In the original round-robin differential-phase-shift (RRDPS) quantum key distribution and its improved method, the photon-number-resolving detectors are must for the security. We present a RRDPS protocol with yes-no detectors only. We get the upper bounds of mutual information of Alice and Eve, and Bob and Eve, and the formula of key rate. Our main idea is to divide all counts into two classes, the counts due to the odd number of photons incident to the detectors and the counts due to the even number photons incident to the detectors. The fact that the bit-flip error rate of the later class is certainly 50% makes it possible for us to perform a tightened estimation of the upper bound of the leakage information. The robustness of original RRDPS against source flaws such as side-channel attacks still holds for the RRDPS with yes-no detectors. The simulation results show that the key rate of RRDPS with yes-no detectors is close to that of RRDPS with photon-number-resolving detectors. Our results make the RRDPS protocol much more practical.

Introduction Quantum key distribution (QKD) provides a information-theoretical secure key distribution method between two parties, Alice and Bob, and the security is based on the laws of quantum physics. Since Bennett and Brassard proposed the first QKD protocol [1], BB84 protocol, many new QKD protocols [2–12] and improved methods [13–15] have been proposed to assure the security with imperfect devices and improve the key rate. The key of those QKD's security is that any eavesdropping of Eve would introduce disturbances, and we could evaluate the upper bound of leakage information according the disturbances. Surprisingly, a QKD protocol named round robin differential phase shift ((RRDPS)) QKD protocol [16] was proposed in which the leakage information could be evaluated without monitoring any signal disturbance. This is so remarkable that has attracted many attentions [17–22]. Not only has it greatly simplified to realization in practice because there is no bases-switching, but also improved the security in side-channel aspect [20]. Notabaly, Yin et al. [21] proposed a tighter upper bound of leakage information and greatly improved the key rate especially with small L compared with the original RRDPS.

The detectors used in original RRDPS [16, 21, 22] are photon-number-resolving (PNR) detectors. This limits the practical application of RRDPS. Thus it is crucially important to study the RRDPS protocol with yes-no detectors only. Here we propose such a RRDPS protocol. Our main idea is to divide all counts into two classes, the counts due to the odd number photons incident to the detectors and the counts due to the even number photons incident to the detectors. The fact that the bit-flip error rate of the later class is certainly 50% makes it possible for us to perform a tightened estimation of the upper bound of the leakage information.

This paper is arranged as follows. We first introduce the original RRDPS protocol. We then present the main results of the upper bound of leakage information and the formula of key rate of RRDPS with yes-no detectors. After that, we present some numerical results of RRDPS with yes-no detectors and compare with RRDPS with PNR detectors. The article ends with some concluding remarks.

Main Results As shown in Figure. 3, in the original RRDPS protocol [16], the communication parties are Alice and Bob. Alice first prepares a train of L pulses and randomly modulates their phases into 0 or π . If Alice's source is single-photon source, she will finally prepare the state as

$$|\Psi\rangle_A = \frac{1}{\sqrt{L}} \sum_{i=1}^L (-1)^{k_i} |i\rangle, \quad (1)$$

where $|i\rangle$ denotes there is one photon in the i th pulse and k_i is randomly 1 or 0. If Alice's source is weak coherent state source, the final state she prepares is

$$|\Psi\rangle'_A = \otimes_{i=1}^L |(-1)^{k_i} \alpha\rangle, \quad (2)$$

where $|\alpha\rangle$ denotes there is a weak coherent state pulse with intensity $|\alpha|^2$ in location i . Then Alice sends this L -pulses train to Bob, and Bob performs interference measurement to the incoming pulses with the set-up shown in Figure. 3.

FIG. 1: Alice first prepares a train of L pulses and randomly modulates their phases into 0 or π and sends this pulses to Bob. Bob performs interference measurement to the incoming pulses with the set-up above. In this set-up, the two detectors are PNR detectors and the delay module will randomly produce $r(r \in [1, L - 1])$ delay. If only one detector response one time in the whole detection process, we call this L -pulses train caused a count and Alice and Bob will record the corresponding bit as the sifted key.

In this set-up, the two detectors are PNR detectors and the delay module will randomly produce $r(r \in [1, L - 1])$ delay. If only one detector responses one time in the whole detection process, we call this L -pulses train causes a count and Bob will announce the detection result $\{a, b\}$, $b = a + r \pmod{L}$ to Alice through a public channel. Bob records the measured phase difference as his sifted key bit S_B and Alice records $S_A = k_a \oplus k_b$ as her sifted key bit.

In the original RRDPS protocol, to evaluate the maximum leakage information, the PNR detectors are needed [16, 21, 22], or else the formula of key rate will no longer hold. But as so far, the technology of PNR detectors are difficult. Here we study the maximum leakage information and key rate formula if the two detectors are yes-no detectors in Figure. 3. We take the single photon case as an example to briefly introduce our conclusions, and the other cases and detailed proof is shown in Supplementary materials.

Inspired by Ref. [21], Eve's optimal collective attack can be given by the following equation if Alice prepares her state as Eq. (22):

$$U_{eve}|i\rangle|e_{000}\rangle = \sum_{n=0}^{\infty} \sum_{j=1}^L c_{ijn} |n_j\rangle |e_{ijn}\rangle, \quad (3)$$

where $|e_{000}\rangle$ is the initial state of Eve's ancilla bits; $|e_{ijn}\rangle$ is the final state of Eve's ancilla state after attacking and $|n_j\rangle$ represents there are n photons in the j th pulse. The coefficient c_{ijn} satisfies $\sum_{n=0}^{\infty} \sum_{j=1}^L |c_{ijn}|^2 = 1$. While considering the leakage information, only the states of $n = 1$ work if the detectors are PNR detectors, and this is just the case of Ref. [21]. But if the detectors are yes-no detectors, we have to take all the $n > 0$ states into consideration.

Consider the mutual information of Alice and Eve, I_{AE} , we have that the state of Alice and Eve after Eve's attacking is

$$|\Psi\rangle_{AE} = \sum_{n=0}^{\infty} \sum_{i=1}^L \sum_{j=1}^L (-1)^{k_i} c_{ijn} |n_j\rangle |e_{ijn}\rangle. \quad (4)$$

If Bob measures such an incoming state and announces $\{a, b\}$, the density matrix (non-normalized) of Eve's ancilla bits will be [23]

$$\begin{aligned} \rho_E = \frac{1}{2} \sum_{n=1}^{\infty} \{ & P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n}] \\ & + P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} (-1)^n \frac{\tilde{c}_{ibn}}{2^n}] \}, \end{aligned} \quad (5)$$

where $P(|x\rangle) \equiv |x\rangle\langle x|$ and $\tilde{c}_{ijn} \equiv c_{ijn}|e_{ijn}\rangle$. The first part of Eq. (27) is caused by detector D_1 , and the second part is caused by detector D_2 . We find that the upper bounds of I_{AE} corresponding to $n = 1, 3, 5, \dots$ and $n = 2, 4, 6, \dots$ are totally different. Here we call the counting events of $n = 1, 3, 5, \dots$ as odd-counts and the counting events of $n = 2, 4, 6, \dots$ as even-counts.

If the single photon pulses train causes an odd-count, the density matrix of Eve is

$$\rho_E^{Odd} = \sum_{n=Odd} \{P[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ian}}{2^n}] + P[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ibn}}{2^n}]\}. \quad (6)$$

The value of $k_i (i \neq a, b)$ is randomly 0 or 1, thus we can average ρ_E^{Odd} with random $k_i (i \neq a, b)$ to simplify the calculation. Without compromising the security, we can assume

$$\langle e_{ijn} | e_{klm} \rangle = \delta_{ik} \delta_{jl} \delta_{nm}. \quad (7)$$

Finally only the states $P[\frac{\tilde{c}_{aan}}{2^n} \pm \frac{\tilde{c}_{ban}}{2^n}]$ and $P[\frac{\tilde{c}_{abn}}{2^n} \pm \frac{\tilde{c}_{bbn}}{2^n}]$ accounts for the Holevo bound which measures the maximum mutual information of two parties if they share a system in quantum information. Thus we can get the upper bound of I_{AE}

$$I_{AE}^{Odd} \leq \phi(1, L) = \text{Max}_{x_1, x_2} \frac{\varphi((L-1)x_1, x_2)}{L-1}, \quad (8)$$

where $\varphi(x, y) = -x \log_2 x - y \log_2 y + (x+y) \log_2 (x+y)$ and $x_1 + x_2 = 1$. Note that the assumption of Eq. (34) would certainly introduce 50% bit-flip error rate, thus Eq. (8) shows that the maximum leakage information of odd-counts is limited even if Eve's attack is optimal and introduces 50% bit-flip error rate. And in general case, $\phi(1, L) < H(\frac{1}{L-1})$, where $H(x)$ is Shannon entropy, $H(x) = -x \log_2 x - (1-x) \log_2 (1-x)$, and $H(\frac{1}{L-1})$ is the upper bound of leakage information proposed in original RRDPS [16].

In Supplementary materials, we prove that if the single photon pulses train causes an even-count, the upper bound of I_{AE}^{Even} equals 1. Dose this mean that we can not extract any secure final keys if we don't know whether the counts is an odd-count or even-count? Luckily, the answer is no. We next consider the mutual information of Bob and Eve, I_{BE} . If the count $\{a, b\}$ is detected by D_1 , the density matrix of Eve is

$$\rho_E^{D_1} = \sum_{n=1} P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n}]. \quad (9)$$

If the count $\{a, b\}$ is detected by D_2 , the density matrix of Eve is

$$\rho_E^{D_2} = \sum_{n=1} P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} (-1)^n \frac{\tilde{c}_{ibn}}{2^n}]. \quad (10)$$

From Eqs. (52) and (55), it is easy to see that $\rho_E^{D_1}$ and $\rho_E^{D_2}$ are the same if n are even numbers, which means Eve can not distinguish whether an even-count is caused by D_1 or D_2 at all, thus $I_{BE}^{Even} = 0$. Different from the situation of I_{AE}^{Odd} , this result needs not the average of random phase and orthogonality assumption Eq. (34). If the single photon cause an odd-count, the upper bound of I_{BE}^{Odd} equals 1. The detailed proof of single photon case and other general cases are shown in Supplementary materials.

We list the main results as following:

If Alice sends out a train of L pulses contained $N (N \leq \frac{L}{2})$ photons, and Bob announces this pulses train causes a count, the upper bounds of mutual information of Alice and Eve, I_{AE} , and the mutual information of Bob and Eve, I_{BE} , are

$$I_{AE}^{Odd}(N) \leq \phi(N, L), \quad I_{BE}^{Even}(N) = 0, \quad (11)$$

where

$$\phi(N, L) = \max_{x_1, x_2, \dots, x_{N+1}} \left\{ \frac{\sum_{k=1}^N \varphi((L-k)x_k, kx_{k+1})}{L-1} \right\}, \quad (12)$$

and $\sum_{k=1}^{N+1} x_k = 1$. And $I_{AE}^{Even} = 1, I_{BE}^{Odd} = 1$.

In short, **I.** If the train causes an odd-count, the maximum mutual information of Alice and Eve is $\phi(N, L)$, but the maximum mutual information of Bob and Eve is 1. **II.** If the train causes an even-count, the maximum mutual information of Bob and Eve is 0, but the maximum mutual information of Alice and Eve is 1. This means if the

final counts contain many odd-counts, the mutual information of Alice and Eve is relatively small while the mutual information of Bob and Eve is pretty large, and vice versa. Thus if the error correction step is based on Alice's or Bob's sifted raw key bits, the final key bits we extract must be zero, since we have no idea about the ratio of odd-counts or even-counts. But if the sifted raw key bits are randomly split into two parts, the first part accounts for γ , and the second part accounts for $1 - \gamma$. The error correction of the first part is based on Alice's sifted raw key bits and the second part is based on Bob's sifted raw key bits. The final key rate is

$$LR = \max_{\gamma} \{ \gamma \max[I_{AB} - I_{AE}, 0] + (1 - \gamma) \max[I_{AB} - I_{BE}, 0] \}. \quad (13)$$

And in general case, at least one of $I_{AB} - I_{AE}$ and $I_{AB} - I_{BE}$ is greater than zero.

If Alice's source is weak coherent state source, and she randomly modulates the mutual phase the different pulses in the train, the state that she prepares is equivalent to the classical mixture of different photon numbers. And the density matrix of the pulses train with intensity μ in photon number space is

$$\rho(\mu) = \sum_{k=0} a_k |k\rangle \langle k|, \quad a_k = \frac{\mu^k e^{-\mu}}{k!}. \quad (14)$$

We denote the total counting rate and error rate of the L -pulses train are Q and E , and the counting rate and error rate of k -photons L -pulses train are Y_k and e_k , in which the ratio of odd-counts is α_k and even-counts is $\beta_k = 1 - \alpha_k$, we have

$$\begin{aligned} I_{AE} &\leq \sum_{n=1} a_n Y_n [\alpha_n \phi(n, L) + \beta_n] \\ &= \sum_{n=1}^{n_{th}} a_n Y_n [\alpha_n \phi(n, L) + \beta_n] + \sum_{n > n_{th}} a_n Y_n \\ &\leq \alpha(Q - e_{src}) \phi(n_{th}, L) + \beta(Q - e_{src}) + e_{src}, \end{aligned} \quad (15)$$

where $e_{src} = \sum_{n > n_{th}} a_n$ and $\alpha + \beta = 1$. We use a fact in the last step of Eq. (15)

$$\sum_{n=0}^{n_{th}} a_n Y_n \alpha_n + \sum_{n=0}^{n_{th}} a_n Y_n \beta_n = \sum_{n=0}^{n_{th}} a_n Y_n \geq Q - e_{src}.$$

And similarly we have

$$I_{BE} \leq \alpha(Q - e_{src}) + e_{src}. \quad (16)$$

Here the n_{th} is the boundary of tagged photons ($n > n_{th}$) and untagged photons ($n \leq n_{th}$) and will be an optimized parameters in the simulation parts to get a better key rate.

The Eqs. (52) and (55) show us an important fact that if a single photon count is an even-count, its bit-flip error rate definitely is $1/2$, whether Eve attacks it or not. This is different from the case of odd-counts, where the bit-flip error rate is $1/2$ only if Eve attacks all the key bits with his optimal attack strategy. And we show that this fact holds for any k -photon counts in Supplementary materials. In fact, we can assume Eve's attacks introduce e_k^{odd} bit-flip error rate of the odd-counts, and we have

$$\alpha_k e_k^{odd} + \frac{1}{2} \beta_k = e_k, \quad (17)$$

which implies $\beta_k \leq 2e_k$. Thus we have $\beta(Q - e_{src}) \leq 2EQ$, which implies

$$\alpha \geq 1 - \frac{2EQ}{Q - e_{src}}, \quad (18)$$

if $Q - e_{src} > 0$.

Combine Eqs. (13)-(16) and we could get the final key rate with observable values of experiment. Finally, we have the following formulas of final key rate

$$\begin{aligned} LR &= \max_{\gamma} \min_{\alpha} \{ \gamma \max[R_1(\alpha), 0] + (1 - \gamma) \max[R_2(\alpha), 0] \}, \\ s.t. \quad &1 - \frac{2EQ}{Q - e_{src}} \leq \alpha \leq 1, \quad 0 \leq \gamma \leq 1 \\ R_1(\alpha) &= \alpha(Q - e_{src})(1 - \phi(n_{th}, L)) - fQH(E), \\ R_2(\alpha) &= (1 - \alpha)(Q - e_{src}) - fQH(E). \end{aligned} \quad (19)$$

TABLE II: List of optimal parameters and the corresponding key rate in different misalignment-error probability, E_d . Here, we set the distance between Alice and Bob is 100 km, and μ : the intensity of the phase-randomized weak coherent state pulses train; α_{min} : the min value of α constrained by Eq. (18); α_{best} : the optimal value of α according to our optimized algorithm; γ : the accounts of the part that the error correction is based on Alice's data, and defined in Eq. (13); L : the length of the pulses train; n_{th} : the boundary of tagged and untagged photons; R : the final key rate.

Numerical Simulation We then show some numerical results and compare with the results of RRDPS with PNR detectors [21]. To clearly show the advantage of our method, we assume the properties of Bob's yes-no detectors and PNR detectors including the repetitive rate, detection efficiency and dark counting rate, are the same. Besides, we assume the PNR detectors could discriminate the single photon from zero, two or more photons perfectly. The performance parameters of the detectors and other experiment devices are list in Table. I. We use the linear model to simulate the observed values of the counting rate, Q , and error rate, E , of the L -pulses train, and the detailed of our numerical simulation method are shown in the Supplementary materials.

We list some optimal parameters and their corresponding key rate under different misalignment-error probability, E_d , in Table. II. Here we set the distance between Alice and Bob is 100 km. The data in Table. II show that the while $E_d = 1.5\%$, 3.0% , 6.0% , 10.0% , optimal $\gamma = 1$ and $\alpha_{best} = \alpha_{min}$, where α_{min} is the min value of α constrained by Eq. (18) and α_{best} is the optimal value of α according to our optimized algorithm. This implies that we can always

FIG. 2: The key rates of the original RRDPS with PNR detectors and our protocol with yes-no detectors versus the distance between Alice and Bob. The green line is the decent degree of the RRDPS with yes-no detectors compared with the key rate of RRDPS with PNR detectors. Here we set the misalignment-error probability, E_d , as 1.5%.

set $\gamma = 1$ and $\alpha = 1 - \frac{2EQ}{Q - e_{src}}$ in the key rate formula of Eq. (85). Besides, we have the following fact that:

$$\begin{aligned} & \max_{\gamma} \min_{\alpha} \{ \gamma \max[R_1(\alpha), 0] + (1 - \gamma) \max[R_2(\alpha), 0] \} \\ & \geq R_1 \left(1 - \frac{2EQ}{Q - e_{src}} \right), \end{aligned}$$

where α is in the range constrained by Eq. (85). Thus without comprising the security, we can rewrite the formula of key rate in Eq. (85) as

$$LR = [(1 - 2E)Q - e_{src}][1 - \phi(n_{th}, L)] - fQH(E). \quad (20)$$

And in general case, the key rate calculated by Eq. (20) is the same as Eq. (85) with the same experiment conditions.

Fig. 2 shows the key rates of the original RRDPS with PNR detectors and our protocol with yes-no detectors versus the distance between Alice and Bob, where we set the misalignment-error probability, E_d , as 0.015. The blue solid line is the results of RRDPS with PNR detectors and the red dashed line is the results of RRDPS with yes-no detectors. Those two line is almost overlapped except the tail of the lines. The green solid line is the decent degree of the RRDPS with yes-no detectors compared with the key rate of RRDPS with PNR detectors, which clearly shows that their key rates differ less than 10% with the distance of Alice and Bob range in 0 – 175 km. This results are intuitive since the formula of key rate with PNR detectors proposed in Ref. [21] is

$$LR_{PNR} = (Q - e_{src})[1 - \phi(n_{th}, L)] - fQH(E). \quad (21)$$

The only difference between Eq. (20) and Eq. (21) is the coefficient, $1 - 2E$, of Q . Thus the results of RRDPS with yes-no detectors and PNR detectors are almost the same if the bit-flip error rate E is small.

Conclusion We present a protocol for RRDPS with yes-no detectors and the upper bounds of mutual information of Alice and Eve, and Bob and Eve as shown in Eq. (11). We present the formula of key rate of RRDPS with yes-no detectors by Eqs. (85) and (20). Our main idea is to divide all counts into two classes, the counts due to the odd number photons incident to the detectors and the counts due to the even number photons incident to the detectors. The fact that the bit-flip error rate of the later class is certainly 50% makes it possible for us to perform a tightened estimation of the upper bound of the leakage information. The major advantages of the original RRDPS protocol, the realization simplicity without bases switching and the source side-channel-free property hold in our protocol. The simulation results show that the key rate of RRDPS with yes-no detectors is close to that of RRDPS with PNR detectors.

I. SUPPLEMENTARY MATERIALS

II. THE UPPER BOUND OF LEAKAGE INFORMATION IN THE SINGLE-PHOTON CASE

As shown in Figure. 3, Alice first prepares a train of L pulses and randomly modulate their phases. If Alice's source is single-photon source, the state she finally prepares is

$$|\Psi\rangle_A = \frac{1}{\sqrt{L}} \sum_{i=1}^L (-1)^{k_i} |i\rangle, \quad (22)$$

where $|i\rangle$ denotes there is one photon in the i th pulse and k_i is randomly 1 or 0. Inspired by the method of evaluating the upper bound of leakage information in Ref. [21], Eve's optimal collective attack can be given by the following equation for the state shown in Eq. (22):

$$U_{eve}|i\rangle|e_{000}\rangle = \sum_{n=0}^{\infty} \sum_{j=1}^L c_{ijn} |n_j\rangle |e_{ijn}\rangle, \quad (23)$$

where $|e_{000}\rangle$ is the initial state of Eve's ancilla bits; $|e_{ijn}\rangle$ is the final state of Eve's ancilla bits after attacking and $|n_j\rangle$ denotes there are n photons in location j . The coefficient c_{ijn} satisfies $\sum_{n=0}^{\infty} \sum_{j=1}^L |c_{ijn}|^2 = 1$. After Eve's attacking, the state of Alice and Eve (unnormalized) is

$$|\Psi\rangle_{AE} = \sum_{n=0}^{\infty} \sum_{i=1}^L \sum_{j=1}^L (-1)^{k_i} c_{ijn} |n_j\rangle |e_{ijn}\rangle. \quad (24)$$

FIG. 3: Experiment set-ups of RRDPs. Alice first prepares a train of L pulses and randomly modulates their phases. Then Alice sends this L -pulses train to Bob, and Bob performs interference measurement to the incoming pulses. If this L -pulses train causes a count, Bob will announce the location of this counts $\{a, b\}$. Bob records the measured phase difference as his sifted key bit S_B and Alice records $S_A = k_a \oplus k_b$ as her sifted key bit.

Through Bob's detection set-up, the state of Eq. (24) is involved into

$$\rightarrow \sum_{ijn} (-1)^{k_i} \tilde{c}_{ijn} \frac{\hat{d}_j^{\dagger, n}}{\sqrt{n!}} |0\rangle, \quad (25)$$

$$\rightarrow \sum_{ijn} (-1)^{k_i} \tilde{c}_{ijn} \frac{1}{2^n \sqrt{n!}} (\hat{d}_{j+r}^{\dagger} + \hat{e}_{j+r}^{\dagger} + \hat{d}_j^{\dagger} - \hat{e}_j^{\dagger})^n |0\rangle \equiv |\Psi\rangle_{AE}^{detect}, \quad (26)$$

where $\tilde{c}_{ijn} \equiv c_{ijn} |e_{ijn}\rangle$ and r is randomly chosen from $1, 2, \dots, L-1$.

A. The mutual information of Alice and Eve

We first consider the upper bound of mutual information of Alice and Eve, I_{AE} . If only one of Bob's detectors responses in location k , then only the states with superscript $j = k - r$ or $j = k$ account. We denote $a = k - r$ and $b = k$, the density matrix of Eve's ancilla bits is

$$\rho_E = \frac{1}{2} \sum_{n=1} \left\{ P \left[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n} \right] + P \left[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} (-1)^n \frac{\tilde{c}_{ibn}}{2^n} \right] \right\} \quad (27)$$

where $P(|x\rangle) \equiv |x\rangle\langle x|$. The first part of Eq. (27) is caused by detector D_1 , and the second part is caused by detector D_2 . We find that the upper bounds of I_{AE} for the case $n = 1, 3, 5, \dots$ or $n = 2, 4, 6, \dots$ are totally different. Here we call the counting event of $n = 1, 3, 5, \dots$ as odd-count and the counting event of $n = 2, 4, 6, \dots$ as even-count.

1. The mutual information of Alice and Eve with odd-count

If the single photon pulses train causes an odd-count, the density matrix of Eve is

$$\rho_E^{Odd} = \sum_{n=Odd} \left\{ P \left[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ian}}{2^n} \right] + P \left[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ibn}}{2^n} \right] \right\}. \quad (28)$$

The value of k_i , ($i \neq a, b$) is randomly 0 or 1, thus we can average ρ_E^{Odd} with random k_i , ($i \neq a, b$) to simplify the calculation. We denote

$$\rho_n^{a,b} = P \left[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ian}}{2^n} \right] + P \left[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ibn}}{2^n} \right], \quad (29)$$

and then we have

$$\begin{aligned}\rho_n^{a,b} &= \frac{1}{2(L-2)} \sum_{j \neq a,b} \sum_{k_j=0,1} \{P[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ian}}{2^n}] + P[\sum_i \frac{(-1)^{k_i} \tilde{c}_{ibn}}{2^n}]\} \\ &= P[\frac{(-1)^{k_a} \tilde{c}_{aan}}{2^n} + \frac{(-1)^{k_b} \tilde{c}_{ban}}{2^n}] + P[\frac{(-1)^{k_a} \tilde{c}_{abn}}{2^n} + \frac{(-1)^{k_b} \tilde{c}_{bbn}}{2^n}] + \sum_{i \neq a,b} \{ \frac{c_{ian}^2}{4^n} P(|e_{ian}\rangle) + \frac{c_{ibn}^2}{4^n} P(|e_{ibn}\rangle) \}.\end{aligned}\quad (30)$$

If $k_a \oplus k_b = 0$, $\rho_n^{a,b}$ will be

$$\rho_{0,n}^{a,b} = P[\frac{\tilde{c}_{aan}}{2^n} + \frac{\tilde{c}_{ban}}{2^n}] + P[\frac{\tilde{c}_{abn}}{2^n} + \frac{\tilde{c}_{bbn}}{2^n}] + \sum_{i \neq a,b} \{ \frac{c_{ian}^2}{4^n} P(|e_{ian}\rangle) + \frac{c_{ibn}^2}{4^n} P(|e_{ibn}\rangle) \} \quad (31)$$

if $k_a \oplus k_b = 1$, $\rho_n^{a,b}$ will be

$$\rho_{1,n}^{a,b} = P[\frac{\tilde{c}_{aan}}{2^n} - \frac{\tilde{c}_{ban}}{2^n}] + P[\frac{\tilde{c}_{abn}}{2^n} - \frac{\tilde{c}_{bbn}}{2^n}] + \sum_{i \neq a,b} \{ \frac{c_{ian}^2}{4^n} P(|e_{ian}\rangle) + \frac{c_{ibn}^2}{4^n} P(|e_{ibn}\rangle) \}.\quad (32)$$

The mutual information of Alice and Eve if Bob announce $\{a, b\}$, $I_{AE}^{a,b}$, could be calculated by the Holevo bound

$$I_{AE}^{a,b} \leq S[\sum_{n=odd} \frac{1}{2Q_{ab}} (\rho_{0,n}^{a,b} + \rho_{1,n}^{a,b})] - \frac{1}{2} S[\frac{1}{Q_{ab}} \sum_{n=odd} \rho_{0,n}^{a,b}] - \frac{1}{2} S[\frac{1}{Q_{ab}} \sum_{n=odd} \rho_{1,n}^{a,b}]. \quad (33)$$

Without compromising the security [21], we can assume

$$\langle e_{ijn} | e_{klm} \rangle = \delta_{ik} \delta_{jl} \delta_{nm}. \quad (34)$$

Then we could get the upper bound of $I_{AE}^{a,b}$

$$\begin{aligned}Q_{ab} I_{AE}^{a,b} &\leq \sum_{n=odd} \left(-\frac{c_{aan}^2}{4^n} \log_2 \frac{c_{aan}^2}{4^n} - \frac{c_{ban}^2}{4^n} \log_2 \frac{c_{ban}^2}{4^n} + \frac{c_{aan}^2 + c_{ban}^2}{4^n} \log_2 \frac{c_{aan}^2 + c_{ban}^2}{4^n} \right. \\ &\quad \left. - \frac{c_{abn}^2}{4^n} \log_2 \frac{c_{abn}^2}{4^n} - \frac{c_{bbn}^2}{4^n} \log_2 \frac{c_{bbn}^2}{4^n} + \frac{c_{abn}^2 + c_{bbn}^2}{4^n} \log_2 \frac{c_{abn}^2 + c_{bbn}^2}{4^n} \right) \\ &= \sum_{n=odd} [\varphi(\frac{c_{aan}^2}{4^n}, \frac{c_{ban}^2}{4^n}) + \varphi(\frac{c_{bbn}^2}{4^n}, \frac{c_{abn}^2}{4^n})],\end{aligned}\quad (35)$$

where

$$Q_{ab} = \sum_{n=odd} \sum_i (\frac{c_{ian}^2}{4^n} + \frac{c_{ibn}^2}{4^n}) \quad (36)$$

$$\varphi(x, y) = -x \log_2 x - y \log_2 y + (x + y) \log_2 (x + y) \quad (37)$$

If we denote $p_{ij}^2 = \sum_{n=odd} \frac{c_{ijn}^2}{4^n}$, with the concavity of $\varphi(x, y)$ and Jensens inequality, we have

$$Q_{ab} I_{AE}^{a,b} \leq \varphi(p_{aa}^2, p_{ba}^2) + \varphi(p_{bb}^2, p_{ab}^2) \quad (38)$$

where

$$Q_{ab} = \sum_i (p_{ia}^2 + p_{ib}^2) \quad (39)$$

The Eq. (38) is the same as Eq. (7) of the security proof in the single-photon case of Ref. [21]. The upper bound of

I_{AE}^{Odd} is

$$\begin{aligned}
I_{AE}^{Odd} &= \frac{\sum_{a<b} Q_{ab} I_{AE}^{a,b}}{\sum_{a<b} Q_{ab}} \\
&\leq \frac{\sum_{a<b} \varphi(p_{aa}^2, p_{ba}^2) + \varphi(p_{bb}^2, p_{ab}^2)}{\sum_{a<b} Q_{ab}} \\
&\leq \frac{\varphi(\sum_{a<b} p_{aa}^2 + p_{bb}^2, \sum_{a<b} p_{ba}^2 + p_{ab}^2)}{\sum_{a<b} Q_{ab}} \\
&= \frac{\varphi[(L-1) \sum_i p_{ii}^2, \sum_{i \neq j} p_{ij}^2]}{(L-1)(\sum_i p_{ii}^2 + \sum_{i \neq j} p_{ij}^2)} \\
&= \frac{\varphi[(L-1)x_1, x_2]}{(L-1)(x_1 + x_2)},
\end{aligned} \tag{40}$$

where $x_1 = \sum_i p_{ii}^2$ and $x_2 = \sum_{i \neq j} p_{ij}^2$. By maximizing the value of $\frac{\varphi[(L-1)x_1, x_2]}{(L-1)(x_1 + x_2)}$ for all $x_1 > 0$ and $x_2 > 0$, we could get the upper bound of I_{AE}^{Odd} .

2. The mutual information of Alice and Eve with even-count

In this part, we want to prove that if the single-photon pulses train causes an even-count, Eve will have all information of Alice's raw key bits. Or in other word, the supremum of I_{AE}^{Even} equals 1. According to Eq. (27), if n is an even number, the density matrix of Eve's ancilla bits will be

$$\rho_E = \sum_{n=even} \{P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n}]\}. \tag{41}$$

We set $c_{ijn} = 0$ if $n \neq 2$ or $i \neq j$, and $c_{ii2} = c$. Then ρ_E will be the following simple form

$$\rho_E = P[(-1)^{k_i} \frac{\tilde{c}_{aa2}}{4} + (-1)^{k_b} \frac{\tilde{c}_{bb2}}{4}]. \tag{42}$$

If $k_a \oplus k_b = 0$,

$$\rho_E^0 = P[\frac{\tilde{c}_{aa2}}{4} + \frac{\tilde{c}_{bb2}}{4}]. \tag{43}$$

If $k_a \oplus k_b = 1$,

$$\rho_E^1 = P[\frac{\tilde{c}_{aa2}}{4} - \frac{\tilde{c}_{bb2}}{4}]. \tag{44}$$

The mutual information of Alice and Eve if Bob announce $\{a, b\}$, $I_{AE}^{a,b}$, could be calculated by the Holevo bound

$$I_{AE}^{a,b} \leq S[\frac{1}{2Q_{ab}}(\rho_E^0 + \rho_E^1)] - \frac{1}{2}S[\frac{1}{Q_{ab}}\rho_E^0] - \frac{1}{2}S[\frac{1}{Q_{ab}}\rho_E^1] = 1, \tag{45}$$

where $Q_{ab} = \frac{c^2}{8}$. Here we use the orthogonality condition Eq. (34). Thus the upper bound of I_{AE}^{even} is

$$I_{AE}^{Odd} = \frac{\sum_{a<b} Q_{ab} I_{AE}^{a,b}}{\sum_{a<b} Q_{ab}} \leq 1. \tag{46}$$

The only inequality we use here is Holevo bound, thus the supremum of I_{AE}^{Even} equals 1.

3. The mutual information of Bob and Eve

If the single photon pulses train causes a count in detector D_1 , the density matrix of Eve is

$$\rho_E^{D_1} = \sum_{n=1} P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n}]. \quad (47)$$

If the single photon pulses train causes a count in detector D_2 , the density matrix of Eve is

$$\rho_E^{D_2} = \sum_{n=1} P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} (-1)^n \frac{\tilde{c}_{ibn}}{2^n}]. \quad (48)$$

It is easy to see that $\rho_E^{D_1}$ and $\rho_E^{D_2}$ are the same if n is even, which means Eve can not distinguish whether an even-count is caused by D_1 or D_2 at all, thus $I_{BE}^{Even} = 0$. Different from the situation of I_{AE}^{Odd} , this result need not the average of random phase and orthogonality assumption Eq. (34). Similar to the case of mutual information of Alice and Eve with even-counts, we want to prove that if the single-photon pulses train causes an odd-count, Eve will have all information of Bob's raw key bits. If n is odd, $\rho_E^{D_1}$ and $\rho_E^{D_2}$ will be

$$\rho_E^{D_1} = \sum_{n=odd} P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} + \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n}], \quad (49)$$

$$\rho_E^{D_2} = \sum_{n=odd} P[\sum_i (-1)^{k_i} \frac{\tilde{c}_{ian}}{2^n} - \sum_i (-1)^{k_i} \frac{\tilde{c}_{ibn}}{2^n}]. \quad (50)$$

If we set $c_{ijn} = 0$ if $n \neq 1$ or $i \neq j$, and $c_{ii1} = c$, $\rho_E^{D_1}$ and $\rho_E^{D_2}$ will be

$$\rho_E^{D_1} = P[\frac{\tilde{c}_{aa1}}{2} + (-1)^{k_a+k_b} \frac{\tilde{c}_{bb1}}{2}], \rho_E^{D_2} = P[\frac{\tilde{c}_{aa1}}{2} - (-1)^{k_a+k_b} \frac{\tilde{c}_{bb1}}{2}]. \quad (51)$$

Since the states of $\rho_E^{D_1}$ and $\rho_E^{D_2}$ with assumption Eq. (34) are two orthometric pure states, $I_{BE}^{a,b} \leq 1$. And thus $I_{BE}^{Odd} \leq 1$.

III. THE UPPER BOUND OF LEAKAGE INFORMATION IN GENERAL CASE

In this part we want to evaluate the upper bound of leakage information in general case. We have shown that if the single-photon pulses train causes an even-count, the mutual information of Alice and Eve is up to 1, and if the single-photon pulses train causes an odd-count, the mutual information of Bob and Eve is up to 1. Honestly speaking, this is a trivial conclusion, thus we will focus on the upper bounds of mutual information of Alice and Eve if the pulses train causes an odd-count and the mutual information of Bob and Eve if the pulses train causes an even-count. Same as the method in Ref. [21], we will prove this in two cases, N is an odd number and N is an even number, where N denotes Alice sends out a N -photons L -pulses train. We assume $N \leq L/2$ in this part.

A. The upper bound of leakage information if N is an odd number

If Alice prepares a N -photon L -pulses train where N is an odd number, the state will be

$$|\Psi\rangle_A = \sum_{i_1} (-1)^{k_{i_1}} |i_1\rangle + \sum_{i_1 < i_2 < i_3} (-1)^{k_{i_1}+k_{i_2}+k_{i_3}} |i_1 i_2 i_3\rangle + \cdots + \sum_{i_1 < i_2 < i_3 < \cdots < i_N} (-1)^{k_{i_1}+k_{i_2}+k_{i_3}+\cdots+k_{i_N}} |i_1 i_2 i_3 \cdots i_N\rangle, \quad (52)$$

where $|i_1 i_2 i_3 \cdots i_k\rangle$ represents a sum of all states that there are odd number photons in the $i_1, i_2, i_3, \dots, i_k$ -th pulses and there are even number photons in the other pulses of the L -pulses train, for $k = 1, 3, 5, \dots, N$. Eve's optimal collective attack can be given by the following equation for the state shown in Eq. (52):

$$U_{eve} |i_1 i_2 i_3 \cdots i_k\rangle |e_{ancilla}\rangle = \sum_{n=0}^{\infty} \sum_{t=1}^L c_{i_1 i_2 \cdots i_k t n} |n_t\rangle |e_{i_1 i_2 \cdots i_k t n}\rangle, \quad (53)$$

and we denote

$$\tilde{c}_{i_1 i_2 \dots i_k t n} \equiv c_{i_1 i_2 \dots i_k t n} |e_{i_1 i_2 \dots i_k t n}\rangle, \quad (54)$$

for $k = 1, 3, 5, \dots, N$. Then Alice and Eve will share the following entanglement state

$$\begin{aligned} |\Psi\rangle_{AE} = & \sum_{n=0}^{\infty} \sum_{t=1}^L \left[\sum_{i_1} (-1)^{k_{i_1}} \tilde{c}_{i_1 t n} + \sum_{i_1 < i_2 < i_3} (-1)^{k_{i_1} + k_{i_2} + k_{i_3}} \tilde{c}_{i_1 i_2 i_3 t n} + \dots \right. \\ & \left. + \sum_{i_1 < i_2 < i_3 < \dots < i_N} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \dots + k_{i_N}} \tilde{c}_{i_1 i_2 i_3 \dots i_N t n} \right] |n_t\rangle \end{aligned} \quad (55)$$

Further, we denote

$$\tilde{c}_{tn} = \sum_{i_1} (-1)^{k_{i_1}} \tilde{c}_{i_1 t n} + \sum_{i_1 < i_2 < i_3} (-1)^{k_{i_1} + k_{i_2} + k_{i_3}} \tilde{c}_{i_1 i_2 i_3 t n} + \dots + \sum_{i_1 < i_2 < i_3 < \dots < i_N} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \dots + k_{i_N}} \tilde{c}_{i_1 i_2 i_3 \dots i_N t n}, \quad (56)$$

Through Bob's detection set-up, the state of Eq. (55) is involved into

$$|\Psi\rangle_{AE} = \sum_{n=0}^{\infty} \sum_{t=1}^L \tilde{c}_{tn} |n_t\rangle \quad (57)$$

$$\rightarrow \sum_{tn} \tilde{c}_{tn} \frac{\hat{d}_t^{\dagger, n}}{\sqrt{n!}} |0\rangle \quad (58)$$

$$\rightarrow \sum_{tn} \tilde{c}_{tn} \frac{1}{2^n \sqrt{n!}} (\hat{d}_{t+r}^{\dagger} + \hat{e}_{t+r}^{\dagger} + \hat{d}_t^{\dagger} - \hat{e}_t^{\dagger})^n |0\rangle \equiv |\Psi\rangle_{AE}^{detect}. \quad (59)$$

If only one of Bob's detectors responses in location k and we denote $a = k - r, b = k$, the density matrix of Eve's ancilla bits is

$$\rho_E = \frac{1}{2} \sum_{n=1} \{P(\tilde{c}_{an} + \tilde{c}_{bn}) + P[\tilde{c}_{an} + (-1)^n \tilde{c}_{bn}]\} \quad (60)$$

The first part of Eq. (60) is caused by detector D_1 , and the second part is caused by detector D_2 . It is easy to see that those two parts are the same if n is an even and thus $I_{BE}^{Even}(N)=0$. If n is odd, we have the following consideration to evaluate the upper bound of mutual information of Alice and Eve.

$$\rho_E = \sum_{n=odd} P(\tilde{c}_{an}) + P(\tilde{c}_{bn}). \quad (61)$$

We first transform $P(\tilde{c}_{an})$ and $P(\tilde{c}_{bn})$ into

$$\begin{aligned}
P(\tilde{c}_{an}) = & P\left\{\sum_{i_1} (-1)^{k_{i_1}} \tilde{c}_{i_1 an} + \sum_{i_1 < i_2 < i_3} (-1)^{k_{i_1} + k_{i_2} + k_{i_3}} \tilde{c}_{i_1 i_2 i_3 an} + \dots \right. \\
& + \sum_{i_1 < i_2 < i_3 < \dots < i_N} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \dots + k_{i_N}} \tilde{c}_{i_1 i_2 i_3 \dots i_N an}\left.\right\} \\
= & P\left\{(-1)^{k_a} \tilde{c}_{aan} + (-1)^{k_b} \tilde{c}_{ban} \right. \\
& + \sum_{i_1 \neq a, b} (-1)^{k_{i_1}} [\tilde{c}_{i_1 an} + (-1)^{k_a + k_b} \tilde{c}_{i_1 aban}] \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} (-1)^{k_{i_1} + k_{i_2}} [(-1)^{k_a} \tilde{c}_{i_1 i_2 aan} + (-1)^{k_b} \tilde{c}_{i_1 i_2 ban}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} (-1)^{k_{i_1} + k_{i_2} + k_{i_3}} [(-1)^{k_a + k_b} \tilde{c}_{i_1 i_2 i_3 aban} + \tilde{c}_{i_1 i_2 i_3 an}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 < i_4 \\ i_1, i_2, i_3, i_4 \neq a, b}} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + k_{i_4}} [(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 i_4 aan} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 i_4 ban}] \\
& + \dots \\
& + \sum_{i_1 < i_2 < i_3 < \dots < i_{N-1}} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \dots + k_{i_{N-1}}} [(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} aan} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} ban}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_N \\ i_1, i_2, \dots, i_N \neq a, b}} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \dots + k_{i_N}} \tilde{c}_{i_1 i_2 i_3 \dots i_N an}\left.\right\}
\end{aligned} \tag{62}$$

The value of k_i , ($i \neq a, b$) is randomly 0 or 1, thus we have

$$\begin{aligned}
P(\tilde{c}_{an}) = & P[(-1)^{k_a} \tilde{c}_{aan} + (-1)^{k_b} \tilde{c}_{ban}] + \sum_{i_1 \neq a, b} P[\tilde{c}_{i_1 an} + (-1)^{k_a + k_b} \tilde{c}_{i_1 aban}] \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 aan} + (-1)^{k_b} \tilde{c}_{i_1 i_2 ban}] + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} P[(-1)^{k_a + k_b} \tilde{c}_{i_1 i_2 i_3 aban} + \tilde{c}_{i_1 i_2 i_3 an}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 < i_4 \\ i_1, i_2, i_3, i_4 \neq a, b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 i_4 aan} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 i_4 ban}] + \dots \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a, b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} aan} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} ban}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_N \\ i_1, i_2, \dots, i_N \neq a, b}} P(\tilde{c}_{i_1 i_2 i_3 \dots i_N an})
\end{aligned} \tag{63}$$

Similarly, $P(\tilde{c}_{bn})$ could be transformed into the following form

$$\begin{aligned}
P(\tilde{c}_{bn}) = & P[(-1)^{k_a} \tilde{c}_{abn} + (-1)^{k_b} \tilde{c}_{bbn}] + \sum_{i_1 \neq a, b} P[\tilde{c}_{i_1 bn} + (-1)^{k_a + k_b} \tilde{c}_{i_1 abbn}] \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 abn} + (-1)^{k_b} \tilde{c}_{i_1 i_2 bbn}] + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} P[(-1)^{k_a + k_b} \tilde{c}_{i_1 i_2 i_3 abbn} + \tilde{c}_{i_1 i_2 i_3 bbn}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 < i_4 \\ i_1, i_2, i_3, i_4 \neq a, b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 i_4 abn} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 i_4 bbn}] + \dots \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a, b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} abn} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} bbn}] \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_N \\ i_1, i_2, \dots, i_N \neq a, b}} P(\tilde{c}_{i_1 i_2 i_3 \dots i_N bn})
\end{aligned} \tag{64}$$

We denote ρ_E as ρ_E^0 if $k_a \oplus k_b = 0$ and ρ_E as ρ_E^1 if $k_a \oplus k_b = 1$, thus the mutual information of Alice and Eve if Bob announces $\{a, b\}$, $I_{AE}^{a,b}$ is

$$I_{A,E}^{a,b} \leq S[\frac{1}{2Q_{ab}}(\rho_E^0 + \rho_E^1)] - \frac{1}{2}S[\frac{\rho_E^0}{Q_{ab}}] - \frac{1}{2}S[\frac{\rho_E^1}{Q_{ab}}], \tag{65}$$

where

$$Q_{ab} = \sum_{n=\text{odd}} [\sum_{i_1} (|\tilde{c}_{i_1 an}|^2 + |\tilde{c}_{i_1 bn}|^2) + \sum_{i_1 < i_2 < i_3} (|\tilde{c}_{i_1 i_2 i_3 an}|^2 + |\tilde{c}_{i_1 i_2 i_3 bn}|^2) + \dots + \sum_{i_1 < i_2 < i_3 < \dots < i_N} (|\tilde{c}_{i_1 i_2 i_3 \dots i_N an}|^2 + |\tilde{c}_{i_1 i_2 i_3 \dots i_N bn}|^2)]. \tag{66}$$

We denote $p_{i_1 i_2 i_3 \dots i_k t}^2 = \sum_{n=\text{odd}} |\tilde{c}_{i_1 i_2 i_3 \dots i_k tn}|^2$ where $k = 1, 2, 3, \dots, N$. And the upper bound of I_{AE} is

$$\begin{aligned}
I_{AE} = & \frac{\sum_{a < b} Q_{ab} I_{AE}^{a,b}}{\sum_{a < b} Q_{ab}} \\
\leq & \frac{1}{\sum_{a < b} Q_{ab}} \sum_{a < b} \sum_{n=\text{odd}} [\varphi(|\tilde{c}_{aan}|^2 + |\tilde{c}_{bbn}|^2, |\tilde{c}_{abn}|^2 + |\tilde{c}_{ban}|^2) \\
& + \sum_{i_1 \neq a, b} \varphi(|\tilde{c}_{i_1 an}|^2 + |\tilde{c}_{i_1 bn}|^2, |\tilde{c}_{i_1 abn}|^2 + |\tilde{c}_{i_1 bbn}|^2) \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} \varphi(|\tilde{c}_{i_1 i_2 aan}|^2 + |\tilde{c}_{i_1 i_2 bbn}|^2, |\tilde{c}_{i_1 i_2 abn}|^2 + |\tilde{c}_{i_1 i_2 ban}|^2) \\
& + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} \varphi(|\tilde{c}_{i_1 i_2 i_3 an}|^2 + |\tilde{c}_{i_1 i_2 i_3 bn}|^2, |\tilde{c}_{i_1 i_2 i_3 abn}|^2 + |\tilde{c}_{i_1 i_2 i_3 bbn}|^2) + \dots \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a, b}} \varphi(|\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} aan}|^2 + |\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} bbn}|^2, |\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} abn}|^2 + |\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} ban}|^2)] \\
\leq & \frac{1}{\sum_{a < b} Q_{ab}} \sum_{a < b} [\varphi(p_{aa}^2 + p_{bb}^2, p_{ab}^2 + p_{ba}^2) + \sum_{i_1 \neq a, b} \varphi(p_{i_1 a}^2 + p_{i_1 b}^2, p_{i_1 ab}^2 + p_{i_1 bb}^2) \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} \varphi(p_{i_1 i_2 aa}^2 + p_{i_1 i_2 bb}^2, p_{i_1 i_2 ab}^2 + p_{i_1 i_2 ba}^2) + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} \varphi(p_{i_1 i_2 i_3 aa}^2 + p_{i_1 i_2 i_3 bb}^2, p_{i_1 i_2 i_3 ab}^2 + p_{i_1 i_2 i_3 ba}^2) \\
& + \dots + \sum_{\substack{i_1 < i_2 < i_3 < \dots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a, b}} \varphi(p_{i_1 i_2 i_3 \dots i_{N-1} aa}^2 + p_{i_1 i_2 i_3 \dots i_{N-1} bb}^2, p_{i_1 i_2 i_3 \dots i_{N-1} ab}^2 + p_{i_1 i_2 i_3 \dots i_{N-1} ba}^2)].
\end{aligned} \tag{67}$$

As shown in Eq. (44) of supplementary note of Ref. [21], we have the following mathematical identities

$$\begin{aligned}
\sum_{a < b} p_{aa}^2 + p_{bb}^2 &= (L-1) \sum_{i_1} p_{i_1 i_1}^2 \\
\sum_{a < b} p_{ab}^2 + p_{ba}^2 &= \sum_{i_1} \sum_{i_2 \neq i_1} p_{i_1 i_2}^2 \\
\sum_{a < b} \sum_{i_1 \neq a, b} p_{i_1 a}^2 + p_{i_1 b}^2 &= (L-2) \sum_{i_1} \sum_{i_2 \neq i_1} p_{i_1 i_2}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_k \\ i_1, i_2, \dots, i_k \neq a, b}} p_{i_1 i_2 \dots i_k a}^2 + p_{i_1 i_2 \dots i_k b}^2 &= (L-k-1) \sum_{i_1 < i_2 < \dots < i_k} \sum_{t \neq i_1, i_2, \dots, i_k} p_{i_1 i_2 \dots i_k t}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_k \\ i_1, i_2, \dots, i_k \neq a, b}} p_{i_1 i_2 \dots i_k a b a}^2 + p_{i_1 i_2 \dots i_k a b b}^2 &= (k+1) \sum_{i_1 < i_2 < \dots < i_{k+2}} \sum_{t=i_1}^{i_{k+2}} p_{i_1 i_2 \dots i_{k+2} t}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_{k+1} \\ i_1, i_2, \dots, i_{k+1} \neq a, b}} p_{i_1 i_2 \dots i_{k+1} a a}^2 + p_{i_1 i_2 \dots i_{k+1} b b}^2 &= (L-k-2) \sum_{i_1 < i_2 < \dots < i_{k+2}} \sum_{t=i_1}^{i_{k+2}} p_{i_1 i_2 \dots i_{k+2} t}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_{k+1} \\ i_1, i_2, \dots, i_{k+1} \neq a, b}} p_{i_1 i_2 \dots i_{k+1} a b}^2 + p_{i_1 i_2 \dots i_{k+1} b a}^2 &= (k+2) \sum_{i_1 < i_2 < \dots < i_{k+2}} \sum_{t \neq i_1, \dots, i_{k+2}} p_{i_1 i_2 \dots i_{k+2} t}^2,
\end{aligned}$$

where $k = 1, 3, 5, \dots, N$. And we define

$$\begin{aligned}
x_1 &\equiv \sum_{i_1} p_{i_1 i_1}^2 \\
x_2 &\equiv \sum_{i_1 \neq i_2} p_{i_1 i_2}^2 \\
x_k &\equiv \sum_{i_1 < i_2 < \dots < i_k} \sum_{t=i_1}^{i_k} p_{i_1 i_2 \dots i_k t}^2 \\
x_{k+1} &\equiv \sum_{i_1 < i_2 < \dots < i_k} \sum_{t \neq i_1, \dots, i_k} p_{i_1 i_2 \dots i_k t}^2
\end{aligned}$$

It is easy to check $\sum_{a < b} Q_{ab} = (L-1)(x_1 + x_2 + \dots + x_{N+1})$. With the concavity of $\varphi(x, y)$ and Jensens inequality, we have

$$I_{AE} \leq \frac{\sum_{k=1}^N \varphi[(L-k)x_k, kx_{k+1}]}{(L-1) \sum_{k=1}^{N+1} x_k}, \quad (68)$$

By searching the maximum value of Eq. (68) in non-negative spaces, we could get the upper bound of I_{AE} .

B. The upper bound of leakage information if N is an even number

If Alice prepares a N -photon L -pulses train where N is an even number, the state will be

$$\begin{aligned}
|\Psi\rangle_A &= |i_1\rangle + \sum_{i_1 < i_2} (-1)^{k_{i_1} + k_{i_2}} |i_1 i_2\rangle + \sum_{i_1 < i_2 < i_3 < i_4} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + k_{i_4}} |i_1 i_2 i_3 i_4\rangle + \dots \\
&+ \sum_{i_1 < i_2 < i_3 < \dots < i_N} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \dots + k_{i_N}} |i_1 i_2 i_3 \dots i_N\rangle,
\end{aligned} \quad (69)$$

where $|i_1 i_2 i_3 \dots i_k\rangle$ represents a sum of all states that there are odd number photons in the $i_1, i_2, i_3, \dots, i_k$ -th pulses and there are even number photons in the other pulses of the L -pulses train, for $k = 2, 4, 6, \dots, N$. And $|i_1\rangle$ represents

a sum of all states that there are only even number photons in any pulse. Similarly to Eqs. (53) and (54), Eve's optimal collective attack is

$$U_{eve}|i_1 i_2 \cdots i_k\rangle|e_{ancilla}\rangle = \sum_{n=0}^{\infty} \sum_{t=1}^L \tilde{c}_{i_1 i_2 \cdots i_k t n} |n_t\rangle, \quad (70)$$

for $k = 1, 2, 4, 6, \dots, N$. And similarly to Eqs. (55)-(60), if only one of Bob's detectors responses in location k and we denote $a = k - r, b = k$, the density matrix of Eve's ancilla bits is

$$\rho_E = \frac{1}{2} \sum_{n=1} \{P(\tilde{c}_{an} + \tilde{c}_{bn}) + P[\tilde{c}_{an} + (-1)^n \tilde{c}_{bn}]\} \quad (71)$$

The first part of Eq. (71) is caused by detector D_1 , and the second part is caused by detector D_2 . It is easy to see that those two parts are the same if n is even and thus $I_{BE}^{Even}(N)=0$. If n is odd, we have the following consideration to evaluate the upper bound of mutual information of Alice and Eve.

$$\rho_E = \sum_{n=odd} P(\tilde{c}_{an}) + P(\tilde{c}_{bn}), \quad (72)$$

where

$$\begin{aligned} P(\tilde{c}_{an}) &= P\{\tilde{c}_{i_1 an} + \sum_{i_1 < i_2} (-1)^{k_{i_1} + k_{i_2}} \tilde{c}_{i_1 i_2 an} |i_1 i_2\rangle + \sum_{i_1 < i_2 < i_3 < i_4} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + k_{i_4}} \tilde{c}_{i_1 i_2 i_3 i_4 an} |i_1 i_2 i_3 i_4\rangle + \cdots \\ &\quad + \sum_{i_1 < i_2 < i_3 < \cdots < i_N} (-1)^{k_{i_1} + k_{i_2} + k_{i_3} + \cdots + k_{i_N}} \tilde{c}_{i_1 i_2 i_3 \cdots i_N an} |i_1 i_2 i_3 \cdots i_N\rangle\} \\ &= P\{\tilde{c}_{i_1 an} + (-1)^{k_a + k_b} \tilde{c}_{aban} \\ &\quad + \sum_{i_1 \neq a, b} (-1)^{k_i} [(-1)^{k_a} \tilde{c}_{i_1 a an} + (-1)^{k_b} \tilde{c}_{i_1 b an}] \\ &\quad + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} (-1)^{k_{i_1} + k_{i_2}} (\tilde{c}_{i_1 i_2 an} + (-1)^{k_a + k_b} \tilde{c}_{i_1 i_2 aban}) \\ &\quad + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} (-1)^{k_{i_1} + k_{i_2} + k_{i_3}} [(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 a an} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 b an}] + \cdots \\ &\quad + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a, b}} (-1)^{k_{i_1} + k_{i_2} + \cdots + k_{i_{N-1}}} [(-1)^{k_a} \tilde{c}_{i_1 i_2 \cdots i_{N-1} a an} + (-1)^{k_b} \tilde{c}_{i_1 i_2 \cdots i_{N-1} b an}] \\ &\quad + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_N \\ i_1, i_2, \dots, i_N \neq a, b}} (-1)^{k_{i_1} + k_{i_2} + \cdots + k_{i_N}} \tilde{c}_{i_1 i_2 \cdots i_N an}\} \end{aligned} \quad (73)$$

The value of $k_i, (i \neq a, b)$ is randomly 0 or 1, thus we have

$$\begin{aligned} P(\tilde{c}_{an}) &= P[\tilde{c}_{i_1 an} + (-1)^{k_a + k_b} \tilde{c}_{aban}] + \sum_{i_1 \neq a, b} P[(-1)^{k_a} \tilde{c}_{i_1 a an} + (-1)^{k_b} \tilde{c}_{i_1 b an}] \\ &\quad + \sum_{i_1 < i_2, i_1, i_2 \neq a, b} P[\tilde{c}_{i_1 i_2 an} + (-1)^{k_a + k_b} \tilde{c}_{i_1 i_2 aban}] + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a, b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 a an} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 b an}] \\ &\quad + \cdots + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a, b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 \cdots i_{N-1} a an} + (-1)^{k_b} \tilde{c}_{i_1 i_2 \cdots i_{N-1} b an}] + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_N \\ i_1, i_2, \dots, i_N \neq a, b}} P(\tilde{c}_{i_1 i_2 \cdots i_N an}) \end{aligned} \quad (74)$$

Similarly,

$$\begin{aligned}
P(\tilde{c}_{bn}) = & P[\tilde{c}_{i_1 bn} + (-1)^{k_a+k_b} \tilde{c}_{abbn}] + \sum_{i_1 \neq a,b} P[(-1)^{k_a} \tilde{c}_{i_1 abn} + (-1)^{k_b} \tilde{c}_{i_1 bbn}] \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a,b} P[\tilde{c}_{i_1 i_2 bn} + (-1)^{k_a+k_b} \tilde{c}_{i_1 i_2 abbn}] + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a,b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 i_3 abn} + (-1)^{k_b} \tilde{c}_{i_1 i_2 i_3 bbn}] \\
& + \cdots + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a,b}} P[(-1)^{k_a} \tilde{c}_{i_1 i_2 \dots i_{N-1} abn} + (-1)^{k_b} \tilde{c}_{i_1 i_2 \dots i_{N-1} bbn}] + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_N \\ i_1, i_2, \dots, i_N \neq a,b}} P(\tilde{c}_{i_1 i_2 \dots i_N bn})
\end{aligned} \tag{75}$$

We denote $p_{i_1 i_2 i_3 \dots i_k t}^2 = \sum_{n=\text{odd}} |\tilde{c}_{i_1 i_2 i_3 \dots i_k t n}|^2$ where $k = 1, 2, 4, 6, \dots, N$. And the upper bound of I_{AE} is

$$\begin{aligned}
I_{AE} = & \frac{\sum_{a < b} Q_{ab} I_{AE}^{a,b}}{\sum_{a < b} Q_{ab}} \\
\leq & \frac{1}{\sum_{a < b} Q_{ab}} \sum_{a < b} \sum_{n=\text{odd}} [\varphi(|\tilde{c}_{i_1 an}|^2 + |\tilde{c}_{i_1 bn}|^2, |\tilde{c}_{aban}|^2 + |\tilde{c}_{abbn}|^2) \\
& + \sum_{i_1 \neq a,b} \varphi(|\tilde{c}_{i_1 aan}|^2 + |\tilde{c}_{i_1 bbn}|^2, |\tilde{c}_{i_1 ban}|^2 + |\tilde{c}_{i_1 bbn}|^2) \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a,b} \varphi(|\tilde{c}_{i_1 i_2 an}|^2 + |\tilde{c}_{i_1 i_2 bn}|^2, |\tilde{c}_{i_1 i_2 aban}|^2 + |\tilde{c}_{i_1 i_2 abbn}|^2) \\
& + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a,b}} \varphi(|\tilde{c}_{i_1 i_2 i_3 aan}|^2 + |\tilde{c}_{i_1 i_2 i_3 bbn}|^2, |\tilde{c}_{i_1 i_2 i_3 abn}|^2 + |\tilde{c}_{i_1 i_2 i_3 ban}|^2) + \dots \\
& + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a,b}} \varphi(|\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} aan}|^2 + |\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} bbn}|^2, |\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} abn}|^2 + |\tilde{c}_{i_1 i_2 i_3 \dots i_{N-1} ban}|^2)] \\
\leq & \frac{1}{\sum_{a < b} Q_{ab}} \sum_{a < b} [\varphi(p_{i_1 a}^2 + p_{i_1 b}^2, p_{aba}^2 + p_{abb}^2) + \sum_{i_1 \neq a,b} \varphi(p_{i_1 aa}^2 + p_{i_1 bb}^2, p_{i_1 ba}^2 + p_{i_1 ab}^2) \\
& + \sum_{i_1 < i_2, i_1, i_2 \neq a,b} \varphi(p_{i_1 i_2 a}^2 + p_{i_1 i_2 b}^2, p_{i_1 i_2 abb}^2 + p_{i_1 i_2 aba}^2) + \sum_{\substack{i_1 < i_2 < i_3 \\ i_1, i_2, i_3 \neq a,b}} \varphi(p_{i_1 i_2 i_3 aa}^2 + p_{i_1 i_2 i_3 bb}^2, p_{i_1 i_2 i_3 ab}^2 + p_{i_1 i_2 i_3 ba}^2) \\
& + \dots + \sum_{\substack{i_1 < i_2 < i_3 < \cdots < i_{N-1} \\ i_1, i_2, \dots, i_{N-1} \neq a,b}} \varphi(p_{i_1 i_2 i_3 \dots i_{N-1} aa}^2 + p_{i_1 i_2 i_3 \dots i_{N-1} bb}^2, p_{i_1 i_2 i_3 \dots i_{N-1} ab}^2 + p_{i_1 i_2 i_3 \dots i_{N-1} ba}^2)],
\end{aligned} \tag{76}$$

where

$$\begin{aligned}
Q_{ab} = & \sum_{n=\text{odd}} [(|\tilde{c}_{i_1 an}|^2 + |\tilde{c}_{i_1 bn}|^2) + \sum_{i_1 < i_2} (|\tilde{c}_{i_1 i_2 an}|^2 + |\tilde{c}_{i_1 i_2 bn}|^2) + \sum_{i_1 < i_2 < i_3 < i_4} (|\tilde{c}_{i_1 i_2 i_3 i_4 an}|^2 + |\tilde{c}_{i_1 i_2 i_3 i_4 bn}|^2) \\
& + \cdots + \sum_{i_1 < i_2 < i_3 < \cdots < i_N} (|\tilde{c}_{i_1 i_2 i_3 \dots i_N an}|^2 + |\tilde{c}_{i_1 i_2 i_3 \dots i_N bn}|^2)] \\
= & p_{i_1 a}^2 + p_{i_1 b}^2 + \sum_{i_1 < i_2} (p_{i_1 i_2 a}^2 + p_{i_1 i_2 b}^2) + \sum_{i_1 < i_2 < i_3 < i_4} (p_{i_1 i_2 i_3 i_4 a}^2 + p_{i_1 i_2 i_3 i_4 b}^2) \\
& + \cdots + \sum_{i_1 < i_2 < i_3 < \cdots < i_N} (p_{i_1 i_2 \dots i_N a}^2 + p_{i_1 i_2 \dots i_N b}^2)
\end{aligned} \tag{77}$$

As shown in Eq. (54) of supplementary note of Ref. [21], we have the following mathematical identities

$$\begin{aligned}
\sum_{a < b} p_{i_1 a}^2 + p_{i_1 b}^2 &= (L-1) \sum_{i_2} p_{i_1 i_2}^2 \\
\sum_{a < b} p_{aba}^2 + p_{abb}^2 &= \sum_{i_1 < i_2} \sum_{i_3=i_1}^{i_2} p_{i_1 i_2 i_3}^2 \\
\sum_{a < b} \sum_{i_1 \neq a, b} p_{i_1 aa}^2 + p_{i_1 bb}^2 &= (L-2) \sum_{i_1 < i_2} \sum_{i_3=i_1}^{i_2} p_{i_1 i_2 i_3}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_k \\ i_1, i_2, \dots, i_k \neq a, b}} p_{i_1 i_2 \dots i_k a}^2 + p_{i_1 i_2 \dots i_k b}^2 &= (L-k-1) \sum_{i_1 < i_2 < \dots < i_k} \sum_{t \neq i_1, i_2, \dots, i_k} p_{i_1 i_2 \dots i_k t}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_k \\ i_1, i_2, \dots, i_k \neq a, b}} p_{i_1 i_2 \dots i_k a b a}^2 + p_{i_1 i_2 \dots i_k a b b}^2 &= (k+1) \sum_{i_1 < i_2 < \dots < i_{k+2}} \sum_{t=i_1}^{i_{k+2}} p_{i_1 i_2 \dots i_{k+2} t}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_{k+1} \\ i_1, i_2, \dots, i_{k+1} \neq a, b}} p_{i_1 i_2 \dots i_{k+1} a a}^2 + p_{i_1 i_2 \dots i_{k+1} b b}^2 &= (L-k-2) \sum_{i_1 < i_2 < \dots < i_{k+2}} \sum_{t=i_1}^{i_{k+2}} p_{i_1 i_2 \dots i_{k+2} t}^2 \\
\sum_{a < b} \sum_{\substack{i_1 < i_2 < \dots < i_{k+1} \\ i_1, i_2, \dots, i_{k+1} \neq a, b}} p_{i_1 i_2 \dots i_{k+1} a b}^2 + p_{i_1 i_2 \dots i_{k+1} b a}^2 &= (k+2) \sum_{i_1 < i_2 < \dots < i_{k+2}} \sum_{t \neq i_1, \dots, i_{k+2}} p_{i_1 i_2 \dots i_{k+2} t}^2,
\end{aligned}$$

where $k = 2, 4, 6, \dots, N$. And we define

$$\begin{aligned}
x_1 &\equiv \sum_{i_2} p_{i_1 i_2}^2 \\
x_2 &\equiv \sum_{i_1 < i_2} \sum_{i_3=i_1}^{i_2} p_{i_1 i_2 i_3}^2 \\
x_k &\equiv \sum_{i_1 < i_2 < \dots < i_k} \sum_{t=i_1}^{i_k} p_{i_1 i_2 \dots i_k t}^2 \\
x_{k+1} &\equiv \sum_{i_1 < i_2 < \dots < i_k} \sum_{t \neq i_1, \dots, i_k} p_{i_1 i_2 \dots i_k t}^2
\end{aligned}$$

It is easy to check $\sum_{a < b} Q_{ab} = (L-1)(x_1 + x_2 + \dots + x_{N+1})$. With the concavity of $\varphi(x, y)$ and Jensens inequality, we have

$$I_{AE} \leq \frac{\sum_{k=1}^N \varphi[(L-k)x_k, kx_{k+1}]}{(L-1) \sum_{k=1}^{N+1} x_k}, \quad (78)$$

By searching the maximum value of Eq. (78) in non-negative spaces, we could get the upper bound of I_{AE} . Eq. (68) and Eq. (78) are actually the same, i.e., the expression of I_{AE} is just Eq. (78) whether N is an odd number or even number.

IV. THE SIMULATION MODEL OF RRDPS WITH SINGLE PHOTON DETECTORS

If Alice prepares the L -pulses trains with phase-randomized weak coherent state source with intensity μ and Bob's detectors are single photon detectors in RRDPS, the counting rate and error counting rate [21] are

$$Q_\mu = \sum_{r=1}^{L-1} \frac{L-r}{L-1} (1-p_d)^{2L-2r-1} e^{-(L-r)\eta\mu/L} (\eta\mu/L + 2p_d), \quad (79)$$

$$T_\mu = \sum_{r=1}^{L-1} \frac{L-r}{L-1} (1-p_d)^{2L-2r-1} e^{-(L-r)\eta\mu/L} p_d. \quad (80)$$

And the error rate is $E_\mu = T_\mu/Q_\mu$. The final key rate of RRDPS with single photon detectors is

$$LR = Q_\mu(1 - fH(E_\mu)) - e_{src} - (Q - e_{src})\phi(n_{th}, L), \quad (81)$$

where $e_{src} = \sum_{k>n_{th}} \frac{\mu^k e^{-\mu}}{k!}$ and

$$\phi(N, L) = \max_{x_1, x_2, \dots, x_{N+1}} \left\{ \frac{\sum_{k=1}^N \varphi((L-k)x_k, kx_{k+1})}{L-1} \right\}, \quad (82)$$

and $\sum_{k=1}^{N+1} x_k = 1$.

V. THE SIMULATION MODELS OF RRDPS WITH YES-NO DETECTORS

If Alice prepares the L -pulses trains with phase-randomized weak coherent state source with intensity μ and Bob's detectors are single photon detectors in RRDPS, the counting rate and error counting rate are

$$Q_\mu = \sum_{r=1}^{L-1} \frac{L-r}{L-1} (1-p_d)^{2L-2r-1} e^{-\frac{\eta\mu(L-r-1)}{L}} [1 - (1-p_d)e^{-\frac{\eta\mu}{L}}], \quad (83)$$

$$T_\mu = \sum_{r=1}^{L-1} \frac{L-r}{L-1} p_d (1-p_d)^{2L-2r-1} e^{-\frac{\eta\mu(L-r)}{L}}. \quad (84)$$

Eqs. (60) and (71) clearly show that the bit-flip error rate of even-counts is 0.5 no matter what Eve does. And thus the final secure key rate is

$$\begin{aligned} LR &= \max_{\gamma} \min_{\alpha} \{ \gamma \max[R_1(\alpha), 0] + (1-\gamma) \max[R_2(\alpha), 0] \}, \\ s.t. \quad &1 - \frac{2EQ}{Q - e_{src}} \leq \alpha \leq 1, \quad 0 \leq \gamma \leq 1, \\ R_1(\alpha) &= \alpha(Q_\mu - e_{src})(1 - \phi(n_{th}, L)) - fQ_\mu H(E_\mu), \\ R_2(\alpha) &= (1-\alpha)(Q_\mu - e_{src}) - fQ_\mu H(E_\mu), \end{aligned} \quad (85)$$

- [23] Since the operation of yes-no detectors is done in the photon number space, we do not have to consider the linear superposition of different photon numbers for the incident light of the detectors.
