COMMUNITY DETECTION IN THE SPARSE HYPERGRAPH STOCHASTIC BLOCK MODEL

SOUMIK PAL AND YIZHE ZHU

Abstract. We consider the community detection problem in sparse random hypergraphs. Angelini et al. in [5] conjectured the existence of a sharp threshold on model parameters for community detection in sparse hypergraphs generated by a hypergraph stochastic block model (HSBM). We solve the positive part of the conjecture for the case of two blocks: above the threshold, there is a spectral algorithm which asymptotically almost surely constructs a partition of the hypergraph correlated with the true partition. Our method is a generalization to random hypergraphs of the method developed by Massoulié in [27] for sparse random graphs.

1. Introduction

Clustering is an important topic in network analysis, machine learning and computer vision [20]. Many clustering algorithms are based on graphs, which represent pairwise relationships among data. Hypergraphs can be used to represent higher order relationships among objects, and they have been shown empirically
to have advantages over graphs [34]. Recently hypergraphs have been used as the data model in machine learning, including recommender system [32], image retrieval [25] and bioinformatics [33].

The stochastic block model (SBM) is a generative model for random graphs with community structures which serves as a useful benchmark for clustering algorithms on graph data. It is natural to have an analogous model for random hypergraphs. In this paper we consider a higher order SBM called hypergraph stochastic block model (HSBM). Before describing HSBM, let’s recall clustering on graph SBMs.

1.1. The Stochastic Block Model for Graphs. In this section we summarize the state-of-the-art results for graph SBM with two blocks of roughly equal size.

Let \( \Sigma_n \) be the set of all pairs \((G, \sigma)\), where \( G = ([n], E) \) is a graph with vertex set \([n]\) and edge set \(E\), \(\sigma = (\sigma_1, \ldots, \sigma_n) \in \{-1, +1\}^n\) are spins on \([n]\), i.e., each vertex \(i \in [n]\) is assigned with a spin \(\sigma_i \in \{-1, +1\}\).

From this finite set \(\Sigma_n\), one can generate a random element \((G, \sigma)\) in two steps.

1. First generate i.i.d random variables \(\sigma_i \in \{-1, +1\}\) equally likely for all \(i \in [n]\).
2. Then given \(\sigma = (\sigma_1, \ldots, \sigma_n)\), we generate a random graph \(G\) where each edge \(\{i, j\}\) is included independently with probability \(p\) if \(\sigma_i = \sigma_j\) and with probability \(q\) if \(\sigma_i \neq \sigma_j\).

The law of this pair \((G, \sigma)\) will be denoted by \(\mathcal{G}(n, p, q)\). In particular, we are interested in the model \(\mathcal{G}(n, p_n, q_n)\) where \(p_n, q_n\) are parameters depending on \(n\). We use the shorthand notation \(\mathbb{P}_{\mathcal{G}_n}\) to emphasize that the integration is taken under the law \(\mathcal{G}(n, p_n, q_n)\).

Imagine \(C_1 = \{i: \sigma_i = +1\}\) and \(C_2 = \{i: \sigma_i = -1\}\) as two communities in the graph \(G\). Observing only \(G\) from a sample \((G, \sigma)\) from the distribution \(\mathcal{G}(n, p_n, q_n)\), the goal of community detection is to estimate the unknown vector \(\sigma\) up to a sign flip. Namely, we construct label estimators \(\hat{\sigma}_i \in \{\pm 1\}\) for each \(i\) and consider the empirical overlap between \(\hat{\sigma}\) and unknown \(\sigma\) defined by

\[
\text{ov}_n(\hat{\sigma}, \sigma) := \frac{1}{n} \sum_{i \in [n]} \sigma_i \hat{\sigma}_i.
\]

We may ask the following questions about the estimation as \(n\) tends to infinity:

1. Exact recovery (strong consistency):
   \[
   \lim_{n \to \infty} \mathbb{P}_{\mathcal{G}_n}\left(\{\text{ov}_n(\hat{\sigma}, \sigma) = 1\} \cup \{\text{ov}_n(\hat{\sigma}, \sigma) = -1\}\right) = 1.
   \]

2. Almost exact recovery (weak consistency): for any \(\epsilon > 0\),
   \[
   \lim_{n \to \infty} \mathbb{P}_{\mathcal{G}_n}\left(\{|\text{ov}(\hat{\sigma}, \sigma) - 1| > \epsilon\} \cap \{|\text{ov}(\hat{\sigma}, \sigma) + 1| > \epsilon\}\right) = 0.
   \]

3. Detection: Find a partition which is correlated with the true partition. More precisely, there exists a constant \(r > 0\) such that it satisfies the following: for any \(\epsilon > 0\),
   \[
   \lim_{n \to \infty} \mathbb{P}_{\mathcal{G}_n}\left(\{|\text{ov}(\hat{\sigma}, \sigma) - r| > \epsilon\} \cap \{|\text{ov}(\hat{\sigma}, \sigma) + r| > \epsilon\}\right) = 0.
   \]

There are many works on these questions using different tools, we list some of them. A conjecture of [11] based on non-rigorous ideas from statistical physics predicts a threshold of detection in the SBM. In particular, if \(p_n = \frac{a}{n}\) and \(q_n = \frac{b}{n}\) where \(a, b\) are positive constants independent of \(n\), then the detection is possible if and only if \((a - b)^2 > 2(a + b)\). This conjecture was confirmed in [28, 30, 27, 6] where [30, 27, 6] provided efficient algorithms to achieve the threshold. Very recently, two alternative spectral algorithms were proposed based on distance matrices [31] and a graph powering method in [3], and they both achieved the detection threshold.

Suppose \(p_n = \frac{a \log n}{n}, q_n = \frac{b \log n}{n}\) where \(a, b\) are constant independent of \(n\). Then the exact recovery is possible if and only if \((\sqrt{a} - \sqrt{b})^2 > 2\), which was solved in [2, 19] with efficient algorithms achieving the threshold. Besides the phase transition behavior, various algorithms were proposed and analyzed in different regimes and more general settings beyond the 2-block SBM [8, 9, 18, 4, 23, 29], including spectral methods, semidefinite programming, belief-propagation, and approximate message-passing algorithms. We recommend [1] for further details.
1.2. Hypergraph Stochastic Block Models. The hypergraph stochastic block model (HSBM) is a generalization of the SBM for graphs which was first studied in [14], where the authors consider hypergraphs generated by the stochastic block models that are dense and uniform. They considered spectral algorithms for exact recovery using hypergraph Laplacians. Subsequently, they extended their results to sparse, non-uniform hypergraphs [15, 16, 17].

For exact recovery, it was shown that the phase transition occurs in the regime of logarithmic average degree in [24, 10, 9] and the exact threshold was given in [22], by a generalization of the techniques in [2]. For detection of HSBM with two blocks, the authors of [5] purposed a conjecture that the phase transition occurs in the regime of constant average degree, based on the performance of the belief-propagation algorithm. Also they conjectured spectral algorithm based on non-backtracking operators on hypergraphs can reach the threshold. In [13], the authors showed there is an algorithm for detection when the average degree is bigger than some constant by reducing it to a bipartite stochastic block model, and they also mentioned a barrier to further improvement. We confirm the positive part of the conjecture in [5] for the case of two blocks: above the threshold, there is a spectral algorithm which asymptotically almost surely constructs a partition of the hypergraph correlated with the true partition.

Now we specify our \(d\)-uniform hypergraph stochastic block model with two clusters. Analogous to \(G(n, p_n, q_n)\), we define \(\mathcal{H}(n, d, p_n, q_n)\) for \(d\)-uniform hypergraphs.

Let \(\Sigma_n\) be the set of all pair \((H, \sigma)\), where \(H = ([n], E)\) is a \(d\)-uniform hypergraph (see Definition 2.1 below) with vertex set \([n]\) and hyperedge set \(E\), \(\sigma = (\sigma_1, \ldots, \sigma_n) \in \{+1, -1\}^n\) are the spins on \([n]\). From this finite set \(\Sigma_n\), one can generate a random element \((H, \sigma)\) in two steps.

1. First generate i.i.d random variables \(\sigma_i \in \{-1, +1\}\) equally likely for all \(i \in [n]\).
2. Then given \(\sigma = (\sigma_1, \ldots, \sigma_n)\), we generate a random hypergraph \(H\) where each hyperedge \(\{i_1, \ldots, i_d\}\) is included independently with probability \(p_n\) if \(\sigma_{i_1} = \cdots = \sigma_{i_d}\) and with probability \(q_n\) if the spins \(\sigma_{i_1}, \ldots, \sigma_{i_d}\) are not the same.

The law of this pair \((H, \sigma)\) will be denoted by \(\mathcal{H}(n, d, p_n, q_n)\). We use the shorthand notation \(\mathbb{P}_{\mathcal{H}_n}\) and \(\mathbb{E}_{\mathcal{H}_n}\) to emphasize that integration is taken under the law \(\mathcal{H}(n, d, p_n, q_n)\). Often we drop the index \(n\) from our notation, but it will be clear from \(\mathbb{P}_{\mathcal{H}_n}\).

1.3. Main Results. We consider the detection problem of the model \(\mathcal{H}(n, d, p_n, q_n)\) in the constant expected degree regime. Let

\[
p_n := \frac{a}{(d-1)}, \quad q_n := \frac{b}{(d-1)},
\]

for some constant \(a \geq b > 0\) and let

\[
\alpha := (d - 1) \frac{a + (2d - 1)b}{2d - 1}, \quad \beta := (d - 1) \frac{a - b}{2d - 1}.
\]
Here $\alpha$ is a constant which measures the expected degree of any vertex, and $\beta$ measures the discrepancy between the number of neighbors with $+$ sign and $-$ sign of any vertex. For $d = 2$, $\alpha, \beta$ are the same parameters for the graph case in [27].

Now we are able to state our main result which is an extension of the result of for graph SBMs in [27]. Note that with the definition of $\alpha, \beta$, we have $\alpha > \beta$. The condition $\beta^2 > \alpha$ in the statement of Theorem (1.1) below implies $\alpha, \beta > 1$, which will be assumed for the rest of the paper.

**Theorem 1.1.** Assume $\beta^2 > \alpha$. Let $(H, \sigma)$ be a random labeled hypergraph sampled from $\mathcal{H}(n, d, p_n, q_n)$ and $B^{(l)}$ be its $l$-th self-avoiding matrix (see Definition 2.6 below). Set $l = c \log(n)$ for a constant $c$ such that $c \log(n) < 1/8$. Let $x$ be a $l_2$-normalized eigenvector corresponding to the second largest eigenvalue of $B^{(l)}$. There exists a constant $t$ such that, if we define the label estimator $\hat{\sigma}_i$ as

$$\hat{\sigma}_i = \begin{cases} +1 & \text{if } x_i \geq t/\sqrt{n}, \\ -1 & \text{otherwise}, \end{cases}$$

then detection is possible. More precisely, there exists a constant $r > 0$ such that the empirical overlap between $\hat{\sigma}$ and $\sigma$ defined similar to (1.1) satisfies the following: for any $\epsilon > 0$,

$$\lim_{n \to \infty} P_{\mathcal{H}_n}(\{|ov_n(\hat{\sigma}, \sigma) - r| > \epsilon\} \bigcap \{|ov_n(\hat{\sigma}, \sigma) + r| > \epsilon\}) = 0.$$

Our algorithm can be summarized in two steps. The first step is a dimension reduction: $B^{(l)}$ has $n^2$ many entries from the original adjacency tensor $T$ (see Definition 2.2) of $n^d$ many entries. The second step is a simple spectral clustering according to leading eigenvectors as the common clustering algorithm in the graph case.

Different from graph SBMs, in the HSBMs, the random hypergraph $H$ we observe is essentially a random tensor. It is not immediately clear which operator to associate to $H$ that encodes the community structure in the bounded expected degree regime. The novelty of our method is a way to project the random tensor into matrix forms (the self-avoiding matrix $B^{(l)}$ and the adjacency matrix $A$) that give us the community structure from their leading eigenvectors.

To analyze $B^{(l)}$, in Section 3 we first develop a moment method suitable for sparse random hypergraphs that controls the spectral norms by counting concatenations of self-avoiding walks on hypergraphs. There are multiple ways to define self-avoiding walks on hypergraphs and our definition (see Definition 2.4) is the only one that works for us when applying the moment method. The growth control of the size of the local neighborhood (Section 4) for HSBMs turns out to be more challenging compared to graph SBMs in [27] due to the dependency between the number of vertices with spin $+$ and $-$, and overlaps between different hyperedges. Both of the issues mentioned above do not appear in the sparse random graph case. To analyze the local structure of HSBMs, we prove a new coupling result between a typical neighborhood of a vertex in the sparse random hypergraph $H$ and a multi-type Galton-Watson hypertree described in Section 5, which is a stronger version of local weak convergence of sparse random hypergraphs (local weak convergence for hypergraphs was recently introduced in [12]). Combining all the new ingredients we obtain the weak Ramanujan property of $B^{(l)}$ for sparse HSBMs as a generalization of the results in [27] (see Section 7).

### 2. Preliminary

**Definition 2.1** (hypergraph). A hypergraph $H$ is a pair $H = (V, E)$ where $V$ is a set of vertices and $E$ is the set of non-empty subsets of $V$ called hyperedges. If any hyperedge $e \in E$ is a set of $d$ elements of $V$, we call $H$ $d$-uniform. In particular, 2-uniform hypergraph is an ordinary graph. A $d$-uniform hypergraph is complete if any set of $d$ vertices is a hyperedge and we denote a complete $d$-uniform hypergraph on $[n]$ by $K_{n,d}$.

**Definition 2.2** (adjacency tensor). Let $H = (V, E)$ be a $d$-uniform hypergraph with $V = [n]$. We define $T$ to be the adjacency tensor of $H$ such that for any set of vertices $\{i_1, i_2, \ldots, i_d\}$,

$$T_{i_1, \ldots, i_d} = \begin{cases} 1 & \text{if } \{i_1, \ldots, i_d\} \in E, \\ 0 & \text{otherwise}. \end{cases}$$
We have the following expansion of the trace of $A$.

Definition 2.3 (adjacency matrix). The adjacency matrix $A$ of a $d$-uniform hypergraph $H = (V, E)$ with vertex set $[n]$ is a $n \times n$ symmetric matrix such that for any $i \neq j$, $A_{ij}$ is the number of hyperedges in $E$ which contains $i, j$ and $A_{ii} = 0$ for $i \in [n]$. Equivalently, we have

$$A_{ij} = \begin{cases} \sum_{e: (i,j) \in e} T_e & \text{if } i \neq j, \\ 0 & \text{if } i = j. \end{cases}$$

Definition 2.4 (walk). A walk of length $l$ on a hypergraph $H$ is a sequence $(i_0, e_1, i_1, \cdots, e_l, i_l)$ such that $i_{j-1} \neq i_j$ and $\{i_{j-1}, i_j\} \subset e_j$ for all $1 \leq j \leq l$. A walk is closed if $i_0 = i_l$ and we call it a circuit. A self-avoiding walk of length $l$ is a walk $(i_0, e_1, i_1, \cdots, e_l, i_l)$ such that

1. $|\{i_0, i_1, \ldots, i_l\}| = l + 1$,
2. Any consecutive hyperedges $e_{j-1}, e_j$ satisfy $e_{j-1} \cap e_j = \{i_j\}$ for $1 \leq j \leq l$,
3. Any two hyperedges $e_j, e_k$ with $1 \leq j < k \leq l, k \neq j + 1$ satisfy $e_j \cap e_k = \emptyset$.

Recall that a self-avoiding walk of length $l$ on a graph is a walk $(i_0, \ldots, i_l)$ without repeated vertices. Our definition is a generalization of the self-avoiding walk to hypergraphs.

Definition 2.5 (cycle and hypertree). A cycle of length $l$ with $l \geq 2$ in a hypergraph $H$ is a walk $(i_0, e_1, i_1, \ldots, i_{l-1}, e_l, i_0)$ such that $i_0, \ldots, i_{l-1}$ are distinct vertices and $e_1, \ldots, e_l$ are distinct hyperedges. A hypertree is a hypergraph which contains no cycles.

Let $\binom{[n]}{d}$ be the collection of all subsets of $[n]$ with size $d$. For any subset $e \in \binom{[n]}{d}$ and $i \neq j \in [n]$, we define

$$A^e_{ij} = \begin{cases} 1 & \text{if } \{i, j\} \in e \text{ and } e \in E, \\ 0 & \text{otherwise}, \end{cases}$$

and we define $A^e_{ii} = 0$ for all $i \in [n]$. With our notation above,

$$A_{ij} = \sum_{e \in \binom{[n]}{d}} A^e_{ij}.$$ 

We have the following expansion of the trace of $A^k$ for any integer $k \geq 0$:

$$\text{tr} A^k = \sum_{i_0, i_2, \ldots, i_{k-1} \in [n]} A_{i_0i_1} A_{i_2i_3} \cdots A_{i_{k-1}i_0} = \sum_{i_0, i_1, \ldots, i_{k-1} \in [n]} \sum_{e_1, \ldots, e_k \in \binom{[n]}{d}} A^e_{i_0i_1} \cdots A^e_{i_{k-1}i_0}.$$ 

Therefore, $\text{tr} A^k$ counts the number of circuits $(i_0, e_1, i_1, \ldots, i_{k-1}, e_k, i_0)$ in the hypergraph $H$ of length $k$. This connection was used in [26] to study the spectra of the Laplacian of random hypergraphs.

From our definition of self-avoiding walks on hypergraphs, we associate a self-avoiding adjacency matrix to the hypergraph.

Definition 2.6 (self-avoiding matrix). Let $H = (V, E)$ be a hypergraph with $V = [n]$. For any $l \geq 1$, a $l$-th self-avoiding matrix $B^{(l)}$ is a $n \times n$ matrix where for $i \neq j \in [n]$, $B^{(l)}_{ij}$ counts the number of self-avoiding walks of length $l$ from $i$ to $j$ and $B^{(l)}_{ii} = 0$ for $i \in [n]$.

$B^{(l)}$ is a symmetric matrix since a time-reversing self avoiding walk from $i$ to $j$ is a self avoiding walk from $j$ to $i$. Let $\text{SAW}_{ij}$ be the set of all self-avoiding walks of length $l$ connecting $i$ and $j$ in the complete $d$-uniform hypergraph on vertex set $[n]$. We denote a walk of length $l$ by $w = (i_0, e_{i_1}, \ldots, i_{l-1}, e_{i_l}, i_l)$. Then for any $i, j \in [n]$,

$$B^{(l)}_{ij} = \sum_{w \in \text{SAW}_{ij}} \prod_{t=1}^{l} A^e_{i_{t-1}i_t}.$$ 

(2.1)
3. Matrix Expansion and Spectral Norm Bounds

Consider a random labeled $d$-uniform hypergraph $H$ sampled from $\mathcal{H}\left(n, d, \frac{a}{(d-1)} , \frac{b}{(d-1)} \right)$ with adjacency matrix $A$ and self-avoiding matrix $B^{(l)}$. Let $\overline{A} := E_{\mathcal{H}_n}[A | \sigma]$. Let
\[
\rho(A) := \sup_{x: \|x\|_2 = 1} \|Ax\|_2
\]
be the spectral norm of a matrix $A$. Recall (2.1), define
\[
\Delta^{(l)}_{ij} := \sum_{w \in \text{SAW}_{ij}^{(l)}} \prod_{t=1}^{l} (A_{i_{t-1}i_t}^{e_{it}} - \overline{A}_{i_{t-1}i_t}^{e_{it}}),
\]
where $\overline{A}_{i_{t-1}i_t}^{e_{it}} = E_{\mathcal{H}_n}[A_{i_{t-1}i_t}^{e_{it}} | \sigma]$. $\Delta^{(l)}$ can be regarded as a centered version of $B^{(l)}$. We first establish a matrix expansion formula which connects $\overline{A}$ and $B^{(l)}$, and then apply the moment method to prove some spectral norm bounds. Recall the definition of $\alpha$ in (1.3).

**Theorem 3.1.** Let $H$ be a random hypergraph sampled from $\mathcal{H}\left(n, d, \frac{a}{(d-1)} , \frac{b}{(d-1)} \right)$ and $B^{(l)}$ be its $l$-th self-avoiding matrix. Then the following holds.

1. There exists some matrices $\{\Gamma^{(l,m)}\}_{m=1}^{l}$ such that for any $l \geq 1$, $B^{(l)}$ satisfies the identity
   \[
   B^{(l)} = \Delta^{(l)} + \sum_{m=1}^{l} (\Delta^{(l-m)} A B^{(m-1)}) - \sum_{m=1}^{l} \Gamma^{(l,m)}.
   \]

2. For any sequence $l_n = O(\log n)$ and any fixed $\epsilon > 0$,
   \[
   \lim_{n \to \infty} P_{\mathcal{H}_n} \left( \rho(\Delta^{(l_n)}) \leq n^{\epsilon} \alpha_{n/2} \right) = 1,
   \]
   and
   \[
   \lim_{n \to \infty} P_{\mathcal{H}_n} \left( \bigcap_{m=1}^{l_n} \left\{ \rho(\Gamma^{(l_n,m)}) \leq n^{\epsilon-1} \alpha_{(l_n+m)/2} \right\} \right) = 1.
   \]

For the rest of this section, we establish Theorem 3.1. For ease of notation, we drop the index $l_n$ in the proof and it will be clear from the law $\mathcal{H}_n$. For any sequences of real numbers $\{a_t\}_{t=1}^{l}, \{b_t\}_{t=1}^{l}$, we have the following expansion identity for $l \geq 2$ (see for example, Equation (15) in [27] and Equation (27) in [6]):
\[
\prod_{t=1}^{l} (a_t - b_t) = \prod_{t=1}^{l} a_t - \sum_{m=1}^{l} \left( \prod_{t=1}^{l-m} (a_t - b_t) \right) b_{l-m+1} \prod_{t=l-m+2}^{l} a_t.
\]
Therefore the following identity holds.
\[
\prod_{t=1}^{l} (A_{i_{t-1}i_t}^{e_{it}} - \overline{A}_{i_{t-1}i_t}^{e_{it}}) = \prod_{t=1}^{l} A_{i_{t-1}i_t}^{e_{it}} - \sum_{m=1}^{l-m} \left( \prod_{t=1}^{l-m} (A_{i_{t-1}i_t}^{e_{it}} - \overline{A}_{i_{t-1}i_t}^{e_{it}}) \right) \overline{A}_{i_{l-m+1}i_{l-m+1}}^{e_{l-m+1}} \prod_{t=l-m+2}^{l} A_{i_{t-1}i_t}^{e_{it}}.
\]

Summing over all $w \in \text{SAW}_{ij}$ yields
\[
\Delta^{(l)}_{ij} = B_{ij}^{(l)} - \sum_{m=1}^{l-m} \sum_{w \in \text{SAW}_{ij}} \left( \prod_{t=1}^{l-m} (A_{i_{t-1}i_t}^{e_{it}} - \overline{A}_{i_{t-1}i_t}^{e_{it}}) \right) \overline{A}_{i_{l-m+1}i_{l-m+1}}^{e_{l-m+1}} \prod_{t=l-m+2}^{l} A_{i_{t-1}i_t}^{e_{it}}.
\]

Introduce the set $Q_{ij}^{m}$ of walks $w$ defined by concatenations of two self-avoiding walks $w_1, w_2$ such that $w_1$ is a self-avoiding walk of length $l - m$ from $i$ to some vertex $k$, and $w_2$ is a self-avoiding walk of length $m$ from $k$ to $j$ for all possible $1 \leq m \leq l$ and $k \in [n]$. So $\text{SAW}_{ij} \subset Q_{ij}^{m}$ for all $1 \leq m \leq l$. Let $R_{ij}^{m} = Q_{ij}^{m} \setminus \text{SAW}_{ij}$. Define the matrix $\Gamma^{(l,m)}$ as
\[
\Gamma^{(l,m)}_{ij} := \sum_{w \in R_{ij}^{m}} \prod_{t=1}^{l-m} (A_{i_{t-1}i_t}^{e_{it}} - \overline{A}_{i_{t-1}i_t}^{e_{it}}) \overline{A}_{i_{l-m+1}i_{l-m+1}}^{e_{l-m+1}} \prod_{t=l-m+2}^{l} A_{i_{t-1}i_t}^{e_{it}}.
\]
From (3.5),
\[
\Delta_{ij}^{(l)} = B_{ij}^{(l)} - \sum_{m=1}^{l} \sum_{w \in Q_{ij}^m \setminus R_{ij}^m} \left( \prod_{i=1}^{l-m} \left( A_{t_{i-1}t_i}^{e_{1t}} - \overline{A}_{t_{i-1}t_i}^{e_{1t}} \right) \right) \prod_{t=m+1}^{l} A_{t_{i-1}t_i}^{e_{1t}} \\
= B_{ij}^{(l)} - \sum_{m=1}^{l} \sum_{w \in Q_{ij}^m} \prod_{i=1}^{l-m} \left( A_{t_{i-1}t_i}^{e_{1t}} - \overline{A}_{t_{i-1}t_i}^{e_{1t}} \right) \prod_{t=m+1}^{l} A_{t_{i-1}t_i}^{e_{1t}} \\
+ \sum_{m=1}^{l} \sum_{w \in R_{ij}^m} \prod_{i=1}^{l-m} \left( A_{t_{i-1}t_i}^{e_{1t}} - \overline{A}_{t_{i-1}t_i}^{e_{1t}} \right) \prod_{t=m+1}^{l} A_{t_{i-1}t_i}^{e_{1t}} + \sum_{m=1}^{l} \Gamma_{ij}^{(l,m)}
\]

From the definition of matrix multiplication, we have
\[
\sum_{w \in Q_{ij}^m} \prod_{i=1}^{l-m} \left( A_{t_{i-1}t_i}^{e_{1t}} - \overline{A}_{t_{i-1}t_i}^{e_{1t}} \right) \prod_{t=m+1}^{l} A_{t_{i-1}t_i}^{e_{1t}} = \sum_{1 \leq i \leq n} \Delta_{i1}^{(l-m)} \overline{A}_{t_{i-1}t_i}^{B_{ij}} = \left( \Delta_{i1}^{(l-m)} \overline{A}B_{ij}^{(m-1)} \right)
\]

Combining (3.7) and (3.8), we have
\[
\Delta_{ij}^{(l)} = B_{ij}^{(l)} - \sum_{m=1}^{l} \left( \Delta_{i1}^{(l-m)} \overline{A}B_{ij}^{(m-1)} \right) + \sum_{m=1}^{l} \Gamma_{ij}^{(l,m)}
\]

Since (3.9) is true for any \( i, j \in [n] \), it implies (3.2). We then prove the following spectral norm bound.

**Lemma 3.2.** For all integers \( k, l \geq 1 \), the following holds:
\[
\mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}] \leq \sum_{v=1}^{k+1} \sum_{h=1}^{k} n^v \left( d - 1 \right)^h \frac{h^2}{n - d + 2} \left( (v + 1)^2(l + 1)^22k(2h+1) \right) \alpha^{v-1} \beta^{h-v+1}.
\]

Since \( \Delta^{(l)} \) is symmetric, all of its eigenvalues are real. We can bound \( \mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}] \) by \( \mathbb{E}_{H_n}[\text{tr}(\Delta^{(l)})^{2k}] \), which can be estimated by the number of circuits of a certain kind on a complete hypergraph \( K_{n,d} \). The estimation is based on a coding argument, and we modify the proof in [27] to count circuits in hypergraphs. Let \( W_{2k,l} \) be the set of all circuits of length \( 2kl \) in the complete hypergraph \( K_{n,d} \) which are concatenations of \( 2k \) many self-avoiding walks of length \( l \). For any circuits \( w \in W_{2k,l} \), we denote it by \( w = (i_0, e_{i_1}, i_1, \ldots, e_{i_{2kl}}, i_{2kl}) \), with \( i_{2kl} = i_0 \).

**Proof.** Note that \( \mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}] \leq \mathbb{E}_{H_n}[\text{tr}(\Delta^{(l)})^{2k}] \), from (3.1), we have
\[
\mathbb{E}_{H_n}
\left[
\text{tr}(\Delta^{(l)})^{2k}
\right] = \sum_{j_1, \ldots, j_{2k} \in [n]} \mathbb{E}_{H_n}
\left[
\Delta_{j_1j_2}^{(l)} \Delta_{j_2j_3}^{(l)} \cdots \Delta_{j_{2k}j_1}^{(l)}
\right] = \sum_{w \in W_{2k,l}} \mathbb{E}_{H_n}
\left[
\prod_{t=1}^{2kl} (A_{t_{i-1}t_i}^{e_{1t}} - \overline{A}_{t_{i-1}t_i}^{e_{1t}})
\right].
\]

The sum is over all circuits \( w \in W_{2k,l} \). For each circuit, the weight it contributes to the sum is the product of \( (A_{ij}^{e_{ij}} - \overline{A}_{ij}^{e_{ij}}) \) over all the hyperedges \( e \) traversed in the circuits. In order to have a upper bound on \( \mathbb{E}_{H_n}[\text{tr}(\Delta^{(l)})^{2k}] \), we need to estimate how many such circuits are included in the sum and what are the weights they contribute.

We also write \( w = (w_1, w_2, \ldots, w_{2k}) \) where each \( w_i \) is a self-avoiding walk of length \( l \). Let \( v \) and \( h \) be the number of distinct vertices and hyperedges traversed by the circuit respectively. The idea is to bound the number of all possible circuits \( w \) in (3.11) with given \( v \) and \( h \), and then sum over all possible \( (v, h) \) pairs.

Fix \( v \) and \( h \), for any circuit \( w \) we form a labeled multigraph \( G(w) \) with labeled vertices \( \{1, \ldots, v\} \) and labeled multiple edges \( \{e_1, \ldots, e_h\} \) by the following rules:
• Label the vertices in $G(w)$ by the order they first appear in $w$, starting from 1. For any pair vertices $i, j \in [v]$, we add an edge between $i, j$ in $G(w)$ whenever a hyperedge appears between the $i$-th and $j$-th distinct vertices in the circuit $w$. $G(w)$ is a multigraph since it’s possible that for some $i, j$, there exists two distinct hyperedges connecting the $i$-th and $j$-th distinct vertices in $w$, which corresponds to two distinct edges in $G(w)$ connecting $i, j$. It’s then clear that the number of edges in $G(w)$ is $h$.

• Label the edges in $G(w)$ by the order in which the corresponding hyperedge appears in $w$ from $e_1$ to $e_h$. At the end we obtain a multigraph $G(w)$ with vertex set $\{1, \ldots, v\}$ and edge set $\{e_1, \ldots, e_h\}$.

It’s crucial to see that the labeling of vertices and edges in $G(w)$ is in order and it tells us how the circuit $w$ is traversed. Consider any edge in $G(w)$ such that its right endpoint (in the order of the traversal of $w$) is a new vertex that has not been traversed by $w$, we call it a tree edge. Denote by $T(w)$ the tree spanned by those edges. It’s clear for the construction that $T(w)$ includes all vertices in $G(w)$, so $T(w)$ is a spanning tree of $G(w)$. Since the labels of vertices and edges are given in $G(w)$, $T(w)$ is uniquely defined. See Figure 2 for an example.

We will break each self-avoiding walk $w_i$ into three types of successive sub-walks where each sub-walk is exactly one of the following 3 types and we encode these sub-walks as follows.

• Type 1: hyperedges with corresponding edges in $G(w) \setminus T(w)$. Given our position in the circuit $w$, we can encode an hyperedge of this type by its right-end vertex. Hyperedges of Type 1 breaks the walk $w_i$ into disjoint sub-walks and we partition these sub-walks into Type 2 and 3 below.

• Type 2: sub-walks such that all their hyperedges correspond to edges of $T(w)$ and have been traversed already by $w_1, \ldots, w_{i-1}$. Each sub-walk is a part of a self-avoiding walk, and it is a path contained in the tree $T(w)$. Given its initial and its end vertices, there will be exactly one such path in $T(w)$, therefore these walks can be encoded by the end vertices.

• Type 3: sub-walks such that their hyperedges correspond to edges of $T(w)$ and they are being traversed for the first time. Given the initial vertex of a sub-walk of this type, since it is traversing $w$ for the first time, the number of edges in $T(w)$ satisfies $k + 1 \leq h - v + 1$. This is because for a hyperedge $e$ between two vertices $i, j$, the number of possible hyperedges containing $i, j$ is at most $\binom{n}{d-2}^h$. Therefore, given $v, h$, the number of circuits that share the same triple sequence (3.12) is at most $n^v \binom{n}{d-2}^h$. For fixed $d$ and large $n$, this is at most $n^v \binom{n}{d-2}^h$. This is the estimate we use below.

We encode any Type 2 or Type 3 sub-walk by 0 if the sub-walk is empty. Now we can decompose each $w_i$ into sequences characterizing by its sub-walks:

$$(3.12) \quad (p_1, q_1, r_1), (p_2, q_2, r_2), \ldots, (p_t, q_t, r_t)$$

Here $r_1, \ldots, r_{t-1}$ are codes from sub-walks of Type 1. From the way we encode such hyperedges, we have $r_i \in \{1, \ldots, v\}$ for $1 \leq i \leq t - 1$. Type 2 and Type 3 sub-walks are encoded by $p_1, \ldots, p_t$ and $q_1, \ldots, q_t$ respectively. Since Type 1 hyperedges break $w$ into disjoint pieces, we use $\{p_i, q_i, r_i\}$ to represent the last piece of the sub-walk and make $r_t = 0$. Each $p_i$ represents the right-end vertex of the Type 2 sub-walk, and $p_t = 0$ if it the sub-walk is empty, hence $q_i \in \{0, \ldots, v\}$ for $1 \leq i \leq t$. Each $q_i$ represents the length of Type 3 sub-walks, so $q_i \in \{0, \ldots, l\}$ for $1 \leq i \leq t$. From the way we encode these sub-walks, there are at most $(v + 1)^2(l + 1)$ many possibilities for each triplet $(p_j, q_j, r_j)$.

We now consider how many ways we can concatenate sub-walks encoded by the triplets to form a circuit $w$. All triplets with $r_j \in [v]$ for $1 \leq j \leq t - 1$ indicate the traversal of an edge not in $T(w)$. Since we know the number of edges in $G(w) \setminus T(w)$ is $(h - v + 1)$, and within a self-avoiding walk $w_i$, edges on $G(w)$ can be traversed at most once, the length of the triplets in (3.12) satisfies $t - 1 \leq h - v + 1$, which implies $t \leq h - v + 2$. Since each hyperedge can be traversed at most $2k$ many times by $w$ due to the constraint that the circuits $w$ of length $2kl$ are formed by self-avoiding walks, so the number of triple sequences for fixed $v, h$ is at most $[(v + 1)^2(l + 1)^2]^{2k(2h-v)}$.

There are multiple $w$ with the same code sequence. However, they must all have the same number of vertices and edges, and the positions where of vertices and hyperedges are repeated must be the same. The number of ordered sequences of $v$ distinct vertices in is at most $n^v$. Given the vertex sequence, the number of ordered sequences of $h$ distinct hyperedges in $K_{n,h}$ is at most $\binom{n}{h-2}^h$. This is because for a hyperedge $e$ between two vertices $i, j$, the number of possible hyperedges containing $i, j$ is at most $\binom{n-2}{d-2}$. Therefore, given $v, h$, the number of circuits that share the same triple sequence (3.12) is at most $n^v \binom{n}{d-2}^h$. For fixed $d$ and large $n$, this is at most $n^v \binom{n}{d-2}^h$. This is the estimate we use below.
To summarize, we have shown that the number of all possible triple sequences we can have from circuits in the sum (3.11) is at most $[(v+1)^2(l+1)]^{2k(2+h−v)}$ and the number of circuits that correspond to the same triple sequence is at most $n^v\binom{n}{d-2}^h$. Combining the two estimates, the number of all possible circuits $w$ with fixed $v$, $h$ is at most

$$n^v\binom{n}{d-2}^h [(v+1)^2(l+1)]^{2k(2+h−v)}.$$  

Now we consider the expected weight of each circuit in the sum (3.11). Given $\sigma$, if $i, j \in e$, we have $A^e_{ij} \sim \text{Ber} \left(p_{\sigma(e)}\right)$, where $p_{\sigma(e)} = \frac{n}{(d−1)}$ if vertices in $e$ have the same spins and $p_{\sigma(e)} = \frac{1}{(d−1)}$ otherwise. 

For a given hyperedge appearing in $w$ with multiplicity $m \in \{1, \ldots, 2k\}$, the corresponding expectation $\mathbb{E}_{H_n} \left[\left(A^e_{ij} - A^e_{ij}\right)^m\right]$ is 0 if $m = 1$. Since $0 \leq A^e_{ij} \leq 1$, for $m \geq 2$, we have

$$\mathbb{E}_{H_n} \left[\left(A^e_{ij} - A^e_{ij}\right)^m \mid \sigma\right] \leq \mathbb{E}_{H_n} \left[\left(A^e_{ij} - A^e_{ij}\right)^2 \mid \sigma\right] \leq p_{\sigma(e)}.$$  

For any hyperedge $e$ corresponding to an edge in $G(w) \setminus T(w)$ we have the upper bound

$$p_{\sigma(e)} \leq \frac{a \lor b}{\binom{n}{d-1}}.$$  

Taking the expectation over $\sigma$ we have

$$\mathbb{E}_{\sigma}[p_{\sigma(e)}] = \frac{a + (2^{d-1} - 1)b}{2^{d-1}\binom{n}{d-1}} = \frac{\alpha}{(d−1)\binom{n}{d-1}}.$$  

Recall the weight of each circuit in the sum (3.11) is given by $\mathbb{E}_{H_n} \left[\prod_{i=1}^{2kl}(A^e_{i;i} - A^e_{i;i})\right]$. Conditioned on $\sigma$, $(A^e_{i;i} - A^e_{i;i})$ are independent random variables for distinct hyperedges. Denote these distinct hyperedges by $e_1, \ldots, e_h$ with multiplicity $m_1, \ldots, m_h$ and we order them such that $e_1, \ldots, e_{v−1}$ are the hyperedges corresponding to edges on $T(w)$. Introduce the random variables $A^e_i \sim \text{Ber} \left(p_{\sigma(e_i)}\right)$ for $1 \leq i \leq h$ and denote $\overline{A^e} = \mathbb{E}_{H_n}[A^e_i \mid \sigma]$. Therefore from (3.13) we have

$$\mathbb{E}_{H_n} \left[\prod_{i=1}^{2kl}(A^e_{i;i} - A^e_{i;i})\right] = \mathbb{E}_{\sigma} \left[\mathbb{E}_{H_n} \left[\prod_{i=1}^{2kl}(A^e_{i;i} - A^e_{i;i}) \mid \sigma\right]\right] = \mathbb{E}_{\sigma} \left[\prod_{i=1}^{h} \mathbb{E}_{H_n} \left[\left(A^e_i - \overline{A^e}\right)^{m_i} \mid \sigma\right]\right] \leq \mathbb{E}_{\sigma} \left[\prod_{i=1}^{h} p_{\sigma(e_i)}\right].
We use the bound (3.14) for \( p_{\sigma(e_1), \ldots, p_{\sigma(e_k)}} \), which implies

\[
E_{\sigma} \left[ \prod_{i=1}^{h} p_{\sigma(e_i)} \right] \leq \left( \frac{a \lor b}{n} \right)^{h-v+1} E_{\sigma} \left[ \prod_{i=1}^{v-1} p_{\sigma(e_i)} \right].
\]

Since \( e_1, \ldots, e_{v-1} \) are hyperedges in a self-avoiding walk, any two hyperedges among \( \{e_1, \ldots, e_{v-1}\} \) share at most 1 vertex, \( p_{\sigma(e_i), p_{\sigma(e_j)}} \) are pairwise independent for all \( 1 \leq i < j \leq v-1 \). Moreover, since the corresponding edges of \( e_1, \ldots, e_{v-1} \) forms the spanning tree \( T(w) \), take any \( e_j \) such that the corresponding edge in \( T(w) \) is attached to some leaf, we know \( e_j \) and \( \bigcup_{i \neq j, 1 \leq i \leq v} e_i \) share exactly one common vertex, therefore \( p_{\sigma(e_j)} \) is independent of \( \prod_{1 \leq i \leq v-1, i \neq j} p_{\sigma(e_i)} \), we then have

\[
E_{\sigma} \left[ \prod_{i=1}^{v-1} p_{\sigma(e_i)} \right] = E_{\sigma} \left[ p_{\sigma(e_j)} \right] \cdot E_{\sigma} \left[ \prod_{1 \leq i \leq v-1, i \neq j} p_{\sigma(e_i)} \right].
\]

Now the corresponding edges of all hyperedges \( \{e_1, \ldots, e_{v-1}\} \setminus \{e_j\} \) form a tree in \( G(w) \) again and the factorization of expectation in (3.17) can proceed as long as we have some edge attached to leaves. Repeating (3.17) recursively, with (3.15), we have

\[
\prod_{i=1}^{v-1} p_{\sigma(e_i)} = \prod_{i=1}^{v-1} E_{\sigma} \left[ p_{\sigma(e_i)} \right] = \left( \frac{\alpha}{(d-1)(n)} \right)^{v-1}. \tag{3.18}
\]

Combining (3.14) and (3.18) we have for each circuit \( w \in W_{2k,l} \) in the sum (3.1), the expected weight it contributes to the sum is bounded by

\[
E_{H_n} \left[ \prod_{i=1}^{2kl} (A_{t_i} - A_{\bar{t}_i}) \right] \leq \left( \frac{a \lor b}{n} \right)^{h-v+1} \left( \frac{\alpha}{(d-1)(n)} \right)^{v-1} \left( a \lor b \right)^{h-v+1}. \tag{3.19}
\]

Since every hyperedge in \( w \) must be visited at least twice to make its expected weight non-zero, and \( w \) is of length \( 2kl \), we must have \( h \leq kl \). In the multigraph \( G(w) \), we have the constraint \( v \leq h + 1 \leq kl + 1 \). Since the first self-avoiding walk in \( w \) of length \( l \) takes \( l+1 \) distinct vertices, we also have \( v \geq l+1 \). So the possible range of \( v \) is \( l+1 \leq v \leq kl+1 \) and \( h \) satisfies \( v-1 \leq h \leq kl \). Putting all the estimates above together, we have

\[
E_{H_n}[\rho(\Delta^{(l)})^{2k}] \leq \sum_{v=l+1}^{kl+1} \sum_{h=v-1}^{kl} n^v \left( \frac{n}{d-2} \right)^h \left( (v+1)^2(l+1) \right)^{2k(2h-v)} \left( \frac{\alpha}{(d-1)(n)} \right)^{v-1} \left( a \lor b \right)^{h-v+1}. \tag{3.20}
\]

This completes the proof of Lemma 3.2. \( \square \)

We now estimate the order of (3.20) when \( l_n = O(\log n) \), we drop the index \( n \) for convenience. Since \( d, k \) are fixed, for sufficiently large \( n \), and some constant \( C > 0 \),

\[
\left( \frac{n}{d-2} \right)^h \leq \left( 1 + \frac{d-2}{n-d+2} \right)^{kl} = 1 + \frac{(d-2)kl}{n} + \sum_{i=2}^{kl} \binom{kl}{i} \left( \frac{(d-2)kl}{n} \right)^i \leq 1 + \frac{C \log n}{n} \leq 2,
\]

and from (3.20),
\[
\mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}] \leq \sum_{v=l+1}^{kl+1} \sum_{h=v-1}^{kl} \left( 1 + \frac{C \log n}{n} \right) n^{v-h}(d-1)^{h-v+1}[(v+1)^2(l+1)]^{2k(2+h-v)}\alpha^{v-1}(a \lor b)^{h-v+1}
\]
\[
\leq 2 \sum_{v=l+1}^{kl+1} \sum_{h=v-1}^{kl} n \left( \frac{(a \lor b)(d-1)}{n} \right)^{h-v+1} [(kl+2)^2(l+1)]^{2k(2+h-v)}\alpha^{v-1}.
\]

Hence
\[
\frac{\mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}]}{na^k[(kl+2)^2(l+1)]^{2k}} \leq 2 \sum_{v=l+1}^{kl+1} \sum_{h=v-1}^{kl} \left[ \frac{(a \lor b)(d-1)}{n} \right]^{h-v+1} [(kl+2)^2(l+1)]^{2k(h-v+1)}\alpha^{v-1-kl}
\]
\[
= 2 \sum_{v=l+1}^{kl+1} \alpha^{v-1-kl} \sum_{h=v-1}^{kl} \left[n^{-1}(a \lor b)(d-1)((kl+2)^2(l+1))^{2k}\right]^{h-v+1}.
\]

(3.21)

Since for fixed \(d,k\) and \(l=O(\log n), n^{-1}(a \lor b)(d-1)((kl+2)^2(l+1))^{2k} = o(1)\) for \(n\) sufficiently large, the leading term in (3.21) is the term with \(h=v-1\). Recall \(\alpha > 1\), for sufficiently large \(n\), we have
\[
\frac{\mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}]}{na^k[(kl+2)^2(l+1)]^{2k}} \leq 3 \sum_{v=l+1}^{kl+1} \alpha^{v-1-kl} = 3 \cdot \frac{\alpha - \alpha^{1-kl}}{\alpha - 1} \leq \frac{3\alpha}{\alpha - 1}.
\]

It implies that
\[
\mathbb{E}_{H_n}[\rho(\Delta^{(l)})^{2k}] \leq \frac{3\alpha}{\alpha - 1} na^k[(kl+2)^2(l+1)]^{2k}.
\]

For any fixed \(\epsilon > 0\), choose \(k\) such that \(1 - 2k\epsilon < 0\), using Markov inequality, we have
\[
P_{H_n}(\rho(\Delta^{(l)}) \geq n^\epsilon \alpha^{l/2}) \leq \mathbb{E}_{H_n}(\rho(\Delta^{(l)})^{2k}) \leq \frac{3\alpha}{\alpha - 1} n^{1-2k\epsilon}[(kl+2)^2(l+1)]^{2k} \leq \frac{3\alpha}{\alpha - 1} C' n^{1-2k\epsilon}(\log n)^6k.
\]

for some constant \(C' > 0\). We have
\[
\lim_{n \to \infty} P_{H_n}(\rho(\Delta^{(l)}) \geq n^\epsilon \alpha^{l/2}) = 0.
\]

This implies (3.3) in the statement of Theorem 3.1.

Using a similar argument, we can prove the following estimate of \(\rho(\Gamma^{(l,m)})\).

**Lemma 3.3.** For all positive integers \(k, l, m, 1 \leq m \leq l\), we have the following upper bound for \(\mathbb{E}_{H_n}[\rho(\Gamma^{(l,m)})^{2k}]\):
\[
\sum_{v=m(l-m)+1}^{k(l+m-2)+1} \sum_{h=v-1}^{k(l-m-2)} n^v \left( \frac{d-1}{d-2} \right)^{h+2k} v^{2k}[(v+1)^2(l+1)]^{4k(2+h-v)} \left( \frac{\alpha}{d-1} \right)^{v-1}(a \lor b)^{h-v+1+2k}.
\]

(3.23)

Proof. For any \(n \times n\) real matrix \(M\), we have \(\rho(M)^{2k} \leq \text{tr}[(MM^T)^k]\), therefore
\[
\mathbb{E}_{H_n}[\rho(\Gamma^{(l,m)})^{2k}] \leq \mathbb{E}_{H_n} \left[ \text{tr} \left( \Gamma^{(l,m)} \Gamma^{(l,m)^\top} \right)^k \right] = \sum_{i_1, \ldots, i_{2k} \in [n]} \mathbb{E}_{H_n} \left[ \Gamma^{(i,m)}_{i_1i_2} \Gamma^{(i,m)^\top}_{i_2i_3} \cdots \Gamma^{(i,m)}_{i_{2k-1}i_{2k}} \right].
\]

(3.24)

Recall the definition of \(\Gamma^{(l,m)}\) from (3.6), the sum in (3.24) can be expanded to be the sum over all circuits \(w = (w_1, \ldots, w_{2k})\) of length \(2kl\) which are obtained by concatenation of \(2k\) walks of length \(l\), and each \(w_i, 1 \leq i \leq 2k\) is a concatenation of two self-avoiding walks of length \(l-m\) and \(m-1\). The weight that each hyperedge in the circuit contributes can be either \(A_{ij}^e - \overline{A_{ij}}^e, \overline{A_{ij}}^e\) or \(A_{ij}^e\). For all circuits \(w\) in (3.24) with nonzero expected weights, there is an extra constraint that each \(w_i\) intersects with some other \(w_j\), otherwise the expected weight that \(w_i\) contributes to the sum (3.24) will be 0. We want to bound the number of such circuits with nonzero expectation.

Let \(v, h\) denoted the number of distinct vertices and hyperedges traversed by the circuit. Here we don’t count the hyperedges that are weighted by \(\overline{A_{ij}}^e\). We associate a multigraph \(G(w)\) for each \(w\) as before, but
the hyperedges with weight \( \overline{A}^{ij}_{ij} \) are not included. Since \( \mathbb{E}_{H_n}[\Gamma^{(l,m)}_{ij}] = 0 \) for any \( i, j \in [n] \), if the expected weight of \( w \) is nonzero, the corresponding graph \( G(w) \) must be connected.

Let \( m \) be fixed. For each circuit \( w \), there are \( 4k \) self-avoiding walks, and each \( w_i \) is broken into two self-avoiding walks of length \( m - 1 \) and \( l - m \) respectively. We adopt the way of encoding each self-avoiding walk as before, except that we must also include the labels of the end point \( j \) after the traversal of an edge \( e \) with weight from \( \overline{A}^{ij}_{ij} \), which gives us the initial vertex of the self-avoiding walk of length \( l - m \) within each \( w_i \). These extra labels tell us how to concatenate the two self-avoiding walks of length \( m - 1 \) and \( l - m \) into the walk \( w_i \) of length \( l \). For each \( w_i \), label is encoded by a number from \( \{1, \ldots, v\} \). So all possible such labels can be bounded by \( v^{2k} \). Then the upper bound on the number of valid triplet sequences with extra labels for fixed \( v, h \) is now given by

\[
v^{2k}[(v + 1)^2(l + 1)]^{4k(2 + h-v)}.
\]

The total number of circuits that have the same triplet sequences with extra labels is at most

\[
n^v \left( \frac{n}{d-2} \right)^{h+2k} v^{2k}[(v + 1)^2(l + 1)]^{4k(2 + h-v)}.
\]

where \( h + 2k \) is the total number of distinct hyperedges we can have in \( w \) including the hyperedges with weights from \( \overline{A}^{ij}_{ij} \). Combining (3.25) and (3.25), the number of all circuits \( w \) with given \( v, h \) is upper bounded by

\[
n^v \left( \frac{n}{d-2} \right)^{h+2k} v^{2k}[(v + 1)^2(l + 1)]^{4k(2 + h-v)}.
\]

We also need to bound the possible range of \( v, h \). There are overall \( 2k(l-1) \) hyperedges traversed in \( w \) (remember we don’t count the edges with weights from \( \overline{A}^{ij}_{ij} \)). Out of these, \( 2k(l-m) \) hyperedges (with multiplicity) with weights coming from \( A^{ij}_{ij} - \overline{A}^{ij}_{ij} \) must be at least doubled for the expectation not to vanish.

Then the number of distinct hyperedges in \( w \) excluding the hyperedge weighted by some \( A^{ij}_{ij} \), satisfies

\[
h \leq k(l-m) + (2k(l-1) - 2k(l-m)) = k(l+m-2).
\]

We have \( v \geq \max\{m, l - m + 1\} \) since each self-avoiding walk of length \( m - 1 \) or \( l - m \) has distinct vertices. Moreover, since \( G(w) \) is connected, \( h \geq v - 1 \), so we have \( v - 1 \geq h \leq k(l+m-2) \). And the range of \( v \) is then given by \( \max\{m, l - m + 1\} \leq v \leq k(l+m-2) + 1 \).

The expected weight that a circuit contributes can be estimated similarly as before. From (3.18), the expected weights from \( v - 1 \) many hyperedges that corresponds to edges on \( T(w) \) is bounded by

\[
\left( \frac{a}{(d-1)(d-2)} \right)^{v-1} (a \lor b)^{h-v+1+2k}.
\]

Similar to (3.14), the expected weights from \( h - v + 1 + 2k \) many hyperedges that corresponds to edges on \( G(w) \setminus T(w) \) together with hyperedges whose weights are from \( \overline{A}^{ij}_{ij} \) is bounded by

\[
\left( \frac{a \lor b}{(d-1)} \right)^{h-v+1+2k}.
\]

Putting all estimates together gives us the following upper bound on \( \mathbb{E}_{H_n}[\rho(T^{(l,m)})^{2k}] \):

\[
\sum_{v=m \lor (l-m+1)}^{k(l+m-2)+1} \sum_{h=v-1}^{k(l+m-2)} n^v \left( \frac{n}{d-2} \right)^{h+2k} v^{2k}[(v + 1)^2(l + 1)]^{4k(2 + h-v)} \left( \frac{a}{(d-1)(d-2)} \right)^{v-1} \left( \frac{a \lor b}{d-1} \right)^{h-v+1+2k}.
\]

(3.27)

This completes the proof of Lemma 3.3.

By taking \( l = O(\log n) \) in (3.27), similar to the discussion in (3.21), we have the leading term in (3.27) is given by the term with \( h = v - 1 \), so for any \( 1 \leq m \leq l \), and sufficiently large \( n \), there are constants
Assume \( B \) of \( \sigma \) from Definition 4.2. In this section we study the structure of the local neighborhoods in the HSBM. Let \( C = (1 \ldots , 1) \in \mathbb{R}^n \) and recall \( \sigma \in \{-1, 1\}^n \). At the end of this section (Section 4.4), we proof the following result on the spectrum of \( B^{(l)} \):

**Theorem 4.1.** Assume \( \beta^2 > \alpha > 1 \) and \( l = c \log n \) with \( c \log (\alpha) < 1/8 \). Then the following holds: for any \( \epsilon > 0 \)

\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \bigcup_{m=1}^{n} \left\{ \rho(\mathcal{H}_n^{(l,m)}) \geq n^{\epsilon-1} \alpha^{(l+m)/2} \right\} \right) = 0.
\]

Theorem 3.1 is then proved.

### 4. Local Analysis

In this section we study the structure of the local neighborhoods in the HSBM. Let \( \mathbf{1} = (1 \ldots , 1) \in \mathbb{R}^n \) and recall \( \sigma \in \{-1, 1\}^n \). At the end of this section (Section 4.4), we proof the following result on the spectrum of \( B^{(l)} \):

**Theorem 4.1.** Assume \( \beta^2 > \alpha > 1 \) and \( l = c \log n \) with \( c \log (\alpha) < 1/8 \). Then the following holds: for any \( \epsilon > 0 \)

\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \bigcup_{m=1}^{n} \left\{ \rho(\mathcal{H}_n^{(l,m)}) \geq n^{\epsilon-1} \alpha^{(l+m)/2} \right\} \right) = 0.
\]

The proof of Theorem 4.1 depends on the spectral norm bounds we establish in Section 3 and the analysis of the local structure of HSBM in this section. We start with a quasi-deterministic growth control of local neighborhoods, and then relate vectors \( B^{(l)} \mathbf{1} \) to the local structures.

**Definition 4.2.** In a hypergraph \( H \), we define the distance \( d(i, j) \) between two vertices \( i, j \) to be the minimal length of walks between \( i \) and \( j \). Define the \( t \)-neighborhood \( V_t(i) \) of a fixed vertex \( i \) to be the set of vertices which have distance \( t \) from \( i \). Define \( V_{\leq t}(i) := \bigcup_{k \leq t} V_k(i) \) to be the set all of vertices which have distance at most \( t \) from \( i \) and \( V_{> t} = [n] \setminus V_{\leq t} \). Let \( V_{\geq t}^\pm(i) \) be the vertices in \( V_i(i) \) with spin \( \pm \) and define it similarly for \( V_{\leq t}^\pm(i) \).

For \( i \in [n] \), define

\[
S_l(i) = |V_l(i)|, \quad D_l(i) = \sum_{j: d(i, j) = l} \sigma_j.
\]

We will show that when \( l = c \log n \) with \( c \log (\alpha) < 1/8 \), \( S_l(i), D_l(i) \) are close to the corresponding quantities \( \langle B^{(l)} \mathbf{1} \rangle_i, \langle (B^{(l)} \sigma) \rangle_i \). In particular, the vector \( (D_l(i))_{1 \leq i \leq n} \) is asymptotically aligned with the second eigenvector of \( B^{(l)} \), from which we get the information on the partitions.

Let \( n^\pm \) be the number of vertices with spin \( \pm \) respectively. Consider the event

\[
\tilde{\Omega} := \{|n^+ - n^-| \leq \log(n) \sqrt{n}\}.
\]
By Hoeffding’s inequality,
\[
\mathbb{P}_n \left( |n\pm n/2| \geq \log(n)\sqrt{n} \right) \leq 2\exp(-2\log^2(n)),
\]
which implies \( \mathbb{P}_n(\tilde{\Omega}) \geq 1 - 2\exp(-2\log^2(n))\). In the rest of this section we will condition on the event \( \tilde{\Omega} \), which will not affect our conclusion and probability bounds, since for any event \( A \), if \( \mathbb{P}_n(A \mid \tilde{\Omega}) = 1 - O(n^{-\gamma}) \) for some \( \gamma > 0 \), we have
\[
\mathbb{P}_n(A) = \mathbb{P}_n(A \mid \tilde{\Omega})\mathbb{P}_n(\tilde{\Omega}) + \mathbb{P}_n(A \mid \tilde{\Omega}^c)\mathbb{P}_n(\tilde{\Omega}^c)
\]
\[
=\mathbb{P}_n(A \mid \tilde{\Omega})(1 - 2\exp(-2\log^2(n))) + O(2\exp(-2\log^2(n))) = 1 - O(n^{-\gamma}).
\]

For two random variable \( X, Y \), we denote \( X \preceq Y \) if \( X \) is stochastically dominant by \( Y \), i.e., \( \mathbb{P}(X \leq x) \geq \mathbb{P}(Y \leq x) \) for any \( x \in \mathbb{R} \). For any event \( A_n \), we say \( A_n \) happens asymptotically almost surely if \( \lim_{n \to \infty} \mathbb{P}_n(A_n) = 1 \).

4.1. Quasi-deterministic Growth Control. We will show \( S_t(i), D_t(i) \) have the following properties.

**Theorem 4.3.** Assume \( \beta^2 > \alpha > 1 \) and \( l = c\log n \), for a constant \( c \) such that \( c\log\alpha < 1/4 \). There exists constants \( C, \gamma > 0 \) such that for sufficiently large \( n \), with probability at least \( 1 - O(n^{-\gamma}) \) the following holds for all \( i \in [n] \) and \( 1 \leq t \leq l \):

\[
S_t(i) \leq C\log(n)\alpha^t,
\]
\[
|D_t(i)| \leq C\log(n)\beta^t,
\]
\[
S_t(i) = \alpha^{t-1}S_t(i) + O(\log(n)\alpha^{t/2}),
\]
\[
D_t(i) = \beta^{t-1}D_t(i) + O(\log(n)\alpha^{t/2}).
\]

We prove Theorem 4.3 in this section. The following identity from Equation (38) in [27] will be helpful in the proof.

**Lemma 4.4.** For any nonnegative integers \( i, j, n \) and nonnegative numbers \( a, b \) such that \( a/n, b/n < 1 \), we have
\[
\frac{ai + bj}{n} - \frac{1}{2} \left( \frac{ai + bj}{n} \right)^2 \leq 1 - (1 - a/n)^i(1 - b/n)^j \leq \frac{ai + bj}{n}.
\]

We will also use the following version of Chernoff bound (see [7]):

**Lemma 4.5.** Let \( X \) be a sum of independent random variables taking values in \( \{0,1\} \). Let \( \mu = \mathbb{E}[X] \). Then for any \( \delta > 0 \),
\[
\mathbb{P}(X \geq (1 + \delta)\mu) \leq \exp(-\mu((1 + \delta)\ln(1 + \delta) - \delta))
\]
\[
\mathbb{P}(X \leq (1 - \delta)\mu) \leq \exp(-\mu((1 - \delta)\ln(1 - \delta) + \delta))
\]

In particular, let
\[
h(x) := x\log(x) - x + 1,
\]
\[
\tilde{h}(x) := \min\{(1 + x)\log(1 + x) - x, (1 - x)\log(1 - x) + x\},
\]

we have
\[
\mathbb{P}(X \geq (1 + \delta)\mu) \leq \exp(-\mu h(1 + \delta)),
\]
\[
\mathbb{P}(|X - \mu| \leq \delta\mu) \geq 1 - 2\exp(-\mu \tilde{h}(\delta)).
\]

For any \( t \geq 0 \), the number of vertices with spin \( \pm \) at distance \( t \) (respectively \( \leq \)) of vertices \( i \) is denoted \( U_t^\pm(i) \) (respectively \( U_t^≤(i) \)) and we know \( S_t(i) = U_t^+(i) + U_t^-(i) \). We will omit index \( i \) when considering quantities related to a fixed vertex \( i \). Let \( n^\pm \) be the number of vertices with spin \( \pm \) and \( \mathcal{N}^\pm \) be the set of vertices with spin \( \pm \). For a fixed vertex \( i \), let
\[
\mathcal{F}_t := \sigma(U_k^+, U_k^-, k \leq t, \sigma_i, 1 \leq i \leq n)
\]
be the $\sigma$-algebra generated by $\{U_k^+, U_k^-, 0 \leq k \leq t\}$ and $\{\sigma_i, 1 \leq i \leq n\}$. In the remainder of the section we condition on the spins $\sigma_i$ of all $i \in [n]$ and assume $\hat{\Omega}$ holds. We denote $\mathbb{P}(\cdot) := \mathbb{P}_{H_k}(\cdot | \hat{\Omega})$. A main difficulty to analyze $U_k^+, U_k^-$ compared to the graph SBM in [27] is that $U_k^\pm$ are no longer independent conditioned on $\mathcal{F}_{k-1}$. Instead, we can only approximate $U_k^\pm$ by counting subsets connected to $V_{k-1}$. To make it more precise, we have the following definition for connected-subsets.

**Definition 4.6.** A connected $s$-subset in $V_k$ for $1 \leq s \leq d - 1$ is a subset of size $s$ which is contained in some hyperedge $e$ in $H$ and the rest $d - s$ vertices in $e$ are from $V_{k-1}$ (see Figure 3 for an example). Define $U_k^{(r)}, 0 \leq r \leq s$ to be the number of connected $s$-subsets in $V_k$ where exactly $r$ many vertices have + signs. For convenience, we write $U_k^{(r)} := U_{k,d-1}^{(r)}$ for $0 \leq r \leq d - 1$. Let $U_{k,s} = \sum_{r=0}^{s} U_k^{(r)}$ be the number of all connected $s$-subsets in $V_k$.

We will show that $\sum_{r=0}^{d-1} rU_k^{(r)}$ is a good approximation of $U_k^+$ and $\sum_{r=0}^{d-1} (d - 1 - r)U_k^{(r)}$ is a good approximation of $U_k^-$, then the concentration of $U_k^{(r)}, 0 \leq r \leq d - 1$ implies concentration of $U_k^\pm$. Since each hyperedge appears independently, conditioned on $\mathcal{F}_{k-1}$ we know $\{U_k^{(r)}, 0 \leq r \leq d - 1\}$ are independent binomial random variables. For $U_k^{(r,d-1)}$, the number of all possible connected $(d - 1)$-subsets with $d - 1$ many + signs is $\binom{n^+ - \sum_{k=1}^{d-k} U_{k-1}^+}{d-1}$, and each such subset is included in the hypergraph if and only if it forms a hyperedge with any vertex in $V_{k-1}$. Therefore each such subset is included independently with probability $1 - \left(1 - \frac{a}{n-d}\right)^{U_k^+} \left(1 - \frac{b}{n-d}\right)^{U_k^-}$. Similarly we have the following distributions for $U_k^{(r)}, 1 \leq r \leq d - 1$:

\begin{align}
U_k^{(d-1)} &\sim \text{Bin} \left(\binom{n^+ - \sum_{k=1}^{d-k} U_{k-1}^+}{d-1}, 1 - \left(1 - \frac{a}{n-d}\right)^{U_k^+} \left(1 - \frac{b}{n-d}\right)^{U_k^-}\right), \\
U_k^{(0)} &\sim \text{Bin} \left(\binom{n^- - \sum_{k=1}^{d-k} U_{k-1}^-}{d-1}, 1 - \left(1 - \frac{a}{n-d}\right)^{U_k^-} \left(1 - \frac{b}{n-d}\right)^{U_k^+}\right), \\
U_k^{(r)} &\sim \text{Bin} \left(\binom{n^+ - \sum_{k=1}^{d-k} U_{k-1}^+}{r}, 1 - \left(1 - \frac{a}{n-d}\right)^{U_k^+} \left(1 - \frac{b}{n-d}\right)^{U_k^-}\right), 1 \leq r \leq d - 2.
\end{align}

We denote $U_k^s := \sum_{s=1}^{d-2} U_{k,s}$ to be the number of all connected $s$-subsets in $V_k$ for $1 \leq s \leq d - 2$. For each $1 \leq s \leq d - 2$, conditioned on $\mathcal{F}_{k-1}$, the number of possible $s$-subsets is at most $\binom{n}{s}$, and each subset is included in the hypergraph independently with probability at most $\left(\frac{a + b}{n-d}\right)^{S_{k-1}} \land 1$, so we have

\begin{align}
U_{k,s} &\sim \text{Bin} \left(\binom{n}{s}, \frac{a + b}{n-d} \left(\frac{S_{k-1}}{d-s}\right) \land 1\right).
\end{align}
With the definitions above, we have the following inequality for \( U_k^{\pm} \) by counting the number of \( \pm \) signs from each type of subsets:

\[
U_k^{+} \leq \sum_{r=0}^{d-1} rU_k^{(r)} + (d-2)U_k^{*},
\]

(4.17)

\[
U_k^{-} \leq \sum_{r=0}^{d-1} (d-1-r)U_k^{(r)} + (d-2)U_k^{*}.
\]

(4.18)

To obtain the upper bound of \( U_k^{\pm} \), we will show that \( U_k^{*} \) is negligible compare to the number of \( \pm \) signs from \( U_k^{(r)} \), and since \( U_k^{(r)}, 1 \leq r \leq d-1 \) are independent binomial random variables, we can prove concentration results of these random variables. For the lower bound of \( U_k^{\pm} \), we need to show that only a negligible portion of \( (d-1) \) connected subsets are overlapped, therefore \( U_k^{+} \) is lower bounded by \( \sum_{r=0}^{d-1} rU_k^{(r)} \) minus some small term, and we can do it similarly for \( U_k^{-} \). We will extensively use Chernoff bound to prove the concentration of \( U_k^{\pm} \) in the following theorem.

**Theorem 4.7.** Let \( \epsilon \in (0, 1) \), and \( l = c \log(n) \) with \( c \log(\alpha) < 1/4 \). For any \( \gamma \in (0, 3/8) \), there exists some constant \( K > 0 \) and such that the following holds with probability at least \( 1 - O(n^{-\gamma}) \) for all \( i \in [n] \).

1. Let \( T := \inf\{ t \leq l : S_t \geq K \log(n) \} \), then \( S_T = \Theta(\log(n)) \).
2. Let \( \epsilon_i := \epsilon \alpha^{-(t-T)/2} \) for some \( \epsilon > 0 \) and

\[
M := \frac{1}{2} \begin{bmatrix}
\alpha + \beta & \alpha - \beta \\
\alpha - \beta & \alpha + \beta
\end{bmatrix}.
\]

(4.19)

Then for all \( t, t' \in \{ T, \ldots, l \} \), \( t > t' \), the vector \( \bar{U}_i := (U_i^{+}, U_i^{-})^\top \) satisfies the coordinate-wise bounds:

\[
U_i^{+} \in \left[ \prod_{s=t'}^{t-1} (1 - \epsilon_s), \prod_{s=t'}^{t-1} (1 + \epsilon_s) \right] (M^{t-t'} \bar{U}_{t'})_1,
\]

(4.20)

\[
U_i^{-} \in \left[ \prod_{s=t'}^{t-1} (1 - \epsilon_s), \prod_{s=t'}^{t-1} (1 + \epsilon_s) \right] (M^{t-t'} \bar{U}_{t'})_2,
\]

(4.21)

where \( (M^{t-t'} \bar{U}_{t'})_j \) is the \( j \)-th coordinate of the vector \( M^{t-t'} \bar{U}_{t'} \) for \( j = 1, 2 \).

**Proof.** In this proof, all constants \( C_i \)'s, \( C, C' \) are distinct for different inequalities unless stated otherwise. By the definition of \( T \), \( S_{T-1} \leq K \log(n) \). Let \( Z_T \) be the number of all hyperedges in \( H \) that are incident to at least one vertex in \( V_{T-1} \). We have \( S_T \leq (d-1)Z_T \), and since the number of all possible hyperedges including a vertex in \( V_{T-1} \) is at most \( S_{T-1} \binom{n}{d-1} \), \( Z_T \) is stochastically dominated by

\[
\text{Bin}\left( K \log(n), \frac{n}{d-1}, \frac{a \lor b}{\binom{n}{d-1}} \right),
\]

which has mean \( (a \lor b)K \log(n) \). Let \( K_1 = (a \lor b)K \). By (4.10) in Lemma 4.5, we have for any constant \( K_2 > 0 \),

\[
\mathbb{P}(Z_T \geq K_2 \log(n) | F_{T-1}) \leq \exp(-K_1 \log(n)h(K_2/K_1))
\]

(4.22)

Taking \( K_2 > K_1 \) large enough such that \( K_1 h(K_2/K_1) \geq 2 + \gamma \), we then have

\[
\mathbb{P}(Z_T \geq K_2 \log(n) | F_{T-1}) \leq n^{-2-\gamma}.
\]

(4.23)

So with probability at least \( 1 - n^{-2-\gamma} \), for a fixed \( i \in [n] \), \( S_T \leq K_3 \log(n) \) with \( K_3 = (d-2)K_2 \). Taking a union bound over \( i \in [n] \), part (1) in Lemma 4.7 holds. We continue to prove (4.20) and (4.21).

**Step 1: base case.** For the first step, we prove (4.20) and (4.21) for \( t = T + 1, t' = T \), which is

\[
U_{T+1}^{\pm} \in [1 - \epsilon, 1 + \epsilon] \left( \frac{\alpha + \beta}{2} U_T^{\pm} + \frac{\alpha - \beta}{2} U_T' \right).
\]

(4.24)
This involves a two-sided estimate of $U_{T+1}^\pm$. The idea is to show the expectation of $U_{T+1}^\pm$ conditioned on $\mathcal{F}_T$ is closed to $\frac{\alpha + \beta}{2} U_T^\pm + \frac{\alpha - \beta}{2} U_T^\pm$ and it’s concentrated around its mean. We first prove the upper bound.

(i) Upper bound. Define the event $A_T := \{ S_T \leq K_3 \log n \}$. We have just shown for a fixed $i$, $\mathbb{P}(A_T) \geq 1 - n^{-2-\gamma}$. Recall $|n^\pm - n/2| \leq \sqrt{n} \log n$ and conditioned on $\mathcal{A}_T$, for some constant $C > 0$,

$$U_{T \leq T}^\pm \leq \sum_{t=0}^T S_t + 1 + TK_3 \log n \leq 1 + lK_3 \log n \leq CK_3 \log^2 n.$$

Conditioned on $\mathcal{F}_T$ and $\mathcal{A}_T$, for sufficiently large $n$, there exists constants $C_1 > 0$ such that

$$\left( \frac{n^+ - U_{T \leq T}^+}{d - 1} \right) \geq C_1 \left( \frac{n}{d - 1} \right).$$

From inequality (4.7), there exists constant $C_2 > 0$ such that

$$1 - \left( 1 - \frac{a}{(n - 1)} \right)^{U_T^+} \left( 1 - \frac{b}{(n - 1)} \right)^{U_T^-} \geq \frac{a U_T^+ + b U_T^-}{(n - 1)} \geq \frac{C_2(a + b) K \log n}{(n - 1)} \geq C_3 K \log n$$

for some constant $C_3 > 0$. We can choose $K$ large enough such that

$$C_3 K \bar{h}(\epsilon/(2d)) \geq 2 + \gamma,$$

then from (4.11) in Lemma 4.5, for any given $\epsilon > 0$ and $\gamma \in (0, 1)$,

$$\mathbb{P} \left( \left| U_{T+1}^{(d-1)} - E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T] \right| \leq \frac{\epsilon}{2d} E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T] \right) \geq \mathbb{P} \left( \left| U_{T+1}^{(d-1)} - E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T] \right| E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T, \mathcal{A}_T] \mathbb{P}(A_T) \right) \geq \left[ 1 - \exp \left( -E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T, \mathcal{A}_T] \bar{h}(\epsilon/(2d)) \right) \right] \geq 1 - n^{-2-\gamma} \geq 1 - n^{-2-\gamma}^2 \geq 1 - 2n^{-2-\gamma}.$$

From the symmetry of $\pm$ labels, the concentration of $U_{T+1}^{(0)}$ works in the same way. Similarly, there exists a constant $C_1 > 0$ such that $E[U_{T+1}^{(r)} \mid \mathcal{F}_T], 1 \leq r \leq d - 2$:

$$E[U_{T+1}^{(r)} \mid \mathcal{F}_T] = \left( \frac{n^+ - U_{T \leq T}^+}{r} \right) \left( \frac{n^- - U_{T \leq T}^-}{d - 1 - r} \right) \left( 1 - \left( 1 - \frac{b}{(n - 1)} \right)^{S_T} \right) \geq C_1 K \log n.$$

We can choose $K$ large enough such that for all $0 \leq r \leq d - 1$,

$$\mathbb{P} \left( \left| U_{T+1}^{(r)} - E[U_{T+1}^{(r)} \mid \mathcal{F}_T] \right| \leq \frac{\epsilon}{2d} E[U_{T+1}^{(r)} \mid \mathcal{F}_T] \right) \geq 1 - 2n^{-2-\gamma}.$$

Next we estimate $U_{T+1}^\pm = \sum_{s=1}^{d-2} U_{T+1,s}$. Recall from (4.16), we have $U_{T+1,s} \leq Z_{T+1,s}$ where

$$Z_{T+1,s} \sim \text{Bin} \left( \frac{n}{S_T}, \left( \frac{a \lor b}{(n - 1)} \right)^{S_T} \right).$$
Conditioned on $\mathcal{A}_T$ we know $K \log n \leq S_T \leq K_3 \log n$, and
\[
E[Z_{T+1,s} \mid \mathcal{A}_T, \mathcal{F}_T] = \binom{n}{s} \frac{a \vee b}{(n-1)} \frac{S_T}{d-s} \leq C_2 \log^{d-s}(n)n^{1+s-d}.
\]
for some constant $C_2 > 0$. Using the fact that $h(x) \geq \frac{1}{2} d^2 \log(x)$ for $x$ large enough, from (4.10), we have for any constant $\lambda > 0$, note that $1 \leq s \leq d-2$, there exists a constant $C_3 > 0$ such that for large $n$,
\[
P(U_{T+1,s} \geq \lambda S_T \mid \mathcal{F}_T, \mathcal{A}_T) \leq \mathbb{P}(Z_{T+1,s} \geq \lambda S_T \mid \mathcal{F}_T, \mathcal{A}_T) \leq \exp \left( -E[Z_{T+1,s} \mid \mathcal{A}_T, \mathcal{F}_T] h \left( \frac{\lambda S_T}{E[Z_{T+1,s} \mid \mathcal{A}_T, \mathcal{F}_T]} \right) \right)
\]
\[
\leq \exp \left( -\frac{1}{2} \lambda S_T \log \left( \frac{\lambda S_T}{E[Z_{T+1,s} \mid \mathcal{A}_T, \mathcal{F}_T]} \right) \right)
\]
\[
\leq \exp \left( -\frac{1}{2} \lambda K \log(n) \log \left( \frac{\lambda K \log(n)}{C_2 \log^{d-s}(n)n^{1+s-d}} \right) \right)
\]
(4.25)
\[
\leq \exp(-\lambda C_3(d-1-s)\log^2 n) \leq \exp(-\lambda C_3 \log^2 n) \leq n^{-2-\gamma}.
\]
Therefore
\[
P(U_{T+1,s} \geq \lambda S_T \mid \mathcal{F}_T) \geq \mathbb{P}(U_{T+1,s} \geq \lambda S_T \mid \mathcal{F}_T, \mathcal{A}_T) \mathbb{P}(\mathcal{A}_T) \geq (1-n^{-2-\gamma})^2 \geq 1-2n^{-2-\gamma}.
\]
So taking $\lambda = \frac{(\alpha - \beta)\epsilon}{4d}$, we have $U_{T+1,s} \leq \frac{(\alpha - \beta)\epsilon}{4d} S_T$ with probability $1 - 2n^{-2-\gamma}$ for any $\gamma \in (0,1)$. Taking a union bound over $2 \leq r \leq d-1$, it implies
(4.26)
\[
U_{T+1}^r \leq \frac{(\alpha - \beta)\epsilon}{4d} S_T
\]
with probability $1 - O(n^{-2-\gamma})$ for any $\gamma \in (0,1)$. Recall from (4.13)-(4.15),
\[
E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T] = \left( \frac{n^+ - \frac{d}{2} U_{T+1}^+ d-1} \right) \left( 1 - \left( 1 - \frac{a}{(n-1)} \right) \left( 1 - \frac{b}{(n-1)} \right) U_{T+1}^+ \right).
\]
Since $n^+ = \frac{n}{2} + O(\sqrt{n} \log n), U_{T+1}^+ = \sum_{k=1}^T S_k = O(\log^2(n))$ and from (4.7),
\[
\left( 1 - \frac{aU_{T+1}^+ + bU_{T-1}^-}{2(n-1)} \right) \frac{aU_{T+1}^+ + bU_{T-1}^-}{(n-1)} \leq 1 - \left( 1 - \frac{a}{(n-1)} \right) \left( 1 - \frac{b}{(n-1)} \right) U_{T+1}^+ \leq \frac{aU_{T+1}^+ + bU_{T-1}^-}{(n-1)} - \frac{bU_{T+1}^+ + bU_{T-1}^-}{(n-1)}
\]
we have that
(4.27)
\[
E[U_{T+1}^{(d-1)} \mid \mathcal{F}_T, \mathcal{A}_T] = \left( \frac{\frac{n}{2} + O(\sqrt{n} \log n)}{d-1} \right) \left( 1 + O \left( \frac{\log(n)}{\sqrt{n}d^{-1}} \right) \right) \frac{aU_{T+1}^+ + bU_{T-1}^-}{(n-1)} - \frac{bU_{T+1}^+ + bU_{T-1}^-}{(n-1)}
\]
Similarly,
(4.28)
\[
E[U_{T+1}^{(0)} \mid \mathcal{F}_T, \mathcal{A}_T] = \left( \frac{1}{2d-1} + O \left( \frac{\log(n)}{\sqrt{n}} \right) \right) \left( aU_{T+1}^+ + bU_{T-1}^- \right).
\]
(4.29)
\[
E[U_{T+1}^{(r)} \mid \mathcal{F}_T, \mathcal{A}_T] = \left( \frac{1}{2d-1} + O \left( \frac{\log(n)}{\sqrt{n}} \right) \right) \left( d-1 \right) \left( bU_{T+1}^+ + bU_{T-1}^- \right), 1 \leq r \leq d-2.
\]
Therefore from (4.27)-(4.29),
\[
\mathbb{E} \left[ \sum_{r=0}^{d-1} r U_{T+1}^{(r)} \mid \mathcal{F}_T, \mathcal{A}_T \right] = \left( 1 + O(\log(n/\sqrt{n})) \right) \frac{1}{2d-1} \left( d-1 \right) \left( aU_{T+1}^+ + bU_{T-1}^- \right) \frac{aU_{T+1}^+ + bU_{T-1}^-}{(n-1)} + \sum_{r=1}^{d-2} \left( d-1 \right) \left( bU_{T+1}^+ + bU_{T-1}^- \right)
\]
(4.30)
\[
= \left( 1 + O(\log(n/\sqrt{n})) \right) \left( \sum_{r=1}^{d-2} \left( d-1 \right) b + \left( d-1 \right) a \right) \frac{aU_{T+1}^+ + bU_{T-1}^-}{(n-1)} + \left( \sum_{r=1}^{d-2} \left( d-1 \right) b + \left( d-1 \right) b \right) \frac{bU_{T+1}^+ + bU_{T-1}^-}{(n-1)}.
\]
Recall \(\alpha = (d-1)\frac{a+(2d-1)-1}{2d-1}\), \(\beta = (d-1)\frac{a-b}{2d-1}\), we have
\[
\left(\sum_{r=1}^{d-2} r \binom{d-1}{r} b + (d-1)a\right) \frac{1}{2d-1} = \frac{\alpha + \beta}{2}, \quad \left(\sum_{r=1}^{d-2} r \binom{d-1}{r} b + (d-1)b\right) \frac{1}{2d-1} = \frac{\alpha - \beta}{2}.
\]

From (4.30),
\[
(4.31) \quad \mathbb{E}\left[\sum_{r=0}^{d-1} rU_T(r) \mid F_T, \mathcal{A}_T\right] = (1 + O(\log n/\sqrt{n})) \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
\]

Since we have shown \(\sum_{r=0}^{d-1} U_T(r)\) concentrated around its mean by \(\frac{\epsilon}{2d}\) with probability at least 1 - \(O(n^{-2-\gamma})\), conditioned on \(\mathcal{A}_T\),
\[
\sum_{r=0}^{d-1} rU_T(r) - \mathbb{E}\left[\sum_{r=0}^{d-1} rU_T(r) \mid F_T\right] \leq \sum_{r=0}^{d-1} rU_T(r) - \mathbb{E}[U_T(r) \mid F_T] \leq \frac{\epsilon}{2d} \sum_{r=0}^{d-1} r\mathbb{E}[U_T(r) \mid F_T]
\]
\[
\leq \frac{\epsilon}{4} \sum_{r=0}^{d-1} r\mathbb{E}[U_T(r) \mid F_T] = \frac{\epsilon}{4} (1 + O(\log n/\sqrt{n})) \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
\]

with probability at least 1 - \(O(n^{-2-\gamma})\). Therefore from (4.31), conditioned on \(\mathcal{A}_T\), for large \(n\),
\[
(4.33) \quad \sum_{r=0}^{d-1} rU_T(r) \in \left[1 - \frac{\epsilon}{3}, 1 + \frac{\epsilon}{3}\right] \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
\]

with probability 1 - \(O(n^{-2-\gamma})\). From (4.17), (4.26) and (4.33), conditioned on \(\mathcal{A}_T\) and \(F_T\),
\[
U_T^+ \leq \sum_{r=0}^{d-1} rU_T(r) + (d-2)U_T^+ \leq \sum_{r=0}^{d-1} rU_T(r) + (d-2)\frac{(\alpha - \beta)\epsilon S_T}{4d}
\]
\[
\leq \sum_{r=0}^{d-1} rU_T(r) + \frac{\epsilon}{4} (\alpha - \beta)S_T \leq \sum_{r=0}^{d-1} rU_T(r) + \frac{\epsilon}{4} \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right)
\]
\[
\leq (1 + \epsilon) \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right)
\]

with probability 1 - \(O(n^{-2-\gamma})\). Since \(\mathbb{P}(\mathcal{A}_T) = 1 - n^{-2-\gamma}\) and by symmetry of ± labels, with probability 1 - \(O(n^{-2-\gamma})\),
\[
(4.34) \quad U_T^+ \leq (1 + \epsilon) \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
\]

(ii) **Lower bound.** To show (4.20), (4.21) for \(t' = T + 1, t = T\), we still need to have a lower bound estimate on \(U_T^+\). We cannot directly bound \(U_T^+\) from below by \(U_T(r)\) since from our definition of the connected \((d-1)\)-subsets, they can overlap with each other, which leads to overcounting of the number vertices with ± labels. In the following we show the overlaps between different connected \((d-1)\)-sets are small which gives us the desired lower bound.

Let \(W_{T+1,i}\) be the set of vertices in \(V_{>t}\) with spin ± and appear in at least \(i\) distinct connected \((d-1)\)-subsets in \(V_{>t}\) for \(i \geq 1\). Let \(W_{T+1,i} = W_{T+1,i}^+ \cup W_{T+1,i}^-\). From our definition, \(W_{T+1,1}^+\) are the vertices with spin ± that appear in at least one connected \((d-1)\)-subsets, so \(|W_{T+1,1}^+| \leq U_T^+\). By counting the multiplicity of vertices with spin +, we have the following relation
\[
(4.35) \quad \sum_{r=0}^{d-1} rU_T(r) = \sum_{i \geq 1} |W_{T+1,i}^+| = |W_{T+1,1}^+| + \sum_{i \geq 2} |W_{T+1,i}^+| \leq U_T^+ + \sum_{i \geq 2} |W_{T+1,i}|.
\]
That implies a lower bound on $U_{T+1}^{+}$:

$$
U_{T+1}^{+} \geq \sum_{r=1}^{d-1} r U_{T+1}^{(r)} - \sum_{i \geq 2} |W_{T+1,i}|.
$$

Next we control $|W_{T+1,2}|$. Let $m = n - |V_{\leq T}|$. We enumerate all vertices in $V_{> T}$ from 1 to $m$ temporarily for the proof of the lower bound. Let $X_i, 1 \leq i \leq m$ be the random variables that $X_i = 1$ if $i \in W_{T+1,2}$ and 0 otherwise, we then have $|W_{T+1,2}| = \sum_{i=1}^{m} X_i$. A simple calculation yields

$$
|W_{T+1,2}|^2 - |W_{T+1,2}| = \left(\sum_{i=1}^{m} X_i\right)^2 - \sum_{i=1}^{m} X_i = 2 \sum_{1 \leq i < j \leq m} X_i X_j.
$$

The product $X_i X_j$ is 1 if $i, j \in W_{T+1,2}$ and 0 otherwise. We further consider 3 events, $E_{ij}^s$ for $s = 0, 1, 2$, where $E_{ij}^0$ is the event that all $(d-1)$-subsets in $V_{> T}$ containing $i, j$ are not connected to $V_T$, $E_{ij}^1$ is the event that there is only one $(d-1)$-subset in $V_{> T}$ containing $i, j$ connected to $V_T$ and $E_{ij}^2$ is the event that there are at least two $(d-1)$-subsets in $V_{> T}$ containing $i, j$ connected to $V_T$. Now we have

$$
E[X_i X_j \mid F_T, A_T] = \mathbb{P}(i, j \in W_{T+1,2} \mid F_T, A_T) = \sum_{r=0}^{2} \mathbb{P}(i, j \in W_{T+1,2} \mid E_{ij}^r, F_T, A_T) \mathbb{P}(E_{ij}^r \mid F_T, A_T).
$$

We estimate the three terms in the sum separately. Conditioned on $E_{ij}^0$, $F_T$ and $A_T$, the two events that $i \in W_{T+1,2}$ and $j \in W_{T+1,2}$ are independent. And the probability that $i \in W_{T+1,2}$ is bounded by

$$
\left(\frac{n}{d-2}\right)^2 \left(\frac{a \lor b}{\frac{n}{d-1}}\right)^2 S_T^2 \leq \frac{C_1 \log^2(n)}{n^2}
$$

for some constant $C_1 > 0$. So we have

$$
\mathbb{P}(i, j \in W_{T+1,2} \mid E_{ij}^0, F_T, A_T) \mathbb{P}(E_{ij}^0 \mid F_T, A_T) \leq \mathbb{P}(i, j \in W_{T+1,2} \mid E_{ij}^0, F_T, A_T)
$$

(4.39)

$$
= \mathbb{P}(i \in W_{T+1,2} \mid E_{ij}^0, F_T, A_T) \mathbb{P}(j \in W_{T+1,2} \mid E_{ij}^0, F_T, A_T) \leq \frac{C_1^2 \log^4 n}{n^4}.
$$

For the term that involves $E_{ij}^1$, we know for some $C_2 > 0$,

$$
\mathbb{P}(E_{ij}^1 \mid F_T, A_T) \leq \left(\frac{n}{d-3}\right) \left(\frac{a \lor b}{\frac{n}{d-1}}\right) S_T \leq \frac{C_2 \log n}{n^2},
$$

and conditioned on $E_{ij}^1$ and $F_T, A_T$, the two events that $i \in W_{T+1,2}$ and $j \in W_{T+1,2}$ are independent again, since we require $i, j$ to be contained in at least 2 connected-subsets. We have

$$
\mathbb{P}(i \in W_{T+1,2} \mid E_{ij}^1, F_T, A_T) \leq \left(\frac{n}{d-2}\right) S_T \left(\frac{a \lor b}{\frac{n}{d-1}}\right) \leq \frac{C_2 \log n}{n}.
$$

Therefore we have

$$
\mathbb{P}(i, j \in W_{T+1,2} \mid E_{ij}^1, F_T, A_T) \mathbb{P}(E_{ij}^1 \mid F_T, A_T)
$$

(4.40)

$$
\leq \frac{C_2^2 \log^2 n}{n^2} \cdot \frac{C_2 \log n}{n^2} = \frac{C_2 \log^3 n}{n^4}.
$$

Conditioned on $E_{ij}^2$, $i, j$ have already been included in 2 connected $(d-1)$ subsets, so

$$
\mathbb{P}(i, j \in W_{T+1,2} \mid E_{ij}^2, F_T, A_T) = 1.
$$
We then have for some $C_3 > 0$,

(4.41) \[ \mathbb{P} (i, j \in W_{T+1,2} \mid E_{ij}^2, F_T, A_T) \mathbb{P}(E_{ij}^2 \mid F_T, A_T) = \mathbb{P}(E_{ij}^2 \mid F_T, A_T) \leq \left( \frac{n}{d-3} \right)^2 S_T^{\gamma} \left( \frac{a \lor b}{(d-1)} \right)^2 \leq \frac{C_3 \log^2 n}{n^4}. \]

Combining (4.39)-(4.41), we have for some constant $C' > 0$,

(4.42) \[ \mathbb{E}[X_i X_j \mid F_T, A_T] \leq \frac{C' \log^4 n}{n^4}. \]

Taking conditional expectation in (4.37), we have

\[ \mathbb{E} \left[ |W_{T+1,2}|^2 \mid F_T, A_T \right] = 2 \sum_{1 \leq i < j \leq m} \mathbb{E}[X_i X_j \mid F_T, A_T] \leq \frac{C' \log^4 n}{n^2}. \]

Then by Markov’s inequality, there exists a constant $C > 0$ such that for any $\lambda > 0$,

\[ \mathbb{P} \left( |W_{T+1,2}| > \lambda S_T \mid F_T, A_T \right) \leq \mathbb{P} \left( |W_{T+1,2}| \mid |W_{T+1,2}| - 1 \right) > \lambda S_T (\lambda S_T - 1) \mid F_T, A_T \]

\[ \leq \mathbb{E}[|W_{T+1,2}| \mid |W_{T+1,2}| - 1] \mid F_T, A_T \leq \frac{C \log^2 n}{\lambda^2 n^2}. \]

Taking $\lambda = \frac{(\alpha - \beta) \epsilon}{4}$, we have for all large $n$,

(4.43) \[ \mathbb{P} \left( |W_{T+1,2}| > \frac{(\alpha - \beta) \epsilon}{4} S_T \mid F_T, A_T \right) = O \left( \frac{\log^2 n}{n^2} \right) \leq n^{-1-\gamma} \]

for any $\gamma \in (0, 1)$. For a fixed vertex $j \in V_{> T}$, the probability that $j \in W_{T+1,i}$ is at most

\[ \left( \frac{n}{d-2} \right)^i S_T^i \left( \frac{a \lor b}{(d-1)} \right)^i, \]

then we have for sufficiently large $n$,

(4.44) \[ \mathbb{E}[|W_{T+1,i}| \mid F_T, A_T] \leq n \left( \frac{n}{d-2} \right)^i S_T^i \left( \frac{a \lor b}{(d-1)} \right)^i \leq n \left( \frac{C_4 \log n}{n} \right)^i \]

for some $C_4 > 0$. For the rest of the terms in (4.35), we have for some constant $C > 0$,

\[ \mathbb{E} \left[ \sum_{i \geq 3} |W_{T+1,i}| \mid F_T, A_T \right] \leq n \sum_{i=3}^\infty \left( \frac{C_4 \log n}{n} \right)^i \leq \frac{C \log^3 n}{n^2}. \]

By Markov’s inequality,

\[ \mathbb{P} \left( \sum_{i \geq 3} |W_{T+1,i}| \geq \frac{(\alpha - \beta) \epsilon}{4} S_T \mid F_T, A_T \right) \leq \frac{C \log^2 (n)}{n^2} \leq n^{-1-\gamma}. \]

Together with (4.43), we have conditioned on $A_T$,

\[ \sum_{i \geq 2} |W_{T+1,i}| \leq \frac{(\alpha - \beta) \epsilon}{2} S_T \]

with probability at least $1 - 2n^{-1-\gamma}$ for any $\gamma \in (0, 1)$ and all large $n$. Note that

\[ \frac{(\alpha - \beta) \epsilon}{2} S_T \leq \frac{\epsilon}{2} \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right), \]

with (4.33), (4.36), and $\mathbb{P}(A_T) \geq 1 - n^{-2-\gamma}$, we have

\[ U_{T+1}^+ \geq \sum_{r=1}^{d-1} \epsilon U_{T+1}^{(r)} - \frac{\epsilon}{2} \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right) \geq (1 - \epsilon) \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right), \]

21
with probability $1 - O(n^{-1 - \gamma})$. By symmetry, the argument works for $U_{T+1}^-$, therefore with probability $1 - O(n^{-1 - \gamma})$ for any $\gamma \in (0, 1)$, we have

$$U_{T+1}^\pm \geq (1 - \epsilon) \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right).$$

From (4.34), we have with probability $1 - O(n^{-1 - \gamma})$ for any $\gamma \in (0, 1)$,

$$U_{T+1}^\pm \in [1 - \epsilon, 1 + \epsilon] \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right),$$

which is the statement (4.20), (4.21) for $t' = T, t = T + 1$.

**Step 2: Induction.** It remains to extend this estimate for all $T < t' \leq t$. We now define the event

$$A_t := \left\{ U_t^\pm \in [1 - \epsilon_{t-1}, 1 + \epsilon_{t-1}] \left( \frac{\alpha + \beta}{2} U_{t-1}^+ + \frac{\alpha - \beta}{2} U_{t-1}^- \right) \right\}$$

for $T + 1 \leq t \leq l$, and recall $\epsilon_t = \epsilon^\alpha (t-T)^{1/2}, A_T = \{S_T \leq K_3 \log n\}$. From the proof above, we have shown $A_{T+1}$ holds with probability $1 - O(n^{-1 - \gamma})$. Conditioned on $A_T, A_{T+1}, \ldots, A_t$ for some fixed $t$ with $T + 2 \leq t \leq l$, the vector $\tilde{U}_t = (U_t^+, U_t^-)$ satisfies (4.20), (4.21) for any $T < t' < t$. Set $t' = T + 1$, from [27], for any integer $k > 0$,

$$M^k = \frac{1}{2} \left[ \begin{array}{cc} \alpha_k + \beta_k & \alpha_k - \beta_k \\ \alpha_k - \beta_k & \alpha_k + \beta_k \end{array} \right],$$

(4.20) implies that

$$U_t^\pm \geq \left( \prod_{s=T+1}^{t-1} (1 - \epsilon_s) \right) \left( \frac{\alpha^{t-T-1} + \beta^{t-T-1}}{2} U_{T+1}^+ + \frac{\alpha^{t-T-1} - \beta^{t-T-1}}{2} U_{T+1}^- \right)$$

$$\geq (1 - O(\epsilon)) \frac{\alpha^{t-T-1}}{2} U_{T+1}^+ \geq (1 - O(\epsilon)) \frac{\alpha^{t-T-1}}{2} \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right)$$

$$\geq (1 - O(\epsilon)) \frac{\alpha^{t-T} (1 - \epsilon)(\alpha - \beta)}{4\alpha} S_T \geq C_1 \alpha^{t-T} \log(n),$$

for some constant $C_1 > 0$. For any $t$ with $T \leq t$, conditioned on $A_T, A_{T+1}, \ldots, A_t$, since $\beta < \alpha$,

$$U_t^\pm \leq \left( \prod_{s=T}^{t-1} (1 + \epsilon_s) \right) \left( \frac{\alpha^{t-T} + \beta^{t-T}}{2} U_T^+ + \frac{\alpha^{t-T} - \beta^{t-T}}{2} U_T^- \right)$$

$$\leq (1 + O(\epsilon)) \frac{\alpha^{t-T} + \beta^{t-T}}{2} S_T \leq (1 + O(\epsilon)) \frac{\alpha^{t-T} K_3 \log(n)}{\log(n)} \leq C_2 \alpha^{t-T} \log(n)$$

for some $C_2 > 0$. Combining lower and upper bounds, $S_t = U_t^+ + U_t^- = \Theta(\alpha^{t-T} \log(n))$. We now show by induction that $A_{t+1}$ holds with high enough probability conditioned on $\{A_j, T \leq j \leq t\}$.

(i) **Upper bound.** Note that $\alpha^t = \epsilon^{t \log n} = n^\epsilon \alpha = o(n^{1/4})$, for some constant $C > 0$

$$U_{\leq t}^+ \leq \sum_{i=1}^{t} S_i \leq C \alpha^{t-T} \log^2 n \leq C \alpha^t \log n = o(n^{1/4} \log n)$$

and $|n^\pm - \frac{n}{2}| \leq \sqrt{n} \log n$, from (4.13)-(4.15), similar to the case for $t = T$, we have

$$\mathbb{E}[U_{t+1}^{(d-1)} | \cap_{j=T}^{t} A_j, F_t] = \left( \frac{n^+ - U_{\leq t}^+}{d-1} \right) \left( 1 - \left( 1 - \frac{a}{(d-1)} \right) \left( 1 - \frac{b}{(d-1)} \right) \right)$$

$$= \left( \frac{n}{2} - O(\sqrt{n} \log n) \right) \left( 1 - \left( 1 - \frac{a}{(d-1)} \right) \left( 1 - \frac{b}{(d-1)} \right) \right)$$

(4.49)
and
\begin{align}
(4.50) \quad \mathbb{E}[U_{t+1}^{(0)} \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t] &= (\frac{1}{2d-1} + O(\frac{\log n}{\sqrt{n}}))(bU_t^+ + aU_t^-) \\
(4.51) \quad \mathbb{E}[U_{t+1}^{(r)} \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t] &= (\frac{1}{2d-1} + O(\frac{\log n}{\sqrt{n}}))(\frac{d-1}{r})(bU_t^+ + bU_t^-), 1 \leq r \leq d - 2.
\end{align}

Therefore, there exists a constant \( C_0 > 0 \) such that for all \( 0 \leq r \leq d - 1 \), \( \mathbb{E}[U_{t+1}^{(r)} \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t] \geq C_0 S_t \). From (4.11) in Lemma 4.5, for any \( 0 \leq r \leq d - 1 \), to show
\begin{equation}
(4.52) \quad \mathbb{P}\left( \left| U_{t+1}^{(r)} - \mathbb{E}[U_{t+1}^{(r)} \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t] \right| \leq \frac{\epsilon}{2d} \mathbb{E}[U_{t+1}^{(r)} \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t] \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t \right) \geq 1 - n^{-2-\gamma},
\end{equation}
it suffices to have
\begin{equation}
(4.53) \quad C_0 S_t \tilde{h} \left( \frac{\epsilon_t}{2d} \right) \geq (2 + \gamma) \log n.
\end{equation}

From (4.11), we took a second-order expansion of \( \tilde{h} \) around 0 and use \( \tilde{h}(x) \geq x^2/3 \) when \( x > 0 \) is small. For \( \gamma \in (0, 1) \), the left hand side in (4.53) is lower bounded by
\begin{equation}
C_1 K \alpha^{t-T} \log(n) \tilde{h} \left( \frac{\epsilon_t}{2d} \right) \geq C_2 \alpha^{t-T} K \log(n) \epsilon_t^2 = C_2 K \log(n) \geq (2 + \gamma) \log n
\end{equation}
by taking \( K \) large enough. Therefore (4.52) holds. We also have
\begin{equation}
U_{t+1,s} \leq Z_{t+1,s}, \quad Z_{t+1,s} \sim \text{Bin} \left( \frac{n}{s}, \frac{a \vee b}{(d-1)n} (d-s) \right),
\end{equation}
and \( Z_{t+1,s} \) has mean \( \left( \frac{n}{s} \right) \frac{a \vee b}{(d-1)n} (d-s) = \Theta \left( \frac{a(d-s)(t-T) \log^d d(n)}{d^{-1-s}} \right) \). We have for \( 1 \leq s \leq d - 2 \), using the fact that \( \tilde{h}(x) \geq \frac{x}{2} \log(x) \) for \( x \) large enough, similar to (4.25), there are constants \( C_1, C_2, C_3, C_4 > 0 \) such that for any \( \lambda > 0 \),
\begin{equation}
\mathbb{P}(U_{t+1,s} \geq \lambda S_t \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t) \leq \mathbb{P}(Z_{t+1,s} \geq \lambda S_t \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t)
\end{equation}

Take
\begin{equation}
(4.54) \quad \lambda = \frac{(\alpha - \beta) \epsilon_t}{4d^2} = \frac{(\alpha - \beta) \epsilon_t \alpha^{-(t-T)/2}}{4d^2},
\end{equation}
we have
\begin{equation}
\mathbb{P}\left( \frac{U_{t+1,s} \geq (\alpha - \beta) \epsilon_t S_t \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t}{4d^2} \right) \leq \exp \left( -C_1 \alpha^{(t-T)/2} \log(n) \cdot \log(C_2 \alpha^{(s-d+\frac{1}{2})(t-T) \log^d d(n)} n^{d-1-s}) \right).
\end{equation}

Since for some constants \( C_4, C_5, C_6 > 0 \),
\begin{equation}
\log(C_2 \alpha^{(s-d+\frac{1}{2})(t-T) \log^d d(n)} n^{d-1-s}) \geq C_4 - C_5 (t - T) \log(n) + \log(\log^d d(n)) + (d - 1 - s) \log n \geq C_6 \log n,
\end{equation}
we have for all \( 1 \leq s \leq d - 2 \),
\begin{equation}
(4.55) \quad \mathbb{P}(U_{t+1,s} \geq \frac{(\alpha - \beta) \epsilon_t S_t \mid \cap_{j=T}^{l} A_j, \mathcal{F}_t}{4d^2}) \leq \exp \left( -C_1 C_6 \log^2 n \right) \leq \frac{1}{n^{2-\gamma}}
\end{equation}
for any \( \gamma \in (0, 1) \). Recall
\begin{equation}
\epsilon_t = \epsilon \alpha^{-(t-T)/2} \geq \epsilon \alpha^{-1/2} = \epsilon \alpha^{-c \log(n)/2} = \frac{\epsilon}{n^{c \log \alpha/2 > n^{-1/8}},}
\end{equation}
we know \( \frac{\log n}{\sqrt{n}} = o(\epsilon_t) \), and from (4.49)-(4.51) and (4.55), conditioned on \( A_t, \ldots, A_i \) and \( F_t \),

\[
U_{i+1}^+ \leq \sum_{r=1}^{d-1} rU_{i+1}^{(r)} + (d-2)U_{i+1}^- \leq (1 + \epsilon_t) \left( \frac{\alpha + \beta}{2} U_i^+ + \frac{\alpha - \beta}{2} U_i^- \right)
\]

with probability at least \( 1 - O(n^{-2\gamma}) \). A similar bound works for \( U_{i+1}^- \), which implies conditioned on \( A_t, \ldots, A_i \),

\[
U_{i+1}^\pm \leq (1 + \epsilon_t) \left( \frac{\alpha + \beta}{2} U_i^\pm + \frac{\alpha - \beta}{2} U_i^\pm \right)
\]

with probability \( 1 - O(n^{-2\gamma}) \) for any \( \gamma \in (0, 1) \).

(ii) Lower bound. It remains to have a lower bound on \( U_{i+1}^\pm \). We need to show that conditioned on \( A_{T+1}, \ldots, A_t \), we have

\[
U_{i+1}^\pm \geq (1 - \epsilon_t) \left( \frac{\alpha + \beta}{2} U_i^\pm + \frac{\alpha - \beta}{2} U_i^\pm \right)
\]

with probability \( 1 - O(n^{-2\gamma}) \) for some \( \gamma \in (0, 1) \). Same as (4.36), we have the following lower bound on \( U_{i+1}^+ \):

\[
U_{i+1}^+ \geq \sum_{r=1}^{d-1} rU_{i+1}^{(r)} - \sum_{i=2}^{r} |W_{i+1,i}|.
\]

Next we control \( |W_{i+1,i}| \). A similar bound works for \( U_{i+1}^- \). Let  \( E_{ij}^s \) for \( s = 0, 1, 2 \), be the similar events as in (4.38) before, now we have

\[
E[X_iX_j \mid |\cap = A_j, F_t] = \mathbb{P}(i, j \in W_{i+1,2} \mid |\cap = A_j, F_t)
\]

\[
= \sum_{r=0}^{\infty} \mathbb{P}(i, j \in W_{i+1,2} \mid E_{ij}^s, |\cap = A_j, F_t) \mathbb{P}(E_{ij}^s \mid |\cap = A_j, F_t).
\]

The three terms in the sum can be estimated separately in the same way as before. By using the upper bound \( C^4T \log n \leq S_t \leq C_0^4T \log n \) for some \( C, C_0 > 0 \), and use the same argument for the case when \( t = T \), we have the following three inequalities for some constants \( C_1, C_2, C_3 > 0 \):

\[
\mathbb{P}(i, j \in W_{i+1,2} \mid E_{ij}^0, F_t) \mathbb{P}(E_{ij}^0 \mid |\cap = A_j, F_t) \leq \frac{C_1^4 \alpha^{4(t-T)} \log^4 n}{n^2},
\]

\[
\mathbb{P}(i, j \in W_{i+1,2} \mid E_{ij}^1, F_t) \mathbb{P}(E_{ij}^1 \mid |\cap = A_j, F_t) \leq \frac{C_2^4 \alpha^{3(t-T)} \log^3 n}{n^2},
\]

\[
\mathbb{P}(i, j \in W_{i+1,2} \mid E_{ij}^2, F_t) \mathbb{P}(E_{ij}^2 \mid |\cap = A_j, F_t) \leq \frac{C_3^4 \alpha^{2(t-T)} \log^2 n}{n^2}.
\]

This implies \( E[X_iX_j \mid |\cap = A_j, F_t] \leq \frac{C^4 \alpha^{4(t-T)} \log^4 n}{n^2} \) for some constant \( C' \geq 0 \). Taking conditional expectation in (4.56), we have

\[
E[|\cap |^2] \leq \frac{C^4 \alpha^{4(t-T)} \log^4 n}{n^2}.
\]

Then by Markov inequality, there exists a constant \( C > 0 \), for any \( \lambda > 0 \),

\[
\mathbb{P}(|W_{i+1,2}| > \lambda S_t \mid |\cap = A_j, F_t) \leq \mathbb{P}(|W_{i+1,2}| > \lambda^2 S_t^2 \mid |\cap = A_j, F_t)
\]

\[
\leq \frac{E[|W_{i+1,2}|^2 \mid |\cap = A_j, F_t]}{\lambda^2 S_t^2} \leq \frac{C \alpha^{2(t-T)} \log^2 n}{ \lambda^2 n^2}.
\]

24
Taking $\lambda = (\alpha - \beta)\epsilon_t$ since $c \log(\alpha) < 1/4$, we have $\alpha^t = n^{c \log \alpha} < n^{1/4}$, we have

$$P \left( |W_{t+1,2}| > \frac{(\alpha - \beta)\epsilon_t}{4} S_t | \cap_{j=T}^{t} A_j, F_t \right) \leq \frac{C\alpha^2(t-T) \log^2 n}{n} \leq \frac{C\alpha^2 \log^2 n}{n^2} \leq n^{-1-\gamma}.$$ 

for any $\gamma \in (0, 1/2)$. For each $|W_{t+1,i}|$ for $i \geq 3$, we have for sufficiently large $n$, there exists a constant $C_4 > 0$

$$E[|W_{t+1,i}| | \cap_{j=T}^{t} A_j, F_t] \leq n \left( \frac{n}{d-2} \right)^i S_t \left( \frac{a \vee b}{d-1} \right)^i \leq n \left( \frac{C_4 \alpha^{-T} \log n}{n} \right)^i$$

For the rest of the terms, we have for some constant $C_4' > 0$

$$E \left[ \sum_{i \geq 3} |W_i| | \cap_{j=T}^{t} A_j, F_t \right] \leq n \sum_{i = 3} \left( \frac{C_4 \alpha^{-T} \log n}{n} \right)^i \leq \frac{C_4' \alpha^{3(T-t)} \log^3(n)}{n^2}.$$ 

By Markov’s inequality, note that

$$P \left( \sum_{i \geq 3} |W_i| \geq \frac{(\alpha - \beta)\epsilon_t}{4} S_t | \cap_{j=T}^{t} A_j, F_t \right) \leq \frac{C_5 \alpha^{-2.5(T-t)} \log^2 n}{n^2} \leq \frac{C_5 \alpha^{-2.5T} \log^2 n}{n^2} \leq n^{-1-\gamma}$$

for any $\gamma \in (0, 3/8)$. Together with the estimate on $W_{t+1,2}$, we have

$$\sum_{i \geq 2} |W_{i+1,2}| \leq \frac{(\alpha - \beta)\epsilon_t}{2} S_t \leq \frac{\epsilon_t}{2} \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right)$$

with probability $1 - 2n^{-1-\gamma}$ for any $\gamma \in (0, 3/8)$. With (4.36) and (4.33), we have

$$U_{i+1}^+ \geq \sum_{r=1}^{d-1} r U_{i+1}^{(r)} - \frac{\epsilon_t}{2} \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right) \geq (1 - \epsilon_t) \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right).$$

with probability $1 - O(n^{-1-\gamma})$. By symmetry, the argument works for $U_{i+1}^-$, therefore with probability $1 - O(n^{-1-\gamma})$ for any $\gamma \in (0, 3/8)$, we have

$$U_{i+1}^+ \geq (1 - \epsilon_t) \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right).$$

With (4.57) and the concentration estimate in (4.32), we have with probability $1 - O(n^{-1-\gamma})$ for any $\gamma \in (0, 3/8)$, $U_{i+1}^\pm \in [1 - \epsilon_t, 1 + \epsilon_t] \left( \frac{\alpha + \beta}{2} U_t^\pm + \frac{\alpha - \beta}{2} U_t^\pm \right)$.

Finally, for fixed $i \in [n]$ and $\gamma \in (0, 3/8)$,

$$P \left( \bigcap_{j=T}^{l} A_j \right) \geq \prod_{t=T+1}^{l} P(A_t | A_{t-1}, \ldots, A_{T+1}, A_T) \cdot P(A_{T+1} | A_T) P(A_T) \geq (1 - n^{-1-\gamma}) (1 - n^{-2-\gamma}) \geq 1 - C_6 \log(n)n^{-1-\gamma}.$$ 

for some constant $C_6 > 0$. Taking a union bound over $i \in [n]$, we have shown $A_t$ holds for all $T \leq t \leq l$ and all $i \in [n]$ with probability $1 - O(n^{-\gamma})$ for any $\gamma \in (0, 3/8)$. This completes the proof of Theorem 4.7. $\square$

With Theorem 4.7, the rest of the proof of Theorem 4.3 follows in the same way from the proof of Theorem 2.3 in [27], we include it in the Appendix (see Section 9.1) for completeness.
4.2. Approximate Independence of Neighborhoods. The approximate independence of neighborhoods of distinct vertices is given in the following lemma.

Lemma 4.8. Consider any two fixed vertices \( i \neq j \), let \( l = c \log(n) \) with constant \( c \log(\alpha) < 1/4 \). Then the total variation distance between the joint law \( \mathcal{L}((U_{k}^{\pm}(i))_{k \leq l}, (U_{k}^{\pm}(j))_{k \leq l}) \) and the law with the same marginals and independence between them, denoted by \( \mathcal{L}((U_{k}^{\pm}(i))_{k \leq l} \otimes (U_{k}^{\pm}(j))_{k \leq l}) \), is \( O(n^{-\gamma}) \) for some \( \gamma > 0 \).

Proof of Lemma 4.8. The two sequences \( (U_{k}^{\pm}(i))_{k \leq l} \) and \( (U_{k}^{\pm}(j))_{k \leq l} \) are independent conditioned on the event \( \{V_{\leq l}(i) \cap V_{\leq l}(j) = \emptyset\} \). It remains to estimate \( \mathbb{P}_{\mathcal{H}_{n}}(\{V_{\leq l}(i) \cap V_{\leq l}(j) = \emptyset\}) \).

Introduce the event
\[
J_{k} := \bigcap_{i \leq k} \{S_{i}(i) \vee S_{i}(j) \leq C \log(n) \alpha^{i}\}, \quad \mathcal{L}_{k} := \{V_{\leq k}(i) \bigcap V_{\leq k}(j) = \emptyset\}
\]
where the constant \( C \) is the same one as in the statement of Theorem 4.3. For any vertex \( v \in [n] \setminus (V_{\leq k}(i) \cup V_{\leq k}(j)) \), Conditioned on \( \mathcal{L}_{k} \) and \( J_{k} \), there are two possible situations where \( v \) is included in \( V_{k+1}(i) \cap V_{k+1}(j) \):

(1) There is a hyperedge containing \( v \) and a vertex in \( V_{k}(i) \) and another hyperedge containing \( v \) and a vertex in \( V_{k}(j) \).

(2) There is a hyperedge containing \( v \) and one vertex in \( V_{k}(i) \) and another vertex in \( V_{k}(j) \).

There exists a constant \( C_{1} > 0 \) such that case (1) happens with probability at most
\[
S_{k}(i)S_{k}(j) \left( \frac{n}{d - 2} \right)^{2} \left( \frac{a \lor b}{(d - 1)} \right)^{2} \leq C_{1} \log^{2}(n) \alpha^{2k}/n^{2}
\]
and case (2) happens with probability at most
\[
S_{k}(i)S_{k}(j) \left( \frac{n}{d - 3} \right)^{2} \left( \frac{a \lor b}{(d - 1)} \right) = C_{1} \log^{2}(n) \alpha^{2k}/n^{2}.
\]
Since \( \alpha^{2l} = n^{2c \log \alpha} = o(n^{1/2}) \), we have for large \( n \),
\[
\mathbb{P}_{\mathcal{H}_{n}}(v \in V_{k+1}(i) \cap V_{k+1}(j) | J_{k}, \mathcal{L}_{k}) \leq 2C_{1} \log^{2}(n) \alpha^{2l}/n^{2} < n^{-1.5}.
\]
Taking a union bound over all possible \( v \), we have for some constant \( C_{2} > 0 \),
\[
\mathbb{P}_{\mathcal{H}_{n}}(V_{k+1}(i) \cap V_{k+1}(j) = \emptyset | J_{k}, \mathcal{L}_{k}) \geq 1 - n^{-1/2}.
\]
Recall from the proof of Theorem 4.3, for all \( 0 \leq k \leq l \), \( \mathbb{P}_{\mathcal{H}_{n}}(J_{k}) = 1 - O(n^{-1-\gamma}) \) for any \( \gamma \in (0, 3/8) \). We then have
\[
\mathbb{P}_{\mathcal{H}_{n}}(V_{k+1}(i) \cap V_{k+1}(j) = \emptyset | J_{k}) \geq \mathbb{P}_{\mathcal{H}_{n}}(V_{k+1}(i) \cap V_{k+1}(j) = \emptyset | J_{k}, \mathcal{L}_{k}) \mathbb{P}_{\mathcal{H}_{n}}(J_{k}) \geq 1 - O(n^{-1/2}).
\]
Finally we have for large \( n \),
\[
\mathbb{P}_{\mathcal{H}_{n}}(\{V_{\leq l}(i) \cap V_{\leq l}(j) = \emptyset\}) = \mathbb{P}_{\mathcal{H}_{n}}(L_{l}) \geq \mathbb{P}_{\mathcal{H}_{n}}(V_{l}(i) \cap V_{l}(j) = \emptyset | L_{l-1}) \mathbb{P}_{\mathcal{H}_{n}}(L_{l-1})
\]
\[
\geq \mathbb{P}_{\mathcal{H}_{n}}(L_{0}) \prod_{k=0}^{l-1} \mathbb{P}_{\mathcal{H}_{n}}(V_{k+1}(i) \cap V_{k+1}(j) = \emptyset | L_{k})
\]
\[
\geq (1 - O(n^{-1/2}))^{l} \geq 1 - n^{-1/3}.
\]
Then the result follows.

4.3. Tangle-free Property. Now we consider number of cycles in \( V_{\leq l}(i) \) of any vertex \( i \in [n] \). We say \( H \) is \( l \)-tangle-free if for any \( i \in [n] \), there is more than one cycle in \( V_{\leq l}(i) \).

Lemma 4.9. Assume \( l = c \log n \) with \( c \log(\alpha) < 1/4 \). Let \((H, \sigma)\) be a sample from \( \mathcal{H}(n, d, \frac{a}{d - l}, \frac{b}{d - l}) \). Then
\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_{n}}(|\{i \in [n] : V_{\leq l}(i) \text{ contains at least one cycle}\}| \leq \log^{4}(n) \alpha^{2l}) = 1,
\]

and

$$\lim_{n \to \infty} P_{n}(H \text{ is } l\text{-tangle-free}) = 1.$$  

**Proof.** Consider the exploration process of the neighborhood of a fixed vertex $i$. Conditioned on $F_{k-1}$, there are two ways to create new cycles in $V_{k-1}(i)$:

1. **Type 1:** a new hyperedge $e \subset V_{k-1}(i)$ containing two vertices in $V_{k-1}(i)$ may appear, which creates a cycle including two vertices in $V_{k-1}(i)$.
2. **Type 2:** two vertices in $V_{k-1}(i)$ may be connected to the same vertex in $V_{k}(i)$ by two new distinct hyperedges.

Define the event

$$\Omega_{k-1}(i) := \{ S_{k-1}(i) \leq C \log(n) \alpha^{k-1} \} ,$$

where the constant $C$ is the same one as in Theorem 4.3. From the proof of Theorem 4.3, $P_{n}(\Omega_{k}(i)) = 1 - O(n^{1-\gamma})$ for some $\gamma \in (0, 3/8)$. Let $E_{k}^{(1)}(i)$ be the number of hyperedges of type 1. Conditioned on $F_{k-1}$, $E_{k}^{(1)}(i)$ is stochastically dominated by

$$\text{Bin}\left(\left(\frac{S_{k-1}(i)}{2}\right)\left(\frac{n}{d-2}\right), a \lor b \mid n\right),$$

Then for some constant $C_{1} > 0$,

$$E_{H_{n}}[E_{k}^{(1)}(i) \mid \Omega_{k-1}(i)] \leq C_{1} \log^{2}(n) \alpha^{2k-2}/n \leq C_{1} \log^{2}(n) \alpha^{2l}/n.$$  

By Markov’s inequality,

$$P_{n}(\{ E_{k}^{(1)}(i) \geq 1 \}) \leq P_{n}(\{ E_{k}^{(1)}(i) \mid \Omega_{k-1}(i) \} P_{n}( \{ E_{k}^{(1)}(i) \geq 1 \} ) P_{n}(\{ E_{k}^{(1)}(i) \mid \Omega_{k-1}(i) \} P_{n}(\{ E_{k}^{(1)}(i) \} ) \Omega_{k-1}(i) ) \Omega_{k-1}(i) ) \leq P_{n}(\{ E_{k}^{(1)}(i) \geq 1 \} ) P_{n}(\{ E_{k}^{(1)}(i) \} ) \Omega_{k-1}(i) ) + O(n^{1-\gamma}) = O(\log^{2}(n) \alpha^{2l}/n).$$

By taking the union bound, the probability that there is a type 1 hyperedge in the $l$-neighborhood of $i$ is

$$P_{H_{n}}\left(\bigcup_{k=1}^{l} \{ E_{k}^{(1)}(i) \} \geq 1 \right) \leq \sum_{k=1}^{l} P_{H_{n}}(\{ E_{k}^{(1)}(i) \} \geq 1 ) = O(\log^{3}(n) \alpha^{2l}/n).$$

The number of hyperedge pair $(e_{1}, e_{2})$ of Type 2 is stochastically dominated by

$$\text{Bin}\left(\left(nS_{k-1}(i)\right)\left(\frac{n}{d-2}\right), \left(a \lor b \mid n\right)\right),$$

which conditioned on $\Omega_{k-1}(i)$ has expectation $O(\log^{2}(n) \alpha^{2l}/n)$. By a Markov’s inequality and a union bound, in the same way as the proof for Type 1, we have the probability there is a type 2 hyperedge pair in the $l$-neighborhood of $i$ is $O(\log^{2}(n) \alpha^{2l}/n)$. Altogether the probability that there are at least one cycles within the $l$-neighborhood of $i$ is $O(\log^{3}(n) \alpha^{2l}/n)$.

Let $Z_{i}$ be the random variable such that $Z_{i} = 1$ if $l$-neighborhood of $i$ contains one cycle and $Z_{i} = 0$ otherwise. From the analysis above, we have

$$E[Z_{i}] = O(\log^{3}(n) \alpha^{2l}/n).$$

By Markov’s inequality,

$$P_{n}\left(\sum_{i \in [n]} Z_{i} \geq \alpha^{2l} \log^{4}(n)\right) \leq \frac{\sum_{i} E[Z_{i}]}{\log^{4}(n) \alpha^{2l}} = O(\log^{3}(n) \alpha^{2l}/\alpha^{2l} \log^{4}(n)) = O(\log^{-1}(n)),$n

$$\lim_{n \to \infty} P_{n}\left(\sum_{i \in [n]} Z_{i} \geq \alpha^{2l} \log^{4}(n)\right) = 0.$$
Then asymptotically almost surely the number of vertices whose $l$-neighborhood contains one cycle at most $\log^2(n)\alpha^{2l}$.

It remains to show $H$ is $l$-tangle free asymptotically almost surely. For a fixed vertex $i \in [n]$, there are several possible cases where there can be two cycles in $V_{\leq l}(i)$.

(1) There is one hyperedge of Type 1 or a hyperedge pair of Type 2 which creates more than one cycles. We discuss in the following cases conditioned on the event $\cap_{t=1}^l \Omega_t(i)$.

(a) The number of hyperedge of the first type which connects to more than two vertices in $V_{k-1}$ is stochastically dominated by

$$\text{Bin}\left(\binom{S_{k-1}}{3}\left(\frac{n}{d-3}, \frac{a \lor b}{n(d-1)}\right)\right)$$

The expectation is at most $O(\alpha^{3l}\log^2(n)/n^2)$.

(b) If the intersection of the hyperedge pair of Type 2 contains 2 vertices in $V_{\geq k}$, it will create two cycles. The number of such hyperedge pairs is stochastically dominated by

$$\text{Bin}\left(\binom{n^2}{2}S_{k-1}\left(\frac{n}{d-3}, \frac{a \lor b}{n(d-1)}\right)^2\right)$$

with mean $O(\log^2(n)\alpha^{2l}/n^2)$.

Then by Markov’s inequality and a union bound, asymptotically almost surely there is no $V_{\leq l}(i)$ such that its neighborhood contains Type 1 hyperedges or Type 2 hyperedge pairs which create more than one cycles.

(2) The remaining case is that there is a $V_{< l}(i)$ where two cycles are created by two Type 1 hyperedges or two Type 2 hyperedge pairs or one Type 1 hyperedge and another hyperedge pairs. By the same argument, under the event $\cap_{t=1}^l \Omega_t(i)$, the probability that such event happens $O(\log^6(n)\alpha^{4l}/n^2)$. Since $\alpha^{4l} = n^{4c\log\alpha} = o(n)$, by taking a union bound over $i \in [n]$ we have $H$ is $l$-tangle-free asymptotically almost surely.

4.4 Small Eigenvalues of $B^{(l)}$. In the next lemma, we translate the local analysis of the neighborhoods to the control of vectors $B^{(m)}_1, B^{(m)}_\sigma$. The proof is the same as the proof of Lemma 4.3 in [27], we include it in the appendix, see Section 9.2.

Lemma 4.10. Let $\mathcal{B}$ be the set of vertices $i$ whose $l$-neighborhood contains a cycle. For $l = c\log n$ with $c \log(\alpha) < 1/4$, asymptotically almost surely the following holds:

(1) for all $m \leq l$ and all $i \notin \mathcal{B}$ the following holds

$$\begin{align*}
(B^{(m-1)}_1)_i &= \alpha^{m-1-l}(B^{(l)}_1)_i + O(\alpha^{(m-1)/2}\log n), \\
(B^{(m-1)}_\sigma)_i &= \beta^{m-1-l}(B^{(l)}_\sigma)_i + O(\alpha^{(m-1)/2}\log n).
\end{align*}$$

(2) For all $i \in \mathcal{B}$:

$$\| (B^{(m)}_\sigma)_i \| \leq \| (B^{(m)}_1)_i \| \leq 2 \sum_{t=0}^m S_t(i) = O(\alpha^m \log n).$$

We now have the following corollary.

Corollary 4.11. For all $m \in \{1, \ldots, l\}$ with $l = c\log n$, $c \log \alpha < 1/4$, it holds asymptotically almost surely that

$$\begin{align*}
\sup_{\|x\|_2 = 1, x^\top B^{(l)}_1 = x^\top B^{(l)}_\sigma = 0} \|1^\top B^{(m-1)}_1 x\|_2 &= O(\sqrt{n}\alpha^{(m-1)/2}\log n), \\
\sup_{\|x\|_2 = 1, x^\top B^{(l)}_1 = x^\top B^{(l)}_\sigma = 0} \|\sigma^\top B^{(m-1)}_1 x\|_2 &= O(\sqrt{n}\alpha^{(m-1)/2}\log n).
\end{align*}$$

The proof is the same as the proof of Corollary 4.1 in [27] and we include it in the Appendix (see Section 9.3). Combining with Theorem 3.1 and Theorem 4.3, we have the following bound for small eigenvalues of $B^{(l)}$.  

28
Theorem 4.12. Assume $\beta^2 > \alpha > 1$ and $l = c \log n$ with $c \log(\alpha) < 1/4$. Then the following holds: for any $\epsilon > 0$

$$
\lim_{n \to \infty} P_{\mathcal{H}_n} \left( \|x\|_2 = 1, x^\top (B^{(l)} \mathbf{1}) = x^\top (B^{(l)} \sigma) = 0 \, \|B^{(l)} x\|_2 \leq n^\epsilon \alpha^{l/2} \right) = 1.
$$

Proof: Using matrix expansion identity (3.2) and the estimates in Theorem 3.1, for $l_2$-normalized vector $x$ with $x^\top B^{(l)} \mathbf{1} = x^\top B^{(l)} \sigma = 0$, we have for sufficiently large $n$ asymptotically almost surely

$$
\|B^{(l)} x\|_2 = \left\| \Delta^{(l)} x + \sum_{m=1}^{l} (\Delta^{(l-m)} B_{m-1}) x - \sum_{m=1}^{l} \Gamma^{(l,m)} x \right\|_2 \\
\leq \rho(\Delta^{(l)}) + \sum_{m=1}^{l} \rho(\Delta^{(l-m)}) \|AB^{(m-1)} x\|_2 + \sum_{m=1}^{l} \rho(\Gamma^{(l,m)}) \\
\leq n^\epsilon \alpha^{l/2} + \sum_{m=1}^{l} n^\epsilon \alpha^{(l-m)/2} \|AB^{(m-1)} x\|_2 + \sum_{m=1}^{l} n^{\epsilon-1} \alpha^{(l+m)/2}
$$

(4.64)

$$
\leq 2n^\epsilon \alpha^{l/2} + \sum_{m=1}^{l} n^\epsilon \alpha^{(l-m)/2} \|AB^{(m-1)} x\|_2.
$$

Recall $\overline{A} = E_{\mathcal{H}_n} [A \mid \sigma]$. We have the following expression for entries of $\overline{A}$. If $i \neq j$ and $\sigma_i = \sigma_j = +1$,

$$
\overline{A}_{ij} = \frac{a}{(d-1)^2} \left( n^2 - 2 \right) + \frac{b}{(d-1)^2} \left( \frac{n^2 - 2}{d-2} - \left( \frac{n^2 - 2}{d-2} \right) \right) = \tilde{a}^+_n,
$$

similarly if $i \neq j$ and $\sigma_i = \sigma_j = -1$,

$$
\overline{A}_{ij} = \frac{a}{(d-1)^2} \left( n^2 - 2 \right) + \frac{b}{(d-1)^2} \left( \frac{n^2 - 2}{d-2} - \left( \frac{n^2 - 2}{d-2} \right) \right) = \tilde{a}^-_n,
$$

If $\sigma_i \neq \sigma_j$, $\overline{A}_{ij} = \frac{b}{(d-1)^2} \left( \frac{n^2 - 2}{d-2} \right) = \tilde{b}_n$. We then have $\tilde{a}^+_n, \tilde{a}^-_n, \tilde{b}_n = O(1/n)$, and conditioned on the event $|n^+ - n/2| \leq \log(n) \sqrt{n}$,

$$
\tilde{a}^-_n - \tilde{a}^+_n = \frac{a-b}{(d-1)^2} \left( \left( \frac{n^2 - 2}{d-2} \right) - \left( \frac{n^2 - 2}{d-2} \right) \right) = \frac{a-b}{(d-1)^2} O(\sqrt{n} \log(n)n^{d/3}) = O \left( \frac{\log n}{n^{3/2}} \right).
$$

Let $R$ be a $n \times n$ matrix such that

$$
R_{ij} = \begin{cases} 
1 & \sigma_i = \sigma_j = -1 \text{ and } i \neq j, \\
0 & \text{otherwise.}
\end{cases}
$$

we then have $\|R\|_2 \leq \sqrt{\sum_{ij} R_{ij}^2} \leq n$. We claim the following decomposition of $\overline{A}$ holds.

(4.65)

$$
\overline{A} = \tilde{a}^+_n \left[ \frac{1}{2} (1 \cdot 1^\top + \sigma \sigma^\top) - I \right] + \tilde{b}_n \left[ \frac{1}{2} (1 \cdot 1^\top - \sigma \sigma^\top) + (\tilde{a}^-_n - \tilde{a}^+_n) R \right]
$$

(4.66)

$$
\overline{A} = \tilde{a}^+_n \cdot 1 \cdot 1^\top + \tilde{a}^-_n \cdot \sigma \sigma^\top + \left( (\tilde{a}^-_n - \tilde{a}^+_n) R - \tilde{a}^-_n I \right).
$$

Since

$$
\| (\tilde{a}^-_n - \tilde{a}^+_n) R - \tilde{a}^-_n I \|_2 \leq |\tilde{a}^-_n - \tilde{a}^+_n| \cdot \|R\|_2 + |\tilde{a}^+_n| = O(\log n / \sqrt{n}),
$$

by (4.66), we have

$$
\| \overline{A} B^{(m-1)} x \|_2 \leq \frac{\tilde{a}^+_n + \tilde{b}_n}{2} \|1 \cdot 1^\top B^{(m-1)} x\|_2 + \frac{\tilde{a}^-_n - \tilde{b}_n}{2} \|\sigma \sigma^\top B^{(m-1)} x\|_2 + \| (\tilde{a}^-_n - \tilde{a}^+_n) R - \tilde{a}^-_n I \|_2 \cdot \|B^{(m-1)} x\|_2
$$

$$
= O(1/n) \|1 \cdot 1^\top B^{(m-1)} x\|_2 + O(1/n) \|\sigma \sigma^\top B^{(m-1)} x\|_2 + O(\log n / \sqrt{n}) \|B^{(m-1)} x\|_2.
$$
By Cauchy inequality,
\[
\|1 \cdot 1^\top B^{(m-1)} x\|_2 \leq \sqrt{n} \|1^\top B^{(m-1)} x\|_2, \quad \|\sigma \sigma^\top B^{(m-1)} x\|_2 \leq \sqrt{n} \|\sigma^\top B^{(m-1)} x\|_2,
\]
Therefore we have
\[
\|\mathcal{A} B^{(m-1)} x\|_2 = O(n^{-1/2})(\|\sigma^\top B^{(m-1)} x\|_2 + \|1^\top B^{(m-1)} x\|_2) + O(\log n / \sqrt{n}) \|B^{(m-1)} x\|_2.
\]
Using (4.62) and (4.63), the right hand side is upper bounded by
\[
O(\alpha^{(m-1)/2} \log n) + O(\|B^{(m-1)} x\|_2 \cdot \log n / \sqrt{n}).
\]
Since \(B^{(m-1)}\) is a nonnegative matrix, the spectral norm is bounded by the maximum row sum (see Theorem 8.1.22 in [21]), we have that
\[
\|B^{(m-1)} x\|_2 \leq \rho(B^{(m-1)}) \leq \max_i \sum_{j=1}^n B^{(m-1)}_{ij}.
\]
By (4.3), (4.59) and (4.61), the right hand side above is \(O(\alpha^{m-1} \log n)\). Combining (4.67), note that
\[
\alpha^{m-1} / \sqrt{n} \leq \alpha^l / \sqrt{n} = n^{c \log \alpha / \sqrt{n}} = o(n^{-1/4}),
\]
it implies
\[
\|\mathcal{A} B^{(m-1)} x\|_2 = O(\alpha^{(m-1)/2} \log n) + O(\alpha^{m-1} \log^2 n / \sqrt{n}) = O(\alpha^{(m-1)/2} \log n).
\]
and by (4.64), we have for any \(\epsilon > 0\),
\[
\|B^{(l)} x\|_2 = O(n^l \alpha^{l/2} \log^2 n) \leq n^{2\epsilon} \alpha^{l/2}
\]
for \(n\) sufficiently large, this completes the proof. \(\square\)

5. Coupling with Multi-type Poisson Hypertrees

Recall the definition of a hypertree from Definition 2.5. We construct a hypertree growth process in the following way.

- Generate a root \(\rho\) with spin \(\tau(\rho) = +\), then generate \(\text{Pois} \left(\frac{\alpha}{2^{d-1}}\right)\) many hyperedges that only intersects at \(\rho\). Call the vertices in these hyperedges except \(\rho\) to be the children of \(\rho\) and of generation 1. Call \(\rho\) to be their parent.
- For \(0 \leq r \leq d - 1\), we define a hyperedge is of type \(r\) if \(r\) many children in the hyperedge has spin \(\tau(\rho)\) and \((d - 1 - r)\) many children has spin \(-\tau(\rho)\). We first assign a type for each hyperedge independently. Each hyperedge will be of type \((d - 1)\) with probability \(\frac{(d-1)^n}{\alpha 2^{d-1}}\) and of type \(r\) with probability \(\frac{(d-1) b(r-1)}{\alpha 2^{d-1}}\) for \(0 \leq r \leq d - 2\). Recall \(\alpha = (d - 1) \frac{2^{d-1}-1}{2^{d-1}}\), we have
  \[
  \frac{(d-1)a}{\alpha 2^{d-1}} + \sum_{r=0}^{d-2} \frac{(d-1)b(r-1)}{\alpha 2^{d-1}} = 1,
  \]
then the probabilities of being various types of hyperedges add up to 1. Because the type is chosen i.i.d for each hyperedge, by Poisson thinning, the number of hyperedges of different types are independent and Poisson.
- We draw the hypertree in a plane and label each child from left to right. For each type \(r\) hyperedge, we uniformly randomly pick \(r\) vertices among \(d - 1\) vertices in the first generation to put spins \(\tau(\rho)\), and the rest \(d - 1 - r\) many vertices are assigned spins \(-\tau(\rho)\).
- After defining the first generation, we keep constructing subsequent generations by induction. For each children \(v\) with spin \(\tau(v)\) in the previous generation, we generate \(\text{Pois} \left(\frac{\alpha}{2^{d-1}}\right)\) many hyperedges that pairwise intersects at \(v\) and assign a type to each hyperedge by the same rule with \(\tau(\rho)\) replaced by \(\tau(v)\). We call such random hypergraphs with spins a multi-type Galton-Watson hypertree, denoted by \((T, \rho, \tau)\) (see Figure 4).
Let $W_t^\pm$ be the number of vertices with $\pm$ spins at the $t$-th generation and $W_t^{(r)}$ be the number of hyperedges which contains exactly $r$ children with spin $+$ in the $t$-th generation. Let

$$G_{t-1} := \sigma(W_k^\pm, 1 \leq k \leq t - 1)$$

be the $\sigma$-algebra generated by $W_k^\pm, 1 \leq k \leq t - 1$. From our definition, $W_0^+, W_0^- = 0$ and $\{W_t^{(r)}\}_{0 \leq r \leq d-1}$ are independent conditioned on $G_{t-1}$, and the laws of $W_t^{(r)}$ are given by

\begin{align}
\mathcal{L}(W_t^{(d-1)}|G_{t-1}) &= \text{Pois}\left( \frac{a}{2^{d-1}} W_{t-1}^+ + \frac{b}{2^{d-1}} W_{t-1}^- \right), \\
\mathcal{L}(W_t^{(0)}|G_{t-1}) &= \text{Pois}\left( \frac{a}{2^{d-1}} W_{t-1}^- + \frac{b}{2^{d-1}} W_{t-1}^+ \right), \\
\mathcal{L}(W_t^{(r)}|G_{t-1}) &= \text{Pois}\left( \frac{b^{(d-1)}_r}{2^{d-1}} (W_{t-1}^- + W_{t-1}^+) \right), \quad 1 \leq r \leq d-2.
\end{align}

We also have

$$W_t^+ = \sum_{r=0}^{d-1} r W_t^{(r)}, \quad W_t^- = \sum_{r=0}^{d-1} (d - 1 - r) W_t^{(r)}.$$

**Definition 5.1.** A rooted hypergraph is a hypergraph $H$ with a distinguished vertex $i \in V(H)$, denoted by $(H, i)$. We say two rooted hypergraphs $(H, i)$ and $(H', i')$ are isomorphic if and only if there is a bijection $\phi : V(H) \to V(H')$ such that $\phi(i) = i'$ and $e \in E(H)$ if and only if $\phi(e) := \{\phi(j) : j \in e\} \in E(H')$.

**Definition 5.2.** Let $(H, i, \sigma)$ be a rooted hypergraph with root $i$ and each vertex $j$ is given a spin $\sigma(j) \in \{-1, +1\}$. Let $(H', i', \sigma')$ be a rooted hypergraph with root $i'$ where for each vertex $j \in V(H')$, a spin $\sigma'(j) \in \{-1, +1\}$ is given. We say $(H, i, \sigma)$ and $(H', i', \sigma')$ are spin-preserving isomorphic and denoted by $(H, i, \sigma) \equiv (H', i', \sigma')$ if and only if there is an isomorphism $\phi : (H, i) \to (H', i')$ with $\sigma(v) = \sigma'(\phi(v))$ for each $v \in V(H)$.

Let $(H, i, \sigma)_l, (T, \rho, \tau)_l$ be the rooted hypergraphs $(H, i, \sigma), (T, \rho, \tau)$ truncated at distance $t$ from $i, \rho$ respectively, and let $(T, \rho, -\tau)$ be the corresponding hypertree growth process where the root $\rho$ has spin $-1$. We prove a local weak convergence of a typical neighborhood of a vertex in the hypergraph $H$ to the hypertree process $T$ we described above. In fact, we prove the following stronger statement.

**Theorem 5.3.** Let $(H, \sigma)$ be a random hypergraph $H$ with spin $\sigma$ sampled from $\mathcal{H}_n$. Let $i \in [n]$ be fixed with spin $\sigma_i$. Let $l = \log(n)$ with $\log(\alpha) < 1/4$, the following holds for sufficiently large $n$.

1. If $\sigma_i = +1$, there exists a coupling between $(H, i, \sigma)$ and $(T, \rho, \tau)$ such that $(H, i, \sigma)_l \equiv (T, \rho, \tau)_l$ with probability at least $1 - n^{-1/5}$.
2. If $\sigma_i = -1$, there exists a coupling between $(H, i, \sigma)$ and $(T, \rho, -\tau)$ such that $(H, i, \sigma)_l \equiv (T, \rho, -\tau)_l$ with probability at least $1 - n^{-1/5}$.
The proof is a generalization of the method by Mossel et al. [28] for sparse random graphs. We now prove the case where \( \sigma_1 = 1 \), and the case for \( \sigma_1 = -1 \) can be treated in the same way. Recall the definition of \( V_i \) from Definition 4.2.

Let \( A_t \) be the event that no vertex in \( V_t \) is connected by two distinct hyperedges to \( V_{t-1} \). Let \( B_t \) be the event that there does not exist two vertices in \( V_t \) that are contained in a hyperedge \( e \subset \( V_t \) \). We can construct the multi-type Poisson hypertree \( (T, \rho, \tau) \) in the following way. For a vertex \( v \in T \), Let \( Y_v^{(r)}, 0 \leq r \leq d - 1 \) be the number of hyperedges incident to \( v \) which among the remaining \( d - 1 \) vertices, \( r \) of them have the same spin with \( \tau(v) \). We have

\[
Y_v^{(d-1)} \sim \text{Pois} \left( \frac{a}{2^{d-1}} \right), \quad Y_v^{(r)} \sim \text{Pois} \left( \frac{(d-1)b}{2^{d-1}} \right), \quad 0 \leq r \leq d - 2.
\]

Note that \( (T, \rho, \tau) \) can be entirely reconstructed from the label of the root and the sequence \( \{Y_v^{(r)}\} \) for \( v \in V(T), 0 \leq r \leq d - 1 \). We define similar random variables for \( (H, i, \sigma) \). For a vertex \( v \in V_t \), let \( X_v^{(r)} \) be the number of hyperedges incident to \( v \), where all the remaining \( d - 1 \) vertices are in \( V_{t+1} \) such that \( r \) of them have spin \( \sigma(v) \). Then we have

\[
X_v^{(d-1)} \sim \text{Bin} \left( \frac{|V_{>t}|}{d-1}, \frac{a}{d-1} \right),
\]

\[
X_v^{(r)} \sim \text{Bin} \left( \frac{|V_{>t}|}{d-1}, \frac{|V_{>t} \setminus \sigma(v)|}{d-1} \right), \quad 0 \leq r \leq d - 2,
\]

and conditioned on \( F_t \) (recall the definition of \( F_t \) from (4.12)) they are independent.

**Lemma 5.4.** Let \( (H, i, \sigma)_t, (T, \rho, \tau)_t \) be the rooted hypergraph truncated at distance \( t \) from \( i, \rho \) respectively. If

1. there is a spin-preserving isomorphism \( \phi \) such that \( (H, i, \sigma)_{t-1} \equiv (T, \rho, \tau)_{t-1} \),
2. for every \( v \in V_{t-1} \), \( X_v^{(r)} = Y_{\phi(v)}^{(r)} \) for \( 0 \leq r \leq d - 1 \),
3. \( A_t, B_t \) hold,

then \( (H, i, \sigma)_t \equiv (T, \rho, \tau)_t \).

**Proof.** Conditioned on \( (H, i, \sigma)_{t-1} \equiv (T, \rho, \tau)_{t-1} \), if \( A_t \) holds, it implies that hyperedges generated from vertices in \( V_{t-1} \) do not overlap (except for the parent vertices in \( V_{t-1} \)). If \( B_t \) holds, vertices in \( V_t \) that are in different hyperedges generated from \( H_{t-1} \) do not connect to each other.

If both \( A_t, B_t \) holds, \( (H, i, \sigma)_t \) is still a hypertree. Since \( X_v^{(r)} = Y_{\phi(v)}^{(r)} \) for \( v \in V_{t-1} \), we can extend the hypergraph isomorphism \( \phi \) by mapping the children of \( v \in V_t \) to the corresponding vertices in the \( t \)-th generation of children of \( \rho \) in \( T \), which keeps the hypertree structure and the spin of each vertex.

To make our notation simpler, for the rest of this section, we will identify \( v \) with \( \phi(v) \). Recall the event

\[
\Omega_t(i) := \{ S_t(i) \leq C \log(n) \alpha^t \}
\]

where the constant \( C \) is the same one as in Theorem 4.3. Now define a new event

\[
C_t := \bigcap_{s \leq t} \Omega_s(i).
\]

As established in the proof of Theorem 4.3, for all \( t \leq l \), \( P_{\mathcal{H}_n}(C_t) = 1 - O(n^{-1-\gamma}) \) for any \( \gamma \in (0, 3/8) \). Note that conditioned on \( C_t \), there exists \( C' > 0 \) such that

\[
|V_{\leq t}| \leq \sum_{s \leq t} C' \log(n) \alpha^t \leq C'' \log^2(n) \alpha^t.
\]

We now estimate the probability of event \( A_t, B_t \) conditioned on \( C_t \).

**Lemma 5.5.** For any \( t \geq 1 \),

\[
P(A_t|C_t) \geq 1 - o(n^{-1/2}), \quad P(B_t|C_t) \geq 1 - o(n^{-1/2}).
\]
Proof. First we fix \( u, v \in V_t \). For any \( w \in V_{\geq t} \), the probability that \((u, w), (v, w)\) are both connected is \(O(n^{-2})\). We know \(|V_{\geq t}| \leq n\) and \(|V_{\geq t}| = O(\log^2(n)\alpha^t)\) conditioned on \(C_t\). Since \(\alpha^t \leq \alpha^{2t} = o(n^{1/2})\), taking a union bound over all \(u, v, w\) we have

\[
P(A_t | C_t) \geq 1 - O(\log^4(n)\alpha^{2t}n^{-1}) = 1 - o(n^{-1/2}).
\]

For the second claim, the probability of having an edge between \(u, v \in V_t\) is \(O(n^{-1})\). Taking a union bound over all pairs of \(u, v \in V_t\) implies

\[
P(B_t | C_t) \geq 1 - O(\log^4(n)\alpha^{2t}n^{-1}) = 1 - o(n^{-1/2}).
\]

\(\square\)

We also need the following bound on the total variation distance between binomial and Poisson random variables, see for example Lemma 4.6 in [28].

**Lemma 5.6.** Let \(m, n\) be integers and \(c\) be a positive constant. The following holds:

\[
\|\text{Bin}\left(m, \frac{c\alpha}{n}\right) - \text{Pois}(c)\|_{TV} = O\left(\frac{1}{n} \sqrt{\frac{m - n}{n}}\right).
\]

Finally we are ready to prove Theorem 5.3.

**Proof of Theorem 5.3.** Fix \(t\) and suppose that \(C_t\) holds, and \((T, \rho)_t \equiv (H, i)_t\). Then for each \(v \in V_t\), recall

\[
X^{(d-1)}_v \sim \text{Bin}\left(\frac{|V_{\geq t}^c(v)|}{d-1}, \frac{a}{d-1}\right), \quad X^{(r)}_v \sim \text{Bin}\left(\frac{|V_{\geq t}^c(v)|}{r}, \frac{b}{n}\right)
\]

and

\[
Y^{(d-1)}_v \sim \text{Pois}\left(\frac{a}{2d-1}\right), \quad Y^{(r)}_v \sim \text{Pois}\left(\frac{b}{2d-1}\right), \quad 0 \leq r \leq d - 2.
\]

We have the following bound for \(V_{\leq t}^c\). Recall \(|n^+ - n^+/2| \leq \sqrt{n} \log n\), for sufficiently large \(n\),

\[
|V_{\geq t}^c| \geq n^+ - |V_{\leq t}| \geq n^+ - n^{-1/2} \log(n) - O(\log^2(n)\alpha^{2t}) \geq \frac{n}{2} - 2\sqrt{n} \log(n),
\]

\[
|V_{\leq t}^c| \leq n^+ \leq \frac{n}{2} + \sqrt{n} \log(n).
\]

Therefore \(|V_{\geq t}^c - \frac{n}{2}| \leq 2\sqrt{n} \log n\). Then from Lemma 5.6,

\[
\|X^{(d-1)}_v - Y^{(d-1)}_v\|_{TV} \leq C \left|\frac{|V_{\geq t}^c(v)|}{d-1} - \frac{1}{2d-1}\right| \left(\frac{n}{d-1}\right) = O(n^{-1/2} \log n),
\]

\[
\|X^{(r)}_v - Y^{(r)}_v\|_{TV} = O(n^{-1/2} \log n).
\]

Therefore we can couple \(X^{(r)}_v\) with \(Y^{(r)}_v\), \(0 \leq r \leq d - 1\) such that

\[
P\left(X^{(r)}_v \neq Y^{(r)}_v\right) = O(n^{-1/2} \log n).
\]

Taking a union bound over all \(v \in V_t\), and \(0 \leq r \leq d - 1\) and recall (5.6), we can find a coupling such that with probability at least

\[
1 - O(\log^3(n)\alpha^t n^{-1/2}) \geq 1 - o(n^{-1/4}),
\]

\(X^{(r)}_v = Y^{(r)}_v\) for every \(v \in V_t\) and \(0 \leq r \leq d - 1\). Lemma 5.5 implies \(A_t, B_t, C_t\) hold simultaneously with probability at least \(1 - o(n^{-1/4})\). Altogether we have that assumptions (2),(3) in Lemma 5.4 hold with probability \(1 - o(n^{-1/4})\), which can be written as

\[
P\left((H, i, \sigma)_{t+1} \equiv (T, \rho, \tau)_{t+1}, C_{t+1} \right) \equiv (T, \rho, \tau)_t, C_t\right) \geq 1 - o(n^{-1/4}).
\]

Since we can certainly couple \(i\) with \(\rho\) from our construction, we have

\[
P\left((H, i, \sigma)_{0} \equiv (T, \rho, \tau)_{0}, C_0\right) = 1.
\]
Therefore we have for large $n$,
\[
\mathbb{P}(\{(H, i, \sigma)\} \equiv (T, \rho, \tau)) = \prod_{t=1}^{\ell} \mathbb{P}\left((H, i, \sigma)_{t} \equiv (T, \rho, \tau), C_{t}\right) \mathbb{P}\left((H, i, \sigma)_{t-1} \equiv (T, \rho, \tau), C_{t-1}\right) \mathbb{P}\left((H, i, \sigma)_{0} \equiv (T, \rho, \tau), C_{0}\right) \\
\geq (1 - \alpha(n^{-1/4}))^\ell \geq 1 - n^{-1/5},
\]
and this completes the proof. \hfill \Box

6. Martingale Convergence

Now we construct two martingales from the Poisson hyper-tree growth process. Define two processes
\[
M_t := \alpha^{-t}(W_t^+ + W_t^-), \quad \Delta_t := \beta^{-t}(W_t^+ - W_t^-).
\]

**Lemma 6.1.** The two processes $\{M_t\}, \{\Delta_t\}$ are $\mathcal{G}_t$-martingales. If $\beta^2 > \alpha > 1$, $\{M_t\}$ and $\{\Delta_t\}$ are uniformly integrable.

**Proof.** Recall $\alpha = (d - 1) \frac{a + (2d - 1)b}{2d - 1}, \beta = (d - 1) \frac{a - b}{2d - 1}$. From (5.1)-(5.3),
\[
\mathbb{E}(W_{t+1}^+ | \mathcal{G}_t) = \sum_{r=0}^{d-1} r \mathbb{E}(W_{t+1}^{(r)} | \mathcal{G}_t) = \frac{(d - 1) + (d - 1)(2d - 1)b}{2d - 1} W_t^+ + \frac{(d - 1)b + (d - 1)(2d - 1)b}{2d - 1} W_t^- \\
= \frac{\alpha + \beta}{2} W_t^+ + \frac{\alpha - \beta}{2} W_t^-.
\]
Similarly $\mathbb{E}(W_{t+1}^- | \mathcal{G}_t) = \frac{\alpha^t + 1}{2} M_t - \frac{\beta^t + 1}{2} \Delta_t$. Therefore
\[
\mathbb{E}[M_{t+1} | \mathcal{G}_t] = \alpha^{-t-1} \mathbb{E}[W_{t+1}^+ + W_{t+1}^- | \mathcal{G}_t] = M_t, \\
\mathbb{E}[\Delta_{t+1} | \mathcal{G}_t] = \beta^{-t-1} \mathbb{E}[W_{t+1}^+ - W_{t+1}^- | \mathcal{G}_t] = \Delta_t.
\]
It follows that $\{M_t\}, \{\Delta_t\}$ are martingales with respect to $\mathcal{G}_t$. we have from (5.1)-(5.4),
\[
\text{Var}(M_t | \mathcal{G}_{t-1}) = \text{Var}(\alpha^{-t}(W_t^+ + W_t^-) | \mathcal{G}_{t-1}) = \alpha^{-2t} \text{Var}\left((d - 1) \sum_{r=0}^{d-1} W_{t}^{(r)} | \mathcal{G}_{t-1}\right) \\
= (d - 1)^2 \alpha^{-2t} \sum_{r=0}^{d-1} \text{Var}(W_{t}^{(r)} | \mathcal{G}_{t-1}) = (d - 1)^2 \alpha^{-2t} \frac{\alpha}{d-1} (W_{t-1}^+ + W_{t-1}^-) \\
= (d - 1) \alpha^{-t} M_{t-1}.
\]
Since $\mathbb{E}M_0 = 1$, by conditional variance formula
\[
\text{Var}(M_t) = \mathbb{E}[\text{Var}(M_t | \mathcal{G}_{t-1})] + \text{EVar}(M_t | \mathcal{G}_{t-1}) = \text{Var}(M_{t-1}) + (d - 1) \alpha^{-t}.
\]
Since \( \text{Var}(M_0) = 0 \), we have for \( t \geq 0 \), \( \text{Var}(M_t) = (d - 1) \frac{1 - \alpha^{-t}}{\alpha - 1} \), so \( \{M_t\} \) is uniformly integrable for \( \alpha > 1 \). Similarly,

\[
\text{Var}(\Delta_t|G_{t-1}) = \text{Var}(\beta^{-t}(W_t^+ - W_t^-)|G_{t-1}) = \beta^{-2t} \text{Var} \left( \sum_{r=0}^{d-1} r W_t^{(r)} - (d - 1 - r) W_t^{(r)} | G_{t-1} \right)
\]

\[
= \beta^{-2t} \sum_{r=0}^{d-1} (2r - d + 1)^2 \text{Var}(W_t^{(r)} | G_{t-1})
\]

\[
= \beta^{-2t} \left( (d - 1)^2 \cdot \frac{a + b}{2d - 1} (W_{t-1}^+ + W_{t-1}^-) + \sum_{r=1}^{d-2} (2r - d + 1)^2 \cdot \frac{b(r+1)}{2d - 1} (W_{t-1}^- + W_{t-1}^+) \right)
\]

\[
= \beta^{-2t} (W_{t-1}^+ + W_{t-1}^-) \left( (d - 1)^2 \cdot \frac{a + b}{2d - 1} + \sum_{r=1}^{d-2} (2r - d + 1)^2 \cdot \frac{b(r+1)}{2d - 1} \right)
\]

\[
= \beta^{-2t} (W_{t-1}^+ + W_{t-1}^-) \left( (d - 1)^2 \cdot \frac{a + b}{2d - 1} + b \cdot (d-1)(2d-1 + 2 - 2d) \right)
\]

\[
= \left( \frac{\alpha}{\beta^2} \right)^t M_{t-1} (d-1)^{-1} \cdot \frac{(d-1)a + (2d-1 + 1 - d)b}{2d-1} = \kappa (\alpha/\beta^2)^t M_{t-1},
\]

where \( \kappa := \frac{(d-1)(a-b) + 2d-1b}{a + (2d-1 - 1)b} \). And we also have the following recursion

\[
\text{Var}(\Delta_t) = \text{Var}(\mathbb{E}[\Delta_t|G_{t-1}]) + \mathbb{E}\text{Var}(\Delta_t|G_{t-1}) = \text{Var}(\Delta_{t-1}) + \kappa \beta^{-2t} \alpha^t.
\]

Since \( \text{Var}(\Delta_0) = 0 \), we have for \( t > 0 \),

\[
\text{(6.1)} \quad \text{Var}(\Delta_t) = \kappa \cdot \frac{1 - (\beta^2/\alpha)^{-t}}{\beta^2/\alpha - 1}.
\]

So we have \( \{\Delta_t\} \) is uniformly integrable if \( \beta^2 > \alpha \).

\( \square \)

By martingale convergence theorem, we have the following corollary.

**Corollary 6.2.** Under \( \beta^2 > \alpha \), the martingale \( \{\Delta_t\} \) converges almost surely and in \( L^2 \) to a unit mean random variable \( \Delta_\infty \). Moreover \( \Delta_\infty \) has a finite variance \( \frac{\kappa}{\beta^2/\alpha - 1} \) and

\[
\lim_{t \to \infty} \mathbb{E}[\Delta_t^2 - \Delta_\infty^2] = 0.
\]

The proof of the following theorem is the same as the proof of Theorem 4.2 in [27], see Section 9.4 in Appendix.

**Theorem 6.3.** Let \( l = c \log n \) with \( c \log \alpha < 1/8 \). For any \( \epsilon > 0 \),

\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \frac{1}{n} \sum_{i=1}^{n} \beta^{-2l} D_l^2(i) - \mathbb{E}[\Delta_l^2] > \epsilon \right) = 0.
\]

Let \( y(n) \in \mathbb{R}^n \) be a random sequence of \( l_2 \)-normalized vectors defined by

\[
y_l^{(n)} := \frac{D_l(i)}{\sqrt{\sum_{j=1}^{n} D_l(j)^2}} , \quad 1 \leq i \leq n.
\]

Let \( x(n) \) be any sequence of random vectors in \( \mathbb{R}^n \) such that for any \( \epsilon > 0 \),

\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} (\|x(n) - y(n)\|_2 > \epsilon) = 0.
\]
For all $\tau \in \mathbb{R}$ that is a point of continuity of the distribution of both $\Delta_\infty$ and $-\Delta_\infty$, for any $\epsilon > 0$, one has the following

\begin{align}
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_\alpha} \left( \frac{1}{n} \sum_{i \in [n]: \sigma_i = +} 1 \left\{ x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}[\Delta_\infty^2]} \right\} - \frac{1}{2} \mathbb{P}(\Delta_\infty \geq \tau) \right) > \epsilon\right) = 0,
\end{align}

\begin{align}
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_\alpha} \left( \frac{1}{n} \sum_{i \in [n]: \sigma_i = -} 1 \left\{ x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}[\Delta_\infty^2]} \right\} - \frac{1}{2} \mathbb{P}(-\Delta_\infty \geq \tau) \right) > \epsilon\right) = 0.
\end{align}

7. Weak Ramanujan Property

The proof of the following Lemma 7.1 follows in the same way as Lemma 4.4 in [27], we include it in the Appendix (see Section 9.5). Let $\bar{S}_l := (S_l(1), \ldots, S_l(n))$ and $\bar{D}_l := (D_l(1), \ldots, D_l(n))$.

**Lemma 7.1.** For $l = c \log(n), c \log(\alpha) < 1/4$, the following hold asymptotically almost surely

\begin{align}
\| B^{(l)} 1 - \bar{S}_l \|_2 &= o(\| B^{(l)} 1 \|_2), \quad (7.1) \\
\| B^{(l)} \sigma - \bar{D}_l \|_2 &= o(\| B^{(l)} \sigma \|_2), \quad (7.2) \\
\langle B^{(l)} 1, B^{(l)} \sigma \rangle &= o \left( \| B^{(l)} 1 \|_2 \cdot \| B^{(l)} \sigma \|_2 \right). \quad (7.3)
\end{align}

The next lemma estimate $\| B^{(l)} \sigma \|_2$ when $x = B^{(l)} \sigma$ and $B^{(l)} 1$.

**Lemma 7.2.** Assume $\beta^2 > \alpha > 1$ and $l = c \log(n)$ with $c \log(\alpha) < 1/8$. Then for some fixed $\gamma > 0$ asymptotically almost surely one has

\begin{align}
\Omega(\alpha^l) \| B^{(l)} 1 \|_2 \leq \| B^{(l)} B^{(l)} 1 \|_2 \leq O(\alpha^l \log n) \| B^{(l)} 1 \|_2, \quad (7.4) \\
\Omega(\beta^l) \| B^{(l)} \sigma \|_2 \leq \| B^{(l)} B^{(l)} \sigma \|_2 \leq O(n^{-\gamma} \alpha^l) \| B^{(l)} \sigma \|_2. \quad (7.5)
\end{align}

**Proof.** For the lower bound in (7.4), note that $B^{(l)}$ is symmetric, we have

\begin{align}
\| B^{(l)} 1 \|_2^2 = \langle B^{(l)} 1, B^{(l)} 1 \rangle = \langle 1, B^{(l)} B^{(l)} 1 \rangle \leq \| 1 \|_2 \| B^{(l)} B^{(l)} 1 \|_2,
\end{align}

therefore from (9.21) in the appendix and (7.1),

\begin{align}
\| B^{(l)} B^{(l)} 1 \|_2 \geq \frac{\| B^{(l)} 1 \|_2^2}{\| 1 \|_2^2} = \Theta(\alpha^l) \| B^{(l)} 1 \|_2.
\end{align}

For the upper bound in (7.4), from Theorem 4.3 (4.3) and Lemma 4.10 (4.61), the maximum row sum of $B^{(l)}$ is $O(\alpha^l \log n)$, since $B^{(l)}$ is nonnegative, the spectral norm $\rho(B^{(l)})$ is bounded by the maximal row sum, (7.4) holds. The lower bound in (7.5) can be proved similarly as in (7.4), from the inequality $\| B^{(l)} \sigma \|_2^2 \leq \| \sigma \|_2 \| B^{(l)} B^{(l)} \sigma \|_2$ together with (9.18) in the appendix and (7.2).

We then proceed to establish the upper bound in (7.5) and we follow the proof of Lemma 4.5 in [27]. Recall $B$ is the set of vertices whose $l$-neighborhood contains cycles. Let $\bar{B} = [n] \setminus B$. Since

\begin{align}
\left( B^{(l)} B^{(l)} \right)_{ij} = \sum_{j \in [n]} B^{(l)}_{ij} (B^{(l)} \sigma)_j,
\end{align}

we can decompose the vector $B^{(l)} B^{(l)} \sigma$ as a sum of three vectors $z + z' + z''$ where

\begin{align}
z_i = 1_{\bar{B}}(i) \sum_{j : \ell(i, j) = l} D_l(j) 1_B(j), \\
z'_i = 1_{\bar{B}}(i) \sum_{j : \ell(i, j) = l} O(\alpha^l \log n) 1_B(j), \\
z''_i = 1_B(i) O(\alpha^{2l} \log^2 n).
\end{align}
The decomposition above depends on whether \( i, j \in B \) and the estimation follows from (4.61). From Lemma 4.9, \( B = O(\alpha^{2l} \log^3(n)) \) asymptotically almost surely, so one has

\[
\|z\|_2^2 = \sum_{i=1}^n (z_i)^2 = \sum_{i \in B} \sum_{j : d(i, j) = l} \sum_{j' : d(i, j') = l} O(\alpha^{2l} \log^2 n) 1_B(j) 1_B(j')
= \sum_{j \in B} \sum_{j' \in B} \sum_{d(i, j) = d(i, j') = l} O(\alpha^{2l} \log^2 n)
= \sum_{j, j' \in B} O(\alpha^{3l} \log^3 n) = O(\alpha^{7l} \log^{11} n),
\]

which implies \( \|z\|_2 = O(\alpha^{7l/2} \log^{11/2} n) \). And similarly \( \|z''\|_2 = O(\alpha^{3l} \log^3 n) \).

We know from (9.19), \( \|B^{(l)}\sigma\|_2 = \Theta(\beta^l \sqrt{n}) \), and since \( c \log \alpha < 1/8 \), we have \( \alpha^{5l/2} = n^{-\gamma} \sqrt{n} \), for some \( \gamma > 0 \), therefore

\[
(7.8) \quad \|z' + z''\|_2 = O(\alpha^{7l/2} \log^{11/2} n) = O(n^{-\gamma} \beta^l) = O(n^{-\gamma} \|B^{(l)}\sigma\|_2).
\]

It remains to upper bound \( \|z\|_2 \). Assume the 2l-neighborhood of \( i \) is cycle-free, then the \( i \)-th entry of \( B^{(l)} B^{(l)} \sigma \), denoted by \( X_i \), can be written as

\[
X_i := (B^{(l)} B^{(l)} \sigma)_i = \sum_{k=1}^n B_{ik}^{(l)} (B^{(l)} \sigma)_k = \sum_{k=1}^n 1_{d(i, k) = l} \sum_{j=1}^n 1_{d(j, k) = l} \sigma_j
\]

\[
(7.9) \quad = \sum_{h=0}^l \sum_{j : d(i, j) = 2h} \sigma_j |\{k : d(i, k) = d(j, k) = l\}|.
\]

We control the magnitude of \( X_i \) in the corresponding hypertree growth process. Since \( 2l = 2c \log n \) and \( 2c \log(\alpha) < 1/4 \), the coupling result in Theorem 5.3 can apply. Let \( C_i \) be the event that coupling between 2l-neighborhood of \( i \) with the Poisson Galton-Watson hypertree has succeeded and \( n^{-\epsilon} \) be the failure probability of the coupling. When the coupling succeed, \( z_i = X_i \), therefore

\[
E(\|z\|_2^2 | \Omega) = \sum_{i \in [n]} n^{-\epsilon} O(\alpha^{2l} \beta^{2l} \log^2 n) + \sum_{i \in [n]} E(X_i^2 1_{C_i} | \Omega)
\]

\[
(7.10) \quad = n^{1-\epsilon} O(\alpha^{2l} \beta^{2l} \log^2 n) + \sum_{i \in [n]} E(X_i^2 1_{C_i} | \Omega).
\]

From (7.9), we have

\[
(7.11) \quad X_i^2 = \sum_{h, h' = 0}^{l} \sum_{j : d(i, j) = 2h} \sum_{j' : d(i, j') = 2h'} \sigma_j \sigma_{j'} |\{k : d(i, k) = d(j, k) = l\}| \cdot |\{k : d(i, k) = d(j', k) = l\}|.
\]

We further classify the pair \( j, j' \) in (7.11) according to their distance. Let \( d(j, j') = 2(h + h' - \tau) \) for \( \tau = 0, \ldots, 2(h + h') \). Let

\[
D^{(l)}_{i, j} := |\{k : d(i, k) = d(j, k) = t\}|
\]

This yields

\[
X_i^2 = \sum_{h, h' = 0}^{l} \sum_{j : d(i, j) = 2h} \sum_{j' : d(i, j') = 2h'} \sigma_j \sigma_{j'} D^{(l)}_{i, j} D^{(l)}_{i, j'}
= \sum_{h, h' = 0}^{l} \sum_{\tau = 0}^{2(h + h')} \sum_{j : d(i, j) = 2h} \sum_{j' : d(i, j') = 2h'} 1_{d(j, j') = 2(h + h' - \tau)} \sigma_j \sigma_{j'} D^{(l)}_{i, j} D^{(l)}_{i, j'}.
\]
Note that conditioned on \( \Omega \) and \( C_i \), similar to the analysis in [27], we have the following holds

\[
\begin{align*}
(7.12) & \quad |\{ k : d(i, k) = d(j, k) = l \}| = O(\alpha^{l-h} \log n), \\
(7.13) & \quad |\{ k' : d(i, k') = d(j', k') = l \}| = O(\alpha^{l-h'} \log n), \\
(7.14) & \quad |\{ j : d(i, j) = 2h \}| = O(\alpha^{2h} \log n), \\
(7.15) & \quad |\{ j' : d(i, j') = 2h', d(j, j') = 2(h + h' - \tau) \}| = O(\alpha^{2h' - \tau} \log n).
\end{align*}
\]

We claim that

\[
(7.16) \quad \mathbb{E}[\sigma_j \sigma_{j'} | C_i] \leq \left( \frac{\alpha}{\beta} \right)^{d(j,j') - 1}
\]

and prove (7.16) in several steps.

(a) If \( j \) is the parent of \( j' \) in the hypertree growth process, we can calculate \( \mathbb{E}_{H_n}[\sigma_j \sigma_{j'} | C_i] \) explicitly. Let \( T_r \) be the event that the hyperedge containing \( j' \) is of type \( r \). Given \( T_r \), by our construction of the hypertree process, the spin of \( j' \) is assigned to be \( \sigma_j \) with probability \( \frac{d}{d + 1} \) and \( -\sigma_j \) with probability \( \frac{d - 1 - r}{d + 1} \), so we have

\[
\mathbb{E}[\sigma_j \sigma_{j'} | C_i] = \sum_{r=0}^{d-1} \mathbb{E}[\sigma_j \sigma_{j'} | T_r, C_i] \mathbb{P}[T_r | C_i] = \sum_{r=0}^{d-1} \left( \frac{r}{d + 1} - \frac{d - 1 - r}{d + 1} \right) \mathbb{P}[T_r | C_i].
\]

Recall

\[
\mathbb{P}[T_{d-1} | C_i] = \frac{(d - 1) a}{\alpha 2^{d-1}}, \quad \mathbb{P}[T_r | C_i] = \frac{(d - 1) b(d - 1)}{\alpha 2^{d-1}}, \quad 0 \leq r \leq d - 2.
\]

A simple calculation implies \( \mathbb{E}[\sigma_j \sigma_{j'} | C_i] = \frac{\alpha}{\beta} \).

(b) If \( d(j, j') = t \) and there is a sequence of vertices \( j, j_1, \ldots, j_{t-1}, j' \) such that \( j_1 \) is a child of \( j \) and \( j_i \) is a child of \( j_{i-1} \) for \( 1 \leq i \leq t \) and \( j' \) is a child of \( j_{t-1} \). We can show that for \( t \geq 1 \), \( \mathbb{E}[\sigma_j \sigma_{j'} | C_i] = \left( \frac{\alpha}{\beta} \right)^t \).

When \( t = 1 \) this has been approved in part (a). Assume it is true for all \( j, j' \) with distance \( \leq t - 1 \). Then when \( d(j, j') = t \), we have

\[
\begin{align*}
\mathbb{E}[\sigma_j \sigma_{j'} | C_i] &= \mathbb{E}[\sigma_j \sigma_{j'} | \sigma_j = \sigma_{j_1}, C_i] \mathbb{P}(\sigma_j = \sigma_{j_1} | C_i) + \mathbb{E}[\sigma_j \sigma_{j'} | \sigma_j = -\sigma_{j_1}, C_i] \mathbb{P}(\sigma_j = -\sigma_{j_1} | C_i) \\
&= \left( \frac{\beta}{\alpha} \right)^{t-1} \mathbb{P}(\sigma_j = \sigma_{j_1} | C_i) - \left( \frac{\beta}{\alpha} \right)^{t-1} \mathbb{P}(\sigma_j = -\sigma_{j_1} | C_i) \\
&= \left( \frac{\beta}{\alpha} \right)^{t-1} \alpha + \beta - \left( \frac{\beta}{\alpha} \right)^{t-1} \alpha - \beta = \left( \frac{\beta}{\alpha} \right)^t.
\end{align*}
\]

This completes the proof for part (b).

(c) If \( j, j' \) are not in the same hyperedge and there exists a vertex \( k \) such that \( j, k \) satisfies the assumption in case (b) with \( d(j, k) = t_1 \) and \( j', k \) satisfies the assumption with \( d(j', k) = t_2 \). Conditioned on \( \sigma_k \), we know \( \sigma_j \) and \( \sigma_{j'} \) are independent. Then we have

\[
\begin{align*}
\mathbb{E}[\sigma_j \sigma_{j'} | C_i] &= \mathbb{E}[\mathbb{E}[\sigma_j \sigma_{j'} | \sigma_k, C_i] | C_i] \\
&= \mathbb{E} \mathbb{E}[\sigma_j \sigma_k | \sigma_k, C_i] \cdot \mathbb{E}[\sigma_{j'} \sigma_k | \sigma_k, C_i] | C_i \\
&= \left( \frac{\beta}{\alpha} \right)^{t_1 + t_2} \leq \left( \frac{\beta}{\alpha} \right)^{d(j,j')}.
\end{align*}
\]

where the last inequality follows from the triangle inequality \( d(j, k) + d(j', k) \geq d(j, j') \).

(d) If \( j, j' \) are in the same hyperedge, we bound \( \sigma_j \sigma_{j'} \) by 1. Combining cases (a)-(d) we have

\[
\mathbb{E}[\sigma_j \sigma_{j'} | C_i] \leq \left( \frac{\beta}{\alpha} \right)^{d(j,j') - 1}.
\]
Hence (7.16) holds. Therefore from (7.16) and (7.12)-(7.15),

\[
\begin{align*}
\mathbb{E}[X^2_{1} | C_i] &\leq \sum_{h,h'=0}^{l} \sum_{\tau=0}^{2(h+h')} \sum_{j: d(i,j)=2h, j': d(i,j')=2h'} 1_{d(j,j')=2(h+h'−\tau)} \mathbb{E}[\sigma_j \sigma_j' | C_i] R_{i,j} R_{i,j'} \\
&\leq \sum_{h,h'=0}^{l} \sum_{\tau=0}^{2(h+h')} \sum_{j: d(i,j)=2h, j': d(i,j')=2h'} 1_{d(j,j')=2(h+h'−\tau)} \left( \frac{\beta}{\alpha} \right)^{2(h+h'−\tau)−1} O(\alpha^{2l−h−h'} \log^2 n) \\
&\leq \sum_{h,h'=0}^{l} \sum_{\tau=0}^{2(h+h')} O(\alpha^{2h} \log n) \left( \frac{\beta}{\alpha} \right)^{2(h+h'−\tau)−1} O(\alpha^{2l−h−h'} \log^2 n) \\
&\leq \sum_{h,h'=0}^{l} \sum_{\tau=0}^{2(h+h')} O(\alpha^{2h} \log n) \cdot O(\alpha^{2h'} \log n) \left( \frac{\beta}{\alpha} \right)^{2(h+h'−\tau)} \cdot O(\alpha^{2l−h−h'} \log^2 n) \\
&= \sum_{h,h'=0}^{l} \sum_{\tau=0}^{2(h+h')} O(\alpha^{2l+2h+h'−\tau} \log^4 n) \left( \frac{\beta}{\alpha} \right)^{2(h+h'−\tau)} \\
&= \sum_{h,h'=0}^{l} \sum_{\tau=0}^{2(h+h')} O(\alpha^{2l} \log^4 n) \cdot (\beta^2/\alpha)^{h+h'−\tau} = O(\beta^{4l} \log^4 n). 
\end{align*}
\]

From (7.10) and (7.17), we have for some \( \epsilon > 0 \),

\[ \mathbb{E}[(||z||_2^2 | \Omega)] = n^{1−\epsilon} O(\alpha^{2l} \beta^{2l} \log^2 n) + O(n \beta^{4l} \log^2 n). \]

Then by Chebyshev’s inequality asymptotically almost surely

\[ ||z||_2 = O(n^{1/2−\epsilon/2} \alpha^l \log^2 n) + O(n^{1/2} \beta^{2l} \log^2 n) \\
= (\sqrt{n} \beta^l \log^2 n) \cdot O(\alpha^l n^{−\epsilon/2} + \beta^l) \\
= (\sqrt{n} \beta^l \log^2 n) \cdot O(\beta^l \lor \alpha^l n^{−\epsilon/2}). \]

Recall \( l = c \log n \). We have \( \beta^l = n^{c \log \beta}, \alpha^l = n^{c \log \alpha} \). So \( \beta^l = n^{−\epsilon'} \alpha^l \) for some \( \epsilon' > 0 \). Since from (9.19), \( ||B^{(l)} \sigma||_2 = \Theta(\sqrt{n} \beta^l) \), we have

\[ ||z||_2 = O(n^{−\gamma} \alpha^l ||B^{(l)} \sigma||_2) \]

for some \( \gamma > 0 \). Combining (7.8), it implies

\[ ||B^{(l)} B^{(l)} \sigma||_2 = ||z + z' + z''||_2 = O(n^{−\gamma} \alpha^l ||B^{(l)} \sigma||_2), \]

then the upper bound in (7.5) follows. \( \square \)

**Definition 7.3.** We say the the sequence of vectors \( \{v_n\}_{n \geq 1} \) is **asymptotically aligned** with the sequence of vectors \( \{w_n\}_{n \geq 1} \) if

\[ \lim_{n \to \infty} \frac{||\langle v_n, w_n \rangle||}{||v_n||_2 \cdot ||w_n||_2} = 1. \]

Together with Lemma 7.1 and Lemma 7.2, we establish the following weak Ramanujan property of \( B^{(l)} \).

**Theorem 7.4.** For \( l = c \log(n) \) with \( c \log(\alpha) < 1/8 \), asymptotically almost surely the two leading eigenvectors of \( B^{(l)} \) are asymptotically aligned with vectors \( \hat{S}_1, \hat{D}_1 \), where the first eigenvalue is of order \( \Theta(\alpha^l) \) up to some logarithmic factor and the second eigenvalue is of order \( \Omega(\beta^l) \). All other eigenvalues are of order \( O(n^{\epsilon^l/2}) \) for any \( \epsilon > 0 \).

**Proof.** From Theorem 4.12 and Lemma 7.2, the top two eigenvalues of \( B^{(l)} \) will be asymptotically in the span of \( B^{(l)} \mathbf{1} \) and \( B^{(l)} \sigma \). By the lower bound in (7.4) and the upper bound in (7.5), the largest eigenvalue of \( B^{(l)} \) will be \( \Theta(\alpha^l) \) up to a logarithmic factor, and the first eigenvector is asymptotically aligned with \( B^{(l)} \mathbf{1} \). From (7.1), \( B^{(l)} \mathbf{1} \) is also asymptotically aligned with \( \hat{S}_1 \), therefore our statement for the first eigenvalue and eigenvector holds.
Since \( B^{(i)} \) and \( B^{(i)} \sigma \) are asymptotically orthogonal from (7.3), together with (7.5), the second eigenvalue of \( B^{(i)} \) is \( \Omega(\beta^i) \) and the second eigenvector is asymptotically aligned with \( B^{(i)} \sigma \). From (7.2), \( B^{(i)} \sigma \) is asymptotically aligned with \( \bar{D} \). So the statement for the second eigenvalue and eigenvector holds. The order of other eigenvalues follows from Theorem 4.12 and the Courant minimax principle (see [21]).

\[
\square
\]

8. Proof of Main Results

Finally we prove our main result (Theorem 1.1). Let \( x^{(n)} \) be the \( l_2 \)-normalized second eigenvector of \( B^{(i)} \), by Theorem 7.4, \( x^{(n)} \) is asymptotically aligned with the \( l_2 \)-normalized vector

\[
y^{(n)}_i = \frac{D_i(i)}{\sqrt{\sum_{j=1}^n D_i(j)^2}}, 1 \leq i \leq n
\]

asymptotically almost surely. So we have \( \|x^{(n)} - y^{(n)}\|_2 \to 0 \) or \( \|x^{(n)} + y^{(n)}\|_2 \to 0 \) asymptotically almost surely. We first assume \( \|x^{(n)} - y^{(n)}\|_2 \to 0 \). Since \( E\Delta_{\infty} = 1 \), from the proof of Theorem 2.1 in [27], there exists a point \( \tau \in \mathbb{R} \), in the set of continuity points of both \( \Delta_{\infty} \) and \( -\Delta_{\infty} \), that satisfies

\[
r := \mathbb{P}(\Delta_{\infty} \geq \tau) - \mathbb{P}(-\Delta_{\infty} \geq \tau) > 0.
\]

Let \( t = \tau/\sqrt{\mathbb{E}(\Delta_{\infty}^2)} \), we have

\[
\frac{1}{n} \sum_{i \in [n]} \sigma_i \hat{\sigma}_i = \frac{1}{n} \sum_{i \in [n]} \sigma_i \left( \mathbb{1}_{\{x_i^{(n)} \geq \tau/\sqrt{n}\}} - \mathbb{1}_{\{x_i^{(n)} < \tau/\sqrt{n}\}} \right) = -\frac{1}{n} \sum_{i \in [n]} \sigma_i + \frac{2}{n} \sum_{i \in [n]} \sigma_i \mathbb{1}_{\{x_i^{(n)} \geq \tau/\sqrt{n\Delta_{\infty}^2}\}}
\]

(8.1)

\[
= \frac{1}{n} \sum_{i \in [n]} \sigma_i + 2 \left( \sum_{i \in \mathcal{N}^+} \mathbb{1}_{\{x_i^{(n)} \geq \tau/\sqrt{n\Delta_{\infty}^2}\}} - \sum_{i \in \mathcal{N}^-} \mathbb{1}_{\{x_i^{(n)} \geq \tau/\sqrt{n\Delta_{\infty}^2}\}} \right).
\]

Note that \( \frac{1}{n} \sum_{i \in [n]} \sigma_i \to 0 \) in probability by the law of large numbers. From (6.5), we have (8.1) converges in probability to \( \mathbb{P}(\Delta_{\infty} \geq \tau) - \mathbb{P}(-\Delta_{\infty} \geq \tau) = r \). If \( \|x^{(n)} + y^{(n)}\|_2 \to 0 \), similarly we have \( \frac{1}{n} \sum_{i \in [n]} \sigma_i \hat{\sigma}_i \) converges to \( -r \) in probability. From these two cases, for any \( \epsilon > 0 \),

\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( |\text{ov}_n(\hat{\sigma}, \sigma) - r| > \epsilon \right) \cap |\text{ov}_n(\hat{\sigma}, \sigma) + r| > \epsilon \right) = 0.
\]

This concludes the proof of Theorem 1.1.

9. Appendix

9.1. Proof of Theorem 4.3.

Proof: Assume all the estimates in statement of Theorem 4.7 hold. For \( t \leq l \), if \( t \leq T \), from the definition of \( T \), we have \( S_l, |D_l| = O(\log n) \). For \( t > T \), from [27], \( M \) satisfies

\[
M^k = \frac{1}{2} \begin{bmatrix} \alpha^k + \beta^k & \alpha^k - \beta^k \\ \alpha^k - \beta^k & \alpha^k + \beta^k \end{bmatrix}.
\]

Using (4.20) and (4.21), we have for \( t > t' \geq T \),

\[
S_t \leq \left( \prod_{s=t'}^{t-1} (1 + \epsilon_s) \right) (1, 1) M^{t-t'} \bar{U}_{t'} \leq \left( \prod_{s=t}^{t-1} (1 + \epsilon_s) \right) \alpha^{t-t'} S_{t'}.
\]

(9.1)

Similarly,

\[
S_t \geq \left( \prod_{s=t'}^{t-1} (1 - \epsilon_s) \right) (1, 1) M^{t-t'} \bar{U}_{t'} \geq \left( \prod_{s=t}^{t-1} (1 - \epsilon_s) \right) \alpha^{t-t'} S_{t'}.
\]

(9.2)

Setting \( t' = T \) in (9.1),

\[
S_t \leq \left( \prod_{s=T}^{t-1} (1 + \epsilon_s) \right) \alpha^{t-T} S_T = O(\alpha^{t-T} \log n) = O(\alpha^t \log n),
\]

(9.3)

Similarly,

\[
S_t \geq \left( \prod_{s=T}^{t-1} (1 - \epsilon_s) \right) \alpha^{t-T} S_T = O(\alpha^{t-T} \log n) = O(\alpha^t \log n).
\]

(9.4)
Recall (9.7), now we have for all $T \leq t' < l$,

\[
\left( \prod_{s=t'}^{t-1} (1 - \epsilon_s) \right) \alpha^{t-t'} S_{t'} \leq S_t \leq \left( \prod_{s=t'}^{t-1} (1 + \epsilon_s) \right) \alpha^{t-t'} S_{t'},
\]

and it implies

(9.3)

\[
\left( \prod_{s=t'}^{t-1} (1 - \epsilon_s) \right) S_{t'} \leq \alpha^{t-t'} S_t \leq \left( \prod_{s=t'}^{t-1} (1 + \epsilon_s) \right) S_{t'}
\]

Note that

\[
\text{max} \left\{ \prod_{s=t'}^{t-1} (1 + \epsilon_s) - 1, 1 - \prod_{s=t'}^{t-1} (1 - \epsilon_s) \right\} = O(\epsilon) = O(\alpha^{-t'/2}),
\]

together with (9.3), we have for all $T \leq t' < l$,

\[
\left( \prod_{s=t'}^{t-1} (1 - \epsilon_s) - 1 \right) S_{t'} \leq S_t - \alpha^{t-t'} S_t \leq \left( \prod_{s=t'}^{t-1} (1 + \epsilon_s) - 1 \right) S_{t'},
\]

which implies

(9.4)

\[
|S_{t'} - \alpha^{t-t'} S_t| \leq O(\alpha^{-t'/2}) S_{t'} = O(\alpha^{t'/2} \log n).
\]

On the other hand, for $t \leq T$, $S_t = O(\log n)$, and let $t' = T$ in (9.4), we have

(9.5)

\[
|S_T - \alpha^{T-t} S_t| = O(\alpha^{T/2} \log n).
\]

So we have for $1 \leq t \leq T$,

\[
|S_t - \alpha^{t-t} S_t| \leq O(\log n) + \alpha^{t-T}(\alpha^{T-t} S_t) = O(\log n) + \alpha^{t-T}(S_T + O(\log(n)\alpha^{T/2}))
\]

\[
= O(\log n) + O(\alpha^{T-t} \log n) = O(\alpha^{t/2} \log n).
\]

The last inequality comes from the inequality $t - T/2 \leq t/2$. Combining (9.4) and (9.6), we have proved (4.5) holds for all $1 \leq t \leq l$. Now we consider $D_t$. Using (4.20) and (4.21), we have

\[
U^{t+1}_{t+1} - U^{-1}_{t+1} \leq (1 + \epsilon_t)(\alpha + \beta/2 U^+ + \alpha - \beta/2 U^-) - (1 - \epsilon_t)(\alpha - \beta U^+ + \beta U^-),
\]

\[
\implies D_{t+1} \leq \beta(U^+ - U^-) + \alpha \epsilon_t (U^+ + U^-) = \beta D_t + \alpha \epsilon_t S_t.
\]

Similarly we have

\[
\beta D_t - \alpha \epsilon_t S_t \leq D_{t+1} \leq \beta D_t + \alpha \epsilon_t S_t.
\]

By iterating, we have for $l \geq t > t' \geq T$,

(9.7)

\[
|D_t - \beta^{t-t'} D_{t'}| \leq \sum_{s=t'}^{t-1} \alpha \beta^{s-t} \epsilon_s S_s.
\]

Recall $S_s = O(\log(n)\alpha^{s-T})$, $|D_T| = O(\log n)$, and $\epsilon_s = \alpha^{-(s-T)/2}$. Taking $t' = T$ in (9.7), we have for $t > T$,

\[
|D_t| \leq \beta^{t-T} |D_T| + \sum_{s=t'}^{t-1} \alpha \beta^{s-t} \epsilon_s S_s = O(\log(n)\beta^t) + O \left( \sum_{s=t'}^{t-1} \alpha \beta^{t-1-s} \log(n) \alpha^{(s-T)/2} \right).
\]

Since $1 < \alpha < \beta^2$,

\[
\sum_{s=t'}^{t-1} \alpha \beta^{t-1-s} \log(n) \alpha^{(s-T)/2} = \beta^{t-1} \alpha^{1-T/2} \log(n) \sum_{s=t'}^{t-1} \left( \frac{\alpha}{\beta^2} \right)^{s/2}
\]

\[
= \beta^{t-1} \alpha^{1-T/2} \log(n) O(\alpha^{T/2} \beta^{-T}) = O(\log(n) \beta^t),
\]

so we have $|D_t| = O(\log n \beta^t)$. The right side of (9.7) is of order

\[
\sum_{s=t'}^{t-1} \alpha \beta^{t-1-s} \alpha^{(s-T)/2} \log(n) = O(\log(n) \beta^{t-t'} \alpha^{t'/2}).
\]
Thus setting \( t = l \) in (9.7), for \( t > t' \geq T \), we have
\[
D_l - \beta^{l-t'} D_{t'} = O(\log(n)\beta^{l-t'} \alpha^{t'/2}),
\]
therefore
\[
D_{t'} = \beta^{t'-l} D_l + O(\log(n)\alpha^{t'/2})
\]
holds for all \( T \leq t' < l \). For \( t' < T \), we have \( D_{t'} = O(\log n) \) and
\[
|D_{t'} - \beta^{t'-l} D_l| \leq O(\log(n)) + \beta^{t'-T} T^{-1}|D_l| = O(\log(n)) + \beta^{t'-T} (|D_T| + O(\log(n)\alpha^{T/2}))
\]
\[
= O(\log(n)) + O(\beta^{t'-T} \alpha^{T/2} \log(n)) = O(\alpha^{t/2} \log(n)),
\]
where the last estimate is because \( \beta^{t'-T} < \alpha^{(t'-T)/2} \) under the condition that \( t' < T \). Altogether we have shown (4.6) holds for all \( 1 \leq t' \leq l \). This completes the proof of Theorem 4.3.

Proof of Lemma 4.10. Let \( i \notin B \) whose \( l \)-neighborhood contains no cycles. For any \( k \in [n] \) and any \( m \leq l \), there is a unique self-avoiding walk of length \( m \) from \( i \) to \( k \) if and only if \( d(i,k) = m \), so we have
\[
B_{ik}^{(m)} = 1_{d(i,k)=m}.
\]
For such \( i \) we have
\[
(B^{(m)} 1)_i = \sum_{k \in [n]} B_{ik}^{(m)} = \sum_{k \in [n]} 1_{d(i,k)=m} = S_m(i),
\]
\[
(B^{(m)} \sigma)_i = \sum_{k \in [n]} B_{ik}^{(m)} \sigma_k = \sum_{k:d(i,k)=m} \sigma_k = D_m(i).
\]
Then (59), (60) follows from Theorem 4.3. By Lemma 4.9, asymptotically almost surely all vertices in \( B \) have only one cycle in \( l \)-neighborhood. For any \( m \leq l \), \( i \in B \), since \( (B^{(m)} 1)_i = \sum_{k \in [n]} B_{ik}^{(m)} \), and only vertices at distance at most \( m \) from \( i \) can be reached by a self-avoiding walk of length \( m \) from \( i \), which will be counted in \((B^{(m)} 1)_i\). Moreover, for any \( k \in [n] \) with \( B_{ik}^{(m)} \neq 0 \), since the \( l \)-neighborhood of \( i \) contains at most one cycle, there are at most 2 self-avoiding walks of length \( m \) between \( i \) and \( k \). Altogether we know
\[
\sum_{k \in [n]} B_{ik}^{(m)} \leq 2 \sum_{\ell=0}^m S_{\ell}(i) = O(\alpha^m \log(n))
\]
asymptotically almost surely. Then (61) follows.

9.3. Proof of Corollary 4.11.

Proof. Let \( B \) be the set of vertices such that their \( l \)-neighborhood contains a cycle. Let \( x \) be a normed vector such that \( x^T B^{(l)} 1 = 0 \). We then have
\[
1^T B^{(m-1)} x = \sum_{i \in [n]} x_i (B^{(m-1)} 1)_i = \sum_{i \notin B} x_i S_{m-1}(i) + \sum_{i \in B} x_i (B^{m-1} 1)_i
\]
\[
= \sum_{i \notin B} x_i (\alpha^{m-1-l}(B^{(l)} 1)_i + O(\alpha^{m-1} \log(n))) + \sum_{i \in B} x_i (B^{m-1} 1)_i
\]
\[
= \sum_{i \notin B} x_i (\alpha^{m-1-l}(B^{(l)} 1)_i + O(\alpha^{m-1} \log(n))) - \sum_{i \in B} x_i (\alpha^{m-1-l}(B^{(l)} 1)_i + O(\alpha^{m-1} \log(n)))
\]
\[
+ \sum_{i \in B} x_i (B^{(m-1)} 1)_i. \tag{9.8}
\]

Since we have \( 1^T B^{(l)} x = 0 \), the first term in (9.8) satisfies
\[
\left| \sum_{i \notin [n]} x_i (\alpha^{m-1-l}(B^{(l)} 1)_i + O(\alpha^{m-1} \log(n))) \right| = \sum_{i \notin [n]} x_i O(\alpha^{m-1} \log n) = O(\sqrt{n} \alpha^{m-1} \log n),
\]
and
where the last inequality above is from Cauchy inequality. From Lemma 4.9, $|B| = O(\alpha^{2l} \log^4 n)$. For the second term in (9.8), recall from (4.61), for $m \leq l$, $|(B^{(m)}1)| = O(\alpha^m \log n)$, then by Cauchy inequality

\[ \left| \sum_{i \in B} x_i (\alpha^{m-1-l} (B^{(l)}1) + O(\alpha^{m-1} \log n)) \right| \leq \sqrt{|B|} O(\alpha^{m-1} \log n) = O(\alpha^{l+m-1} \log^3 n) \]

Similarly the third term satisfies

\[ \left| \sum_{i \in B} x_i (B^{(m-1)}1) \right| = O(\alpha^{l+m-1} \log^3 n). \]

Note that $\alpha^{l+m-1} \leq \alpha^{2l} \leq \alpha^{2c \log n} = n^{2c \log \alpha} = o(n^{1/2})$, altogether we have

\[ |1^T B^{(m-1)}x| = O(\sqrt{n \alpha^{m-1}} \log n + \alpha^{l+m-1} \log^3 n) = O(\sqrt{n \alpha^{m-1}} \log n). \]

(4.62) then follows. Using the property $x^T B^{(i)} \sigma = 0$ instead of $x^T B^{(i)} 1 = 0$ and follows the same argument, (4.63) follows.

\[ \square \]

9.4. Proof of Theorem 6.3.

\textbf{Proof.} From Theorem 5.3, For each $i \in [n]$, there exists a coupling such that with probability $1 - O(n^{-\epsilon})$ for some positive $\epsilon$, $\beta^{-1} \sigma(i) D_i(i) = \Delta_i$ and we denote this event by $C$. When the coupling fails, by Theorem 4.3, $\beta^{-1} \sigma(i) D_i(i) = O(\log(n))$ with probability $1 - O(n^{-\gamma})$ for some $\gamma > 0$. Recall the event:

\[ \Omega_{k-1}(i) := \{ S_{k-1}(i) \leq C \log(n) \alpha^{k-1} \}. \]

and we define

\[ \Omega := \bigcap_{i=1}^n \Omega(i), \quad \Omega(i) := \bigcap_{k \leq \ell} \Omega_k(i). \]

We have

\[ \mathbb{E} \left( \frac{1}{n} \sum_{i=1}^n \beta^{-2l} D_i^2(i) \mid \Omega \right) = O(\log^2(n)) n^{-\epsilon} + \mathbb{E}(\Delta_i^2 1_C \mid \Omega). \]

Moreover,

\[ \mathbb{E}(\Delta_i^2 1_C \mid \Omega) = \mathbb{E}(\Delta_i^2 1_C - \mathbb{E}(\Delta_i^2 1_C 1_\Omega) - \mathbb{P}(\Omega) \mathbb{E}(\Delta_i^2 1_{\Omega^c})). \]

(9.12)

Since we know $\mathbb{P}(\Omega \cap C) \rightarrow 1$ and (6.2), we have the first two terms in (9.12) converges to 0. The third term also converges to 0 by dominated convergence theorem. So we have

\[ \mathbb{E} \left( \frac{1}{n} \sum_{i=1}^n \beta^{-2l} D_i^2(i) \mid \Omega \right) \rightarrow \mathbb{E}(\Delta_i^2). \]

We then estimate the second moment. Note that

\[ \mathbb{E} \left( \frac{1}{n} \sum_{i=1}^n \beta^{-2l} D_i^2(i) \mid \Omega \right)^2 = \frac{1}{n^2} \mathbb{E} \left( \sum_{i=1}^n \beta^{-4l} D_i^4(i) \mid \Omega \right) + \frac{2}{n^2} \sum_{i < j} \beta^{-4l} \mathbb{E}(D_i(i) D_j(j) \mid \Omega), \]

and from Theorem 4.3, the first term is $O(\log^4(n)/n) = o(1)$. Next we show the second term

\[ \frac{2}{n^2} \sum_{i < j} \beta^{-4l} \mathbb{E}(\mathbb{1}_\Omega D_i(i) D_j(j) \mid \Omega) = \frac{2}{n^2} \sum_{i < j} \beta^{-4l} \frac{1}{\mathbb{P}(\Omega)} \mathbb{E}(\mathbb{1}_\Omega D_i(i) D_j(j)) = o(1). \]

Since $\mathbb{P}(\Omega) = 1 - O(n^{-\gamma})$, it suffices to show

\[ \frac{2}{n^2} \sum_{i < j} \beta^{-4l} \mathbb{E}(\mathbb{1}_\Omega D_i(i) D_j(j)) = o(1). \]
Now consider $\beta^{-4l}E(1_{\Omega(i) \cap \Omega(j)} D_l^2(i) D_l^2(j))$. From Lemma 4.8, when $i \neq j$, $D_l(i)$, $D_l(j)$ are asymptotically independent. On the event that the coupling with independent copies fails (recall the failure probability is $O(n^{-\gamma})$), we bound $D_l^2(i) D_l^2(j)$ by $O(\beta^{4l} \log^4(n))$. When the coupling succeeds, $\beta^{-4l}E(1_{\Omega(i) \cap \Omega(j)} D_l(i)^2 D_l(j)^2)$ is equal to $\beta^{-4l}E(1_{\Omega(i)} D_l(i)^2)E(1_{\Omega(j)} D_l(j)^2)$. Then from (6.3),

$$\frac{2}{n^2} \sum_{i<j} \beta^{-4l}E(1_{\Omega(i) \cap \Omega(j)} D_l(i)^2 D_l(j)^2) = O \left( \frac{1}{n^2} \sum_{i<j} \beta^{-4l}E(1_{\Omega(i)} D_l(i)^2)E(1_{\Omega(j)} D_l(j)^2) + O(n^{-2\gamma} \log^4 n) \right)$$

(9.15) $$= O \left( \left( \mathbb{E}(\Delta_{\infty}^2) \right)^2 \right) = O(1).$$

So we have from (9.13), (9.14), and (9.15),

$$\mathbb{E} \left( \frac{1}{n} \sum_{i=1}^{n} \beta^{-2l} D_l^2(i) \mid \Omega \right)^2 = O(1)$$

Therefore with (9.11), by Chebyshev’s inequality, conditioned on $\Omega$, in probability we have

$$\lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{n} \beta^{-2l} D_l^2(i) = \mathbb{E}(\Delta_{\infty}^2).$$

Since $\mathbb{P}(\Omega) \to 1$, (6.3) follows. We now establish (6.5). Without loss of generality we discuss the case of + sign. Since $\tau$ is a continuous point of the distribution of $\Delta_{\infty}$, for any fixed $\delta > 0$, we can find two bounded $K$-Lipschitz function $f, g$ for some constant $K > 0$ such that

$$f(x) \leq 1_{x \geq \tau} \leq g(x), x \in \mathbb{R}$$

and

$$0 \leq \mathbb{E}(g(\Delta_{\infty}) - f(\Delta_{\infty})) \leq \delta.$$

Consider the empirical sum $\frac{1}{n} \sum_{i \in N^+} f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}), we have

$$\left| \frac{1}{n} \sum_{i \in N^+} f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) - \frac{1}{n} \sum_{i \in N^+} f(\beta^{-l} D_l(i)) \right| \leq \frac{1}{n} \sum_{i \in N^+} \left| f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)} - \sum_{i \in N^+} f(y_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) \right| + \frac{1}{n} \sum_{i \in N^+} \left| f(y_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) - \sum_{i \in N^+} f(\beta^{-l} D_l(i)) \right|

\leq \frac{K}{n} \sum_{i \in N^+} \left| (x_i^{(n)} - y_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) \right| + \frac{K}{n} \sum_{i \in N^+} \left| y_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)} - \beta^{-l} D_l(i) \right|

The first term converges to 0 by the assumption that $\|x - y\| \to 0$ in probability. The second term converges to 0 in probability from (6.3). Moreover $\frac{1}{n} \sum_{i \in N^+} f(\beta^{-l} D_l(i))$ converges in probability to $\frac{1}{2} \mathbb{E} f(\Delta_{\infty})$. So we have

(9.16) $$\lim_{n \to \infty} \frac{1}{n} \sum_{i \in N^+} f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) = \frac{1}{2} \mathbb{E} f(\Delta_{\infty}),$$

and the same holds for $g$. If follows that

$$\lim_{n \to \infty} \left| \frac{1}{n} \sum_{i \in [n]; \sigma_i = +} 1_{\{x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}(\Delta_{\infty})} \}} - \frac{1}{2} \mathbb{P}(\Delta_{\infty} \geq \tau) \right| \leq \delta$$

for any $\delta > 0$, therefore (6.5) holds.
9.5. Proof of Lemma 7.1.

Proof. In (7.1), the coordinates of two vectors on the left hand side agree at $i$ if the $l$-neighborhood of $i$ contains no cycle. Recall $B$ is the set of vertices whose $l$-neighborhood contains a cycle, from Lemma 4.9, and (4.61), we have asymptotically almost surely,

$$
\|B^{(i)}1 - S_i\|_2 \leq \sqrt{|B|O(\log(n) \alpha^l)} = O(\log^3(n) \alpha^{2l}) = o(\sqrt{n}).
$$

From (6.3) we have

$$
\|\tilde{D}_i\|_2 = \Theta(\sqrt{n} \beta^l)
$$
asymptotically almost surely, and $\|B^{(i)}1\|_2 \geq \|\tilde{D}_i\|_2$, therefore (7.1) follows. Similar to (9.17), we have

$$
\|B^{(i)}\sigma - \tilde{D}_i\|_2 = o(\sqrt{n}), \quad \|B^{(i)}\sigma\|_2 = \|\tilde{D}_i\|_2 + o(\sqrt{n}) = \Theta(\sqrt{n} \beta^l).
$$

Then (7.2) follows. It remains to show (7.3). Using the same argument as in Theorem 6.3, we have the following convergence in probability

$$
\lim_{n \to \infty} \frac{1}{n} \sum_{i \in [n]} \alpha^{-2l}S^2(i) = \mathbb{E}M^2_{\infty},
$$
where $M_{\infty}$ is the limit of the martingale $M_i$. Similarly, the following convergences in probability hold

$$
\lim_{n \to \infty} \frac{1}{n} \sum_{i \in [n]} \alpha^{-l} \beta^{-l}S(i)D_i(i) = \lim_{n \to \infty} \frac{1}{n} \sum_{i \in N^+} \alpha^{-l} \beta^{-l}S(i)D_i(i) + \lim_{n \to \infty} \frac{1}{n} \sum_{i \in N^-} \alpha^{-l} \beta^{-l}S(i)D_i(i)
$$

$$
= \frac{1}{2} \mathbb{E}M_{\infty}D_{\infty} - \frac{1}{2} \mathbb{E}M_{\infty}D_{\infty} = 0.
$$

Thus $\langle \tilde{S}_i, \tilde{D}_i \rangle = o(n \alpha^l \beta^l)$ asymptotically almost surely. From (9.20) we have

$$
\|\tilde{S}_i\|_2 = \Theta(\sqrt{n} \alpha^l),
$$
therefore together with (9.18), we have

$$
\|\tilde{S}_i\|_2 \cdot \|\tilde{D}_i\|_2 = \Theta(n \alpha^l \beta^l).
$$
together with (7.1) and (7.2), we have (7.3) holds. \qed
