## Abstract

Chimera states are spatiotemporal patterns in which coherence and incoherence coexist. We observe the coexistence of synchronous (coherent) and desynchronous (incoherent) domains in a neuronal network. The network is composed of coupled adaptive exponential integrate-and-fire neurons that are connected by means of chemical synapses. In our neuronal network, the chimera states exhibit spatial structures both with spikes and bursts activities. Furthermore, those desynchronised domains not only have either spike

or burst activity, but we show that the structures switch between spikes and bursts as the time evolves. Moreover, we verify the existence of multicluster chimera states.

## 1 Introduction

In dynamical systems, the word chimera has been used to describe the coexistence of coherent and incoherent patterns [1, 2]. Chimera states were first observed by Umberger et al. in 1989 [3]. Kuramoto and Battogtokh [4] reported spatiotemporal patterns of coexisting coherence and incoherence in non locally coupled phase oscillators [5].

There are experimental evidences of chimera states in coupled chaotic optoelectronic oscillators [6], mechanical systems [7, 8], network of electrochemical reactions [9], and populations of coupled chemical oscillators [10, 11]. Totz et al. [12] reported the existence of spiral wave chimera states in coupled chemical oscillators. They carried out experiments with coupled Belousov-Zhabotinsky chemical oscillators.

Numerical analysis of coupled systems have showed the coexistence of coherent and incoherent domains [13, 14], and basin riddling in chimera dynamics [15]. Chimera states were found in simulations of different neuronal networks, e.g., coupled Hindmarsh-Rose neurons [16, 17], coupled FitzHugh-Nagumo neurons [18, 19], coupled Hodgkin-Huxley neurons [20, 21], network of integrate-and-fire neurons [22, 23], and network composed of heterogeneous neurons [24]. Rothkegel and Lehnertz [25] found chimera states in small-worlds networks of excitatory integrate-and-fire-like models [26]. Hizanidis et al. [27] observed synchronous, metastable and chimera states in a modular organisation of the *C. elegans* neuronal network. Ren et al. [28] showed the coexistence of different periodic states in Hindmarsh-Rose neuron network with both chemical and electrical connections. Santos et al. [29] reported the presence of chimeras in the neuronal networks. They considered a network model based on the cat cerebral cortex and identified two different chimera patterns characterised by desynchronised spikes and bursts. In the human brain, there are analogies between chimera state collapses and epileptic seizures [30].

In this paper, we study a network of adaptive exponential integrate-and-fire neurons [31]. Brette and Gerstner [32] introduced the adaptive exponential integrate-and-fire (AEIF) as a simple model that mimics the membrane potential of the neuron in vivo. Our neuronal network is a ring of coupled AEIF, in which the neurons are connected by chemical synapses. We observe the existence of chimera states with desynchronised spikes or bursts.

The main novelty of our work is to show chimera states whose neurons change between spikes and bursts activities as the system evolves. In addition, we observe multicluster chimera states that were found by Yao et al. [33] in Kuramoto networks of phase coupled oscillators. In our neuronal network, the multicluster chimera states is composed not only of temporal changes between spikes and burts, but also of domains with spike and burst patterns.

This paper is organised as follows: Section 2 introduces the neuronal network model. In Section 3, we show and analyse the time evolution of chimera states in our neuronal network. In the last Section, we draw our conclusions.

## 2 Adaptive Exponential Integrate-and-Fire Neuronal Network

We build a network composed of  $N$  coupled AEIF neurons. The neuron  $i$  is symmetrically connected with  $R$  nearest neighbours on either side. The neuronal network is composed of adaptive exponential integrate-and-fire neurons and it is given by

$$\begin{aligned}
C_m \frac{dV_i}{dt} &= -g_L(V_i - E_L) + g_L \Delta_T \exp\left(\frac{V_i - V_T}{\Delta_T}\right) \\
&\quad -w_i + I_i + (V_{\text{REV}} - V_i) \sum_{j=i-R, j \neq i}^{i+R} g_j, \\
\tau_w \frac{dw_i}{dt} &= a(V_i - E_L) - w_i, \\
\tau_s \frac{dg_i}{dt} &= -g_i,
\end{aligned} \tag{1}$$

where  $V_i$  is the membrane potential,  $w_i$  is the adaptation current, and  $g_i$  is the synaptic conductance. We consider: membrane capacitance  $C_m = 200$  pF, resting potential  $E_L = -70$  mV, leak conductance  $g_L = 12$  nS, slope factor  $\Delta_T = 2$  mV, spike threshold potential  $V_T = -50$  mV, adaptation time constant  $\tau_w = 300$  ms, level of subthreshold adaptation  $a = 2$  nS, synaptic time constant  $\tau_s = 2.728$  ms, injection of current  $I_i = 500$  pA, and synaptic reversal potential  $V_{\text{REV}} = 0$  mV (excitatory synapses). When  $V_i$  is larger than a threshold,  $V_i > V_{\text{thres}}$  [34],  $V_i$ ,  $w_i$ , and  $g_i$  are updated following the rules

$$\begin{aligned}
V_i &\rightarrow V_r, \\
w_i &\rightarrow w_i + b,
\end{aligned} \tag{2}$$

$$g_i \rightarrow g_i + g_{\text{ex}},$$

where  $V_r = -58$  mV,  $b = 70$  pA, and  $g_{\text{exc}}$  is the intensity of the excitatory synaptic conductance.

Figure 1: Action potential of the neuron  $i$  in our neuronal network for (a) spikes ( $CV_i = 0.008$ ), (b) spikes and bursts ( $CV_i = 0.529$ ), and (c) bursts ( $CV_i = 0.833$ ).

Depending on the control parameters, the AEIF neurons can generate spike or burst firings, and the network can also exhibit synchronous and desynchronous behaviour. In all simulations, we consider that the individual uncoupled neurons perform spike activities for the chosen parameters. With regard to the initial conditions,  $V_i$  and  $w_i$  are randomly distributed in the intervals  $[-58, -43]$  mV and  $[0, 70]$  pA, respectively. We analyse the solution of the neuronal network model during 2s and discard a transient time equal to 4s.

To identify spike or burst activities, we calculate the coefficient of variation ( $CV_i$ )

$$CV_i = \frac{\sigma_{\text{ISI}_i}}{\overline{\text{ISI}_i}}, \quad (3)$$

where  $\overline{\text{ISI}_i}$  is the mean value of the time difference between two consecutive firings (inter-spike interval) of the neuron  $i$  and  $\sigma_{\text{ISI}_i}$  is the standard deviation of  $\text{ISI}_i$ . In Fig. 1, we see the action potential of the neuron  $i$  for (a) spikes ( $CV_i = 0.008$ ), (b) spikes and bursts ( $CV_i = 0.529$ ), and (c) bursts ( $CV_i = 0.833$ ).

The mean value of CV ( $\overline{CV}$ ) is given by

$$\overline{CV} = \frac{1}{N} \sum_{i=1}^N CV_i. \quad (4)$$

For  $\overline{CV} < 0.5$  and  $\overline{CV} \geq 0.5$  the neuronal network exhibits spikes and bursts, respectively [35]. Figure 2 shows the parameter space  $R \times g_{\text{ex}}$  for  $\overline{CV}$  in colour

Figure 2: (Colour online) Parameter space  $R \times g_{\text{ex}}$  for  $\overline{\text{CV}}$ , where we consider  $N = 1000$  coupled AEIF neurons and 50 different initial conditions. The regions have spiking ( $\overline{\text{CV}} < 0.5$ ), bursting ( $\overline{\text{CV}} \geq 0.5$ ) neurons, and the coexistence of bursting and spiking can be seen according to the colour.

scale. The regions for  $\overline{\text{CV}} < 0.5$  and  $\overline{\text{CV}} \geq 0.5$  correspond to spike and burst activities, respectively. In the transition region, we identify the coexistence of spike and burst behaviours for different neurons in the network. Synchronous and desynchronous behaviours also occur for different values as  $R$  and  $g_{\text{ex}}$ .

### 3 Chimera States

In the chimera states there are spatiotemporal patterns characterised by the coexistence of coherent and incoherent domains. The spatial coherence and incoherence can be identified by the local order parameter [36]

$$Z_j(t) = \left| \frac{1}{2\delta + 1} \sum_{|j-k| \leq \delta} e^{i\phi_k(t)} \right|, \quad k = 1, \dots, N. \quad (5)$$

The phase is defined as

$$\phi_k(t) = 2\pi m + 2\pi \frac{t - t_{k,m}}{t_{k,m+1} - t_{k,m}}, \quad (6)$$

where  $t_{k,m}$  is the time of the  $m$ th spike of the neuron  $k$ ,  $t_{k,m} < t < t_{k,m+1}$ , and the spike happens for  $V_k > V_{\text{thres}}$ . In our simulations, we use  $\delta = 5$

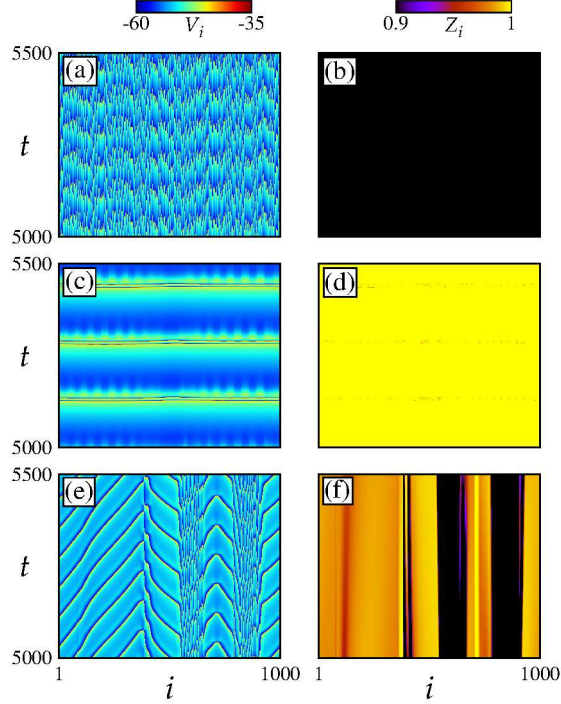

Figure 3: (Colour online) Time evolution of  $V_i$  and  $Z_i$  of each neuron  $i$  for incoherent pattern for  $R = 20$  and  $g_{\text{ex}} = 0.01$  nS ((a) and (b)), synchronised behaviour for  $R = 48$  and  $g_{\text{ex}} = 0.21$  nS ((c) and (d)), and chimera state for  $R = 20$  and  $g_{\text{ex}} = 0.44$  nS ((e) and (f)).

and consider a pattern to be synchronised when  $Z_j(t) > 0.9$ . The coherent (synchronised) and incoherent (desynchronised) domains are identified with a minimum size equal to  $2\delta + 1$  neighbours.

In Fig. 3, we present different types of dynamic behaviour by varying the parameters  $R$  and  $g_{\text{ex}}$ . Figures 3(a) and 3(b) display the neuronal network having incoherent pattern. Depending on the parameters, the network can exhibit synchronisation (Figs. 3(c) and 3(d)). We find chimera states with coexisting synchronous and desynchronous domains, as shown in Figs. 3(e) and 3(f).

Our AEIF neuronal network can exhibit different firing patterns, such as spikes, bursts, or both spikes and bursts. Figure 4 exhibits the values of  $V_i$ ,  $Z_i$ , and  $\text{CV}_i$  for chimera with spiking neurons (4(a), 4(b), and 4(c)) and chimera with bursting neurons (4(d), 4(e), and 4(f)).

A phenomenon not seen before is that the chimera states keep switching, in the desynchronous domains, between spikes and bursts as the system

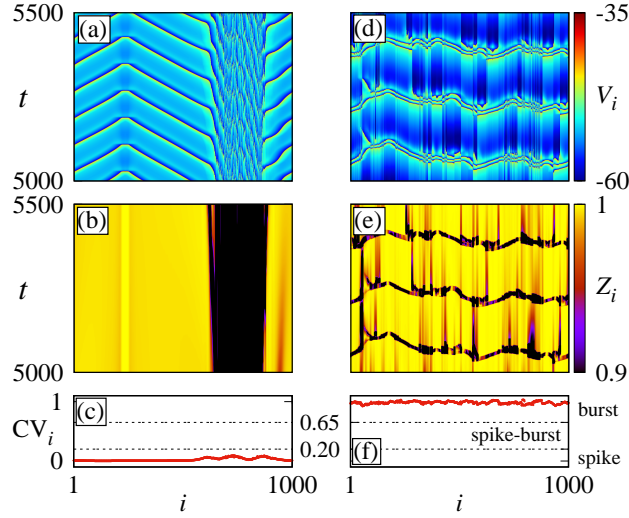

Figure 4: (Colour online)  $V_i$  and  $Z_i$  in colour scale for  $t \times i$ , and  $CV_i \times i$ . Chimera with spiking neurons for  $R = 40$  and  $g_{\text{ex}} = 0.22$  nS ((a), (b), and (c)), and chimera with bursting neurons for  $R = 24$  and  $g_{\text{ex}} = 0.46372$  nS ((d), (e), and (f)).

evolves in time, which we call spike-burst chimera (SBC). The SBC is found through  $Z_j(t)$  and  $CV_i$ . We identify SBC when the  $CV_i$  values are in the interval  $[0.2, 0.65]$ . In Fig. 5, we calculate  $V_i$ ,  $Z_i$ , and  $CV_i$  for parameters when the SBC states are present. Figs. 5(a), 5(b), and 5(c) display a SBC with synchronised spikes for  $R = 40$  and  $g_{\text{ex}} = 0.233$  nS. The SBC can have synchronised bursts, as shown in Figs. 5(d), 5(e), and 5(f) for  $R = 20$  and  $g_{\text{ex}} = 0.48$  nS.

In Fig. 6, we show the presence not only SBC, but also multicluster chimera states [33]. The network has groups of neurons with different patterns, such as spikes ( $CV_i \leq 0.20$ ), bursts ( $CV_i \geq 0.65$ ), and a mixture of spikes and bursts ( $0.20 < CV_i < 0.65$ ). Beurrier et al. [37] reported that the transition from spike to mixed burst activities in subthalamic nucleus neurons of rat and primates is one of the features of Parkinson's disease. There are two groups with spiking neurons, where one group has 217 neurons and the other 134 neurons, as well as one group with 511 bursting neurons. The SBC is identified by means of three groups with 22, 105, and 11 neurons that change between spike and burst patterns over time.

Figure 7(a) shows in the parameter space  $R \times g_{\text{ex}}$  the regions for chimera state (CS) and spike-burst chimera (SBC) states, as well as the regions where there are no chimera states (NC). We perform an average of 50 different random initial conditions to compute each point in the parameter space.

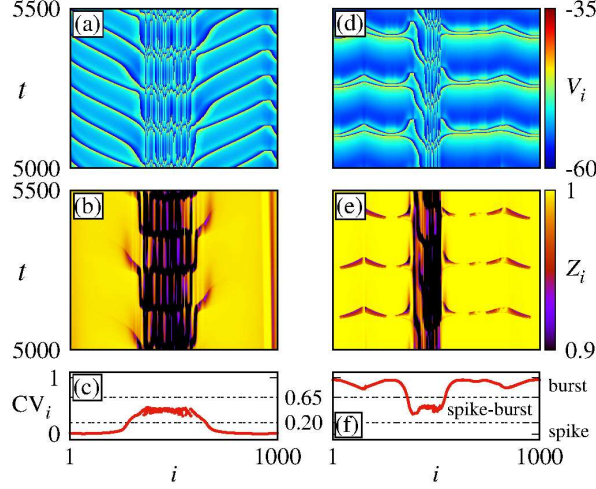

Figure 5: (Colour online)  $V_i$  and  $Z_i$  in colour scale for  $t \times i$ , and  $CV_i \times i$ . The SBC with synchronised spikes for  $R = 40$  and  $g_{\text{ex}} = 0.233$  nS ((a), (b), and (c)), and synchronised bursts for  $R = 20$  and  $g_{\text{ex}} = 0.48$  nS ((d), (e), and (f)).

The regions in blue and white colours represent CS and NC, respectively. The small region in red colour denotes the values of  $R$  and  $g_{\text{ex}}$  in which SBC is observed. Figure 7(b) displays the values of  $\overline{CV}$  as a function of  $g_{\text{ex}}$  for  $R = 25$ . We observe that  $\overline{CV}$  increases in the transitions from NC to CS and from CS to SBC, showing a scenario from spike to burst activities. When we fix  $g_{\text{ex}}$  and vary  $R$ , we find a similar behaviour. There are two disjoint regions with chimera states (CS) in Fig. 7(a), where the region II has a standard deviation of ISI greater than the region I, consequently  $\overline{CV}$  in the region II is greater than in the region I, as shown in Fig. 7(b).

## 4 Conclusions

We study an adaptive exponential integrate-and-fire neuronal network. In the network, each neuron is symmetrically coupled to the nearest neighbours. The connectivity between the neurons is given by excitatory synapses. Depending on the control parameters, the neurons can exhibit spike or burst activities.

Researches have reported the coexistence of spatiotemporal patterns, known as chimera states. There are evidences of chimera states in the brain, e.g., unihemispheric slow-wave sleep in some mammals. The coexistence of synchronous and desynchronous domains has been observed in neuronal net-

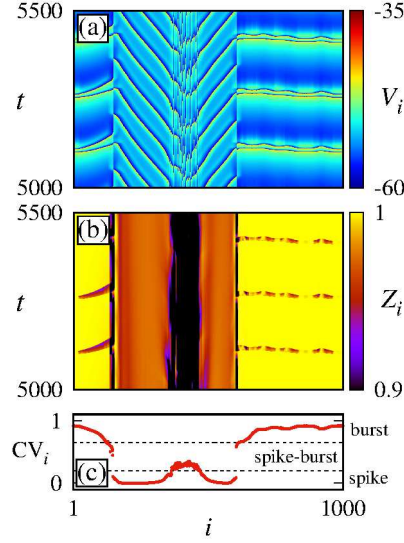

Figure 6: (Colour online)(a)  $V_i$  and (b)  $Z_i$  in colour scale for  $t \times i$ , and (c)  $CV_i \times i$ . Figure exhibits multicluster chimera states, where we consider  $R = 21$  and  $g_{\text{ex}} = 0.45$  nS.

work models.

In our network, chimera states are found by varying the number of nearest neighbours and the excitatory synaptic conductance. Depending on the coupling strength, multichimera state can arise for small  $R$  values [38]. We verify the existence of different types of chimera states according to the spike and burst patterns. In this work, we show the existence of chimera states with neurons that change between spike and burst activities as the system evolves in time. Moreover, we also identify multicluster chimera states composed of different groups of neurons with spike and burst patterns, as well as spikes and bursts changing over time.
