Omega^1(H)\) since
\[
(c \otimes h) \text{ad}(1 \otimes g) = c \otimes \text{hd}_H g, \quad (a \otimes 1) \text{ad}(b \otimes f) - (ab \otimes 1) \text{ad}(1 \otimes f) = \text{ad}_A(b \otimes f)
\]
for all \(a, b, c \in A\) and \(f, g, h \in H\).

Since \(d(\omega \otimes 1) = \text{ad}_A \omega \) and \(d(1 \otimes \eta) = \text{ad}_H \eta\) for all \(\eta \in \Omega(H)\) and \(\omega \in \Omega(A)\), we show that the graded Leibniz rule hold as follow
\[
d(\eta \omega) \equiv d(1 \otimes \eta)(\omega \otimes 1))
\]
then we have
\[
\begin{align*}
(-1)^{|\eta_2||\omega_1|}(d_H \eta_1 \triangleright \omega_1 \otimes \eta_2 \triangleleft \triangleleft \omega_2) + (-1)^{|\eta_1||\omega_1|+|\omega_1|}(\eta_1 \triangleleft \triangleleft \omega_1 \otimes \eta_2 \triangleright \omega_2)
+ (-1)^{|\eta_2||\omega_1|+|\omega_2|}(\eta_1 \triangleright \omega_1 \otimes \eta_2 \triangleleft \triangleleft \omega_2)
\end{align*}
\]
we get
\[
\begin{align*}
(-1)^{|\eta_1||\omega_2|}(d_H \eta_1 \triangleright \triangleleft \triangleleft \omega_1 \otimes \eta_2 \text{ad}(d_H \omega_2))
+ (-1)^{|\eta_2||\omega_2|+|\omega_2|}(\eta_1 \triangleright \triangleleft \triangleleft \omega_1 \otimes \eta_2 \text{ad}(d_H \omega_2))
\end{align*}
\]
Finally since \(\eta \otimes 1 = 0\) and thus \(\Omega(A) \otimes \Omega(H)\) is a DGA. Finally since \(\Delta\) is a super tensor co-prod such as in Lemma 2.1 \(d\) is a super-coderivation. \(\square\)

**Remark 3.2.** If \(A\) is finite dimensional, it is known cf \cite{Sc} that \(A \otimes H\) acts on \(A^*\) as module algebra by
\[
(\phi \text{ad})(a) = \phi(h \triangleright a), \quad \phi \triangleright a = (\phi(a_1), a_2),
\]
for all \(\phi \in A^*, a \in A\), and \(h \in H\). Similarly for a left action on \(H^*\). However, for differentiability, we would need \(\Omega(A^*)\) or \(\Omega(H^*)\) to be specified. We focus in the next section on a special case where this is not a problem.

### 3.2. Exterior algebra on generalised quantum doubles \(D(A, H)\). Let \(A, H\) be dually paired Hopf algebras with duality pairing \(\langle \: , \: \rangle : H \otimes A \rightarrow k\). Then, \(A\) acts on \(H\) and \(H\) acts on \(A\) by the following actions
\[
h \triangleright a = h_{\langle 3 \rangle} \langle Sh_{\langle 1 \rangle}, a_{\langle 2 \rangle} \rangle \langle h_{\langle 3 \rangle}, a_{\langle 2 \rangle} \rangle, \quad h \triangleright a = a_{\langle 2 \rangle} \langle Sh_{\langle 1 \rangle}, a_{\langle 2 \rangle} \rangle \langle h_{\langle 2 \rangle}, a_{\langle 3 \rangle} \rangle,
\]
and one has a generalised quantum double \(D(A, H) = A^{op} \otimes H\) \cite{Ho} \cite{Sc}. In this case, the product becomes \((a \otimes b)(c \otimes d) = \langle Sh_{\langle 1 \rangle}, c_{\langle 1 \rangle}, c_{\langle 2 \rangle} a \otimes b, d, c_{\langle 3 \rangle} \rangle\). The finite-dimensional case with \(A = H^*\) is Drinfeld’s \(D(H)\) from \cite{Dr}.
Let $\Omega(A)$ be a strongly bicovariant exterior algebra. We see that
\[
d_A(\omega \cdot_\tau \eta) = (d_\omega \cdot_\tau \eta) + (d_\eta \cdot_\tau \omega)
\]
for all $\omega, \tau \in \Omega(A)$. Therefore we can define $\Omega(A)^{op} := \Omega(A)^{op}$ with differential $d_A$.

Also let $\Omega(H)$ be a strongly bicovariant exterior algebra and suppose that the above pairing can be extended to a super Hopf algebra pairing $\langle \, , \rangle : \Omega(H) \otimes \Omega(A) \to k$ by $0$ for degree $\geq 1$. So we have
\[
\eta \omega = \begin{cases} \eta_{(2)} \langle S\eta_{(1)}, \omega_{(1)} \rangle \omega_{(2)} \langle \eta_{(3)}, \omega_{(3)} \rangle & \text{if } \omega \in A \\ 0 & \text{otherwise}, \end{cases}
\]
\[
\eta \rho \omega = \begin{cases} \omega_{(2)} \langle S\eta_{(1)}, \omega_{(1)} \rangle \omega_{(3)} \langle \eta_{(2)}, \omega_{(3)} \rangle & \text{if } \eta \in H \\ 0 & \text{otherwise}, \end{cases}
\]
where only the part of $\Delta_2^2 \eta$ in $H \otimes \Omega(H) \otimes H$ contributes in the first action, and only the part of $\Delta_2^2 \omega$ in $A \otimes \Omega(A) \otimes A$ contributes in the second action.

One can check that the above actions obey conditions (3.1) - (3.3) for a super double cross product. Therefore, there is a super double cross product $\Omega(A)^{op} \otimes \Omega(H)$ with product
\[
(\omega \otimes \eta)(\tau \otimes \xi) = (1)^{|\eta|+|\omega|+|\tau|+|\xi|} \langle S\eta_{(1)}, \omega_{(1)} \rangle \tau_{(2)} \omega_{(2)} \xi_{(3)} \eta_{(3)} \tau_{(3)}
\]
for all $\omega, \tau \in \Omega(A)$, $\eta, \xi \in \Omega(H)$ and super tensor product coalgebra. Note that in the above product, $\tau_{(2)}$ and $\omega$ are crossed with $\eta_{(2)}$ and so we should have generated a factor $(-1)^{|\eta_{(2)}|+|\omega|+|\tau|+|\xi|}$ but $\langle \, , \rangle$ is 0 on degree $\geq 1$, and the part of $\Delta_2^2 \eta$ in $H \otimes \Omega(H) \otimes H$ and the part of $\Delta_2^2 \omega$ in $A \otimes \Omega(A) \otimes A$ contribute, so $|\eta_{(2)}| = |\eta|$ and $|\tau_{(2)}| = |\tau|$.

Proposition 3.3. Let $A, H$ be dually paired Hopf algebras and $D(A, H) = A^{op} \otimes H$.

Let $\Omega(A)$ and $\Omega(H)$ be dually paired strongly bicovariant exterior algebras as above. Then $\Omega(D(A, H)) := \Omega(A)^{op} \otimes \Omega(H)$ is a strongly bicovariant exterior algebra on the generalised quantum double $D(A, H)$ with differential
\[
d(\omega \otimes \eta) = \omega \otimes d_H \eta + (-1)^{|\omega|} \omega \otimes d_H \eta,
\]
for all $\eta \in \Omega(H)$ and $\omega \in \Omega(A)$. Moreover, the action of $D(A, H)$ on $H$ defined by $g \delta(a \otimes h) = (g_{(2)}, a)(S h_{(1)}) g_{(1)} h_{(2)}$ is differentiable and extends to an action of $\Omega(D(A, H))$ on $\Omega(H)$ by
\[
\xi \rho(\omega \otimes \eta) = \begin{cases} (-1)^{|\eta_{(1)}||\xi|} \langle \xi_{(1)}, \omega \rangle \langle S \eta_{(1)}, \xi_{(2)} \rangle \eta_{(2)} & \text{if } \omega \in A \\ 0 & \text{otherwise}, \end{cases}
\]
where only the part of $\Delta_\omega \xi$ in $\Omega(H) \otimes H$ contributes. Explicitly
\[
\xi \rho(\omega \otimes \eta) = (-1)^{|\eta_{(1)}||\xi|} \langle \xi_{(1)}, \omega \rangle \langle S \eta_{(1)}, \xi_{(2)} \rangle \eta_{(2)},
\]
where $\Delta_R \xi = \xi^{\otimes 3} \otimes \xi^{\otimes 3}$ is the right coaction of $H$ on $\Omega(H)$. Similarly with left-right reversal for a differentiable left action of $D(A, H)$ on $A$.

Proof. The first part of the lemma follows from Theorem 3.1. One can check the stated action makes $\Omega(H)$ a super right $\Omega(D(A, H))$-module algebra. Moreover, $\Delta_\omega \xi = \Delta_R \xi + \text{terms of higher degree on the second factor}$, giving the explicit formula stated. It also respects $d$ since
\[
d_H(\xi \rho(\omega \otimes \eta)) = (-1)^{|\eta_{(1)}||\xi|} \langle \xi_{(1)}, \omega \rangle d_H((S \eta_{(1)}) \xi_{(2)} \eta_{(2)})}

Moreover, \( \Omega(1) \) graded Leibniz rule holds, and \( d \) is a super-coderivation. By Proposition 3.3, later in Proposition 4.8) with the following bimodule relations and comultiplication

Let \( \Omega(1) \) ant exterior algebras, and the following cross-relations, comultiplication, and duality pairing

\(|d_H x, t| = (1 - q^2)t x, \quad \Delta x = 1 \otimes x + x \otimes t |

where \( y, s \) are another copies of \( x, t \), regarded as generators of \( A^{op} = U_q(b_+)^{op} = U_q^{-1}(b_+) \) and \( q^2 \neq 1 \). Let \( \Omega(U_q(b_+)) \) be strongly bicovariant (it will be constructed later in Proposition 3.3) with the following bimodule relations and comultiplication

\(|d_H t) = t^2 dt, \quad (dx) x = q^2 x dx, \quad (dx) t = td x, \quad (dt) x = q^2 x dt + (q^2 - 1) dx |

\(|d_H t)^2 = 0, \quad d d x = - x d t, \quad \Delta x = d x \otimes x + x \otimes d x |

Then \( \Omega(D(U_q(b_+))) \) contains \( \Omega(U_q(b_+)) \) and \( \Omega(U_q^{-1}(b_+)) \) as sub-strongly bicovariant exterior algebras, and the following cross-relations

\(|ts = st, \quad ty = q^{-2}yt, \quad xs = q^{-2}sx, \quad xy = q^{-2}yx + \frac{1 - st}{1 - q^2} |

\(|d_H t) s = s d t, \quad (dx) s = q^{-2} s dx, \quad (dx) x = q^2 x dx, \quad (dt) y = q^{-2}y dt, \quad

\(|dy) t = q^2 td y, \quad (dx) y = q^{-2}y dx - \frac{sd t}{1 - q^2}, \quad (dy) x = q^2 x dy + \frac{td s}{q^2 - 1} |

\(|d d s = - s d t, \quad d d y = q^{-2}y d t, \quad d x d s = - q^{-2}d x s, \quad d x d y = - q^{-2}d x y - \frac{d s d t}{1 - q^2} |

Moreover, \( \Omega(D(U_q(b_+))) \) acts differentiably on \( U_q(b_+) \).

**Proof.** One can check that \( \langle \cdot, \cdot \rangle \) extends by 0 on degree \( \geq 1 \). Then the stated crossed relations can be found by direct calculation and one can check that the graded Leibniz rule holds, and \( d \) is a super-coderivation. By Proposition 3.3, \( \Omega(U_q^{-1}(b_+)) \otimes \Omega(U_q(b_+)) \) acts differentiable by

\(|t x t = t, \quad t x = (1 - q^{-2})t x, \quad x a = (1 - q^{-2})a x |

\(|d H t) a t = q^2 dt, \quad (dx) a x = (q^2 - 1)a x | d x, \quad (dx) a x = (q^2 - 1)a x |

\(|t x d t = (1 - q^2) d t, \quad t d x = (q^2 - 1)a x | d x, \quad x a d t = (q^2 - 1) a x | d x |

\(|d x) a d t = (dx) a d t = (dx) a x = 0, \quad (dx) a d x = (1 - q^2) a d x |

\(|t a s = q^{-2} s, \quad t a y = 0, \quad x a s = x, \quad x a y = \frac{t}{1 - q^2} |

\(|d x) a s = q^{-2} d t, \quad (dx) a y = 0, \quad (dx) a s = d x, \quad (dx) a y = \frac{dt}{1 - q^2} |

\(|t a d s = t a d y = x a d s = x a d y = 0 |

\]
Remark 3.5. It is known\(^6\) that \(D(U_q(b_+))/((st^{-1})-1) \cong U_q(sl_2)\) by
\[
x \mapsto x_+, K, \quad y \mapsto x_-, t \mapsto K^2,
\]
where here \(U_q(sl_2)\) is generated by \(K, x_\pm\) with the following relation
\[
KK^{-1} = K^{-1}K, \quad Kx_\pm = q^{\pm 1}x_\pm K, \quad [x_+, x_-] = \frac{K^2 - K^{-2}}{q - q^{-1}}.
\]
However, \(\Omega(D(U_q(b_+)))\) in Example 3.3 above does not descend to \(\Omega(U_q(sl_2))\) since \(d(st^{-1}) = 0\) gives \(ds = q^{-2}dt\).

Example 3.6. Let \(U(sl_2)\) be the enveloping algebra of \(sl_2\) with generators \(a, b,\) for \(a, b \in \mathbb{C}\) with primitive coproducts and relations \([a, b] = 2\lambda \epsilon_{abc} x_c\), where \(\lambda \in i\mathbb{R}\) is a purely imaginary number and \(\epsilon_{abc}\) is the totally antisymmetric tensor.

Let \(\mathbb{C}[SU_2]\) be the classical 3D strongly bicovariant exterior algebra with the following bimodule relations\(\Box\)
\[
\langle dx_a, x_b \rangle = \lambda \epsilon_{abc} dx_c - \lambda^2 \delta_b^a \theta, \quad [\theta, x_a] = dx_a
\]
and primitives coproducts on \(dx_a\) and \(\theta\).

Let \(\mathbb{C}[SU_2]\) be the classical 3D strongly bicovariant exterior algebra with
\[
\langle dx_a, x_b \rangle = \lambda \epsilon_{abc} dx_c - \lambda^2 \delta_b^a \theta, \quad [\theta, x_a] = dx_a
\]
and primitives coproducts on \(dx_a\) and \(\theta\).

Let \(\mathbb{C}[SU_2]\) be the commutative Hopf algebra generated as usual by \(t = \{t^i_j\}\), with determinant \(t^i_1 t^j_1 - t^i_2 t^j_2 = 1\) and \(\Delta t^i_j = t^i_k \otimes t^k_j\). Also let \(\Omega(\mathbb{C}[SU_2])\) be the classical 3D strongly bicovariant exterior algebra with
\[
\langle dt^i_j, dt^k_l \rangle = 0, \quad \langle dt^i_j, dt^l_k \rangle = 0, \quad \langle dt^i_j, dt^l_j \rangle = \delta^i_j + \delta^l_j \delta^i_k + t^i_k \otimes dt^j_k,
\]
where \(\Delta t^i_j = t^i_k \otimes t^k_j\). Then \(\Omega(\mathbb{C}[SU_2]) \cong \Omega(U(sl_2))\) is strongly bicovariant and contains \(\Omega(\mathbb{C}[SU_2])\) and \(\Omega(U(sl_2))\) as sub-strongly bicovariant exterior algebras, and the following cross bimodule relations
\[
[x_a, t^i_j] = -\lambda (t^i_k (\sigma_a^k)^j - (\sigma_a^k)^i j), \quad [x_a, dt^i_j] = -\lambda (dt^i_k (\sigma_a^k)^j - (\sigma_a^k)^i j)
\]
and this gives the stated cross relation on degree 0 as found previously in \(\Box\). One can check that \(\langle , \rangle\) extends to the pairing between \(\Omega(\mathbb{C}[SU_2])\) and \(\Omega(U(sl_2))\) by 0 for degree \(\geq 1\), giving the rest of stated crossed relations on \(\Omega(\mathbb{C}[SU_2]) \cong \Omega(U(sl_2))\).

One can also check that the graded Leibniz rule holds, \(d\) is a super-coderivation. Each factor is a \(*\)-calculus (in the usual sense that \(*\) commutes with \(d\) and is a graded antilinear order-reversing involution), with the usual \(*\)-structure given by
\[
x_a^* = x_a, \quad \theta^* = -\theta, \quad (dx_a)^* = dx_a, \quad (t^i_j)^* = S t^i_j, \quad (dt^i_j)^* = S dt^i_j.
\]
One can check that these result in a \(*\)-calculus, e.g.
\[
[x_a, dt^i_j]^* = [(dt^i_j)^*, x_a^*] = [S dt^i_j, x_a] = -\lambda (dt^i_k (\sigma_a^k)^j - (\sigma_a^k)^i j) = -\lambda (dt^i_k (\sigma_a^k)^j - (\sigma_a^k)^i j)^*.
\]
By Proposition 3.3 the action of \(\Omega(\mathbb{C}[SU_2]) \cong \Omega(U(sl_2))\) on \(\Omega(U(sl_2))\) as a super module algebra is given by
\[
x_a \triangleleft x_b = [x_a, x_b], \quad (dx_a) \triangleleft x_b = [dx_a, x_b], \quad x_a \triangleleft dx_b = [x_a, dx_b], \quad (dx_a) \triangleleft dx_b = [dx_a, dx_b],
\]
\[
x_a dt^i_j = x_a \delta^i_j - 1 \lambda (\sigma_a)^i_j, \quad (dx_a) dt^i_j = dx_a \delta^i_j, \quad x_a \omega dt^i_j = 0
\]
\[
\theta dt^i_j = \theta \delta^i_j, \quad (dx_a) \omega dt^i_j = 0, \quad \theta \omega dt^i_j = 0.
\]

\[
\square
\]

**Remark 3.7.** One can replace \(A^{op}\) by \(A\) in the above construction and regard the Hopf algebra pairing \(\langle \ , \ \rangle\) as a skew pairing \(\sigma : H \otimes A \to k\) defined as a convolution-invertible map satisfying
\[
\sigma(bg, a) = \sigma(h, a_{(1)})\sigma(g, a_{(2)}), \quad \sigma(h, ab) = \sigma(h_{(2)}, a)\sigma(h_{(1)}, b).
\]
Here \(\langle S(\ ) , \ )\) provides \(\sigma^{-1}\) if we start with a Hopf algebra pairing. The above is then equivalent to a generalised quantum double \(A \bowtie \triangleleft H\). By extending to \(\sigma : \Omega(H) \otimes \Omega(A) \to k\) by 0 for degree \(\geq 1\), we have a super double cross product \(\Omega(A) \bowtie \triangleleft \Omega(H)\), and by Theorem 3.4 we have \(\Omega(A \bowtie \triangleleft H) := \Omega(A) \bowtie \triangleleft \Omega(H)\). In this approach, we work with a strongly bicovariant exterior algebra \(\Omega(A)\) rather than \(\Omega(A)^{op}\).

### 3.3. Exterior algebra on \(A \bowtie \triangleleft R A\)

Recall that a coquasitriangular Hopf algebra is a Hopf algebra \(A\) equipped with involution-invertible \(R : A \otimes A \to k\) such that
\[
\mathcal{R}(ab, c) = \mathcal{R}(a, c_{(1)})\mathcal{R}(b, c_{(2)})
\]
\[
\mathcal{R}(a, bc) = \mathcal{R}(a_{(1)}, c)\mathcal{R}(a_{(2)}, b), \quad a_{(1)}b_{(1)}\mathcal{R}(b_{(2)}, a_{(2)}) = \mathcal{R}(b_{(2)}, a_{(1)})b_{(1)}a_{(2)}
\]
for all \(a, b, c \in A\). In this case we can view \(A\) as skew-paired with itself by \(\sigma = \mathcal{R}\) in Remark 3.7 and have \(\Omega(A) = A \bowtie \triangleleft A\) with \(A\) left and right acting on itself by
\[
b \omega = b_{(2)}\mathcal{R}(Sb_{(1)}, a_{(1)})\mathcal{R}(b_{(2)}, a_{(2)}), \quad b \omega = a_{(2)}\mathcal{R}(Sb_{(1)}, a_{(1)})\mathcal{R}(b_{(2)}, a_{(2)})
\]
for all \(a, b \in A\) to give the double cross product structure. The product is \((a \otimes b)(c \otimes d) = \mathcal{R}(Sb_{(1)}, a_{(1)})a_{(2)}c_{(2)} \otimes b_{(1)}d\mathcal{R}(b_{(2)}, c_{(3)})\) for all \(a, b, c, d \in A\), see [S].

Let \(\Omega(A)\) be a strongly bicovariant exterior algebra, viewed as a super-coquasitriangular Hopf algebra with \(\mathcal{R}\) extended by 0 on degree \(\geq 1\). The above actions extend to actions of \(\Omega(A)\) on itself by
\[
\eta \omega = \begin{cases} 
\eta_{(2)}\mathcal{R}(S\eta_{(1)}, \omega_{(1)})\mathcal{R}(\eta_{(2)}, \omega_{(2)}) & \text{if } \omega \in A \\
0 & \text{otherwise}
\end{cases}
\]
\[
\eta \omega = \begin{cases} 
\omega_{(2)}\mathcal{R}(S\eta_{(1)}, \omega_{(1)})\mathcal{R}(\eta_{(2)}, \omega_{(3)}) & \text{if } \eta \in A \\
0 & \text{otherwise}
\end{cases},
\]
where only the part of \(\Delta^2 \eta \in A \otimes \Omega(A) \otimes A\) contributes in the first action, and only the part of \(\Delta^2 \omega \in A \otimes \Omega(A) \otimes A\) contributes in the second action. One can check that these actions obey (3.1)–(3.6) and thus we have a super double version \(\Omega(A) \bowtie \triangleleft \Omega(A)\) with product coproduct
\[
(\omega \otimes \eta)(\tau \otimes \xi) = (-1)^{|\eta||\tau|} \mathcal{R}(S\eta_{(1)}, \tau_{(1)})\omega\tau_{(2)} \otimes \eta_{(2)}\xi\mathcal{R}(\eta_{(3)}, \tau_{(3)})
\]
\[
\Delta_\omega(\omega \otimes \eta) = (-1)^{|\eta_{(1)}||\omega_{(1)}|} \omega_{(1)} \otimes \eta_{(1)} \otimes \omega_{(2)} \otimes \eta_{(2)}.
\]
for all \(\omega, \eta, \tau, \xi \in \Omega(A)\). Note that in the above product, the crossing between \(\eta_{(2)}\) and \(\tau_{(2)}\) should have generated a factor \((-1)^{|\eta_{(2)}||\tau_{(2)}|}\) but \(\mathcal{R}\) is 0 on degree \(\geq 1\), so only the parts of \(\Delta^2 \eta\) and \(\Delta^2 \tau\) in \(A \otimes \Omega(A) \otimes A\) contributes, resulting in \(|\eta_{(2)}| = |\eta|\) and \(|\tau_{(2)}| = |\tau|\).

**Corollary 3.8.** Let \(\Omega(A)\) be a strongly bicovariant exterior algebra on a coquasitriangular Hopf algebra \(A\). Then \(\Omega(A) \bowtie \triangleleft \Omega(A)\) is a strongly bicovariant exterior algebra on \(A \bowtie \triangleleft R A\) with differential
\[
d(\omega \otimes \eta) = dA\omega \otimes \eta + (-1)^{|\omega|} \omega \otimes dA\eta,
\]
and $\mathbb{A}$ acts differentiably on $A$ by $ac(b \otimes c) = R(a_{(2)}, b)(Sc_{(1)})a_{(1)}c_{(2)}$ for all $a, b, c \in A$ extending to an action of $\Omega(A) \otimes_{\mathbb{R}} \Omega(A)$ on $\Omega(A)$ by

$$\tau \circ (\omega \otimes \eta) = \begin{cases} (-1)^{|\eta(1)||\tau|} R(\tau(2), \omega)(S\eta(1)) \tau(1)\eta(2) & \text{if } \omega \in A \\ 0 & \text{otherwise} \end{cases},$$

where only the part of $\Delta, \tau \in A \otimes \Omega(A)$ contributes. Moreover, there is a coaction $\Delta_R : A \to A \otimes A \otimes A$ given by $\Delta_R a = a_{(2)} \otimes S(a_{(1)} \otimes a_{(3)})$ which is differentiable with $\Delta_R \omega = (-1)^{|\omega(1)||\omega(2)|} S\omega(1) \otimes \omega(3)$.

**Proof.** The first part of the statement follows from Proposition 3.3 where $\langle, \rangle$ is replaced by $R$, and $(S(\cdot), \cdot)$ is replaced by $R^{-1}$ as in Remark 3.7. For the new part, since $\Omega(A)$ is strongly bicovariant, then $\Delta_R : \Omega(A) \to \Omega(A) \otimes \Omega(A) \otimes \Omega(A)$ above is globally defined. One can check that it respects $d$ since

$$\Delta_R(d\omega) = (-1)^{|d\omega(1)|} |d\omega(2)| (d\omega(3)) \otimes S(d\omega(1)) \otimes (d\omega(3))$$

$$= (-1)^{|d\omega(1)| + |d\omega(2)| + |d\omega(3)|} (d\omega(1)) \otimes (d\omega(2)) \otimes (d\omega(3))$$

$$= (-1)^{|d\omega(1)| + |d\omega(2)| + |d\omega(3)|} (d\omega(1)) \otimes (d\omega(2)) \otimes (d\omega(3))$$

$$= (dA \otimes \text{id} + (-1)^{|d\omega(1)|} |d\omega(2)| + |d\omega(3)|) \Delta_R \omega.$$

□

**Example 3.9.** Let $R \in M_n(R) \otimes M_n(R)$ be a $q$-Hecke $R$-matrix and $A(R)$ the FRT bialgebra generated by $t = (t^i_j)$. We assume that there is a grouplike central $D \in A(R)$ and we let $A = A(R)[D^{-1}]$ and $\Omega(A)$ its strongly bicovariant exterior algebra as explained in Section 2.7. Then $\Omega(A) \otimes A$ has the cross relations and comultiplication

$$Rt_1s_2 = s_2t_1R, \quad (ds_2)t_1R = R(t_1)ds_2, \quad R(dt_1)s_2 = s_2dt_1R, \quad Rd_1ds_2 = -ds_2dt_1R$$

$$\Delta t = t \otimes t, \quad \Delta s = s \otimes s, \quad \Delta s dt = dt \otimes t + t \otimes dt, \quad \Delta s ds = ds \otimes s + s \otimes ds,$$

where $s$ is the copy of $t$. Furthermore $\Omega(A) \otimes A$ acts and coacts differentiably on $A$.

**Proof.** One can find the stated relations since $A$ is a coquasitriangular with $R(t_1, t_2) = R$ and $R(St_1, t_2) = R^{-1}$, and $\Omega$ extends as super coquasitriangular structure on $\Omega(A)$ by zero in degree $\geq 1$. One can check that Leibniz rule hold and $d$ is a super-coderivation. By Corollary 3.8 the action of $\Omega(A) \otimes A$ on $\Omega(A)$ as a super module algebra is given by

$$t_1 \otimes t_2 = (St_2)t_1t_2, \quad (dt_1) \otimes t_2 = (St_2)(dt_1)t_2, \quad t_1 \otimes dt_2 = (Sdt_2)t_1t_2 + (St_2)t_1dt_2$$

$$t_1 \otimes ds_2 = t_1R, \quad (dt_1) \otimes ds_2 = (dt_1)R, \quad t_1 \otimes ds_2 = 0,$$

and the coaction of $\Omega(A) \otimes A$ on $\Omega(A)$ as a super comodule algebra is given by

$$\Delta_R t = t \otimes S s \otimes t, \quad \Delta_R dt = dt \otimes S s \otimes t + t \otimes S s dt.$$
3.4. Exterior algebras by super double cross coproduct. Let \( H \) and \( A \) be bialgebras or Hopf algebras with \( A \) a right \( \mathcal{H} \)-comodule algebra with right coaction \( \alpha : A \to \mathcal{H} \otimes A \) and \( H \) a left \( A \)-comodule algebra with left coaction \( \beta : H \to A \otimes H \). Suppose that \( \alpha \) and \( \beta \) are compatible as in [8] such that they form a double cross coproduct \( H \bowtie A \).

Now let \( \Omega(\mathcal{H}) \) and \( \Omega(A) \) be strongly bicovariant exterior algebras, and let \( \alpha \) and \( \beta \) be differentiable with extensions \( \alpha_\ast : \Omega(A) \to \Omega(A) \otimes \Omega(\mathcal{H}) \) and \( \beta_\ast : \Omega(\mathcal{H}) \to \Omega(A) \otimes \Omega(\mathcal{H}) \) as super comodule algebras (commuting with \( d \) for the graded tensor product differential). Suppose further that \( \alpha_\ast \) and \( \beta_\ast \) are compatible as in [8] such that they form a double cross product differential. Suppose further that \( \alpha_\ast \) and \( \beta_\ast \) are compatible as in [8] such that they form a double cross product algebra structure, counit, and coproduct of the usual double cross coproduct [8]. Then there is a super double cross coproduct \( \Omega(\mathcal{H}) \bowtie \Omega(A) \) with super tensor product differential \( d(\eta \otimes \omega) = d_H \eta \otimes \omega + (-1)^{\lvert \eta \rvert} \eta \otimes d_A \omega \).

**Theorem 3.10.** Let \( A, H \) be bialgebras or Hopf algebras forming a double cross coproduct \( H \bowtie A \) and \( \Omega(A), \Omega(\mathcal{H}) \) strongly bicovariant exterior algebras with \( \alpha, \beta \) differentiable and \( \alpha_\ast, \beta_\ast \), satisfying (3.7)-(3.9). Then \( \Omega(\mathcal{H}) \bowtie \Omega(A) := \Omega(\mathcal{H}) \bowtie \Omega(A) \) is a strongly bicovariant exterior algebra on \( H \bowtie A \) with differential.

\[
\Delta_{\ast}(\eta \otimes \omega) = ([id \otimes H \eta \otimes \omega] + (-1)^{\lvert \eta \rvert} \eta \otimes d_A \omega) \]

**Proof.** Since the algebra structure is the super tensor product, the graded Leibniz rule is already proved in Lemma 2.4. We need to prove \( d \) is a super-coderivation. Thus,

\[
\Delta_{\ast} d(\eta \otimes \omega) = \Delta_{\ast}(d_H \eta \otimes \omega) + (-1)^{\lvert \eta \rvert} \Delta_{\ast}(\eta \otimes d_A \omega)
\]

In the first equality we expand \( d(\eta \otimes \omega) \) by its definition, with its comultiplication in the second equality. Notice that \( \beta_\ast(d_H \eta \otimes \omega) = \beta'(\beta_\ast(\eta \otimes \omega)) \) and \( \alpha_\ast(d_A \omega) = d'(\alpha_\ast(\omega)) \), and thus we obtain the third equality by Leibniz rule of \( d' \) on \( \alpha_\ast(\omega) \beta_\ast(\eta) \). Expanding \( d' = d_A \otimes id + (-1)^{\lvert \eta \rvert} id \otimes d_H \), one can rewrite to obtain fourth equality, which is equivalent to the fifth equality. \(\square\)
Corollary 3.11. Under the condition of Theorem 3.10, the left coaction $\Delta_L : H \rightarrow H\multimap A \otimes H$ as a comodule algebra by $\Delta_L h = (h_1) \otimes \beta(h_2)$ is differentiable. Similarly, the right coaction $\Delta_R : A \rightarrow A \otimes H\multimap A$ as a comodule algebra by $\Delta_R a = \alpha(a_1) \otimes a_2$, is differentiable.

Proof. Write $\alpha(a) = a^{(\alpha)} \otimes a^{(\gamma)}$ and $\beta(h) = h^{(\alpha)} \otimes h^{(\beta)}$ (summations understood). We check that $\Delta_L$ is a coaction:

$$
(id \otimes \Delta_L)\Delta_L h = h(1) \otimes h_2^{(\alpha)} \otimes h_3^{(\gamma)}(1) \otimes h_4^{(\beta)}(2) \otimes h_5^{(\beta)}(2) \otimes h_6^{(\beta)}(2) \otimes h_7^{(\beta)}(2)
$$

We applied the definition of $\Delta_L$ twice in the first equality, and we used the condition (3.8) on $h_2^{(\alpha)}$ in our notation of $\alpha$ and $\beta$ to obtain the second equality. Then since $\beta$ is a coaction, we rewrote $(id \otimes \beta)(h_3^{(\gamma)}(1) \otimes h_4^{(\beta)}(2) \otimes h_5^{(\beta)}(2)) = (\Delta_R \otimes id)\beta(h_3^{(\gamma)}(1))$ to obtain the third equality, which is equivalent to the fourth equality. Then we used condition (3.9) to get the fifth equality, which is equal to the sixth equality. We also check that $\Delta_L$ is an algebra map:

$$
\Delta_L(hg) = (h(1) \otimes g(1)) \otimes \beta(h(2) \otimes g(2)) = h(1) \otimes \beta(h(2))g(1) \otimes \beta(g(2)) = (\Delta_L h)(\Delta_L g).
$$

Thus, $H$ is a left $H\multimap A$-comodule algebra. The proof for $\Delta_R$ is similar. Since $\beta_*$ and $\alpha_*$ globally exist as assumed in Theorem 3.10, it is clear that we can define

$$
\Delta_L \eta = \eta(1) \otimes \beta_*(\eta(2)), \quad \Delta_R \omega = \alpha_*(\omega(1)) \otimes \omega(2)
$$

for all $\eta \in \Omega(H)$ and $\omega \in \Omega(A)$, and that they have the required properties by our assumptions on $\alpha_*$, $\beta_*$. For example on degree 1 we have

$$
\Delta_L d_H h = d_H h(1) \otimes \beta(h(2)) + h(1) \otimes \beta_*(d_H h(2)),
$$

$$
\Delta_R d_A a = \alpha_*(d_A a(1)) \otimes a(2) + \alpha(a(1)) \otimes d_A a(2).
$$

As an application, we find in principle a strongly bicovariant exterior algebra on the quantum codouble $codU_q(SU_2) = U_q(SU_2)^{\text{cop}} \multimap C_q[SU_2]$ as a version of $C_q[SU_{1,1}]$, as discussed in the Introduction. We omit details since this is essentially equivalent in this case to $C_q[SU_2] \times C_q[SU_2]$ in Example 3.9.

4. DIFFERENTIALS ON BIPRODUCT HOPF ALGEBRAS OBTAINED BY BOSONISATION

Here we cover quantum differentials on one of two cases where the Hopf algebra is a cross product as an algebra, which is typical for an inhomogeneous quantum groups, namely biproducts or also known as bosonisations[23, 12, 13, 8]. We start with a reinterpretation of Corollary 3.8.
4.1. The special case of transmutation. Given a coquasitriangular Hopf algebra \((A,\mathcal{R})\), its transmutation is a braided-Hopf algebra \(\underline{A}\) introduced in [11] as one a main construction in the theory. Here \(\underline{A}\) has the same coalgebra structure as \(A\) but modified product \(a \triangleright \triangleright b = a_{(2)}b_{(2)}\mathcal{R}(Sa_{(1)}a_{(3)},Sb_{(1)})\), and living in the braided category of right-modules \(\mathcal{M}^A\) where the right coaction is given by adjoint coaction \(\text{Ad}^\mathcal{R}a = a_{(2)} \triangleright a_{(3)}\). Furthermore there is a right action of \(A\) on \(\underline{A}\) given by \(b \triangleright a = b_{(1)}\mathcal{R}(b_{(2)},a) = b_{(2)}\mathcal{R}(Sa_{(1)},a)\) making \(\underline{A} \in \mathcal{M}^A\) (this follows from a functor \(\underline{A} \in \mathcal{M}^A\) see [8]. Either by cobosonisation dual to [13] or from the crossed module point of view, one has an ordinary Hopf algebra \(\underline{A} \triangleright \triangleright A\). It is known [8] Thm. 7.4.10 that \(A \triangleright \triangleright \underline{A} \cong \underline{A} \triangleright \triangleright A\). Similarly, regarding a strongly bicovariant \(\Omega(A)\) as coquasitriangular by extending \(\mathcal{R}\) by zero, it transmutates to a super-braided-Hopf algebra \(\Omega(A)\). We write \(\Omega(A) \cong A \triangleright \triangleright \underline{A}\) as generated by \(A,\Lambda^1\) as discussed above.

Lemma 4.1. [17] Prop. 8 If \(\Omega(A)\) is a strongly bicovariant exterior algebra on a coquasitriangular Hopf algebra \(A\) then \(\Omega(\underline{A}) := \Omega(A)\) is a braided exterior algebra on \(\underline{A}\) generated by \(\Lambda\) and \(\Lambda^1\) with relations

\[
a \cdot v = av, \quad v \cdot a = a_{(2)}(v \triangleright \triangleright a_{(3)})\mathcal{R}(v \triangleright \triangleright, Sa_{(1)}), \quad v \cdot w = vw
\]

for all \(v, w \in \Lambda^1\) and \(a \in \underline{A}\), and the differential map of \(\Omega(\underline{A})\) is the same as the differential map of \(\Omega(A)\).

By construction, \(\Omega(\underline{A}) := \Omega(A)\) is a super braided-Hopf algebra in \(\mathcal{M}^{\Omega(A)}\) by the adjoint coaction and the induced action. Thus, we have super bosonisation \(\Omega(A) \triangleright \triangleright (\underline{A})\) as in [8] but now with signs,

\[
(\omega \triangleright \eta)(\rho \circ \xi) = ((-1)^{|\eta|\tau}|\omega_{(1)} \triangleright \eta_{(2)}\xi_{(2)}\mathcal{R}((S\eta_{(1)}\eta_{(3)}),\tau_{(2)}S\xi_{(1)}))
\]

\[
\Delta_s(\omega \triangleright \eta) = (-1)^{|\eta_0|(|\omega_1|+|\eta_1|)}\omega_1(\triangleright \eta_2) \triangleright \eta_3 \triangleright \eta_4(1)
\]

for all \(\omega, \tau \in \Omega(A)\) and \(\eta, \xi \in \Omega(\underline{A})\).

Proposition 4.2. Let \(\Omega(A)\) be a strongly bicovariant exterior algebra on a coquasitriangular Hopf algebra \(A\) and \(\underline{A}\) the transmutation of \(A\). Then \(\Omega(A) \triangleright \triangleright (\underline{A})\) is a strongly bicovariant exterior algebra on \(A \triangleright \triangleright \underline{A}\). Moreover, \(\Omega(A \triangleright \triangleright \underline{A}) \cong \Omega(A) \triangleright \triangleright (\underline{A})\) as an isomorphism of differential exterior algebras.

Proof. For the first part, we define \(d\) to be the graded sum of \(d_A\) and \(d_{\underline{A}}\) as in Theorem 3.1. That this gives a strongly bicovariant exterior algebra is a special case of Theorem 4.3 proven later, so here we omit the details. It is also clear once we have proven the asserted isomorphism of exterior algebras. To this end, let \(\varphi : A \triangleright \triangleright R \rightarrow A \triangleright \triangleright \underline{A}\) \(\varphi(a \circ b) = ab_{(1)} \cdot b_{(2)}\) be the Hopf algebra isomorphism by [4] Thm. 7.4.10]. We extend this to a map \(\varphi_s : \Omega(A) \triangleright \triangleright \Omega(A) \rightarrow \Omega(A) \triangleright \triangleright (\underline{A})\) by \(\varphi_s(\omega \circ \eta) = \omega\eta_{(1)} \cdot \eta_{(2)}\) for all \(\omega, \eta \in \Omega(A)\). It is straightforward to check that \(\varphi_s\) is a super-Hopf algebra map. We also need to check that \(\varphi_s\) commutes with \(d\) and note that \(d\) on both sides is the graded sum of the \(d\) on each tensor factor. We check

\[
d(\varphi_s(\omega \circ \eta)) = d(\omega\eta_{(1)} \cdot \eta_{(2)}) = d_A(\omega\eta_{(1)}) \cdot \eta_{(2)} + (-1)^{|\omega|\eta_{(1)}}\omega\eta_{(1)} \cdot d_A\eta_{(2)}
\]

\[
= (d_A\omega)\eta_{(1)} \cdot \eta_{(2)} + (\omega) \cdot (d_A\eta_{(1)}) \cdot \eta_{(2)} + (\omega) \cdot (d_A\eta_{(1)}) \cdot (d_A\eta_{(2)})
\]

\[
\varphi_s(\varphi_s(d_A\omega \circ \eta) + (-1)^{|\omega|d_A\eta_{(1)}}d_A\eta_{(2)}) = \varphi_s(d_A\omega \circ \eta) + (-1)^{|\omega|d_A\eta_{(1)}}d_A\eta_{(2)}
\]

\[
\varphi_s(d_A\omega \circ \eta) = \omega S\eta_{(1)} \cdot \eta_{(2)}.
\]
4.2. Exterior algebras by super bosonisation. We now generalise the first part of Proposition [23] replacing \( A \) by any Hopf algebra with and \( \Delta \) by any braided Hopf algebra \( B \) in the category of right \( A \)-crossed modules. Thus, let \( A \) be a Hopf algebra with strongly bicovariant exterior algebra \( \Omega(A) \). Let \( B \) be a right \( A \)-comodule algebra with coaction \( \Delta_R b = b^R \otimes b^M \) such that \( \Delta_R \) extends to \( \Delta_{R*} : \Omega(B) \rightarrow \Omega(B) \otimes \Omega(A) \) by \( \Delta_{R*} \eta = \eta^{R*} \otimes \eta^{M*} \) as a differentiable coaction.

We now come to the genuinely new data: (i) assume that \( A \) also acts on \( \Omega(B) \) so as to make this an \( A \)-crossed module algebra (an algebra in \( \mathcal{M}_A^A \)); (ii) suppose that this action is extends differentiably to \( \odot : \Omega(B) \odot \Omega(A) \rightarrow \Omega(B) \); (iii) suppose that \( B \) is a braided Hopf algebra in \( \mathcal{M}_A^A \); (iv) suppose that \( \Omega(B) \) is braided strongly bicovariant in the sense that \( \Delta \) extends to a degree preserving super braided coproduct \( \Delta \), making \( \Omega(B) \) a super-braided Hopf algebra in \( \mathcal{M}_{\Omega(A)}^\Omega \) and \( d_\mathcal{B} \) a super-coderivation in the sense of [21].

Also note that given a super-braided Hopf algebra \( \Omega(B) \in \mathcal{M}_{\Omega(A)}^\Omega \), the usual bosonisation formulae extend with signs to define a super bosonisation \( \Omega(A) \odot \Omega(B) \) with

\[
\Delta_v(\omega \otimes \eta) = (-1)^{|\eta||\tau(1)|} \omega_{\tau(1)} \otimes (\eta_{\sigma(2)}) \xi
\]

for all \( \omega, \tau, \xi \in \Omega(A) \) and \( \eta, \xi \in \Omega(B) \).

**Theorem 4.3.** Let \( A \) be a Hopf algebra and let \( B \) be a braided Hopf algebra in \( \mathcal{M}_A^A \), \( \Omega(A) \) a strongly bicovariant exterior algebra and \( \Omega(B) \) a braided strongly bicovariant exterior algebra in \( \mathcal{M}_{\Omega(A)}^{\Omega} \) (so the action and coaction of \( A \) is differentiable and \( d_B \) is a super coderivation). Then \( \Omega(A \odot B) \) is a strongly bicovariant exterior algebra on \( \odot B \) with differential

\[
d(\omega \otimes \eta) = d_A \omega \otimes \eta + (-1)^{|\omega|} \omega \otimes d_B \eta
\]

for all \( \omega \in \Omega(A) \), \( \eta \in \Omega(B) \).

**Proof.** First note that \( \Omega^4(A \odot B) = \langle (a \odot b) d(c \odot d) \rangle = \langle d_{A \odot B} c \otimes b \rangle = \Delta(\Omega^4(B)) = \Delta(B) \odot \Delta(B) \) since

\[
(a \odot b) d(c \odot d) = (ac \odot 1)(b \otimes 1) \quad \text{for all} \quad a, c \in A \quad \text{and} \quad b, d \in B.
\]

The graded Leibniz rule holds since

\[
d(\eta \omega) = d(1 \otimes \eta)(\omega \otimes 1) = (-1)^{\eta |\omega|} \omega(1) \eta(1) \otimes \eta(2) \omega(2) + (-1)^{|\eta| + |\omega(1)|} \omega(1) \eta(1) \otimes \omega(2) \eta(2)
\]

for all \( \eta \in \Omega(B) \) and \( \omega \in \Omega(A) \). Clearly \( d^2 = 0 \) and thus \( \Omega(A \odot B) \) is a DGA. We also show that the calculus on \( A \odot B \) is strongly bicovariant by showing that \( d \) is a super-coderivation as follow

\[
\Delta_v d(\omega) = \Delta_v(\Delta_v(\omega)) + (-1)^{|\omega|} \Delta_v(\Delta_v(\omega)) \Delta_v(d(\eta))
\]

which is

\[
= (-1)^{|\omega| + |\eta|} \omega(1) \eta(1) \otimes \omega(2) \eta(2) + (-1)^{|\eta| + |\omega|} \omega(1) \eta(1) \otimes \omega(2) \eta(2) + (-1)^{|\eta| + |\omega|} \omega(1) \eta(1) \otimes \omega(2) \eta(2) + (-1)^{|\eta| + |\omega|} \omega(1) \eta(1) \otimes \omega(2) \eta(2)
\]

for all \( \eta \in \Omega(B) \) and \( \omega \in \Omega(A) \). Clearly \( d^2 = 0 \) and thus \( \Omega(A \odot B) \) is a DGA.
\[
\Delta_R((db)b)\triangleleft a = (db)b\|\omega_{11}(b)\|\omega_{12}(b)\|\omega_{13}(b)\|\omega_{21}(b)\|\omega_{22}(b)\|\omega_{23}(b)
\]

\[
= (d \otimes d + (-1)^{|d|} \otimes d) \Delta_\ast(\omega \eta),
\]

which completes the proof. \qed

In practice, since \( \Omega(A) \) and \( \Omega(B) \) are generated by their elements of degree 0 and 1, we can construct the bosonisation \( \Omega(A) \bowtie \Omega(B) \) providing that we know the action and coaction on degree 0 and degree 1.

**Lemma 4.4.** (i) If \( B \) is an \( A \)-crossed module with differentiable action and coaction obeying

\[
\Delta_R((db)b)\triangleleft a = \Delta_R((db)b)\triangleleft a - \Delta_R((db)b)\triangleleft a
\]

for all \( b \in B \) and for all \( a \in A \), then \( \Omega(B) \) is a super \( \Omega(A) \)-crossed module algebra.

(ii) Furthermore, if \( B \) is a braided Hopf algebra in \( \mathcal{M}_A^A \),

\[
\Delta_B(db) = \Delta_B(db)\triangleleft (d_A b) + \Delta_B(db)\triangleleft (b_A) - \Delta_B((db)\triangleleft a)
\]

is well-defined and \( \Omega(B) \) is the maximal prolongation of \( \Omega(B) \), then \( \Omega(B) \) is a braided strongly bi-coinvariant calculus, i.e. a super braided Hopf algebra in \( \mathcal{M}_{\Omega(A)}^{\Omega(A)} \) such that \( d_B \) is a super-coderivation in the sense of (2.2).

**Proof.** (i) We first check,

\[
\Delta_R((db)b)\triangleleft a = \Delta_R((db)b)\triangleleft a - \Delta_R((db)b)\triangleleft a
\]

\[
= (d \otimes d + (-1)^{|d|} \otimes d) \Delta_\ast(\omega \eta),
\]

This makes \( B \) a crossed module as regards the action and coaction of \( \Omega^1(A) \).

Similarly for \( \Omega^1(B) \), where we check using (2.2).

\[
\Delta_R((db)b)\triangleleft a = \Delta_R((db)b)\triangleleft a
\]

\[
= (d \otimes d + (-1)^{|d|} \otimes d) \Delta_\ast(\omega \eta),
\]

which completes the proof. \qed
Since the action and coaction extend to \( \eta : \Omega(B) \otimes \Omega(A) \to \Omega(B) \) and \( \Delta_{RB} \), differentiably, and both exterior algebras are generated by degrees 0, 1, it follows that \( \Delta_{RB}(\eta_2 \omega) \) obeys the crossed module condition in general, making \( \Omega(B) \) a super \( \Omega(A) \)-crossed module.

(ii) We need to prove that \( \Delta_1 \xi = (\Delta_1 \xi)(\Delta_1 \eta) \), and it suffices to prove that \( \Delta_1 \) extends to \( \Omega^2(B) \) since \( \Omega(B) \) is the maximal prolongation of \( \Omega^1(B) \). Applying \( \Delta_1 \) to \( bd_{BC} = 0 \), we have

\[
\left( b_{(1)} de_{(1)} \otimes \left( (b_{(2)} \eta_1 c_{(1)} \eta) \right) c_{(2)} \right) = 0, \quad \left( b_{(1)} c_{(1)} \eta \otimes \left( (b_{(2)} \eta_1 c_{(1)} \eta) \right) c_{(2)} + \left( b_{(2)} \eta_1 c_{(1)} \eta \right) d_{BC} \right) c_{(2)} \right) = 0.
\]

Applying \( d_{B} \) to \( \eta \) and \( d_{B} \) to the second equation, we have

\[
\left( b_{(1)} de_{(1)} \otimes \left( (b_{(2)} \eta_1 c_{(1)} \eta) \right) c_{(2)} \right) = 0
\]

which is the \( \Omega^2(B) \otimes B \) part of \( \Delta_1 ((d_{B} b) d_{BC}) \). Applying \( \eta \) to \( d_{B} \) to the second equation and \( \eta \) to \( d_{B} \) to the first equation and subtracting them, we have

\[
\left( (b_{(2)} \eta_1 c_{(1)} \eta) c_{(2)} + \left( b_{(2)} \eta_1 c_{(1)} \eta \right) d_{BC} \right) c_{(2)} = 0
\]

which is the \( \Omega^1(B) \otimes \Omega^1(B) \) part of \( \Delta_1 ((d_{B} b) d_{BC}) \) and thus completes the proof. \( \square \)

This lemma assists with the data needed for Theorem 4.3. Finally, we note that \( B \) is canonically a \( A \bowtie B \)-comodule algebra by \( \Delta_{RB} = \left( b_{(1)} \otimes b_{(2)} \right) \otimes b_{(3)} \).

**Corollary 4.5.** Under the condition of Theorem 4.3, \( \Delta_R : B \to B \otimes A \bowtie B \) is differentiable.

**Proof.** Since \( \Delta_{RB} : \Omega(B) \to \Omega(B) \otimes \Omega(A) \) and \( \Delta_1 \) globally exist as assumed in Theorem 4.3, it is clear that \( \Delta_{RB} \eta = \eta_2 \eta_1 \eta_1 \eta_1 \otimes \eta_1 \eta_1 \eta_1 \eta_1 \) is well-defined and gives a coaction of \( \Omega(A \bowtie B) \) on \( \Omega(B) \). For example, on degree 1 we have

\[
\Delta_{RB}(d_{B} b) = d_{B} b_{(1)} \otimes b_{(2)} \otimes b_{(3)} + b_{(1)} \otimes d_{A} b_{(2)} \otimes b_{(3)} + b_{(1)} \otimes b_{(2)} \otimes d_{B} b_{(3)}.
\]

\( \square \)

**Remark 4.6.** In the special case of \( A \bowtie A \cong A \bowtie B \) as in Proposition 4.2, the latter coacts on \( A \) differentiably and we recover Corollary 4.5.

We will give some \( q \)-deformed examples of the preceding section and for this it is convenient to use \( R \)-matrix methods starting with the FRT bialgebra \( R(A) \) and its strongly bicovariant exterior algebra. We start with some results at this level for \( R \) a \( q \)-Hecke solution of the braid relations, before moving to specific examples in following subsections. We use notations and conventions of [8].

4.3. **Exterior algebra on** \( A \bowtie V(R) \). Let \( A(R) \) be the FRT algebra and suppose that \( A(R) \) has a central grouplike element \( D \) such that \( A = A(R)[D^{-1}] \) is a Hopf algebra. Let \( \Omega(A) \) be a strongly exterior algebra on \( A \) extended from \( \Omega(A(R)) \) as explained in Section 2.6. We take the same \( \Delta_R x = x \otimes t \) on \( V(R) \) as in Lemma 2.7 but now viewed as a coaction of \( A \).
Theorem 4.7. Let $A = A(R)[D^{-1}]$ with $R$-Hecke and $V(R)$ the right-covariant braided plane as above. Then $\Omega(V(R))$ is a super-braided-Hopf algebra with $x_1, dx_1$ primitive in the crossed module category $\mathcal{M}_{\Omega(A)}^k$ with coaction $\Delta_R^+$ as in Lemma 4.3 and

$$x_1 \triangleleft t_2 = x_1 q^{-1} R_{21}^{-1}, \quad (dx_1) \triangleleft t_2 = dx_1 q^{-1} R, \quad x_1 \triangleleft dt_2 = (q^2 - 1) dx_1 P, \quad dx_1 \triangleleft dt_2 = 0,$$

where $P$ is a permutation matrix. This defines a strongly bivacuum exterior algebra $\Omega(\mathbb{A} \triangleleft V(R)) := \Omega(A) \triangleleft \Omega(V(R))$ with relations, coproducts, and antipodes

$$x_1 t_2 = t_2 x_1 q^{-1} R_{21}^{-1}, \quad (dx_1) t_2 = t_2 dx_1 q^{-1} R, \quad x_1 dt_2 = (dt_2) bx_1 q^{-1} R_{21}^{-1} + (q^{-2} - 1) t_2 dx_1 P$$

$$dx_1 dt_2 = -dt_2 dx_1 q^{-1} R, \quad \Delta x = 1 \otimes x + x \otimes t, \quad \Delta dx = 1 \otimes dx + dx \otimes t + x \otimes dt$$

$$Sx = -xSt, \quad Sdx = -(dx)St - xSdt.$$

Proof. Note that the degree 0 part is the Hopf algebra $\mathbb{A} \triangleleft V(R)$ and is just the $q$-Hecke case of construction of inhomogeneous quantum groups by cobosonisation in [8]. Note that the action of $\Omega^2(A)$ is not given as far as we know by some general construction and one has to check by hand that we indeed obtain $\Omega(V(R))$ as a super right $\Omega^2(A)$-crossed module as follow. First, we have

$$\Delta_R(x_1 \triangleleft t_2) = x_1 \triangleleft t_2 \otimes (St_2) t_1 t_2 = x_1 q^{-1} R_{21}^{-1} \otimes (St_2) t_1 t_2 = (id \otimes St_2)(x_1 q^{-1} R_{21}^{-1} \otimes t_1 t_2)$$

$$= (id \otimes St_2)(x_1 \otimes t_2 t_1 q^{-1} R_{21}^{-1}) = x_1 \otimes (St_2) t_2 t_1 q^{-1} R_{21}^{-1} = x_1 \otimes t_1 q^{-1} R_{21}^{-1}$$

Next, we have

$$\Delta_R^+(dx_1) \triangleleft t_2) = (dx_1) \triangleleft t_2 \otimes (St_2) t_1 t_2 + x_1 \triangleleft t_2 \otimes (St_2)(dt_2) t_1 t_2$$

$$= dx_1 q^{-1} R \otimes (St_2) t_1 t_2 + x_1 q^{-1} R_{21}^{-1} \otimes (St_2)(dt_2) t_1 t_2$$

$$= (id \otimes St_2)(dx_1 q^{-1} R \otimes t_1 t_2 + x_1 q^{-1} R_{21}^{-1} \otimes t_1 t_2)$$

$$= (id \otimes St_2)(dx_1 x_1 t_2 q^{-1} R \otimes x_1 \otimes t_2 dt_1 q^{-1} R)$$

$$= dx_1 x_1 t_1 q^{-1} R + x_1 \otimes dt_1 q^{-1} R.$$

This verify the conditions of Lemma 4.3 (i) hold and therefore $\Omega(V(R))$ is a super right $\Omega^2(A)$-crossed module, but one can also check directly that $\Delta_R^+(x_1 \triangleleft dt_2)$ and $\Delta_R^+((dx_1) \triangleleft dt_2)$ obey the crossed module axiom.

One can also check that $\Omega(V(R))$ is indeed a super-Hopf algebra in this category with $x_1, dx_1$ primitive with the braiding for $\Omega(V(R))$ in the crossed module category comes out from the action and coaction of $\Omega^2(A)$ as

$$\Psi(x_1 \otimes x_2) = x_2 \otimes x_1 q^{-1} R_{21}^{-1}, \quad \Psi(dx_1 \otimes x_2) = x_2 \otimes dx_1 q^{-1} R$$

$$\Psi(x_1 \otimes dx_2) = dx_2 \otimes x_1 q^{-1} R_{21}^{-1} + (q^{-2} - 1) x_2 \otimes x_1 P, \quad \Psi(dx_1 \otimes dx_2) = dx_2 \otimes x_1 q^{-1} R,$$

and $V(R)$ is a braided Hopf algebra with respect to this action. This verify that the conditions of Lemma 4.3 (ii) hold. We exhibit directly that the construction works by showing that the super coproduct $\Delta_+$ of $\Omega(\mathbb{A} \triangleleft V(R))$ is indeed well-defined degree 1. We let $\lambda = q^{-2} - 1$. Then

$$\Delta_+(x_1 dt_2) = dt_2 \otimes x_1 t_2 + t_2 \otimes x_1 dt_2 + x_1 dt_2 \otimes t_1 t_2 + x_1 t_2 \otimes t_1 dt_2$$

$$= t_2 \otimes x_1 t_2 q^{-1} R_{21}^{-1} + t_2 \otimes dt_2 x_1 q^{-1} R_{21}^{-1} + t_2 \otimes t_1 dt_2$$

$$+ dt_2 x_1 t_1 q^{-1} R_{21}^{-1} + t_2 \otimes dt_2 x_1 t_1 q^{-1} R_{21}^{-1} + t_2 \otimes x_1 q^{-1} R_{21}^{-1} \otimes t_1 dt_2$$

$$\Delta_+(dt_2 x_1 q^{-1} R_{21}^{-1}) = (dt_2 \otimes t_2 x_1 + dt_2 x_1 \otimes t_2 t_1 + t_2 \otimes (dt_2) x_1 + t_2 x_1 \otimes (dt_2) t_1) q^{-1} R_{21}^{-1}$$

$$= (dt_2 \otimes t_2 x_1 + dt_2 x_1 \otimes t_2 t_1 + t_2 \otimes (dt_2) x_1) q^{-1} R_{21}^{-1} + q^{-1} t_2 x_1 \otimes R t_1 dt_2.$$
We can view a circle, for some parameter which has a strongly bicovariant exterior algebra with are all known to be \( q^t \) by Lemma 2.6 and those implied for 4.4. This is read off immediately from Theorem 4.7 but one can also simple reduced quantum group is differentiable for the exterior algebras above.

We also know by Corollary 4.5 that the right \( A \lhd V(R) \)-coaction \( \Delta_R x = x \otimes t + 1 \otimes x \in V(R) \otimes A \lhd V(R) \) on \( V(R) \) justifying our view of it as an inhomogeneous quantum group is differentiable for the exterior algebras above.

4.4. Calculations for the smallest \( R \)-matrices. The construction in Theorem 4.7 includes the standard q-deformation \( R \)-matrix for the \( SL_n \) for \( n \) as these are all known to be q-Hecke when normalised correctly, see [8]. In this case \( A = \mathbb{C}_q[GL_n] \) and \( V(R) = \mathbb{C}^n_q \) is the standard quantum-braided plane with relations \( x_j x_i = q x_i x_j \) for all \( j > i \). Thus we obtain \( \Omega(\mathbb{C}_q[GL_n])\triangleright\mathbb{C}^n_q \) such that the canonical coaction of \( \mathbb{C}_q[GL_n]\triangleright\mathbb{C}^n_q \) on \( \mathbb{C}^n_q \) is differentiable. In this section, we show \( n = 1 \) and \( n = 2 \) explicitly.

For \( n = 1 \), \( R = (q) \), \( D = t \) and \( A = \mathbb{C}[t, t^{-1}] \) is the algebraic circle with \( \Delta t = t \otimes t \) which has a strongly bicovariant exterior algebra with

\[
(dt)t = q^2 t dt, \quad (dt)^2 = 0, \quad \Delta_x t = t \otimes dt + dt \otimes t.
\]

by Lemma 2.6 and those implied for \( t^{-1} \). (This is the standard bicovariant calculus a circle, for some parameter \( q \)). We have \( B = V(R) = \mathbb{C}[x] \) with calculus \( (dx)x = q^2 x dx \), \( (dx)^2 = 0 \), which is \( A \)-covariant with \( \Delta_R x = x \otimes t \) by Lemma 2.7.

**Proposition 4.8.** We can view \( B = V(R) = \mathbb{C}[x] \) as a braided-Hopf algebra in \( \mathcal{M}_A^1 \) as part of \( \Omega(B) \) a super braided-Hopf algebra in \( \mathcal{M}^{2(D(A))}_A \) with

\[
x \otimes t = q^{-2} x, \quad x \otimes dt = (q^{-2} - 1) dx, \quad dx \otimes t = dx, \quad dx \otimes dt = 0
\]

\[
\Delta q x = x \otimes t, \quad \Delta_R dx = dx \otimes t + x \otimes dt.
\]

\( (dx)x = q^2 x dx \), \( (dx)^2 = 0 \), \( \Delta x = 1 \otimes x + x \otimes 1 \), \( \Delta dx = 1 \otimes dx + dx \otimes 1 \).

The super bosonisation defines a strongly bicovariant exterior algebra \( \Omega(\mathbb{C}_q[B_+]) := \Omega(A)\triangleright\Omega(B) \) with relations and comultiplication

\[
x t = q^{-2} t x, \quad (dt)x = t dx, \quad (dt)^2 = q^{-2} x dt + (q^2 - 1) t dx, \quad dx \otimes t = -dt dx
\]

\[
\Delta x = 1 \otimes x + x \otimes t, \quad \Delta dx = 1 \otimes dx + dx \otimes t + x \otimes dt
\]

where we identify \( A \triangleleft B = \mathbb{C}_q[B_+] \) the quantisation of the positive Borel subgroup of \( SL_2 \) (a quotient of \( \mathbb{C}_q[SL_2] \)). Moreover, the coaction \( \Delta_R : \mathbb{C}[x] \to \mathbb{C}[x] \otimes \mathbb{C}[B_+] \) given by \( \Delta_R x = 1 \otimes x + x \otimes t \) is differentiable.

**Proof.** This is read off immediately from Theorem 4.7 but one can also simple enough to verify the key facts by hand.

**Remark 4.9.** The Hopf algebra \( \mathbb{C}_q[B_+] \) is also called the Sweedler-Taft algebra (but we think of it as a q-deformed coordinate algebra). One can also think of it as \( U_q(b_+) \) and in this case the exterior algebra is the two dimensional \( \Omega(U_q(b_+)) \) found in [22]. In addition, we can work on \( q \) primitive root of unity case where now \( A = \mathbb{C}[t]/(t^n - 1) \) and \( B = \mathbb{C}[x]/(x^n) \), giving us the the exterior algebra of the reduced quantum group \( c_q[B_+] \) with additional relations \( t^n = 1 \) and \( x^n = 0 \).
We now compute the rather more complicated \( n = 2 \) case where \( A = C_q[GL_2] \). We recall that this has generators \( t_1^2 = a, t_2^2 = b, t_1^2 = c, t_2^2 = d \) with relations, invertible determinant, coproduct and antipode

\[
\begin{align*}
ba &= qab, & ca &= qac, & db &= qbd, & dc &= qcd \\
cb &= bc, & da - ad &= (q - q^{-1})bc, & ad - q^{-1}bc &= da - qcb &= D \\
\Delta(a \ b) &= (a \ b) \otimes (a \ b) = (a \ c) \otimes (b \ c) \\
S(a \ b) &= D^{-1} \begin{pmatrix} d & -qb \\ -q^{-1}c & a \end{pmatrix}.
\end{align*}
\]

Next, \( A \) has an obvious 1-parameter family of coquasitriangular structures

\[
(4.1) \quad \mathcal{R}(t_1 \otimes t_2) = R_\alpha = q^\alpha \begin{pmatrix} q^0 & 0 & 0 & 0 \\ 0 & q & 0 & 0 \\ 0 & q^{-1} & 0 & 0 \\ 0 & 0 & 0 & q \end{pmatrix}
\]

with \( R = R_0 \) the \( q \)-Hecke normalisation. The choice of \( \mathcal{R} \) means a 1-parameter family \( \Omega_\alpha(C_q[GL_2]) \) it we use the standard construction for coquasitriangular Hopf algebras. We refer to [18] for a recent treatment, which gives this calculus in the form \( C_q[GL_2] \triangleleft \Lambda \) where the left-invariant 1-forms \( \Lambda^1 \) has basis \( \varphi_1 = e_a, \varphi_2 = e_b, \varphi_3 = e_c, \varphi_4 = e_d \) and \( 2 \times 2 \) resulting in super coproduct and relations

\[
\Delta \varphi_s = 1 \otimes \varphi_s + \varphi_s \otimes \varphi_s, \quad E_s^i t^j = E_s^i t^j = t^i k E_m(r \alpha)^{m \ k \ i} E_r^{r \ j}.
\]

Explicitly, this is

\[
e_a \begin{pmatrix} a \ b \\ c \ d \end{pmatrix} = q^{2\alpha} \begin{pmatrix} q^2 & b \\ c & d \end{pmatrix} e_a, \quad [e_a, \begin{pmatrix} a \ b \\ c \ d \end{pmatrix}]_{q^{1+2\alpha}} = q^{1+2\alpha} \begin{pmatrix} 0 & a \\ 0 & c \end{pmatrix} e_a
\]

and

\[
[e_a, \begin{pmatrix} b \\ d \end{pmatrix}]_{q^{2+2\alpha}} = q^{2\alpha} \begin{pmatrix} a & \lambda b e_a \\ c & \lambda c e_a \end{pmatrix}
\]

where \( \lambda = q - q^{-1} \). When \( \alpha = -\frac{1}{2} \) the calculus descends to the quotient \( D = 1 \) giving the standard 4D calculus on \( C_q[SL_2] \) as in [25] but otherwise we are in the same family but with a different \( q \)-factor in the commutation relations. It is inner with \( \theta = e_a + e_d \), so that

\[
dt^i j = t^i k (R_{\alpha 21} R_{\alpha})^k j r \varphi_s - t^i j \theta = [\theta, t^i j].
\]

On the other hand, the crossed module braiding \( \Psi \) on \( \Lambda^1 \) is given in [18] is given by an expression with an equal number of \( R_\alpha \) and its appropriate inverse, so does not depend on the normalisation factor in \( R_\alpha \) and hence the left-invariant exterior algebra \( \Lambda = B_-(\Lambda^1) = T \Lambda^1 / \ker(\text{id} - \Psi) \) is the same as for the standard 4D calculus on \( C_q[SL_2] \), namely the usual Grassmannian variables on \( e_a, e_b, e_c \) and

\[
e_a e_d + e_d e_a + q^{-1} \lambda c e_b = 0, \quad e_d e_c + q^2 e_c e_d + q^{-1} \lambda a e_c = 0 \\
e_a e_d + q^2 e_d e_a + q^{-1} \lambda b e_a = 0, \quad e_c^2 - e_b^2 - e_c^2 = 0, \quad e_a^2 = q^{-1} \lambda c e_b
\]

and with exterior derivative

\[
d e_a = q^{-1} \lambda b e_c, \quad d e_b = \lambda (q^{-1} e_a - q c d) e_b, \quad d e_c = \lambda e_c (q^{-1} e_a - q c d), \quad d e_d = q^{-1} \lambda c e_b.
\]

This gives a full structure on exterior algebra \( \Omega_\alpha(C_q[GL_2]) = C_q[GL_2] \triangleleft \Lambda \)

We next consider the quantum-braided plane \( B = C_q^2 \) generated by \( x_1, x_2 \) with relation \( x_2 x_1 = q x_1 x_2 \) and viewed initially as a braided-Hopf algebra in the category
of right $\mathbb{C}_q[GL_2]$ modules and with exterior algebra $\Omega(\mathbb{C}_q^2)$ with standard relations and coaction from Lemma 2.6.

\[(dx_i)x_j = q^2 x_i dx_j, \quad (dx_1)x_2 = qx_2 dx_1, \quad (dx_2)x_1 = qx_1 dx_2 + (q^2 - 1)x_2 dx_1\]

(4.2)

\[(dx_i)^2 = 0, \quad dx_2 dx_1 = -q^{-1} dx_1 dx_2, \quad \Delta x_i = x_j \otimes t_i.\]

**Lemma 4.10.** The 4D strongly bicovariant calculus $\Omega(\mathbb{C}_q[GL_2])$ in Lemma 2.6 has relations

\[\begin{align*}
(da)a &= q^2 ada, \quad (da)b = qbda, \quad (da)c = qcd a, \quad (da)d = dda \\
(db)a &= qadb + (q^2 - 1)bda, \quad (db)b = q^2 bdb, \quad (db)c = cd b + (q - q^{-1})dda, \quad (db)d = qdd b \\
(dca)a &= qadc + (q^2 - 1) cda, \quad (dc)b = bdc + (q - q^{-1}) dda, \quad (dc)c = q^2 cdc, \quad (dc)d = qddd \\
(dd)a &= add + (q - q^{-1})(bdc + cdb + (q - q^{-1}) dda), \quad (dd)b = qbd d + (q^2 - 1) dd b \\
(dd)c &= qcd d + (q^2 - 1) ddc, \quad (dd)d = q^2 dd d
\end{align*}\]

along with implied relations for $D^{-1}$, and is isomorphic to $\Omega_0(\mathbb{C}_q[GL_2])$. Moreover, it is the unique strongly bicovariant exterior algebra obeying $[da, d] = 0$ such that the canonical right coaction on $\mathbb{C}_q[GL_2]$ on $\mathbb{C}_q^2$ is differentiable.

**Proof.** The displayed calculus is a routine calculation from the Lemma 2.6 while the last part of the statement is as follows. Requiring $\Delta_{R'}((dx_i)x_j) = \Delta_{R'}(q^2 x_i dx_j)$ we obtain all the relations stated except for those stated for $(da)d, (db)c, (dc)b, (dd)a, (dc)db$ and $(dd)da$, but we also get the following additional conditions

\[\begin{align*}
(dcb) + q^{-1}(da)d &= bdc + qdda, \quad (dcb) + q^{-1}(da)d = cd b + qdda \\
(dcb) + q(dd)a &= q^2 bdc + (q^2 - 1) cdb + qdd a + q(q^2 - 1) dda \\
(dcb) + q(dd)a &= q^2 bdc + (q^2 - 1) cdb + qdd a + q(q^2 - 1) dda.
\end{align*}\]

If we assume that $(da)d = q^3 dda$ then we obtain the following

\[\begin{align*}
(db)c &= cdb + (q - q^{-3}) dda, \quad (dc)b = bdc + (q - q^{-3}) dda \\
(dd)a &= add + (q - q^{-1})(bdc + cdb) + (q^2 - q^{-2} - 2) dda.
\end{align*}\]

This gives a family of 4D calculus of $\mathbb{C}_q[GL_2]$ which coacts differentially on $\mathbb{C}_q^2$. If further $\Omega(\mathbb{C}_q[GL_2])$ is strongly bicovariant, then left-covariant condition gives $\beta = 0$ and thus we obtain the stated calculus. We also have

\[\begin{align*}
dD &= add - q^{-1} bdc - q^{-1} cdb + q^{-2} dda \\
(\delta t_j^i)D &= q^2 Ddt^i_j, \quad (dD)t^i_j = t^i_j D + (q^2 - 1) Ddt^i_j.
\end{align*}\]

By applying $d$ to the stated bimodule relations, we obtain

\[\begin{align*}
(da)^2 &= (db)^2 = (dc)^2 = (dd)^2 = (dD)^2 = 0 \\
 dbda &= -q^{-1} dadb, \quad dcda = -q^{-1} da dc, \quad ddd b = -q^{-1} db dc, \quad ddd c = -q^{-1} dcd d \\
 dcbd &= -db dc + (q - q^{-1}) dda d, \quad ddda = -ddaa, \quad dD dt^i_j = -q^{-2} dt^i_j dD
\end{align*}\]

for the degree 2 relations.

Finally, working in this calculus, consider the basis of left-invariant 1-form $\omega_a = \varpi(a), \omega_b = \varpi(b), \omega_c = \varpi(c), \omega_d = \varpi(d)$, where $\varpi(a) = (S_{a_1})_{da_{2}}$ is the quantum Maurer-Cartan form. Explicitly we have basic forms and relations

\[\begin{align*}
\omega_a &= D^{-1}(dda - q b dbc), \quad \omega_b = D^{-1}(ddb - q q^{-1} b dc) \\
\omega_c &= D^{-1}(adc - q^{-1} cda), \quad \omega_d = D^{-1}(add - q^{-1} cdb) \\
\omega_a \left( \begin{array}{c} a \\ b \\ c \\ d \end{array} \right) &= \left( \begin{array}{c} q^2 a b \\ q^2 c d \end{array} \right) \omega_a, \quad [\omega_b, \left( \begin{array}{c} a \\ b \\ c \\ d \end{array} \right) ] = \lambda \left( \begin{array}{c} b \\ d \end{array} \right) \omega_a, \quad [\omega_c, \left( \begin{array}{c} a \\ b \\ c \\ d \end{array} \right) ] = \lambda \left( \begin{array}{c} 0 \\ a \end{array} \right) \omega_a
\end{align*}\]
\[ [\omega_d, \begin{pmatrix} a \\ c \end{pmatrix}] = \begin{pmatrix} q \lambda \omega_c + \lambda^2 a \omega_a \\ q \lambda \omega_c + \lambda^2 c \omega_a \end{pmatrix}, \quad [\omega_d, \begin{pmatrix} b \\ d \end{pmatrix}] = \lambda \begin{pmatrix} a \\ c \end{pmatrix} \omega_b \]

where \( \lambda = q - q^{-1} \), and exterior derivative

\[ da = a \omega_a + b \omega_c, \quad db = a \omega_b + b \omega_d, \quad dc = c \omega_a + d \omega_c, \quad cw_b + dw_d. \]

It is then a straightforward calculation to prove that \( \varphi : \Omega(\mathbb{C}_q[GL_2]) \to \Omega_0(\mathbb{C}_q[GL_2]) \) given by the identity map for elements of degree 0 and

\[ \varphi(\omega_a) = q a e_a, \quad \varphi(\omega_b) = \lambda e_c, \quad \varphi(\omega_c) = \lambda e_b, \quad \varphi(\omega_d) = q a e_d + \lambda^2 e_a \]

is an isomorphism. \( \square \)

We are now ready to state our example of Theorem 4.7.

**Proposition 4.11.** Let \( \Omega(A) = \Omega(\mathbb{C}_q[GL_2]) \) be the strongly bicovariant exterior algebra in Lemma 4.10 and \( B = \mathbb{C}_q^2 \) be viewed as a braided-Hopf algebra in \( \mathcal{M}_A^q \) as part of \( \Omega(B) = \Omega(\mathcal{C}_q^2) \) a super braided Hopf algebra in the category of \( \Omega(\mathbb{C}_q[GL_2]) \)-crossed modules with (co)action and coproduct

\[ x_1 q \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} q^{-2} x_1 (q^{-2} - 1) x_2 \\ q^{-1} x_1 \end{pmatrix}, \quad x_2 q \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} 0 \\ q^{-1} x_2 0 \end{pmatrix} \]

\[ x_1 q \begin{pmatrix} da \\ db \\ dc \\ dd \end{pmatrix} = \begin{pmatrix} (q^{-2} - 1) dx_1 (q^{-2} - 1) dx_2 \\ 0 \end{pmatrix}, \quad dx_1 q \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} 0 \\ dx_1 0 \end{pmatrix} \]

\[ x_2 q \begin{pmatrix} da \\ db \\ dc \\ dd \end{pmatrix} = \begin{pmatrix} (q^{-2} - 1) dx_1 (q^{-2} - 1) dx_2 \\ 0 \end{pmatrix}, \quad dx_2 q \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} 0 \\ (1 - q^{-2}) dx_1 dx_2 \end{pmatrix} \]

\[ dx_i - ad^k = 0, \quad \Delta_R x_1 = x_1 \otimes a + x_2 \otimes c, \quad \Delta_R x_2 = x_1 \otimes b + x_2 \otimes c \]

\[ \Delta_R dx_1 = dx_1 \otimes a + dx_2 \otimes c + x_1 \otimes da + x_2 \otimes dc \]

\[ \Delta_R dx_2 = dx_1 \otimes b + dx_2 \otimes d + x_1 \otimes db + x_2 \otimes dd \]

\[ \Delta x_i = x_i \otimes 1 + 1 \otimes x_i, \quad \Delta dx_i = dx_i \otimes 1 + 1 \otimes dx_i. \]

Its super bosonisation is a strongly bicovariant exterior algebra \( \Omega(\mathbb{C}_q[GL_2] \ltimes \mathbb{C}_q^2) := \Omega(\mathbb{C}_q[GL_2] \ltimes \Omega(\mathbb{C}_q^2)) \) with sub-exterior algebras \( \Omega(\mathbb{C}_q[GL_2]), \Omega(\mathbb{C}_q^2) \) and cross relations and super coproduct

\[ x_1 \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} q^{-2} ax_1 q^{-1} bx_1 (q^{-2} - 1) ax_2 \\ q^{-1} cx_1 q^{-1} dx_1 (q^{-2} - 1) cx_2 \end{pmatrix}, \quad x_2 \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} 0 \\ q^{-1} cx_1 q^{-2} dx_2 \end{pmatrix} \]

\[ dx_1 \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} adx_1 q^{-1} bdx_1 \\ cx_1 q^{-1} ddx_1 \end{pmatrix}, \quad dx_2 \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} = \begin{pmatrix} 0 \\ q^{-1} cdx_2 + (1 - q^{-2}) bdx_1 bdx_2 \end{pmatrix} \]

\[ x_1 \begin{pmatrix} da \\ db \\ dc \\ dd \end{pmatrix} = \begin{pmatrix} (q^{-2} - 1) dx_1 + (q^{-2} - 1) adx_1 q^{-1} (db)x_1 + (q^{-2} - 1)((da)x_2 + adx_2) \\ q^{-2} (dc)x_1 + (q^{-2} - 1) cdx_1 q^{-1} (dd)x_1 + (q^{-2} - 1)((dc)x_2 + cdx_2) \end{pmatrix} \]

\[ x_2 \begin{pmatrix} da \\ db \\ dc \\ dd \end{pmatrix} = \begin{pmatrix} (q^{-2} - 1)(da)x_2 + (q^{-2} - 1) bdx_1 q^{-2} (db)x_2 + (q^{-2} - 1) bdx_2 \\ q^{-2} (dc)x_2 + (q^{-2} - 1) ddx_1 q^{-2} (dd)x_2 + (q^{-2} - 1) ddx_2 \end{pmatrix} \]

\[ dx_1 \begin{pmatrix} da \\ db \\ dc \\ dd \end{pmatrix} = \begin{pmatrix} 0 \\ q^{-1} cdx_2 + (1 - q^{-2}) bdx_1 bdx_2 \end{pmatrix} \]

\[ dx_2 \begin{pmatrix} da \\ db \\ dc \\ dd \end{pmatrix} = \begin{pmatrix} 0 \\ q^{-1} cdx_2 + (1 - q^{-2}) bdx_1 bdx_2 \end{pmatrix} \]

\[ \Delta x_i = 1 \otimes x_i + \Delta_R (x_i), \quad \Delta_x (dx_i) = 1 \otimes dx_i + \Delta_R (dx_i) \]

along with the coproduct of \( \Omega(\mathbb{C}_q[GL_2]) \) a sub-super Hopf algebra. Moreover, the canonical coaction \( \Delta_R : \mathbb{C}_q^2 \to \mathbb{C}_q^2 \otimes \mathbb{C}_q[GL_2] \otimes \mathbb{C}_q^2 \) is differentiable.
On the dual side, we assume that $\beta$ for all $\omega$ $A \triangleleft$ algebra by an action $f$ further to an $\Omega(A)$ and that $\beta$ is differentiable. This entails that $\Omega(A)$ is $H$-covariant i.e. an $H$-module algebra by an action $\triangleright : H \otimes \Omega(A) \to \Omega(A)$ commuting with $d$ and that this extends further to an $\Omega(H)$-module algebra by $\triangleright : \Omega(H) \otimes \Omega(A) \to \Omega(A)$ such that
\begin{equation}
\Delta_A(\eta \triangleright \omega) = (d_H \eta) \triangleright \omega + (1)^{|\eta|} \eta \triangleright (d_A \omega)
\end{equation}
for all $\omega \in \Omega(A)$ and $\eta \in \Omega(H)$.

On the dual side, we assume that $\beta$ extends to a degree-preserving super coaction $\beta_* : \Omega(H) \to \Omega(H) \otimes \Omega(A)$, denoted by $\beta_*(\eta) = \eta^{\overline{\tau} \overline{\omega}}$, such that $\Omega(H)$ is a super $\Omega(A)$-comodule coalgebra and
\begin{equation}
\beta_*(d_H \eta) = d_H \eta^{\overline{\tau} \overline{\omega}} \otimes \eta^{\overline{\tau} \overline{\omega}} + (1)^{|\eta|} \eta \otimes d_A \eta^{\overline{\tau} \overline{\omega}}.
\end{equation}

5. DIFFERENTIALS ON BICROSSPRODUCT HOPF ALGEBRAS

We conclude quantum differentials for the second main construction for cross product algebras as inhomogeneous quantum groups, the bicrossproducts from [10] using the notation of [5].

5.1. Exterior algebras by super bicrossproduct. Let $H$ and $A$ be two Hopf algebras with $A$ a left $H$-module algebra by left action $\triangleright$ and $H$ be a right $A$-comodule coalgebra by map $\beta : H \to H \otimes A$ denoted $\beta(h) = h^{\overline{\omega}} \otimes h^{\overline{\omega}}$. We suppose in this section that $\triangleright$ and $\beta$ are compatible as in [10] such that the cross (or smash) product by $\triangleright$ and cross coproduct by $\triangleright$ form a ‘bicrossproduct’ Hopf algebra $A \triangleright \Delta H$. In the same spirit as Section 4 we now construct a strongly bicovariant exterior algebra on $A \triangleright \Delta H$ by a super bicrossproduct.

To this end, suppose that $\Omega(A)$ and $\Omega(H)$ are strongly bicovariant exterior algebras and that $\triangleright$ is differentiable. This entails that $\Omega(H)$ is $H$-covariant i.e. an $H$-module algebra by an action $\triangleright : H \otimes \Omega(A) \to \Omega(A)$ commuting with $d$ and that this extends further to an $\Omega(H)$-module algebra by $\triangleright : \Omega(H) \otimes \Omega(A) \to \Omega(A)$ such that
\begin{equation}
\Delta_A(\eta \triangleright \omega) = (d_H \eta) \triangleright \omega + (1)^{|\eta|} \eta \triangleright (d_A \omega)
\end{equation}
for all $\omega \in \Omega(A)$ and $\eta \in \Omega(H)$.

On the dual side, we assume that $\beta$ extends to a degree-preserving super coaction $\beta_* : \Omega(H) \to \Omega(H) \otimes \Omega(A)$, denoted by $\beta_*(\eta) = \eta^{\overline{\tau} \overline{\omega}}$, such that $\Omega(H)$ is a super $\Omega(A)$-comodule coalgebra and
\begin{equation}
\beta_*(d_H \eta) = d_H \eta^{\overline{\tau} \overline{\omega}} \otimes \eta^{\overline{\tau} \overline{\omega}} + (1)^{|\eta|} \eta \otimes d_A \eta^{\overline{\tau} \overline{\omega}}.
\end{equation}

If further $\triangleright$ and $\beta_*$ obey the super bicrossproduct conditions:
\begin{equation}
\epsilon(\eta \triangleright \omega) = \epsilon(\eta) \epsilon(\omega)
\end{equation}
\begin{equation}
\Delta_*(\eta \triangleright \omega) = (1)^{|\eta|} (\eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}} + (1)^{|\eta|} \eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}} \omega^{\overline{\tau} \overline{\omega}}(\eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}) \otimes \eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}})
\end{equation}
\begin{equation}
(1)^{|\eta|} (\eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}} + (1)^{|\eta|} \eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}} \omega^{\overline{\tau} \overline{\omega}}(\eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}) \otimes \eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}})
\end{equation}
\begin{equation}
(1)^{|\eta|} (\eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}} + (1)^{|\eta|} \eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}} \omega^{\overline{\tau} \overline{\omega}}(\eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}) \otimes \eta^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}}^{\overline{\tau} \overline{\omega}})
\end{equation}
then we have a bicrossproduct super Hopf algebra $\Omega(A) \triangleright \Delta \Omega(H)$ with product and coproduct
\begin{equation}
(\omega \otimes \eta)(\tau \otimes \xi) = (1)^{|\eta(\omega)|} \tau \omega(\eta(\omega) \otimes \eta(\xi) \otimes \eta(\xi) \otimes \eta(\omega))
\end{equation}
\[ \Delta_\ast (\omega \otimes \eta) = (1)^{|\omega|+|\eta|} \omega_1 \otimes \eta_1 \otimes \omega_2 \otimes \eta_2 \]

for all \( \omega, \tau \in \Omega(A) \) and for all \( \eta, \xi \in \Omega(H) \). We omit the proof since this close to the usual version \[10\] just with some extra signs.

**Theorem 5.1.** Let \( A, H \) be Hopf algebras and form a bicrossproduct \( A \triangleright \bowtie H \) and let \( \Omega(A) \) and \( \Omega(H) \) be strongly bicovariant exterior algebras with \( \triangleright, \ast \) obey the conditions \[5.1\]-\[5.6\]. Then \( \Omega(A \triangleright \bowtie H) := \Omega(A) \triangleright \bowtie \Omega(H) \) is a strongly bicovariant exterior algebra on \( A \triangleright \bowtie H \) with differential

\[
\Delta_\ast (\omega \otimes \eta) = \Delta_A \omega \otimes \eta + (1)^{|\omega|} \omega \otimes \Delta_H \eta.
\]

**Proof.** This is clear since the super algebra structure here is a left reversal of the right-handed super cross product and the super coalgebra structure is the super right cross coproduct, both are already proved in Theorem 4.3 with the same form of \( \Delta_\ast \) \( \square \).

In practice, we typically only need to know that the bicrossproduct action \( \triangleright \) and coaction \( \ast \) extend to degree 1 to construct the super bicrossproduct, since the extension to higher degrees is determined. Note also that if \( \Omega(A) \) is an \( H \)-module algebra and if \( \Omega(H) \) is the maximal prolongation of \( \Omega^1(H) \), then by the left-hand reversal of Lemma 4.1, \( \Omega(A) \) is a super \( \Omega(H) \)-module algebra such that \[5.1\] holds.

**Lemma 5.2.** Let \( A, H \) be Hopf algebras forming a bicrossproduct \( A \triangleright \bowtie H \). Let \( \Omega(A) \) be a super left \( \Omega(H) \)-module algebra such that \[5.1\] holds, suppose that the coaction extends to a well-defined map \( \ast : \Omega^1(H) \rightarrow \Omega^1(H) \otimes A \otimes H \otimes \Omega^1(A) \) by

\[
\ast((h \triangleright a)h) = h_1 \otimes (h_2 \triangleright a_1) \otimes h_3 \otimes (h_4 \triangleright a_2) = h_1 \otimes (h_2 \triangleright a_1) \otimes (h_3 \triangleright a_2) = h_1 \otimes (h_2 \triangleright a_1) \otimes (h_3 \triangleright a_2)
\]

for all \( h, g \in H \), and suppose that the action obeys \( \ast(\omega \eta) = \ast(\eta \omega) \) and

\[
\Delta_\ast (h \triangleright \bowtie a) = h_1 \otimes (h_2 \triangleright \bowtie a_1) \otimes h_3 \otimes (h_4 \triangleright \bowtie a_2) = h_1 \otimes (h_2 \triangleright \bowtie a_1) \otimes (h_3 \triangleright \bowtie a_2) = h_1 \otimes (h_2 \triangleright \bowtie a_1) \otimes (h_3 \triangleright \bowtie a_2)
\]

for all \( h \in H \) and \( a \in A \). If \( \Omega(H) \) is the maximal prolongation of \( \Omega^1(H) \), and \( \Omega(A) \) is the maximal prolongation of \( \Omega^1(A) \), then \( \ast \) extends to all degrees obeying \[5.4\]-\[5.6\] and form \( \Omega(A) \triangleright \bowtie \Omega(H) \) by Theorem 5.7.

**Proof.** (i) First we first check that \( \ast((d_H h)g) \) also satisfies \[5.5\] for products from the other side,

\[
\beta_\ast((d_H h)g) = \Delta_\ast ((d_H h)g) - h \triangleright d_H g
\]

\[
= d_H (hg) \otimes (h) - (hg) \otimes (h) - h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2)
\]

\[
= h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2) - h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2)
\]

\[
= (d_H h_1 \otimes h_2) \triangleright a_1 \otimes h_2 (d_A \triangleright a_2) - h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2)
\]

\[
= (d_H h_1 \otimes h_2) \triangleright a_1 \otimes h_2 (d_A \triangleright a_2) - h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2)
\]

\[
= ((d_H h_1 \otimes h_2) \triangleright a_1) \otimes h_2 (d_A \triangleright a_2) - h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2)
\]

Next, we prove that \( \ast \) extends by \[5.5\] to \( \Omega^2(H) \) for the maximal prolongation. Suppose \( h \triangleright d_H g = 0 \) in \( \Omega^1(H) \) (a sum of such terms understood) then \( \ast((d_H h)g) = 0 \) tells us that

\[
h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2) = 0, \quad h_1 (d_H \triangleright a_1) \otimes h_2 (d_A \triangleright a_2) = 0.
\]
Applying $d_H \otimes \text{id}$ to the first equation, we have the following $\Omega^2(H) \otimes A$-part of $\beta_*(d_H \text{id} \otimes \text{id} + d_H \text{id} \otimes \text{id})$

$$d_H h_1 \rightarrow d_H g \rightarrow \otimes (h_1 \rightarrow (h_2 \rightarrow g \rightarrow 0) = 0.$$ 

Applying $\text{id} \otimes d_A$ to the second equation, we have the following $H \otimes \Omega^2(A)$-part of $\beta_*(d_H \text{id} \otimes \text{id} + d_H \text{id} \otimes \text{id})$

$$(d_H h_1) \rightarrow (d_H g) \rightarrow \otimes ((h_2 \rightarrow d_A g) + h_1 \rightarrow ((d_H h_2) \rightarrow d_A g \rightarrow 0)) = 0.$$ 

Finally, applying $d_H \otimes \text{id}$ to the second equation and $\text{id} \otimes d_A$ to the first equation and subtracting them, we have the $\Omega^1(H) \otimes \Omega^1(A)$-part of $\beta_*(d_H \text{id} \otimes \text{id} + d_H \text{id} \otimes \text{id})$

$$(d_H h_1) \rightarrow (d_H g) \rightarrow \otimes ((h_2 \rightarrow d_A g) + h_1 \rightarrow ((d_H h_2) \rightarrow d_A g \rightarrow 0)) = 0.$$ 

Since $\vartheta : \Omega(H) \otimes \Omega(A) \rightarrow \Omega(A)$ is defined and $\Omega(H)$ is the maximal prolongation of $\Omega^1(H)$, $\beta_*$ can be extended further to higher degree obeying (5.4). 

(ii) Next we check that $\Delta_*((d_H h) \vartheta a)$ satisfies (5.4)

$$\Delta_*((d_H h) \vartheta a) = \Delta_*((d_H h) \vartheta a) - h \vartheta d_A a$$

and one can further find that

$$\Delta_*((d_H h) \vartheta a) = (h_1 \rightarrow \vartheta a) \otimes h_1 \rightarrow (h_2 \rightarrow g \rightarrow 0) = (h_2 \rightarrow g \rightarrow 0) + (h_1 \rightarrow \vartheta a) \otimes h_1 \rightarrow (h_2 \rightarrow g \rightarrow 0) = (h_2 \rightarrow g \rightarrow 0) + (h_2 \rightarrow g \rightarrow 0)$$

for all $a \in A$ as also required for (5.4). We can extend further to $\Delta_*((d_H h) \vartheta d_A a)$ and prove that (5.4) as follow

$$\Delta_*((d_H h) \vartheta d_A a) = \Delta_*((d_H h) \vartheta d_A a)$$

This then extends to all degrees since $\Delta_*$ of $\Omega(A)$ and $\vartheta : \Omega(H) \otimes \Omega(A) \rightarrow \Omega(A)$ are defined by assumption and $\beta_* : \Omega(H) \rightarrow \Omega(H) \otimes \Omega(A)$ is now defined since $\Omega(H)$ is the maximal prolongation of $\Omega^1(H)$.

(iii) Finally, we check that $\beta_*$ obeys (5.6). In fact by applying $d_H \otimes \text{id} + \text{id} \otimes d_A$ to $h_1 \rightarrow (h_2 \rightarrow a) h_2 \rightarrow (h_1 \rightarrow \vartheta a)$
combined with assumption (3), we have
\[ dh_{h(2)}^\Box \otimes (h_{1(1)} \triangleright a)h_{h(2)}^\Box + h_{h(2)}^\Box \otimes (dh_{h(1(1))} \triangleright a)h_{h(2)} + h_{h(2)}^\Box \otimes (h_{1(1)} \triangleright a)dAh_{h(2)} = dh_{h(2)}^\Box \otimes h_{1(1)}^\Box \triangleright a + h_{1(1)}^\Box \otimes dAh_{1(1)} + h_{1(1)}^\Box \otimes (dh_{h(2)} \triangleright a) \]
which is equivalent to
\[ (dh_{h(2)}^\Box \otimes (dh_{h(1(1))} \triangleright a)(dh_{h(2)}^\Box) \otimes (dh_{h(1(1))} \triangleright a) = (dh_{h(2)}^\Box \otimes (dh_{h(1(1))} \triangleright a)(dh_{h(2)}^\Box) \otimes (dh_{h(1(1))} \triangleright a). \]

Furthermore, one can find that
\[ (hdhg(1(1)) \triangleright (hdhg(1) \triangleright a)(hdhg(1(1)) \triangleright a) = (hdhg(1(1)) \triangleright (hdhg(1) \triangleright a)(hdhg(1(1)) \triangleright a). \]

We can also extend this by applying \( dh \otimes id + id \otimes dA \) to the assumption (3), where we have
\[ dh_{h(2)}^\Box \otimes h_{1(1)}^\Box \triangleright dAh_{h(2)} = dh_{h(2)}^\Box \otimes h_{1(1)}^\Box \triangleright dAh_{h(2)} + \]
which is equivalent to
\[ (-1)^{(dh_{h(2)})} (dh_{h(2)}) \otimes (dh_{h(2)}) \otimes (dh_{h(2)}) (dh_{h(2)}) \otimes (dh_{h(2)}) \]
\[ = (dh_{h(2)}) (dh_{h(2)}) \otimes (dh_{h(2)}) (dh_{h(2)}) \otimes (dh_{h(2)}) \]

Since \( \triangleright \) and \( \triangleright \) are defined for \( \Omega(H) \), one can extend the above equation further to higher degree by applying \( dh \otimes id + (-1)^{1} id \otimes A \) to the lower degree equation, and thus \( \triangleright \) obeys (5.6). This completes the proof.

This lemma assists with the data for Theorem 5.1. Moreover, as part of theory of bicrosproduct Hopf algebras, there is a covariant right coaction \( \Delta_{R} : H \rightarrow H \otimes A \triangleright H \) given by \( \Delta_{R} h = h_{1(1)}^\Box \otimes h_{1(1)}^\Box \otimes h_{h(2)} \).

**Corollary 5.3.** If \( \triangleright \) and \( \triangleright \) obey the conditions in Theorem 5.1 then \( \Delta_{R} : H \rightarrow H \otimes A \triangleright H \) as above is differentiable.

**Proof.** Since the coaction \( \Omega(H) \rightarrow \Omega(H) \otimes \Omega(A) \) and action \( \Omega(H) \otimes \Omega(A) \rightarrow \Omega(A) \) are globally exist as assumed in Theorem 5.3, it is clear that \( \Delta_{R} \eta = d_{\eta(1)^{\Box}} \otimes d_{\eta(1)^{\Box}} \otimes d_{\eta(2)} \) is well-defined and gives a coaction of \( \Omega(A \triangleright H) \) on \( \Omega(H) \). For example, on degree 1 we have
\[ \Delta_{R}(dh) = dh_{h_{1(1)}^\Box \otimes h_{1(1)}^\Box \otimes h_{h(2)} + h_{h_{1(1)}^\Box \otimes dAh_{1(1)}^\Box \otimes h_{h(2)} + h_{h_{1(1)}^\Box \otimes h_{1(1)}^\Box \otimes dAh_{h(2)}}. \]

5.2. **Examples of bicrosproduct exterior algebras.** We now turn to some examples of exterior algebras constructed as super bicrosproducts. Our warm-up example is the ‘Planck scale’ Hopf algebra \( \mathbb{C}[g, g^{-1}] \triangleright \mathbb{C}[p] \) generated by \( g, g^{-1}, p \)
with \[ [p, g] = \lambda(1 - g)g, \quad \Delta g = g \otimes g, \quad \Delta p = 1 \otimes p + p \otimes g \]
where \( \lambda = \epsilon \frac{h}{\hbar} \) is an imaginary constant built from Planck’s constant and the gravitational constant \( G \), and \( g = e^{-x} \) where \( x \) is the spatial position in \( \mathbb{R} \) (while we work algebraically with \( g \) as a generator). This turned out to be a Drinfeld twist of \( U(b_{+}) \) and we will obtain the same calculus as found in [19] by twisting methods. Let \( \mathbb{C}[r] \) be another copy of \( \mathbb{C}[p] \) and let \( \Omega(\mathbb{C}[r]) \) be an exterior algebra with \( r, dr = \lambda dr, \quad (dr)^{2} = 0 \).

Also as part of the theory of bicrosproducts there is a natural coaction \( \Delta_{R} : \mathbb{C}[r] \rightarrow \mathbb{C}[r] \otimes \mathbb{C}[g, g^{-1}] \triangleright \mathbb{C}[p] \) given by \( \Delta_{R}r = 1 \otimes p + r \otimes g \) making \( \mathbb{C}[r] \) a comodule-algebra. This coaction extends to \( \Omega(\mathbb{C}[r]) \) by \( \Delta_{R}dr = dr \otimes g \).
Proposition 5.4. There is a unique strongly biequivariant exterior algebra $\Omega(C[g, g^{-1}]\boxtimes \mathbb{C}[p])$ such that $\Delta_R$ is differentiable. This has relations

$$\begin{align*}
[dg, g] &= 0, & [p, dp] &= dp, & [dp, g] &= \lambda gdg, & [dg, p] &= \lambda(1 - g)dg \\
(dg)^2 = (dp)^2 &= 0, & dpdg &= -gdg
\end{align*}$$

Furthermore, $\Omega(C[g, g^{-1}]\boxtimes \mathbb{C}[p]) = \Omega(C[g, g^{-1}]\boxtimes \Omega(C[p])$ with coproduct

$$\Delta g = g \otimes g, \quad \Delta dp = dp \otimes g + g \otimes dg.$$

Proof. If it exists then $\Delta_{R^*} dr = dr \otimes g + 1 \otimes dp + r \otimes dg$. For this to extend in a well-defined way to $\Omega^1(C[p])$ as in [23] we require $\Delta_{R^*}(dr \cdot r) = 0$ which gives $[p, dp] = \lambda dp$, $[dg, g] = 0$ and

$$[dg, p] + [dp, g] + \lambda gdg = 0.$$

By requiring $(\Delta_{R^*}(dr))^2 = 0$ we find that $[g, dp] = \lambda gdg$ which implies $[dg, p]$ as stated. We also find the relations on degree 2 as stated. One can check that they obey Leibniz rule, making $\Omega(C[g, g^{-1}]\boxtimes \mathbb{C}[p])$ an exterior algebra.

Furthermore, one can find that $\Omega(C[p])$ is a super right $\Omega(C[g, g^{-1}])$-comodule and $\Omega(C[g, g^{-1}])$ is a super right $\Omega(H)$-module by the following actions and coactions

$$\begin{align*}
\rho \cdot g &= \lambda(1 - g)g, & dp \cdot g &= -\lambda gdg, & \varphi \cdot dg &= \lambda(1 - g)dg, & dp \cdot dg &= 0 \\
\beta(p) &= p \otimes g, & \beta_*(dp) &= dp \otimes g + p \otimes dg.
\end{align*}$$

It is a routine calculation to show that the stated action and coaction obey the condition on Theorem 5.1. Therefore super bicrossproduct $\Omega(C[g, g^{-1}]\boxtimes \Omega(C[p])$ gives the same exterior algebra as $\Omega(C[g, g^{-1}]\boxtimes \mathbb{C}[p])$ and with the stated coproduct.

The next most complicated example in this context is the quantum Poincaré group $C[\text{Poinc}_{1,1}] = C[SO_{1,1}]\boxtimes U(\mathbb{R} \times \mathbb{R})$ for which we follow the construction in [10]. Here $C[SO_{1,1}]$ is the ‘hyperbolic Hopf algebra’ generated by $c = \cosh \alpha$ and $s = \sinh \alpha$ with relations $c^2 - s^2 = 1$ and $cs = sc$. (We work algebraically with $c, s$ and do not need $\alpha$ itself.) This is a Hopf algebra with

$$\begin{align*}
\Delta \left( \begin{array}{c} c \\ s \end{array} \right) &= \left( \begin{array}{cc} c & s \\ s & c \end{array} \right) \otimes \left( \begin{array}{cc} c & s \\ s & c \end{array} \right), & \epsilon \left( \begin{array}{c} c \\ s \end{array} \right) &= \left( \begin{array}{c} 1 \\ 0 \\ 0 \\ 1 \end{array} \right), & S \left( \begin{array}{c} c \\ s \end{array} \right) &= \left( \begin{array}{c} c \\ -s \\ -s \\ c \end{array} \right).
\end{align*}$$

Also recall that $U(\mathbb{R} \times \mathbb{R})$ is a Hopf algebra generated by $a_0$ and $a_1$ with relation $[a_0, a_1] = \lambda a_0$ for some $\lambda \in \mathbb{C}$, and primitive comultiplication $\Delta a_i = 1 \otimes a_i + a_i \otimes 1$ for $i = 0, 1$. $C[SO_{1,1}]$ coacts on $U(\mathbb{R} \times \mathbb{R})$ and $U(\mathbb{R} \times \mathbb{R})$ acts on $C[SO_{1,1}]$ by

$$\begin{align*}
a_0 \cdot \left( \begin{array}{c} c \\ s \end{array} \right) &= \lambda \left( \begin{array}{c} s^2 \\ sc \end{array} \right), & a_1 \cdot \left( \begin{array}{c} c \\ s \end{array} \right) &= \lambda \left( \begin{array}{c} cs - s \\ c^2 - c \end{array} \right), & \Delta_R (a_0 a_1) &= \Delta_R (a_0 a_1) \otimes \left( \begin{array}{cc} c & s \\ s & c \end{array} \right).
\end{align*}$$

Thus their bicrossproduct $C[\text{Poinc}_{1,1}] = C[SO_{1,1}] \boxtimes U(\mathbb{R} \times \mathbb{R})$ contains $C[SO_{1,1}]$ as sub-Hopf algebra, $U(\mathbb{R} \times \mathbb{R})$ as subalgebra, and with the following additional cross-relations and coproducts [10]

$$\begin{align*}
[a_0, \begin{array}{c} c \\ s \end{array}] &= \lambda s \begin{array}{c} s \\ c \end{array}, & [a_1, \begin{array}{c} c \\ s \end{array}] &= \lambda(c - 1) \begin{array}{c} s \\ c \end{array}, & \Delta a_i &= 1 \otimes a_i + \Delta_R a_i.
\end{align*}$$

Finally, we let $U(\mathbb{R} \times \mathbb{R})$ be another copy with generators $t, x$ in place of $a_0, a_1$ with exterior algebra [24]

$$\begin{align*}
[dx, x] &= \lambda \theta', & [dx, t] &= 0, & [dt, x] &= \lambda dx, & [dt, t] &= \lambda(dt - \theta'), & [\theta', x] &= 0, & [\theta', t] &= -\lambda \theta' \\
\Delta \theta' &= 0, & (dx)^2 &= (dt)^2 = 0, & dx dt &= -dt dx, & dx \theta' &= -\theta' dx, & dt \theta' &= -\theta' dt.
\end{align*}$$
It is known that this is covariant under $\mathbb{C}_A[\text{Poinc}_{1,1}]$ by coaction
\[
\Delta_R: U(\mathbb{R}\rhd\mathbb{R}) \to U(\mathbb{R}\rhd\mathbb{R}) \otimes \mathbb{C}_A[\text{Poinc}_{1,1}], \quad \Delta_R(t \, x) = 1 \otimes (a_0 \ a_1) + (t \ x) \otimes \begin{pmatrix} c \ s \\ s \ c \end{pmatrix}
\]
in the same matrix notation as for coproducts above.

**Proposition 5.5.** There is a unique strongly bicovariant exterior algebra $\Omega(\mathbb{C}[\text{Poinc}_{1,1}])$ such that the above coaction on $U(\mathbb{R}\rhd\mathbb{R})$ is differentiable. It contains $\Omega(U(\mathbb{R}\rhd\mathbb{R}))$ as sub-exterior algebra and has the additional relations on degree 1 and 2
\[
(dcs) = sdc, \quad (dc)c = cdc = sds = (ds)s
\]
\[
\begin{aligned}
[a_0, \begin{pmatrix} c \\ ds \end{pmatrix}] = \lambda s \begin{pmatrix} dcs \\ ds \end{pmatrix}, \quad \{a_1, \begin{pmatrix} c \\ ds \end{pmatrix}\} = \lambda (c-1)\begin{pmatrix} dcs \\ ds \end{pmatrix}, \quad [\theta', \begin{pmatrix} c \\ ds \end{pmatrix}] = \lambda (c-1)\begin{pmatrix} dcs \\ ds \end{pmatrix}
\end{aligned}
\]
Furthermore, $\Omega(\mathbb{C}[\text{Poinc}_{1,1}]) = \Omega(\mathbb{C}[\text{SO}_{1,1}]) \circ \Omega(U(\mathbb{R}\rhd\mathbb{R}))$ with coproduct that of $\mathbb{C}_A[\text{Poinc}_{1,1}]$ on degree 0 and
\[
\Delta, dc = dc \otimes c + ds \otimes s + c \otimes dc + s \otimes ds, \quad \Delta ds = dc \otimes s + ds \otimes c + c \otimes ds + s \otimes dc
\]
\[
\begin{aligned}
\Delta, da_0 &= 1 \otimes da_0 + da_0 \otimes c + da_1 \otimes s + a_0 \otimes dc + a_1 \otimes ds \\
\Delta, da_1 &= 1 \otimes da_1 + da_0 \otimes s + da_1 \otimes c + a_0 \otimes ds + a_1 \otimes dc \\
\Delta, \theta' &= 1 \otimes \theta' + \theta' \otimes 1 - 1 \otimes da_0 - da_0 \otimes 1 + \Delta, da_0.
\end{aligned}
\]

**Proof.** If $\Delta_{R^*}$ exists obeying (2.20), we will need
\[
\begin{aligned}
\Delta_{R^*} dt &= 1 \otimes da_0 + dt \otimes c + dx \otimes s + t \otimes dc + x \otimes ds \\
\Delta_{R^*} dx &= 1 \otimes da_1 + dt \otimes s + dx \otimes c + t \otimes ds + x \otimes dc \\
\Delta_{R^*} \theta' &= 1 \otimes \theta' - 1 \otimes da_0 + \theta' \otimes 1 - dt \otimes 1 + \Delta_{R^*} dt
\end{aligned}
\]
By requiring $\Delta_{R^*}([dt, x]) = \Delta_{R^*}(\lambda dx)$ and $\Delta_{R^*}([dx, t]) = 0$, we find
\[
(ds)c = cds, \quad (dc)s = sdc, \quad (dc)c + (ds)s - ldc - sds = 0.
\]
\[
\begin{aligned}
[a_0, c] &= [a_0, ds], \quad [da_1, s] - [a_0, dc] + \lambda ((ds)s - ldc) = 0 \\
[a_0, dc] &= [da_0, s] - \lambda ds, \quad [da_0, c] - [a_0, dc] + \lambda ((dc)c - sds - dc) = 0
\end{aligned}
\]
Additionally, from $(c^2 - s^2) = 0$ combined with the condition $dc \otimes c + ds - ldc - sds = 0$ above, we find that $(dc)c = sds$ and $(ds)s = cdc$. But then by requiring $\Delta_{R^*}([dx, x]) = \Delta_{R^*}(\lambda \theta')$ we also find that $(dc)c = cdc$ and $(ds)s = sds$. Thus we have $(dc)c = cdc = sds = (ds)s$. Also by requiring $\Delta_{R^*}(dx)^2 = 0$ and $\Delta_{R^*}(dt)^2 = 0$ one can find that
\[
\begin{aligned}
[a_0, \begin{pmatrix} c \\ ds \end{pmatrix}] &= \lambda s \begin{pmatrix} dcs \\ ds \end{pmatrix}, \quad [da_1, \begin{pmatrix} c \\ ds \end{pmatrix}] = \lambda (c-1)\begin{pmatrix} dcs \\ ds \end{pmatrix}
\end{aligned}
\]
leading to the stated bimodule relations. The relations involving $\theta'$ are obtained by using the other relations. One can also find that the stated relations on degree 2 hold and $\Omega(\mathbb{C}_A[\text{Poinc}_{1,1}])$ contains $\Omega(U(\mathbb{R}\rhd\mathbb{R}))$ from the above calculation.

Furthermore, $\Omega(\mathbb{C}[\text{SO}_{1,1}])$ is a super $\Omega(U(\mathbb{R}\rhd\mathbb{R}))$-module and $\Omega(U(\mathbb{R}\rhd\mathbb{R}))$ is a super $\Omega(\mathbb{C}[\text{SO}_{1,1}])$-comodule with actions and coactions
\[
\begin{aligned}
da_0 \triangleright \begin{pmatrix} c \\ ds \end{pmatrix} &= \lambda s \begin{pmatrix} dcs \\ ds \end{pmatrix}, \quad da_1 \triangleright \begin{pmatrix} c \\ ds \end{pmatrix} = \lambda (c-1)\begin{pmatrix} dcs \\ ds \end{pmatrix}
\end{aligned}
\]
\[ \beta_\ast (da_0) = da_0 \otimes c + da_1 \otimes s + a_0 \otimes dc + a_1 \otimes ds \]
\[ \beta_\ast (da_1) = da_0 \otimes s + da_1 \otimes c + a_0 \otimes ds + a_1 \otimes dc \]
\[ \theta \lopto (c) = \lambda (c - 1) \frac{dc}{ds} \quad \beta_\ast (\theta') = \theta' \otimes 1 - da_0 \otimes 1 + \beta_\ast (da_0) \]
and one can check that they obey the conditions for Theorem 5.1. Therefore we can apply the super bicrossproduct and identify \( \Omega(C_3[Poinc_{1,1}]) = \Omega(C[S0_{1,1}]) \bowtie \Omega(U(R \rtimes R)) \)
with coproducts as stated.
