I. INTRODUCTION

Tensor factorization is a generalization of principal component analysis to tensors, in which one wishes to exhibit the closest rank-$K$ approximation to a tensor. It has numerous applications in signal processing and machine learning, e.g., for compressing data while keeping as much information as possible, in data visualization, etc. [1].

An approach to explore computational and/or statistical limits of tensor factorization is to consider a statistical model, as done in [2]. The model is the following: draw $K$ column vectors, evaluate for each of them their $p$th tensor power and sum those $K$ symmetric order-$p$ tensors. For $p = 2$, and if no degeneracy occurs, this sum is exactly the eigendecomposition of a rank-$K$ positive semidefinite matrix. Tensor factorization can then be studied as an inference problem, namely, to estimate the initial $K$ vectors from noisy observations of the tensor and to determine information theoretic limits for this task. To do so, we focus on proving formulas for the asymptotic mutual information between the noisy observed tensor and the original $K$ vectors. Such formulas were first rigorously derived for $p = 2$ and $K = 1$, i.e., rank-one matrix factorization: see [3] for the case with a binary input vector, [4] for the restricted case in which no discontinuous phase transition occurs, [5] for a single-sided bound and, finally, [6] for the fully general case. The proof in [6] combines interpolation techniques with spatial coupling and an analysis of the Approximate Message-Passing (AMP) algorithm. Later, and still for $p = 2$, [7] went beyond rank-one by using a rigorous version of the cavity method. Reference [8] applied the heuristic replica method to conjecture a formula for any $p$ and finite $K$, which is then proved for $p \geq 2$ and $K = 1$. Reference [8] also details the AMP algorithm for tensor factorization and shows how the single-letter variational expression for the mutual information allows one to give guarantees on AMP’s performance. Afterwards, [9], [10] introduced the adaptive interpolation proof technique which they applied to the case $p \geq 2$, $K = 1$. Other proofs based on interpolations recently appeared, see [11] ($p = 2$, $K = 1$) and [12] ($p \geq 2$, $K = 1$).

In this work, we prove the conjectured replica formula for any finite-rank $K$ and any even order $p$ using the adaptive interpolation method. We also underline what is missing to extend the proof to odd orders.

The adaptive interpolation method was introduced in [9], [10] as a powerful improvement to the Guerra-Toninelli interpolation scheme [13]. Since then, it has been applied to many other inference problems in order to prove formulas for the mutual information, e.g., [14], [15]. While our proof outline is similar to [10], there are two important new ingredients. First, to establish the tight upper bound, we have to prove the regularity of a change of variable given by the solutions to an ordinary differential equation. This is non-trivial when the rank becomes greater than one. Second, the same bound requires one to prove the concentration of the overlap (a quantity that fully characterizes the system in the high-dimensional limit). When the rank is greater than one, this overlap is a matrix and a recent result [16] on the concentration of overlap matrices can be adapted to obtain the required concentration in our interpolation scheme.

II. LOW-RANK SYMMETRIC TENSOR FACTORIZATION

We study the following statistical model. Let $n$ be a positive integer. $X_1, \ldots, X_n$ are random column vectors in $\mathbb{R}^K$, independent and identically distributed (i.i.d.) with distribution $P_X$. They form the rows of the $n \times K$ matrix $X$, i.e., $X$ has entries $X_{ij} = (X_i)_j$. These vectors are not directly observed. Instead, for each $p$-tuple $(i_1, \ldots, i_p) \in [n]^p$ with $i_1 \leq i_2 \leq \cdots \leq i_p$, one is given access to the noisy observation

$$Y_{i_1 \ldots i_p} = \sqrt{\frac{\lambda(p - 1)!}{n^{p-1}}} \sum_{k=1}^K X_{i_1}^k X_{i_2}^k \ldots X_{i_p}^k + Z_{i_1 \ldots i_p},$$

(1)

where $\lambda$ is a known signal-to-noise ratio (SNR) and the noise $Z_{i_1 \ldots i_p}$ is i.i.d. with respect to the standard normal distribution $\mathcal{N}(0, 1)$. All the observations (1) are combined into the symmetric order-$p$ tensor $Y_i = \sqrt{\frac{\lambda(p-1)!}{n^{p-1}}} \sum_{k=1}^K (X_{i,k})^{\otimes p} + Z_i$, $X_{i,k}$ being the $k^{th}$ column of $X$.

Our main result is the proof of a formula for the mutual information in the limit $n \to +\infty$ while the rank $K$ is kept
fixed. This formula is given as the optimization of a potential over the cone of $K \times K$ symmetric positive semi-definite matrices $S_k^+$. Let $Z \sim \mathcal{N}(0, I_K)$ and $X \sim P_X$. Define the convex (see [17] Appendix A) function

$$\psi : S \in S_k^+ \mapsto \mathbb{E} \ln \int dP_X(x) e^{\gamma^T S_x x + \tilde{Z}^T \sqrt{S_x} - \frac{1}{2} x^T S_x},$$

and the potential

$$\phi_{p, \lambda}(S) = \psi \left( \lambda S^{(p-1)} \right) - \frac{\lambda (p - 1)}{2p} \sum_{\ell, \ell' = 1}^K (S^{(p)})_{\ell \ell'};$$

where $S^{(p)}$ is the $k$th Hadamard power of $S$. Remember that the Hadamard product $A \odot B$, where $A$ and $B$ are matrices of the same dimension, is the matrix of same dimension with entries given by $(A \odot B)_{ij} = A_{ij}B_{ij}$. Note that, by the Schur Product Theorem [18], the Hadamard product of two matrices in $S_k^+$ is also in $S_k^+$. Introducing the second moment matrix $\Sigma_X \equiv \mathbb{E}[X^T X]$ in $S_k^+$, the conjectured replica formula [13] reads:

$$\lim_{n \to +\infty} \frac{1}{n} I(X; Y) = \frac{\lambda}{2p} \sum_{\ell, \ell' = 1}^K (\Sigma^{(p)})_{\ell \ell'} - \sup_{S \in S_k^+} \phi_{p, \lambda}(S).$$

**Remark:** We can reduce the proof of [3] to the case $\lambda = 1$ by rescaling properly $P_X$. From now on, we set $\lambda = 1$ and denote $\phi_p \equiv \phi_{p,1}$.

Before proving [3], we introduce important information-theoretic quantities, adopting the statistical mechanics terminology. Define the Hamiltonian for all $x \in \mathbb{R}^{n \times K}$:

$$\mathcal{H}_n(x; Y) \equiv \sum_{t \in \mathcal{I}} \frac{(p - 1)!}{2n^{p-1}} \left( \sum_{\ell = 1}^K \prod_{a = 1}^p x_{i_a, \ell} \right)^2 - \sum_{t \in \mathcal{I}} \sqrt{\frac{(p - 1)!}{n^{p-1}}} \mathcal{Y}_{i_1 \ldots i_p} \prod_{\ell = 1}^K x_{i_a, \ell},$$

where $\mathcal{I} \equiv \{ i \in [n]^p : i_a \leq i_{a+1} \}$. Using Bayes’ rule, the posterior density written in Gibbs-Boltzmann form is

$$dP_X(x \mid Y) = \frac{1}{Z_n(Y)} \left( \prod_{j=1}^n dP_X(x_j) \right) e^{-\mathcal{H}_n(x; Y)},$$

with $Z_n(Y) \equiv \int \prod_j dP_X(x_j) \exp(-\mathcal{H}_n(x; Y))$ the normalization factor. Finally, we define the free entropy

$$f_n \equiv \frac{1}{n} \mathbb{E} \ln Z_n(Y),$$

which is linked to the mutual information through the identity

$$\frac{1}{n} I(X; Y) = \frac{1}{2p} \sum_{\ell, \ell' = 1}^K (\Sigma^{(p)})_{\ell \ell'} - f_n + O(n^{-1}).$$

In [3], $O(n^{-1})$ is a quantity such that $nO(n^{-1})$ is bounded uniformly in $n$. Thanks to [5], the replica formula [3] will follow directly from the next two bounds on the asymptotic free entropy.

**Theorem 1:** (Lower bound) Assume $p$ is even and $P_X$ is such that its first $2p$ moments are finite. Then

$$\liminf_{n \to \infty} f_n \geq \sup_{S \in S_k^+} \phi_p(S).$$

**Theorem 2:** (Upper bound) Assume $p$ is even and $P_X$ is such that its first $4p - 4$ moments are finite. Then

$$\limsup_{n \to \infty} f_n \leq \sup_{S \in S_k^+} \phi_p(S).$$

**III. ADAPTIVE PATH INTERPOLATION**

We introduce a “time” parameter $t \in [0, 1]$. The adaptive interpolation interpolates from the original channel $\mathbf{1}$ at $t = 0$ to a decoupled channel at $t = 1$. In between, we follow an interpolation path $R(\cdot, \epsilon) : [0, 1] \to S_k^+$, which is a continuously differentiable function parametrized by a “small perturbation” $\epsilon \in S_k^+$ and such that $R(0, \epsilon) = \epsilon$. More precisely, for $t \in [0, 1]$, we observe

$$\mathcal{Y}(t; \epsilon) = \sqrt{\frac{(1-t)(p-1)!}{n^{p-1}}} \sum_{k=1}^K \prod_{a=1}^p X_{i_a, k} + Z_{i, \epsilon}, \quad i \in \mathcal{I};$$

$$\tilde{Z}_{j, \epsilon} = \sqrt{R(t, \epsilon)} X_{j} + \tilde{Z}_{j}, \quad j \in [n].$$

The noise $\tilde{Z}_{j} \sim \mathcal{N}(0, I_K)$ is independent of both $X$ and $Z$. The associated interpolating Hamiltonian reads

$$\mathcal{H}_{t, \epsilon}(x; \mathbf{Y}(t; \epsilon), \tilde{\mathbf{Y}}(t, \epsilon)) \equiv \mathcal{H}_t(x; \mathbf{Y}(t)) + \mathcal{H}_{t, \epsilon}(x; \tilde{\mathbf{Y}}(t, \epsilon)),$$

where

$$\mathcal{H}_t(x; \mathbf{Y}(t)) \equiv \sum_{i \in \mathcal{I}} \sqrt{\frac{(1-t)(p-1)!}{n^{p-1}}} \mathcal{Y}_{i} \prod_{a=1}^p x_{i_a, k},$$

$$\mathcal{H}_{t, \epsilon}(x; \tilde{\mathbf{Y}}(t, \epsilon)) \equiv \sum_{j=1}^n \frac{1}{2} R(t, \epsilon) x_j - \tilde{Z}_{j, \epsilon}^T \sqrt{R(t, \epsilon)} x_j.$$
which denotes an expectation with respect to the posterior distribution, i.e.,
\[ \langle g(x) \rangle_{t, \epsilon} = \int g(x) \prod_{j=1}^{n} dP_X(x_j) e^{-\mathcal{H}_{t, \epsilon}(x; Y)} \frac{\mathcal{Z}_{t, \epsilon}(Y)}{\mathcal{Z}_{t, \epsilon}(Y_{t, \epsilon})}. \] (12)
Combining (11) with the fundamental theorem of calculus
\[ f_n(0, \epsilon) = f_n(1, \epsilon) - \int_0^1 f_n'(t, \epsilon) dt , \] (13)
where \( f_n'(t, \epsilon) \) being the t-derivative of \( f_n(t, \epsilon) \), we obtain the sum-rule of the adaptive interpolation.

**Proposition 1 (Sum-rule):** Let \( Q = \frac{1}{2} x^T X \in \mathbb{R}^{K \times K} \) be the overlap matrix whose entries are
\[ Q_{t, \epsilon} = \frac{1}{n} \sum_{j=1}^{n} x_{jt} x_{jt'} . \]
Assume \( P_X \) has finite (2p)\(^{th}\)-order moments. Then
\[ f_n = \mathcal{O}(\| \epsilon \|) + \mathcal{O}(n^{-1}) + \psi(R(1, \epsilon)) \]
where \( \mathcal{O}(\| \epsilon \|) \) and \( \mathcal{O}(n^{-1}) \) are independent of \( \epsilon \) and \( n \), respectively.

**Proof:** See [17] Appendix B for the computation of the t-derivative \( f_n'(t, \epsilon) \).

Theorems 1 and 2 are proved in the next section by plugging two different choices for \( R(\cdot, \epsilon) \) in the sum-rule (14).

**IV. MATCHING BOUNDS**

**A. Lower bound: proof of Theorem 1**

A lower bound on \( f_n \) is obtained by choosing the interpolation function \( R(t, 0) = t S^{p(p-1)} \) with \( S \) a \( K \times K \) symmetric positive semidefinite matrix, i.e., \( \epsilon = 0 \) and \( R'(t, \epsilon) = S^{p(p-1)} \). Then the sum-rule (14) reads
\[ f_n = \mathcal{O}(n^{-1}) + \phi_p(S) \]
where \( \phi_p(r, q) = q^p - p q r^{p-1} + (p-1) p^p \). If \( p \) is even then \( \phi_p \) is non-negative on \( \mathbb{R}^2 \) and (15) directly implies
\[ f_n \geq \phi_p(S) + \mathcal{O}(n^{-1}) . \]
Taking the liminf on both sides of this inequality, and bearing in mind that the inequality is valid for all \( S \in \mathcal{S}_K^+ \), ends the proof of Theorem 1.

We have at our disposal a wealth of interpolation paths when considering any continuously differentiable \( R(\cdot, \epsilon) \). However, to establish the lower bound (6), we only need a simple linear interpolation, i.e., \( R'(t, \epsilon) = S^{p(p-1)} \). Such an interpolation dates back to Guerra [13], and was already used by [7], [8] to derive the lower bound (6) for both cases \( K = 1 \), any order \( p \), and \( p = 2 \), any finite-rank \( K \). Now, we turn to the proof of the upper bound (7), and we will see how the flexibility in the choice of \( R(\cdot, \epsilon) \) constitutes an improvement on the classical interpolation.

**B. Upper bound: proof of Theorem 2**

1) Interpolation determined by an ordinary differential equation (ODE): The sum-rule (14) suggests to pick an interpolation path satisfying
\[ \forall (t, \epsilon) \in \{0, \ldots, K\}^2 : (R'(t, \epsilon)\epsilon)_{t, \epsilon} = \mathbb{E}((Q_{t, \epsilon})_{t, \epsilon})^{p-1}. \] (16)
The integral in (14) can then be split in two terms; one similar to the second summand in (2), and one that will vanish in the high-dimensional limit if the overlap concentrates. The next proposition states that (16) indeed admits a solution, which at first sight is not clear as the overlap concentrates. The non-trivial properties required to show the upper bound (7) are also proved.

**Proposition 2:** For all \( \epsilon \in \mathcal{S}_K^+ \), there exists a unique global solution \( R(\cdot, \epsilon) : [0, 1] \to \mathcal{S}_K^+ \) to the first-order ODE
\[ \forall t \in [0, 1] : \frac{dR(t, \epsilon)}{dt} = \mathbb{E}((Q_{t, \epsilon})_{t, \epsilon})^{p-1}, \quad R(0) = \epsilon . \]
This solution is continuously differentiable and bounded. If \( p \) is even then \( \forall t \in [0, 1], R(t, \cdot) \) is a \( \mathbb{C}^{\epsilon} \)-diffeomorphism from \( \mathcal{S}_K^+ \) (the open cone of \( K \times K \) symmetric positive definite matrices) into \( R(t, \mathcal{S}_K^+) \) whose Jacobian determinant is greater than one, i.e.,
\[ \forall \epsilon \in \mathcal{S}_K^+ : \det J_{R(t, \cdot)}(\epsilon) \geq 1. \] (17)
Here \( J_{R(t, \cdot)} \) denotes the Jacobian matrix of \( R(t, \cdot) \).

**Proof:** We now rewrite (16) explicitly as an ODE. Let \( R \) be a matrix in \( \mathcal{S}_K^+ \). Consider the problem of inferring \( X \) from the following observations:
\[
\begin{cases}
\psi_{t}(t) = \sqrt{1 - \epsilon} \sum_{k=1}^{K} p \prod_{a=1}^{p} X_{i,a} x_{k} + z_{t}, \quad t \in \mathcal{I}; \\
\psi_{t}(t,R) = \sqrt{R} X_{j} + \sqrt{R}, \quad j \in [n].
\end{cases}
\] (18)
It is reminiscent of the interpolating problem (3). One can form a Hamiltonian similar to (9), where \( R(t, \epsilon) \) is simply replaced by \( R \), and \( (-)_{t, R} \) denotes the Gibbs bracket associated to the posterior of this model. One now defines the function
\[ F_n : [0, 1] \times \mathcal{S}_K^+ \to \mathcal{S}_K^+ (t, R) \to \mathbb{E}((Q_{t, \epsilon})_{t, \epsilon})^{p-1} . \]
Note that \( \mathbb{E}(Q_{t, \epsilon})_{t, \epsilon} \) is a symmetric positive semi-definite matrix. Indeed, from the Nishimori identity [13],
\[ \mathbb{E}(Q_{t, R}) = \frac{1}{n} \mathbb{E}((X)_{t, R}^{T} X) = \frac{1}{n} \mathbb{E}((X)_{t, R}^{T} (X)_{t, R}) . \]
By the Schur Product Theorem (13), the Hadamard power \( \mathbb{E}((Q_{t, R})_{t, \epsilon})^{p-1} \) also belongs to \( \mathcal{S}_K^+ \). Therefore, by the Cauchy-Lipschitz theorem, there exists a unique global solution \( R(\cdot, \epsilon) \) to the \((K + 1)/2\)-dimensional ODE:
\[ \forall t \in [0, 1] : \frac{dR(t, \epsilon)}{dt} = F_n(t, R(t)) , \quad R(0) = \epsilon \in \mathcal{S}_K^+ . \]

1 The Nishimori identity is a direct consequence of the Bayes formula. In our setting, it states \( \mathbb{E}(g(x, X)_{t, R}) = \mathbb{E}(g(x, X')_{t, R}) = \mathbb{E}(g(x, X))_{t, R} \) where \( x, X \) are two samples drawn independently from the posterior distribution given \( Y(t), \tilde{Y}(t, R) \). Here \( g \) can also explicitly depend on \( Y(t), \tilde{Y}(t, R) \).
Each initial condition $\epsilon \in S^+_K$ is tied to a unique solution $R(\cdot, \epsilon)$. This implies that the function $\epsilon \mapsto R(t, \epsilon)$ is injective. Its Jacobian determinant is given by Liouville’s formula [19]:

$$\det J_{R(t, \cdot)}(\epsilon) = \exp \int_0^t ds \sum_{1 \leq \ell \leq K} \frac{\partial (F_n \| \ell \cdot)}{\partial R \| \ell \cdot} \bigg|_{s, R(t, \epsilon)}.$$  

(19)

Thanks to [19], we can show that the Jacobian determinant is nonnegative for all $(t, R) \in [0, 1] \times S^+_K$. A lengthy computation (see [17] Appendix C) leads to the identity

$$\sum_{1 \leq \ell \leq K} \frac{\partial (F_n \| \ell \cdot)}{\partial R \| \ell \cdot} \bigg|_{t, R} = n(p - 1) \sum_{1 \leq \ell \leq K} E[(Q_{\ell \ell} \| t, R)]^{p-2} \Delta_{\ell \ell},$$  

(20)

where

$$\Delta_{\ell \ell} \equiv E\left(\frac{Q_{\ell \ell} + Q_{\ell \ell}}{2} - \frac{(x^\top X + x^\top X)_{\ell \ell}}{n}\right)^2,$$

(21)

If $p$ is even then $E[(Q_{\ell \ell} \| t, R)]^{p-2}$ is nonnegative. We show next that the $\Delta_{\ell \ell}$’s are nonnegative, thus ending the proof of [17]. The second expectation on the right-hand side (r.h.s.) of [21] satisfies (we omit the subscripts of the Gibbs bracket):

$$E\left(\frac{Q_{\ell \ell} + Q_{\ell \ell}}{2} - \frac{(x^\top X + x^\top X)_{\ell \ell}}{n}\right)^2 = E\left(\frac{(x^\top X + x^\top X)_{\ell \ell}}{2n} - \frac{(x^\top X + x^\top X)_{\ell \ell}}{2n}\right)^2 \leq E\left(\frac{(x^\top X + x^\top X)_{\ell \ell}}{2n} - \frac{(x^\top X + x^\top X)_{\ell \ell}}{2n}\right)^2 = E\left(\frac{Q_{\ell \ell} + Q_{\ell \ell}}{2} - \frac{(x^\top X + x^\top X)_{\ell \ell}}{2n}\right)^2.$$

The inequality is a simple application of Jensen’s inequality, while the equality that follows is an application of the Nishimori identity. The final upper bound is nothing but the first expectation on the r.h.s. of [21]. Therefore $\Delta_{\ell \ell} \geq 0$.  

2) Proof of Theorem [2] Let $\epsilon$ be a symmetric positive definite matrix, i.e., $\epsilon \in S^+_K$. We interpolate with the unique solution $R(\cdot, \epsilon) : [0, 1] \mapsto S^+_K$ to [16]. Under this choice, the sum-rule [13] reads:

$$f_n = \psi(R(1, \epsilon)) - \frac{p - 1}{2p} \sum_{\ell \cdot \leq \ell \cdot} \int_0^1 dt E[(Q_{\ell \ell} \| t, \epsilon)]^p \left. + \frac{1}{2p} \int_0^1 dt \sum_{t \cdot \leq t \cdot} E[Q_{\ell \ell}((Q_{\ell \ell} \| t, \epsilon)^{p-1} - E[(Q_{\ell \ell} \| t, \epsilon)]^{p-1})]_{t \cdot, t \cdot} + O(\| \epsilon \|) + O(n^{-1}).ight.$$

Using the convexity of $\psi$, we obtain by Jensen’s inequality:

$$\psi(R(1, \epsilon)) = \psi\left(\epsilon + \int_0^1 dt E[(Q_{t \cdot \epsilon})^p]^{(p-1)}\right) = \mathcal{O}(\| \epsilon \|) + \psi\left(\int_0^1 dt E[(Q_{t \cdot \epsilon})^p]^{(p-1)}\right) \leq \mathcal{O}(\| \epsilon \|) + \int_0^1 dt \psi(E[(Q_{t \cdot \epsilon})^p]^{(p-1)}).$$

(23)

Combining both [22] and [23] directly gives

$$f_n \leq \mathcal{O}(n^{-1}) + \mathcal{O}(\| \epsilon \|) + \int_0^1 dt \phi_p(E[(Q_{t \cdot \epsilon})])$$

$$+ \frac{1}{2p} \int_0^1 dt \sum_{t \cdot \leq t \cdot} E[Q_{\ell \ell}((Q_{\ell \ell} \| t, \epsilon)^{p-1} - E[(Q_{\ell \ell} \| t, \epsilon)]^{p-1})]_{t \cdot, t \cdot} \leq \mathcal{O}(n^{-1}) + \mathcal{O}(\| \epsilon \|) + \sup_{S \in S^+_K} \phi_p(S) \quad (24)$$

$$+ \frac{1}{2p} \int_0^1 dt \sum_{t \cdot \leq t \cdot} E[Q_{\ell \ell}((Q_{\ell \ell} \| t, \epsilon)^{p-1} - E[(Q_{\ell \ell} \| t, \epsilon)]^{p-1})]_{t \cdot, t \cdot}.$$  

In order to end the proof of [7], we must show that the second line of the upper bound [24] vanishes when $n$ goes to infinity. This will be the case if the overlap matrix $Q$ concentrates on its expectation $E(Q_{t \cdot \epsilon})$. Indeed, provided that the $(4p - 4)^{th}$ order moments of $P_X$ are finite, there exists a constant $C_X$ depending only on $P_X$ such that:

$$\left| \frac{1}{2p} \int_0^1 dt \sum_{t \cdot \leq t \cdot} E[Q_{\ell \ell}((Q_{\ell \ell} \| t, \epsilon)^{p-1} - E[(Q_{\ell \ell} \| t, \epsilon)]^{p-1})]_{t \cdot, t \cdot} \right| \leq \frac{C_X}{2} \int_0^1 dt E[\|Q - E(Q_{t \cdot \epsilon})\|^2]_{t \cdot, t \cdot}^{1/2}. \quad (25)$$

However, proving that the r.h.s. of [25] vanishes is only possible after integrating on a well-chosen set of “perturbations” $\epsilon$ (that play the role of initial conditions in the ODE in Proposition [3]). In essence, the integration over $\epsilon$ smoothens the phase transitions that might appear for particular choices of $\epsilon$ when $n$ goes to infinity.

We now describe the set of perturbations on which to integrate. Let $(s_n) \in (0, 1)^n$ be a sequence such that $s_n$ goes to 0 and $s_n^{K+1}/n$ diverges to infinity when $n \to +\infty$. Define the following sequence of subsets:

$$\xi_n \equiv \left\{ \epsilon \in \mathbb{R}^K \mid \forall \ell \neq \ell' : \epsilon_{\ell \ell'} = \epsilon_{\ell' \ell} \in [s_n, 2s_n] \right\} \bigcup \left\{ \epsilon : \epsilon_{\ell \ell} \in [2Ks_n, (2K + 1)s_n] \right\}.$$

Those are subsets of symmetric strictly diagonally dominant matrices with positive diagonal entries, hence they are included in $S^{++}_K$ (see [20] Corollary 7.2.3). The volume of $\xi_n$ is

$$V_{\xi_n} = s_n^{K(K+1)/2}.$$

Fix $t \in [0, 1]$. First using the Cauchy-Schwarz inequality, and then making the change of variable $\epsilon \rightarrow R \equiv R(t, \epsilon)$, which
is justified because $\epsilon \mapsto R(t, \epsilon)$ is a $C^1$-diffeomorphism (see Proposition \[9\]), one obtains

$$
\int_{\mathcal{E}_n} d\epsilon \mathbb{E} \left[ \|Q - \mathbb{E}(Q)\|_{t, \epsilon}^2 \right]^{1/2} 
\leq V_{\mathcal{E}_n}^{-1/2} \left( \int_{\mathcal{E}_n} d\epsilon \mathbb{E} \left[ \|Q - \mathbb{E}(Q)\|_{t, \epsilon}^2 \right]^{1/2} \right)
= V_{\mathcal{E}_n}^{-1/2} \left( \int_{\mathcal{R}_n \times \det J_{R(t, \epsilon)}(\epsilon)} dR \mathbb{E} \left[ \|Q - \mathbb{E}(Q)\|_{t, R}^2 \right]^{1/2} \right)
\leq V_{\mathcal{E}_n}^{-1/2} \left( \int_{\mathcal{R}_n} dR \mathbb{E} \left[ \|Q - \mathbb{E}(Q)\|_{t, R}^2 \right]^{1/2} \right),
$$

(26)

where $\mathcal{R}_{n,t} \equiv R(t, \mathcal{E}_n)$. The last inequality follows from (17). It is not difficult to show that all the $\mathcal{R}_{n,t}$'s are included in the convex set $\{ S \in S_{K_\epsilon}^+: \| S \| \leq 4K^{1/2} + \text{Tr}(\Sigma_X)^{p-1} \}$. The convex hulls of $\mathcal{R}_{n,t}$, denoted $\mathcal{C}(\mathcal{R}_{n,t})$, are therefore uniformly bounded subsets of $S_{K_\epsilon}^+$. This uniform boundedness ensures that the free entropy associated to (13) has a variance that vanishes as $O\left( \frac{1}{n^2} \right)$ (see [17 Appendix D]) uniformly in $t \in [0, 1]$ and $R \in \bigcup_{s \in [0, 1]} C(\mathcal{R}_{k,s})$.

Such concentration of the free entropy is essential to guarantee the concentration of overlap matrices in a Bayesian inference framework. Then, we can adapt the proof of [16, Theorem 3] to show the existence of a constant $C_{p,K,P_X}$ depending only on $p$, $K$, and $P_X$ such that:

$$
\int_{\mathcal{C}(\mathcal{R}_{n,t})} dR \mathbb{E} \left[ \|Q - \mathbb{E}(Q)\|_{t, R}^2 \right]_{t, R} \leq \frac{C_{p,K,P_X}}{s_{n/6}^{3/2}}.
$$

(27)

Note that the integral over the convex hull $\mathcal{C}(\mathcal{R}_{n,t})$ is an upper bound on the integral over $\mathcal{R}_{n,t}$. Combining (25), (26), and (27), one finally obtains:

$$
\int_{\mathcal{E}_n} \frac{d\epsilon}{V_{\mathcal{E}_n}} \int_{\delta} \frac{d\delta}{2\pi} \sum_{t,t'} \mathbb{E} \left[ \langle Q_{t'}^p \rangle \langle Q_{t}^p \rangle^{p-1} - \mathbb{E}[\langle Q_{t'}^p \rangle^{p-1}] \right]_{t, t'}
\leq C_X \sqrt{\frac{C_{p,K,P_X}}{V_{\mathcal{E}_n} s_{n/6}^{3/2}}}
= C_X \sqrt{\frac{C_{p,K,P_X}}{s_{n/6}^{3/2} + \text{Tr}(\Sigma_X)^{p-1}}}
$$

(28)

To conclude the proof, we integrate the inequality (24) over $\epsilon$ and, then, make use of (23) and

$$
\frac{1}{V_{\mathcal{E}_n}} \int_{\mathcal{E}_n} d\epsilon \mathcal{O}(\|\epsilon\|) \leq \mathcal{O}(1) \max_{\epsilon \in \mathcal{E}_n} \|\epsilon\| = \mathcal{O}(1) s_{n/6} = o_n(1).
$$

This gives the inequality

$$
f_n = \frac{1}{V_{\mathcal{E}_n}} \int_{\mathcal{E}_n} df_n \leq \sup_{S \in S_{k\epsilon}^+} \phi_p(S) + o_n(1),
$$

which directly implies the upper bound (7).

V. FUTURE WORK

We leave for future work the extension of both Theorems [12] and [9] to the odd-order case. For Theorem [9] it requires proving that the last summand on the r.h.s. of (15) is nonnegative. When $K = 1$, both $\mathbb{E}(Q)_{t, \epsilon}$ and $R$ are nonnegative so that $h_p(r, q)$’s non-negativity for $r, q \geq 0$ suffices [8]. However, for $K > 1$, we can only say that $\mathbb{E}(Q)_{t, \epsilon}$, $R \geq 0$. Regarding Theorem [2] the whole proof directly applies to $p$ odd if we can show that the divergence (20) is nonnegative, which is more difficult than for $p$ even. Indeed, while the $\Delta_{t, \epsilon}$’s are still $\geq 0$, it is not necessarily the case of the $E[(Q_{t'})_{t, R}]^{p-2}$ as $p = 2$ is odd.
