The number of flats of a hyperplane arrangement is considered as a generalization of the Bell number and the Stirling number of the second kind. In 1998, Robert Gill gave the exponential generating function of the number of flats of the extended Catalan arrangements, using species. In this article, we introduce the species of flats of the extended Catalan and Shi arrangements and they are given by iterated substitution of species of sets and lists. Moreover, we enumerate the flats of these arrangements in terms of infinite matrices.

1. Introduction

A hyperplane arrangement is a finite collection of affine subspaces of codimension 1 in an affine space over an arbitrary field \( \mathbb{K} \). In spite of its simple definition, arrangements are investigated in a variety of ways, such as topological, algebrogeometric, and combinatorial aspects. A standard reference for hyperplane arrangements is [13].

Given an arrangement \( \mathcal{A} \), let \( L(\mathcal{A}) \) denote the set of nonempty intersections of hyperplanes in \( \mathcal{A} \). Note that the ambient space is a member of \( L(\mathcal{A}) \) since it is regarded as the intersection over the empty set. We call an element of \( L(\mathcal{A}) \) a flat. Define a partial order on \( L(\mathcal{A}) \) by the reverse inclusion, that is, \( X \leq Y \iff X \supseteq Y \) for \( X, Y \in L(\mathcal{A}) \). We call \( L(\mathcal{A}) \) the intersection poset of \( \mathcal{A} \). This poset plays an important role in the theory of hyperplane arrangements. For each nonnegative integer \( k \), let

\[
L_k(\mathcal{A}) := \{ X \in L(\mathcal{A}) \mid \dim X = k \}.
\]

When \( \mathcal{A} \) is central, that is, the intersection of all hyperplanes in \( \mathcal{A} \) is nonempty, the poset \( L(\mathcal{A}) \) is a geometric lattice.

A set partition of a finite set \( V \) is a collection \( \pi = \{B_1, \ldots, B_k\} \) of nonempty subsets \( B_i \subseteq V \) such that \( B_i \cap B_j = \emptyset \) for \( i \neq j \) and \( \bigcup_{i=1}^{k} B_i = V \). Each \( B_i \) is called a block of \( \pi \). Introduce a partial order on set partitions of \( S \) by \( \pi \leq \pi' \) if \( \pi \) refines \( \pi' \), that is, each block of \( \pi \) is a subset of some block of \( \pi' \), and the collection of the set partitions of \( S \) forms a lattice.

For a positive integer \( n \), let \( [n] \) be the set \( \{1, \ldots, n\} \) and \( [0] \) the empty set. The number of set partitions of \( [n] \) is called the Bell number, denoted by \( B(n) \), and the number of set partitions of \( [n] \) into \( k \) blocks is called the Stirling number of the second kind, denoted \( S(n,k) \).

Let \( \mathcal{B}_n \) denote the \( n \)-dimensional braid arrangement (also known as the Weyl arrangement of type \( A_{n-1} \)), which consists of hyperplanes \( \{x_i - x_j = 0\} \) for \( 1 \leq i < j \leq n \), where \( x_1, \ldots, x_n \) denote coordinates of \( \mathbb{R}^n \). It is well known that there exists an isomorphism from \( L(\mathcal{B}_n) \) to the lattice of set partitions of \( [n] \) which sends a \( k \)-dimensional flat to a set partition into \( k \) blocks. Therefore we have \( |L(\mathcal{B}_n)| = B(n) \) and \( |L_k(\mathcal{B}_n)| = S(n,k) \). Thus the numbers of flats and \( k \)-dimensional flats of an arrangement may be considered to be generalizations of the Bell and Stirling numbers.

Define the extended Catalan arrangement \( \mathcal{C}_n^m \) and the extended Shi arrangement \( \mathcal{S}_n^m \) as follows:

\[
\mathcal{C}_n^m := \{ \{x_i - x_j = a\} \mid 1 \leq i < j \leq n, -m \leq a \leq m \}, \quad (m \geq 0),
\]

\[
\mathcal{S}_n^m := \{ \{x_i - x_j = a\} \mid 1 \leq i < j \leq n, 1 - m \leq a \leq m \}, \quad (m \geq 1).
\]
Note that $C_0^n = B_n$ for every nonnegative integer $n$ and $L_0(C_n^m) = L_0(S_n^m) = \emptyset$ unless $n = 0$. Gill [8] investigated the intersection posets of the extended Catalan arrangements. First Gill determined the number of maximal elements of the poset $L(C_n^m)$ as follows.

**Theorem 1.1** (Gill [8, Theorem 1]). Let $m$ be a nonnegative integer. Then

$$\sum_{n=1}^{\infty} |L_1(C_n^m)| \frac{x^n}{n!} = \frac{e^x - 1}{1 - m(e^x - 1)}.$$

In the paper, the use of species for counting flats of $L(C_n^m)$ is a noteworthy point. The theory of species was initiated by Joyal [11]. Standard references for species are [2, 3]. Let $B$ denote the category of finite sets and bijections and $E$ the category of finite sets and maps. A species is a functor $F: B \to E$. The value of a species $F$ at a finite set $V$ is denoted by $F[V]$. Moreover, we write simply $F[n]$ instead of $F[[n]]$. The symbol $F(x)$ is used for the exponential generating function $F(x) := \sum_{n=0}^{\infty} |F[n]| \frac{x^n}{n!}$.

**Example 1.2.** Let $E$ denote the species of sets. Namely $E[V] := \{V\}$. Then we have $|E[n]| = 1$ for every $n$ and thus $E(x) = \sum_{n=0}^{\infty} x^n = e^x$.

**Example 1.3.** Let $L$ denote the species of lists. Namely

$$L[V] := \{ (v_1, \ldots, v_n) \mid n = |V| \text{ and } V = \{v_1, \ldots, v_n\} \}.$$

We have $|L[n]| = n!$ for every $n$ and hence $L(x) = \sum_{n=0}^{\infty} x^n = \frac{1}{1-x}$.

Making use of species enables us to calculate generating functions systematically. Namely we can define operations for species such as sum, product, and so on. These operations are compatible with the corresponding operations for the generating functions. Hence we may say that species is a refinement of the exponential generating function.

**Example 1.4.** Given species $F$ and $G$, we define the sum $F + G$ by $(F + G)[V] := F[V] \sqcup G[V]$, where $\sqcup$ means the disjoint union. Then we have $(F + G)(x) = F(x) + G(x)$. Moreover, every species $F$ has a canonical decomposition $F = \sum_{k=0}^{\infty} F_k$, where

$$F_k[V] := \begin{cases} F[V] & \text{if } |V| = k, \\ \emptyset & \text{otherwise}. \end{cases}$$

Furthermore, let $F_+ := \sum_{k=0}^{\infty} F_k$. Then we have $F_+(x) = F(x) - F(0)$. Especially

$$E_+(x) = e^x - 1, \quad E_k(x) = \frac{x^k}{k!}, \quad \text{and} \quad L_+(x) = \frac{1}{1-x} - 1 = \frac{x}{1-x}.$$

In this article, we frequently use the operation $F \circ G$ of species, called substitution (or composition).
Definition 1.5. Let $F$ and $G$ be species with $G[\varnothing] = \varnothing$. Define

$$(F \circ G)[V] := \bigsqcup_{\pi \in \Pi[V]} \left( F[\pi] \times \prod_{B \in \pi} G[B] \right),$$

where $\Pi$ denotes the species of set partitions.

Substitution of species corresponds substitution of generating functions, that is, $(F \circ G)(x) = F(G(x))$. It is a functional tool for computing the generating function and explains why the exponential function $e^x$ sometimes appears in the generating function.

Example 1.6. By definition, the exponential generating function of the Bell numbers is given by $\Pi(x)$. The species of set partitions $\Pi$ coincides with the species $E \circ E +$ (See Example 2.2 for details). Hence we have the following.

$$\Pi(x) = (E \circ E +)(x) = \exp(e^x - 1).$$

Example 1.7. Given a species $F$, let $F^{\circ m}_+$ be the $m$-times iterated self-substitution of $F_+$. For the species $L$ of lists, we have

$$L^{\circ 2}_+(x) = (L_+ \circ L_+)(x) = \frac{x}{1 - \frac{x}{1 - 2x}} = \frac{x}{1 - 2x}.$$  

More generally, one can show easily that

$$L^{\circ m}_+(x) = \frac{x}{1 - mx}.$$  

The construction of the extended Catalan arrangement $C^m_n$ is functorial in $n$. Namely, for every finite set $V$, we may construct the corresponding Catalan arrangement in the vector space $\mathbb{R}^V = \text{Map}(V, \mathbb{R})$ and hence there exist species $L^C_m$ and $L_k^C_m$ such that $L^C_m[n] = L(C^m_n)$ and $L_k^C_m[n] = L_k(C^m_n)$. Gill’s second theorem is as follows.

Theorem 1.8 (Gill [8, Theorem 2]). For every $m \geq 0$, the equality $L^C_m = E \circ L_1^C_m$ holds. Moreover, the bivariate generating function of $|L_k(C^m_n)|$ is given by

$$\sum_{n=0}^{\infty} \sum_{k=0}^{n} |L_k(C^m_n)| t^k x^n \frac{1}{n!} = \exp \left( t \frac{e^x - 1}{1 - m(e^x - 1)} \right).$$

We write $F = G$ if there exists a natural isomorphism between species $F$ and $G$. In this paper, we will improve Gill’s results in terms of species as follows.

Theorem 1.9. Let $m$ and $k$ be nonnegative integers. Then

$$L_k^C_m = E_k \circ L^{\circ m}_+ \circ E_+ \quad \text{and} \quad L^C_m = E \circ L^{\circ m}_+ \circ E_+.$$  

4
This theorem together with Example 1.4, Example 1.6, and Example 1.7 leads to the following corollary. Note that one can deduce Theorem 1.1 and Theorem 1.8 from this corollary.

**Corollary 1.10.**

\[
L_k C_m(x) = \sum_{n=0}^{\infty} \frac{L_k(C_m^n)}{n!} x^n = \frac{1}{k!} \left( \frac{e^x - 1}{1 - m(e^x - 1)} \right)^k,
\]

\[
L C_m(x) = \sum_{n=0}^{\infty} \frac{|L(C_m^n)|}{n!} x^n = \exp \left( \frac{e^x - 1}{1 - m(e^x - 1)} \right).
\]

We will also give an analog for the extended Shi arrangement \( S^m_n \). However, the construction of \( S^m_n \) cannot be regarded as a functor on \( \mathbb{B} \) since the construction requires the linear order on the set \([n]\). For this reason, from now on, we consider \( \mathbb{L} \)-species, that is, a functor \( F: \mathbb{L} \to \mathbb{E} \), where \( \mathbb{L} \) denotes the category of linearly ordered sets and order-preserving bijections. Contrary we also call an ordinary species a \( \mathbb{B} \)-species. Note that every \( \mathbb{B} \)-species can be considered as an \( \mathbb{L} \)-species via the forgetful functor from \( \mathbb{L} \) to \( \mathbb{B} \).

Let \( L S^m \) and \( L_k S^m \) denote the \( \mathbb{L} \)-species such that \( L S^m[n] = L(S^m_n) \) and \( L_k S^m[n] = L_k(S^m_n) \). The following is another main result of this article.

**Theorem 1.11.** Let \( m \) and \( k \) be nonnegative integers. Then

\[
L_k S^m = E_k \circ L^m_+ \quad \text{and} \quad L S^m = E \circ L^m_+.
\]

**Corollary 1.12.**

\[
L_k S^m(x) = \sum_{n=0}^{\infty} \frac{|L_k(S^m_n)|}{n!} \frac{x^n}{n!} = \frac{1}{k!} \left( \frac{x}{1 - m x} \right)^k,
\]

\[
L S^m(x) = \sum_{n=0}^{\infty} \frac{|L(S^m_n)|}{n!} \frac{x^n}{n!} = \exp \left( \frac{x}{1 - m x} \right).
\]

Moreover, we will give explicit formulas for the numbers \(|L_k(S^m_n)|\) and \(|L_k(C_m^n)|\) of \( k \)-dimensional flats of \( n \)-dimensional extended Catalan and Shi arrangements with infinite matrices. Let \([a_{ij}]\) denote the infinite matrix whose entry in the \( i \)-th row and the \( j \)-th column is \( a_{ij} \), where \( i \) and \( j \) run over all positive integers. Let \( c := [c(j, i)] \) and \( S := [S(j, i)] \), where \( c(j, i) \) denote the **unsigned Stirling number of the first kind**, that is, the number of ways to partition a \( j \)-element set into \( i \) cycles. Note that most of tables, including Table 5 consisting of such numbers are lower triangular. However, our infinite matrices \( c \) and \( S \) are transposed and hence upper
triangular. Namely,
\[
c = \begin{bmatrix}
1 & 1 & 2 & 6 & 24 & \cdots \\
0 & 1 & 3 & 11 & 50 & \cdots \\
0 & 0 & 1 & 6 & 35 & \cdots \\
0 & 0 & 0 & 1 & 6 & \cdots \\
0 & 0 & 0 & 0 & 1 & \cdots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \ddots
\end{bmatrix}, \quad S = \begin{bmatrix}
1 & 1 & 1 & 1 & \cdots \\
0 & 1 & 3 & 7 & 15 & \cdots \\
0 & 0 & 1 & 6 & 25 & \cdots \\
0 & 0 & 0 & 1 & 10 & \cdots \\
0 & 0 & 0 & 0 & 1 & \cdots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \ddots
\end{bmatrix}.
\]

Theorem 1.13.

\[\left|L_i(C^m_j)\right| = (Sc)^m S \quad \text{and} \quad \left|L_i(S^m_j)\right| = (Sc)^m.\]

From Theorem 1.13, we may also calculate the matrices recursively as follows.
\[
C^0 \xrightarrow{c} S^1 \xrightarrow{S} C^1 \xrightarrow{c} S^2 \xrightarrow{S} C^2 \xrightarrow{c} \cdots
\]

The organization of this paper is as follows.

In §2, we give some examples of substitutions of species. Also, we introduce tree notation for the species \(L^{em}_{\emptyset}\). Although actually this notation is not required for the proofs of our main theorems, it helps us to recognize elements of \(L^{em}_{\emptyset}\).

In §3, we review the theory of gain graphs developed by Zaslavsky. Since the extended Catalan and Shi arrangements are expressed by using gain graphs, the intersection posets of these arrangements can be represented by a kind of partitions of the vertices of the corresponding gain graphs. This guarantees that it suffices to know the 1-dimensional flats in order to know all flats, that is, \(LC^m = E \circ L1C^m\) and \(LS^m = E \circ L1S^m\).

In §4, we give proofs of Theorem 1.9, Theorem 1.11, and Theorem 1.13.

In §A, as an appendix we give numerical tables for the number of flats with ID numbers in the On-Line Encyclopedia of Integer Sequences (OEIS) [10].

Note that we will construct several natural transformations in this article. However, we will omit proofs of commutativity of diagrams for the natural transformations since they are obvious.

2. Substitution of species

2.1. Examples

First recall the definition of substitution of species.

**Definition 2.1.** Let \(F\) and \(G\) be species with \(G[\emptyset] = \emptyset\). Define

\[
(F \circ G)[V] := \bigsqcup_{\pi \in \Pi(V)} \left( F[\pi] \times \prod_{B \in \pi} G[B] \right),
\]

where \(\Pi\) denotes the species of set partitions.
The substitution $F \circ G$ has the external and internal structure. Namely, for each set partition $\pi$, we take an element of $F[\pi]$, which is the external structure. For every block $B$ of $\pi$, we choose an element of $G[B]$, which is the internal structure. In the usual case, a constituent of the external structure is labeled with blocks of a partition and if we “substitute” the labels with internal structures, then we obtain an element of $(F \circ G)[V]$.

**Example 2.2.** Let $G$ be a species such that if $g \in G[B], g' \in G[B']$, and $g = g'$, then $B = B'$. We will see that the species $E \circ G$ may be considered as a species of set partitions consisting of $G$-structures.

By definition,

$$(E \circ G)[V] = \bigsqcup_{\pi \in \Pi[V]} \left( E[\pi] \times \prod_{B \in \pi} G[B] \right) = \bigsqcup_{\pi \in \Pi[V]} \left( \{\pi\} \times \prod_{B \in \pi} G[B] \right).$$

For any set partition $\pi = \{B_1, \ldots, B_k\}$, every element $(\pi, (g_{B_1}, \ldots, g_{B_k})) \in \{\pi\} \times \prod_{B \in \pi} G[B]$ can be identified with the set $\{g_{B_1}, \ldots, g_{B_k}\}$. Then the set $(E \circ G)[V]$ is identified with

$$\{ \{g_{B_1}, \ldots, g_{B_k}\} \mid \{B_1, \ldots, B_k\} \in \Pi[V], \ g_{B_i} \in G[B_i]\}.$$ 

Especially $E \circ E_+$ gives set partitions consisting of sets, that is, ordinary set partitions. Namely $E \circ E_+ = \Pi$.

**Example 2.3.** Let $G$ be as above. By the similar discussion, we may say that the species $L \circ G$ may be considered as a species of lists consisting of $G$-structures. Namely the set $(L \circ G)[V]$ can be identified naturally with

$$\{ \{g_{B_1}, \ldots, g_{B_k}\} \mid \{B_1, \ldots, B_k\} \in \Pi[V], \ g_{B_i} \in G[B_i]\}.$$ 

The species $L \circ E_+$ is known as a species of set compositions (or ordered set partitions). The cardinality $|(L \circ E_+)[n]|$ is called the ordered Bell number (or Fubini number). For instance $|(L \circ E_+)[3]| = 13$ since it consists of the following set compositions (Here we omit commas).

$$\{ (1\{2\}3), (1\{2\}3), (1\{3\}2), (1\{3\}2), (1\{2\}3), (1\{3\}2), (1\{2\}3), (1\{3\}2), (1\{2\}3), (1\{3\}2), (1\{2\}3), (1\{3\}2), (1\{2\}3), (1\{3\}2), (1\{2\}3) \}.$$ 

**Example 2.4.** The species $E_1$ of singletons behaves as the identity element with respect to substitution. Namely, $E_1 \circ G = G$ and $F \circ E_1 = F$.

A lot of researchers have been studied iterated substitutions of species of sets and lists. For example, Motzkin [12] investigated several structures including, “sets of sets” $E \circ E_+$, “sets of lists” $E \circ L_+$, “lists of sets” $L \circ E_+$, and “lists of lists” $L \circ L_+$. Sloane and Wieder [15] call an element of $(E \circ L_+ \circ E_+)[n]$ a hierarchical ordering (or society). Callan [4, Section 2] gave a bijection between lists of noncrossing sets and sets of lists $E \circ L_+$. Hedmark [9, Subsection 5.2] introduced an $\alpha$-colored partition lattice for a positive integer $\alpha$ and stated that it can be regarded as $L_+^{\alpha} \circ E_+$. 

7
2.2. Tree notation for $L^+_m$

The species $L^+_m$ can be considered as the species of "m-dimensional lists". For example $(((49)(5))((3)(71)(6))(82)))$ is an element of $L^+_3[9]$. However, it is difficult to understand the structure of this at first glance. Hence we introduce tree notation for $L^+_m$.

The idea is very simple. We just regard a list as an ordered rooted tree of height one with labeled leaves, where an ordered rooted tree means a rooted tree whose sibling sets are linearly ordered as lists. For example the lists (123) and (2413) are expressed as in Figure 1.

Then the species $L^+_m$ can be regarded as a rooted tree of height $m$. For example, $(((49)(5))((3)(71)(6))(82))) \in L^+_3[9]$ is expressed as the left in Figure 2. We also can express elements of $L^+_m \circ E_+$ by taking labels consisting of sets. For example $(((\{57\}\{3\})(\{149\}\{26\}\{8\})) \in (L^+_2 \circ E_+)[9]$ is as the right in Figure 2.

3. Gain graphs and the associated posets

3.1. Review of graphic arrangements

First we recall graphic arrangements and their intersection lattices. Let $\Gamma = (V_\Gamma, E_\Gamma)$ be a simple graph on vertex set $V_\Gamma = [n]$. We can associate $\Gamma$ with a hyperplane arrangement $A_\Gamma$ in $\mathbb{K}^n$, called the graphic arrangement, consisting of hyperplanes defined by $\{x_i - x_j = 0\}$ with $\{i, j\} \in E_\Gamma$, where $x_1, \ldots, x_\ell$ denote coordinates of $\mathbb{K}^\ell$.

Also, we can construct a matroid $M_\Gamma$ on $E_\Gamma$, called the graphic matroid, from the linear independence of $A_\Gamma$. Hence the lattice of flats $L(M_\Gamma)$ is naturally isomorphic to the intersection lattice $L(A_\Gamma)$. Rota [14] first introduced $L(M_\Gamma)$ and called it the bond lattice of the graph $\Gamma$.

It is well known that the lattices $L(A_\Gamma)$ and $L(M_\Gamma)$ also can be represented by using set partitions as explained below. A connected partition of $\Gamma$ is a set partition of $V_\Gamma$ whose every block induces a connected subgraph of $\Gamma$. Let $L(\Gamma)$ be the set of all connected partitions of $\Gamma$ with the partial order defined by refinement. Namely, $\pi \leq \pi'$ if each block of $\pi'$ is the union of some blocks of $\pi$. We
call $L(\Gamma)$ the lattice of connected partitions (or the lattice of contractions), which is naturally isomorphic to $L(\mathcal{A}_\Gamma)$ and $L(\mathcal{M}_\Gamma)$. Thus we can associate a simple graph $\Gamma$ with three isomorphic lattices $L(\Gamma), L(\mathcal{A}_\Gamma)$ and $L(\mathcal{M}_\Gamma)$.

Note that the braid arrangement $\mathcal{B}_n$ can be regarded as a graphic arrangement with the complete graph $K_n$. Since $L(K_n)$ consists of all set partitions of $[n]$, the number of flats of the braid arrangement is associated with the Bell number and the Stirling number of the second kind.

3.2. Gain graphs and affinographic arrangements

The extended Catalan and Shi arrangements are represented by using gain graphs. Gain graphs were introduced by Zaslavsky \cite{Zaslavsky1995} for abstraction of linear independence of two kind of hyperplanes of the form

$$\{x_i - x_j = a\} \text{ and } \{x_i - ax_j = 0\} \quad (a \neq 0).$$

Roughly speaking, a gain graph is a graph with labeled edges $(i,j,a)$, which corresponds to the hyperplanes above. However, since

$$\{x_i - x_j = a\} = \{x_j - x_i = -a\} \quad \text{and} \quad \{x_i - ax_j = 0\} = \{x_j - a^{-1}x_i = 0\},$$

we must identify $(i,j,a)$ with $(j,i,-a)$ for the former case and $(i,j,a)$ with $(j,i,a^{-1})$ for the latter case. Although these two cases can be treated uniformly to a certain extent, we are interested in the former case in this article since extended Catalan and Shi arrangements consists of these hyperplanes. For this reason, we use the additive notation for labels of gain graphs. Here we give a formal definition of gain graphs.

**Definition 3.1.** A simple gain graph is a triple $\Gamma = (V_\Gamma, E_\Gamma, G_\Gamma)$ satisfying the following conditions.

(i) $V_\Gamma$ is a finite set.

(ii) $G_\Gamma$ is a group (not necessarily finite).

(iii) $E_\Gamma$ is a finite subset of $\{ (u, v, a) \in V_\Gamma \times V_\Gamma \times G_\Gamma \mid u \neq v \}$ divided by the equivalence relation $\sim$ generated by $(u, v, a) \sim (v, u, -a)$.

Let $\{u,v\}_a$ denote the equivalence class containing $(u, v, a)$ and hence note that $\{u,v\}_a = \{v,u\}_{-a}$. Elements in $V_\Gamma$ and $E_\Gamma$ are called vertices and edges of the gain graph $\Gamma$. The group $G_\Gamma$ is called the gain group of $\Gamma$.

Note that we quite simplify the notion of gain graphs for our purpose. Especially we do not consider multiple edges with the same elements in the gain group, loops, or half edges. See Zaslavsky \cite{Zaslavsky1995} for a general treatment. Although we use additive notation for the gain group, we do not assume that the gain group is commutative. However, for the main results in this article, one may assume that the gain group is always commutative.
**Definition 3.2.** Suppose that $\Gamma$ is a gain graph on $[n]$ and $G_\Gamma = K^+$, the additive group of a field $K$. Define an affine arrangement $A_\Gamma$ in $K^n$ by

\[ A_\Gamma := \{ x_i - x_j = a \mid \{ i, j \} \in E_\Gamma \}. \]

We call $A_\Gamma$ the **affinographic arrangement** of $\Gamma$.

Note that every simple graph may be regarded as a gain graph such that all elements in the gain group are 0 and then the graphic arrangement coincides with the affinographic arrangement. Hence there is no confusion to use the same symbol $A_\Gamma$ for the graphic and affinographic arrangements.

**Definition 3.3.** Let $G$ be a group and $A \subseteq G$ a finite subset. For every positive integer $n$, define $K_A^m$ as a gain graph on $[n]$ with gain group $G$ and edges

\[ E_{K_A^m} := \{ \{ i, j \} \mid 1 \leq i < j \leq n, a \in A \}. \]

We call $K_A^m$ the **complete gain graph with gain** $A$.

**Remark 3.4.** The construction of $K_A^m$ requires the linear order on $[n]$ unless $-A = A$.

**Example 3.5.** For integers $a, b$ with $a \leq b$, let $[a, b] := \{ a, a + 1, \ldots, b \} \subseteq \mathbb{Z}$. Then

\[ C_m^m = A_{K_{[-m,m]}^m} \quad \text{and} \quad S_m^m = A_{K_{[1-m,m]}^m}. \]

Moreover, $A_{K_{[1,m]}^m}$ is known as the (extended) Linial arrangements.

Let $v_1, v_2, \ldots, v_r$ be distinct vertices of a gain graph $\Gamma$. A **path** on the vertices $v_1, \ldots, v_r$ is a set of edges $\{ v_1, v_2 \}_{a_1}, \{ v_2, v_3 \}_{a_2}, \ldots, \{ v_{r-1}, v_r \}_{a_{r-1}}$. A **cycle** on the vertices $v_1, \ldots, v_r$ is a set of edges $\{ v_1, v_2 \}_{a_1}, \{ v_2, v_3 \}_{a_2}, \ldots, \{ v_{r-1}, v_r \}_{a_{r-1}}, \{ v_r, v_1 \}_{a_r}$. The cycle is called **balanced** if $a_1 + a_2 + \cdots + a_r = 0$. This definition is independent of choice of the initial vertex and the direction of the cycle. A subset $S \subseteq E_\Gamma$ is called **balanced** if any cycle contained in $S$ is balanced. A balanced subset $S \subseteq E_\Gamma$ is called **balanced-closed** if

\[ S = \{ e \in E_\Gamma \mid e \text{ forms a balanced cycle together with a subset of } S \}. \]

**Definition 3.6.** Given a gain graph $\Gamma$, define a poset $L(M_\Gamma)$ by

\[ L(M_\Gamma) := \{ F \subseteq E_\Gamma \mid F \text{ is balanced and balanced-closed} \}. \]

and its order is given by inclusion. The poset $L(M_\Gamma)$ is called the **poset of balanced flats** of $\Gamma$.

**Remark 3.7.** The poset $L(M_\Gamma)$ is denoted by the symbol $\text{Lat}^b$ in Zaslavsky’s papers and is actually the poset of flats of the **semimatroid** $M_\Gamma$ associated with a gain graph $\Gamma$. Ardila [1] introduced the notion of semimatroid for combinatorial abstraction of linear independence of affine arrangements and described a relation between semimatroids and geometric semilattices introduced by Wachs and Walker [16], which is a generalization of a well-known relation between matroids and geometric lattices.
In this paper we omit the definition of semimatroids. There is no problem considering that the definition of $L(M_\Gamma)$ is Definition 3.6. However, we will state the outline. Roughly speaking, a semimatroid is defined by the ground sets, the collection of central sets, and the rank function. An equivalent definition can be found in [7, Subsection 4.1]. Given an affine arrangement $A$, we can define the corresponding semimatroid $M_A$ if we define the ground set by $A$, the collection of central sets by central subarrangements of $A$, and the rank function by the rank of arrangements. Moreover, keep in mind that we can define flats and the poset of flats $L(M)$ of each semimatroid $M$ and the intersection poset $L(A)$ of an affine arrangement $A$ is naturally isomorphic to $L(M_A)$.

When $G_\Gamma = \mathbb{K}^+$, the linear independence of the affinographic arrangement $A_\Gamma$ yields a semimatroid on $E_\Gamma$. Zaslavsky [18, 19, 20, 21, 22] gave an abstraction of this semimatroid, that is, defined the semimatroid $M_\Gamma$ on $E_\Gamma$ for a gain graph $\Gamma$ with any gain group. The semimatroid $M_\Gamma$ is called the balanced semimatroid [22] or the semimatroid of graph balance [7].

**Theorem 3.8 (Zaslavsky [21 Corollary 4.5(a)]).** Let $\Gamma$ be a gain graph on $[n]$ and the gain group is $\mathbb{K}^+$. Then the map

$$L(M_\Gamma) \longrightarrow L(A_\Gamma)$$

$$F \mapsto \bigcap\{x_i - x_j = a\}.$$  

is an isomorphism of posets.

### 3.3. Poset of connected partitions

Let $G$ be a group. A $G$-labeled set is pair $(V, \theta)$ of a set $V$ and a map $\theta : V \rightarrow G$. Two $G$-labeled sets $(V, \theta)$ and $(V, \eta)$ are said to be equivalent if there exists an element $g \in G$ satisfying $\theta(v) = g + \eta(v)$ for any $v \in V$. Let $[V, \theta]$ denote the equivalent class containing $(V, \theta)$.

Let $\Gamma$ be a gain graph. Consider an equivalence class of $G_\Gamma$-labeled sets $[B, \theta]$ with $B \subseteq V_\Gamma$. Define $\Gamma[B, \theta]$ as a gain graph on $B$ with gain group $G_\Gamma$ and edges

$$E_{\Gamma[B, \theta]} := \{ \{u, v\}_a \in E_\Gamma \mid u, v \in B, \; \theta(u) + a = \theta(v) \}$$

$$= \{ \{u, v\}_{-\theta(u) + \theta(v)} \in E_\Gamma \mid u, v \in B \}.$$  

One can show that the gain graph $\Gamma[B, \theta]$ is independent of choice of a representative $(B, \theta)$.

A connected partition of $\Gamma$ is a collection $\pi = \{[B_1, \theta_1], \ldots, [B_k, \theta_k]\}$ such that $\{B_1, \ldots, B_k\}$ is a set partition of $V_\Gamma$ and each $\Gamma[B_i, \theta_i]$ is connected, that is, there exists a path joining any two distinct vertices.

Let $\pi$ and $\pi'$ be connected partitions. We say that $\pi$ refines $\pi'$, denoted $\pi \leq \pi'$ if for any $[B, \theta] \in \pi$ there exist $[B', \theta'] \in \pi'$ and $g \in G_\Gamma$ such that $B \subseteq B'$ and $\theta(v) = g + \theta'(v)$ for any $v \in B$. Let $L(\Gamma)$ denote the set of all connected partitions, which forms a poset together with the refinement. Call $L(\Gamma)$ the poset of connected partitions of $\Gamma$.

Note that when a simple graph $\Gamma$ is viewed as a gain graph, connected partitions coincide with the usual connected partitions of the simple graph $\Gamma$. Therefore the poset of connected partitions of a gain graph is a generalization of the lattice of connected partitions of a simple graph.
Remark 3.9. For any finite group $G$ Dowling [6] introduced $G$-labeled sets and $G$-partitions, which is equivalent to $K_n^G$-partitions, and showed that the collection consisting of $G$-partitions of the subsets of $[n]$ forms a geometric lattice. This lattice is known as the Dowling lattice.

Theorem 3.10 (Zaslavsky [17, Lemma 3.1A and 3.1B]). Given a gain graph $\Gamma$, the following map is an isomorphism of posets.

$$L(\Gamma) \rightarrow L(M_{\Gamma}), \quad \pi \mapsto \bigcup_{[B, \theta] \in \pi} E_{\Gamma|B,\theta}.$$  

Corollary 3.11. Let $\Gamma$ be a gain graph on $[n]$ and the gain group is $\mathbb{K}^+$.  

(1) If $[B, \theta]$ is a block of a connected partition of $\Gamma$ with $B = \{i_1, \ldots, i_r\}$, then

$$X_{[B, \theta]} := \bigcap_{\{i,j\} \in E_{\Gamma|B,\theta}} \{x_i - x_j = a\} = \{x_{i_1} + \theta(i_1) = \cdots = x_{i_r} + \theta(i_r)\}.$$  

(2) The following map is an isomorphism of posets.

$$L(\Gamma) \rightarrow L(A_{\Gamma}), \quad \pi \mapsto \bigcap_{[B, \theta] \in \pi} X_{[B, \theta]}.$$  

(3) For any nonnegative integer $k$, the isomorphism in (2) induces a bijection between $L_k(\Gamma)$ and $L_k(A_{\Gamma})$, where

$$L_k(\Gamma) := \{\pi \in L(\Gamma) \mid |\pi| = k\}.$$  

Proof. (1) Recall $E_{\Gamma|B,\theta} = \{\{i,j\}_{-\theta(i)+\theta(j)} \in E_{\Gamma} \mid i,j \in B\}$. The hyperplane corresponding to the edge $\{i,j\}_{-\theta(i)+\theta(j)}$ is

$$\{x_i - x_j = -\theta(i) + \theta(j)\} = \{x_i + \theta(i) = x_j + \theta(j)\}.$$  

Since $\Gamma|B,\theta$ is connected, the intersection coincides with the right hand side.  

(2) This follows from Theorem 3.8 and 3.10.  

(3) Obvious from (2). \hfill $\square$

3.4. Partitional decompositions

Let $G$ be a group and $A \subseteq G$ a finite subset. The construction of the complete gain graph with gain $A$ is considered to be an $\mathbb{L}$-species. Namely, for each finite linearly ordered set $V$, we may construct the complete gain graph $K^A_V$ on $V$ with gain $A$ and its poset of connected partitions $L(K^A_V)$ in an obvious way. In other words, there exist $\mathbb{L}$-species $LK^A$ and $L_kK^A$ such that $LK^A[n] = L(K^A_n)$ and $L_kK^A[n] = L_k(K^A_n)$. 

12
Proposition 3.12. Let $G$ be a group and $A \subseteq G$ a finite subset. Then

$$L_k K^A = E_k \circ L_1 K^A \quad \text{and} \quad L K^A = E \circ L_1 K^A$$

Proof. Let $[B, \theta]$ be a block of a connected partition of $K^A_n$. Then the block $[B, \theta]$ may be regarded as an element of $L_1 K^A[B]$. This identification leads to the desired natural isomorphisms of the species. \qed

3.5. Integral gain graphs and height functions

We call a gain graph with the gain group $\mathbb{Z}$ an integral gain graph. The notion of height function on an integral gain graph was introduced in [5].

Definition 3.13. A height function on a finite set $V$ is a function $h : V \rightarrow \mathbb{Z}$ such that $\min(h(V)) = 0$. Let $H$ denote the species of height functions.

Let $\mathbb{Z}_+$ denote the set of positive integers. Given a nonnegative integer $\ell$, a tuple $\alpha = (\alpha_1, \ldots, \alpha_k) \in \mathbb{Z}_+^k$ is called an integer composition of length $k$. Note that there exists a unique integer composition $\emptyset$ of length 0. When $\alpha$ is a tuple, including a list and an integer composition, let $\ell(\alpha)$ denote the length of $\alpha$.

Definition 3.14. Define a species $I$ by

$$I[V] := \{ (\sigma, \alpha) \mid \sigma \in (L_+ \circ E_+)[V], \ \ell(\alpha) = \ell(\sigma) - 1 \}.$$  

Let $h$ be a height function on $V$ and we write $h(V) = \{a_1, \ldots, a_k\}$ with $0 = a_1 < a_2 < \cdots < a_k$. We define the set composition $\sigma_h$ and the integer composition $\alpha_h$ by

$$\sigma_h := (h^{-1}(a_1), \ldots, h^{-1}(a_k)),$$

$$\alpha_h := (a_2 - a_1, \ldots, a_k - a_{k-1}).$$

Now we prove that a height function is identified with a pair of set and integer compositions (See Figure 3).

Lemma 3.15. $H = I$. 

Figure 3: A height function and the corresponding set and integer compositions
Proof. Define a natural transformation \( \eta: H \rightarrow I \) by \( \eta_V(h) := (\sigma_h, \alpha_h) \). Let \((\sigma, \alpha) \in P[V] \) and write \( \sigma = (B_1, \ldots, B_k) \) and \( \alpha = (\alpha_1, \ldots, \alpha_{k-1}) \). Define a natural transformation \( \zeta: I \rightarrow H \) by
\[
\zeta_V(v) := \sum_{i=1}^{i-1} \alpha_i \text{ if } v \in B_i.
\]
It is easy to show that \( \eta \) and \( \zeta \) are inverse to each other. Hence we conclude that \( H = I \).

4. Proofs

4.1. Proof of Theorem 1.9

In order to describe \( LC^m \), we need to determine the species \( L_1K^{[-m,m]} \) by Corollary 3.11(2) and Proposition 3.12.

For an integer composition \( \alpha = (\alpha_1, \ldots, \alpha_k) \), define \( \max(\alpha) \) by
\[
\max(\alpha) := \begin{cases} 
\max \{ \alpha_i | 1 \leq i \leq k \} & \text{if } \alpha \neq \emptyset, \\
0 & \text{if } \alpha = \emptyset.
\end{cases}
\]

Definition 4.1. Let \( m \) be a nonnegative integer. We define a species \( P^m \) by
\[
P^m[V] := \{ (\sigma, \alpha) \in I[V] | \max(\alpha) \leq m \},
\]
where \( I \) is the species defined in Definition 3.14.

Note that \( P^0 = E = L_1K^{[0]} \) since \( P^0[V] \) consists of a single element \(((V), \emptyset)\). Furthermore, the following lemma holds.

Lemma 4.2. Let \( m \) be a nonnegative integer. Then \( L_1K^{[-m,m]} = P^m \).

Proof. First note that every element in \( L_1K^{[-m,m]}[V] = L_1(K^{[-m,m]}_V) \) is identified with the height function \( h: V \rightarrow \mathbb{Z} \) such that the gain graph \( K^{[-m,m]}_V[V, h] \) is connected. Hence, by Lemma 3.15 it is satisfied to show that for every height function \( h: V \rightarrow \mathbb{Z} \), the gain graph \( K^{[-m,m]}_V[V, h] \) is connected if and only if \( \max(\alpha_h) \leq m \).

Write \( \sigma_h = (B_1, \ldots, B_k) \) and \( \alpha_h = (\alpha_1, \ldots, \alpha_{k-1}) \). If \( \max(\alpha_h) \leq m \), that is, \( \alpha_i \leq m \) for each \( i \in \{1, \ldots, k-1\} \), then there exists an edge \( \{u, v\}_{\alpha_i} \) such that \( u \in B_i \) and \( v \in B_{i+1} \). Therefore \( K^{[-m,m]}_V[V, h] \) is connected.

Now suppose that \( K^{[-m,m]}_V[V, h] \) is connected. For every \( p \in \{1, \ldots, k-1\} \) we will prove that \( \alpha_p \leq m \). By the connectedness, there exists an edge \( \{u, v\}_a \) such that \( u \in B_i \) (\( 1 \leq i \leq p \)) and \( v \in B_j \) (\( p+1 \leq j \leq k \)). Then we have
\[
m \geq a = h(v) - h(u) = \alpha_{j-1} + \alpha_{j-2} + \cdots + \alpha_i \geq \alpha_p.
\]
Therefore \( \max(\alpha_h) \leq m \) and hence the assertion holds.
Let \( \alpha = (\alpha_1, \ldots, \alpha_k) \) and \( \alpha' = (\alpha'_1, \ldots, \alpha'_i) \) be tuples. The **concatenation** \( \alpha \ast \alpha' \) is defined by

\[
\alpha \ast \alpha' := (\alpha_1, \ldots, \alpha_k, \alpha'_1, \ldots, \alpha'_i).
\]

**Lemma 4.3.** Let \( m \) be a nonnegative integer. Then \( P^m = L^m_+ \circ E_+ \).

**Proof.** We prove the assertion by induction on \( m \). Since \( P^0 = E_+ = E_1 \circ E_+ = L^0_+ \circ E_+ \), the assertion holds when \( m = 0 \). Suppose that \( m > 0 \). In order to prove \( P^m = L^m_+ \circ E_+ \), we construct a natural transformation \( \eta: L^m_+ \circ P^{m-1} \rightarrow P^m \) and prove that \( \eta \) is a natural isomorphism. Suppose that \(( (\tau_1, \beta_1), \ldots, (\tau_k, \beta_k) ) \) is a set partition \( \epsilon \) for some \( \{ B_1, \ldots, B_k \} \in \Pi[V] \). Therefore we may define a natural transformation \( \eta \) by

\[
\eta_V( ( (\tau_1, \beta_1), \ldots, (\tau_k, \beta_k) ) ) := (\sigma, \alpha) \in P^m[V].
\]

We construct another natural transformation \( \zeta: P^m \rightarrow L^m_+ \circ P^{m-1} \). Let \( (\sigma, \alpha) \in P^m[V] \) and suppose the number of \( m \)'s appearing in \( \alpha \) is \( k \). Decompose \( \alpha \) as \( \alpha = \beta_1 \ast (m) \ast \beta_2 \ast (m) \ast \cdots \ast (m) \ast \beta_k \). Then each \( \beta_i \) satisfies max(\( \beta_i \)) \( \leq m - 1 \) since max(\( \alpha \)) \( \leq m \). Moreover, decompose \( \sigma \) as \( \sigma = \tau_1 \ast \cdots \ast \tau_k \) such that \( |\tau_i| = |\beta_i| + 1 \). Then there exists a set partition \( \{ B_1, \ldots, B_k \} \in \Pi[V] \) such that \( \sigma_i \in (L_+ \circ E_+)[B_i] \) for each \( i \in \{ 1, \ldots, k \} \). Therefore we may define a natural transformation \( \zeta \) by

\[
\zeta_V( ( (\tau_1, \beta_1), \ldots, (\tau_k, \beta_k) ) ) \in (L^m_+ \circ P^{m-1})[V].
\]

It is obvious that \( \eta \) and \( \zeta \) are inverse to each other. Thus \( P^m = L^m_+ \circ P^{m-1} \). \( \square \)

**Proof of Theorem 1.9.** By Corollary 3.11(3) and Lemma 4.2 and Lemma 4.3

\[
L_1 C^m = L_1 K^{[-m,m]} = P^m = L^m_+ \circ E_+.
\]

Moreover by Corollary 3.11(2) and Proposition 3.12

\[
L^m C = L K^{[-m,m]} = E \circ L_1 K^{[-m,m]} = E \circ L^m_+ \circ E_+.
\]

Use Corollary 3.11(3) to obtain \( L_k C^m = E_k \circ L^m_+ \circ E_+ \). \( \square \)
Example 4.4. Consider \((B_1 B_2)(B_3 B_4 B_5) = (\{57\}\{3\})(\{149\}\{26\}\{8\})) \in (L^2 \circ E)[9]\) (See Figure 4). We will construct the corresponding flat of the extended Catalan arrangement \(C_{29}\). First, for each \(i\), let \(\alpha_i\) denote the height of the minimal tree containing leaves \(B_i\) and \(B_{i+1}\). In this case we have the integer composition \(\alpha = (\alpha_1, \alpha_2, \alpha_3, \alpha_4) = (1, 2, 1, 1)\). Take the partial sum of \(\alpha\), and we obtain the sequence of heights \((0, 1, 3, 4, 5)\). Namely we define a height function \(h\) by the following table.

\[
\begin{array}{c|ccccccccc}
v & 5 & 7 & 3 & 1 & 4 & 9 & 2 & 6 & 8 \\
h(v) & 0 & 0 & 1 & 3 & 3 & 4 & 4 & 5 & \\
\end{array}
\]

The corresponding flat is

\[
\{x_5 = x_7 = x_3 + 1 = x_1 + 3 = x_4 + 3 = x_9 + 3 = x_2 + 4 = x_6 + 4 = x_8 + 5\}.
\]

4.2. Proof of Theorem 1.11

All species in this section are \(L\)-species and \(V\) denotes a finite linearly ordered set. The symbols \(\min(B)\) and \(\max(B)\) stand for the minimum and the maximum elements of a subset \(B \subseteq V\).

Definition 4.5. Let \(m\) be a positive integer. Define an \(L\)-species \(Q^m\) by

\[
Q^m[V] := \{ (\sigma, \alpha) \in P^m[V] \mid \alpha_i = m \Rightarrow \min(B_i) < \max(B_{i+1}) \},
\]

where \(P^m\) is the species defined in Definition 4.1 and \(\alpha_i\) and \(B_i\) denote the \(i\)-th entries of \(\alpha\) and \(\sigma\), respectively.

Lemma 4.6. Let \(m\) be a positive integer. Then \(L_1K_{[1-m,m]} = Q^m\).

Proof. Similarly to the proof of Lemma 4.2, it is satisfied to show that \(K_{V}^{[1-m,m]}[V, h]\) is connected if and only if \(\max(\alpha_h) \leq m\) and \(\alpha_i = m\) implies \(\min(B_i) < \min(B_{i+1})\) for each height function \(h\) on a finite linearly ordered set \(V\), where we write \(\sigma_h = (B_1, \ldots, B_k)\) and \(\alpha_h = (\alpha_1, \ldots, \alpha_{k-1})\).

First we assume that the latter conditions and prove that \(K_{V}^{[1-m,m]}[V, h]\) is connected. If \(\alpha_i \leq m - 1\), then there exists an edge connecting a vertex in \(B_i\) and a vertex in \(B_{i+1}\). Suppose that \(\alpha_i = m\). Then
the condition \( \min(B_i) < \min(B_{i+1}) \) guarantees the existence of the edge \( \{u, v\}_m \) such that \( u = \min(B_i) \) and \( v = \max(B_{i+1}) \). Thus \( K^{[m, m]}_V[V, h] \) is connected.

Second assume that \( K^{[1-m, m]}_V[V, h] \) is connected. Let \( p \in \{1, \ldots, k-1\} \) and we will prove that \( \alpha_p \) satisfies the desired conditions. Without loss of generality we may assume that \( \alpha_p \geq m \). From the connectedness there exists an edge \( \{u, v\}_m \) such that \( u \in B_i \ (1 \leq i \leq p) \), \( v \in B_j \ (p + 1 \leq j \leq k) \). If \( j - i \geq 2 \), then

\[
m \geq a = h(v) - h(u) = \alpha_{j-1} + \alpha_{j-2} + \cdots + \alpha_i > \alpha_p,
\]

which contradicts to the assumption \( \alpha_p \geq m \). Hence \( j - i = 1 \), equivalently \( i = p \) and \( j = p + 1 \). In other words, there exists an edge \( \{u, v\}_{\alpha_p} \) such that \( u \in B_p \) and \( B_{p+1} \). If \( \alpha_p > m \), then \( K^{[1-m, m]}_V[V, h] \) is disconnected, which is a contradiction. Therefore \( \alpha_p = m \). This implies \( \min(B_p) \leq u < v \leq \max(B_{p+1}) \).

Thus the assertion holds.

**Lemma 4.7.** Let \( m \) be a positive integer. Then \( Q^m = L^m_+ \).

**Proof.** We proceed by induction on \( m \). Suppose that \( m = 1 \). We may omit integer compositions from the notation of \( Q^1 \) since only integer compositions consisting of 1 are allowed. Namely we may consider \( Q^1 \) as

\[
Q^1[V] = \{ (B_1, \ldots, B_k) \in (L_+ \circ E_+)[V] \mid \min B_i < \max B_{i+1} \ (1 \leq i \leq k - 1) \}.
\]

Now we construct a natural transformation \( \eta : L_+ \rightarrow Q^1 \). Let \( (v_1, \ldots, v_n) \in L_+[V] \) be a list of a finite linearly ordered set \( V \). Suppose that \( (v_i, \ldots, v_{i_{k-1}}) \) is the sublist such that \( \{i_1, \ldots, i_{k-1}\} = \{ i \in [n] \mid v_i < v_{i+1} \} \). For each \( j \in \{1, \ldots, k\} \), put \( B_j := \{ v_i \in V \mid i_{j-1} < i \leq i_j \} \), here we consider \( i_0 := 0 \) and \( i_k := n \). Then \( \min B_j = v_{i_j} < v_{i_{j+1}} = \max B_{j+1} \) for each \( j \in \{1, \ldots, k-1\} \). Hence we may define \( \eta \) by

\[
\eta_V((v_1, \ldots, v_n)) := (B_1, \ldots, B_k) \in Q^1.
\]

Next we construct a natural transformation \( \zeta : Q^1 \rightarrow L_+ \). Given an element \( (B_1, \ldots, B_k) \in Q^1[V] \), let \( \beta_i \) be the list of \( B_i \) with decreasing order for each \( i \in \{1, \ldots, k\} \). Define \( \zeta \) by

\[
\zeta_V((B_1, \ldots, B_k)) := \beta_1 \ast \cdots \ast \beta_k \in L_+[V].
\]

One can show that \( \eta \) and \( \zeta \) are inverse to each other and hence \( Q^1 = L_+ \).

Assume that \( m \geq 2 \). We will prove that \( Q^m = L_+ \circ Q^{m-1} \). First we construct a natural transformation \( \eta : L_+ \circ Q \rightarrow Q^m \). Take an element \( ((\tau_1, \beta_1), \ldots, (\tau_k, \beta_k)) \in (L_+ \circ Q^{m-1})[V] \). For each \( i \in \{1, \ldots, k\} \), let \( T(\tau_i) \) and \( I(\tau_i) \) denote the terminal and initial entries of \( \tau_i \) and define an integer \( \mu_i \) by

\[
\mu_i := \begin{cases} 
    m & \text{if } \min T(\tau_i) < \max I(\tau_i), \\
    m - 1 & \text{if } \min T(\tau_i) > \max I(\tau_i).
\end{cases}
\]
Now we define $\sigma$ and $\alpha$ by

$$\begin{align*}
\sigma &:= \tau_1 \cdots \tau_k, \\
\alpha &:= \beta_1 \ast (\mu_1) \ast \beta_2 \ast (\mu_2) \cdots \ast (\mu_{k-1}) \ast \beta_k.
\end{align*}$$

Then we have $(\sigma, \alpha) \in P_m[V]$, that is, $\sigma \in (L_+ \circ E_+)[V]$, $\ell(\alpha) = \ell(\sigma) - 1$, and $\max(\alpha) \leq m$. Moreover the definition of $\mu_i$ leads to $(\sigma, \alpha) \in Q^m[V]$. Thus we define $\eta$ by

$$\eta_V(((\tau_1, \beta_1), \ldots, (\tau_k, \beta_k))) := (\sigma, \alpha) \in Q^m[V].$$

Next we construct another natural transformation $\zeta : Q^m \rightarrow L_+ \circ Q^{m-1}$. Suppose that $(\sigma, \alpha) \in Q^m[V]$ and write $\sigma = (B_1, \ldots, B_\ell)$ and $\alpha = (\alpha_1, \ldots, \alpha_{\ell-1})$. Let

$$S := \{ i \in [\ell-1] \mid \alpha_i = m \} \cup \{ i \in [\ell-1] \mid \alpha_i = m-1 \text{ and } \min B_i > \max B_{i+1} \}.$$ 

Suppose that $S = \{i_1, \ldots, i_{k-1}\}$ and decompose $\alpha$ as

$$\alpha = \beta_1 \ast (\alpha_{i_1}) \ast \beta_2 \ast (\alpha_{i_2}) \ast \cdots \ast (\alpha_{i_{k-1}}) \ast \beta_k.$$ 

Moreover decompose $\sigma = \tau_1 \cdots \tau_k$ with $|\tau_i| = |\beta_i| + 1$ for each $i \in \{1, \ldots, k\}$. Then $\max(\beta_i) \leq m-1$ and note that if $\beta_i$ contains an entry $\alpha_j$ such that $\alpha_j = m-1$, then $\min B_j > \max B_{j+1}$ by the definition of $S$. Hence we may define $\zeta$ by

$$\zeta_V((\sigma, \alpha)) := ((\tau_1, \beta_1), \ldots, (\tau_k, \beta_k)) \in (L_+ \circ Q^{m-1})[V].$$

It is easy to show that $\eta$ and $\zeta$ are inverse to each other and hence $Q^m = L_+ \circ Q^{m-1}$. Finally by the induction hypothesis we have

$$Q^m = L_+ \circ Q^{m-1} = L_+ \circ L_+^{o(m-1)} = L_+^{om},$$

which is the desired result.

**Proof of Theorem 1.11.** By Corollary 3.11(3) and Lemma 4.6 and 4.7

$$L_1 S^m = L_1 K^{[1-m,m]} = Q^m = L_+^{om}.$$ 

Moreover by Corollary 3.11(2) and Proposition 3.12

$$L S^m = L K^{[1-m,m]} = E \circ L_1 K^{[1-m,m]} = E \circ L_+^{om}.$$ 

Similarly by Corollary 3.11(3), we obtain $L_k S^m = E_k \circ L_+^{om}$. 

18
Example 4.8. Consider $$(((v_1v_2)(v_3))(v_4)(v_5v_6)(v_7))(v_8v_9)) = (((49)(5))(3)(71)(6))(82)) \in L_{[9]}^3$$ (See Figure 5). We will construct the corresponding flat of the extended Shi arrangement $$S^3_9$$. First let $$\alpha$$ be the integer composition obtained in a similar way in Example 4.4. In this case $$\alpha = (1, 2, 3, 2, 1, 2, 3, 1)$$. Next define the integer composition $$\alpha'$$ by

$$\alpha'_i := \begin{cases} 
\alpha_i & \text{if } v_i < v_{i+1}, \\
\alpha_i - 1 & \text{if } v_i > v_{i+1}.
\end{cases}$$

In this case $$\alpha' = (1, 1, 2, 2, 0, 2, 3, 0)$$. Take the partial sum of $$\alpha'$$, we have the sequence of heights $$(0, 1, 2, 4, 6, 6, 8, 11, 11)$$. Define the height function $$h$$ by the following table.

<table>
<thead>
<tr>
<th>v</th>
<th>4</th>
<th>9</th>
<th>5</th>
<th>3</th>
<th>7</th>
<th>1</th>
<th>6</th>
<th>8</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>h(v)</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>4</td>
<td>6</td>
<td>6</td>
<td>8</td>
<td>11</td>
<td>11</td>
</tr>
</tbody>
</table>

The corresponding flat is

$$\{x_4 = x_9 + 1 = x_5 + 2 = x_3 + 4 = x_7 + 6 = x_1 + 6 = x_6 + 8 = x_8 + 11 = x_2 + 11\}.$$ 

4.3. Proof of Theorem 1.13

Let $$F$$ be a species with $$F[\emptyset] = \emptyset$$. We consider the infinite matrix $$[|(E_i \circ F)[j]|]$$. Note that almost all entries of each column of the matrix are 0 since

$$\sum_{i=1}^{\infty} |(E_i \circ F)[j]| = |(E \circ F)[j]| < \infty.$$ 

We show that substitution of species is compatible with product of the infinite matrices.

**Proposition 4.9.** Let $$F$$ and $$G$$ be species with $$F[\emptyset] = G[\emptyset] = \emptyset$$. Then

$$\left[|(E_i \circ F)[j]| \right] \left[|(E_i \circ G)[j]| \right] = \left[|(E_i \circ F \circ G)[j]| \right].$$
Proof. Fix a positive integer $i$. By definition, we have

$$(E_i \circ F \circ G)(x) = \sum_{j=0}^{\infty} |(E_i \circ F \circ G)[j]| \frac{x^j}{j!}.$$  

We give another calculation of the series as follows.

$$(E_i \circ F \circ G)(x) = (E_i \circ F)(G(x))$$

$$= \sum_{k=0}^{\infty} |(E_i \circ F)[k]| \frac{G(x)^k}{k!}$$

$$= \sum_{k=0}^{\infty} |(E_i \circ F)[k]| (E_k \circ G)(x)$$

$$= \sum_{k=0}^{\infty} |(E_i \circ F)[k]| \sum_{j=0}^{\infty} |(E_k \circ G)[j]| \frac{x^j}{j!}$$

$$= \sum_{j=0}^{\infty} \left( \sum_{k=0}^{\infty} |(E_i \circ F)[k]| |E_k \circ G[j]| \right) \frac{x^j}{j!}.$$  

Therefore we have

$$|E_i \circ F \circ G[j]| = \sum_{k=0}^{\infty} |E_i \circ F[k]| |E_k \circ G[j]|$$

for any positive integers $i$ and $j$. Hence the assertion holds. \square

Example 4.10. Let $C$ denote the species of cyclic permutations. Then the substitution $E \circ C$ coincides with the species of permutations. As mentioned in [2, p. 346], we have that $L = E \circ C$ as $L$-species. Indeed let each permutation $\sigma \in (E \circ C)[n]$ correspond to the list $(\sigma(1), \sigma(2), \ldots, \sigma(n)) \in L[n]$. It is easy to see that this correspondence is bijective. Note that $L$ and $E \circ C$ are not isomorphic as $B$-species.

The Lah number is the number of ways to partition a $j$-element set into $i$ nonempty lists. Therefore $
\left[(E_i \circ L_+)[j]\right]$ is the infinite upper triangular matrix consisting of Lah numbers and we can recover the following well-known equality.

$$\left[(E_i \circ L_+)[j]\right] = \left[(E_i \circ E_+ \circ L_+)[j]\right]$$

$$= \left[(E_i \circ E_+)[j]\right] \left[(E_i \circ L_+)[j]\right]$$

$$= S(j, i) [c(j, i)] = Sc,$$

where recall that $c(j, i)$ and $S(j, i)$ denote the unsigned Stirling numbers of the first and second kind and $c$ and $S$ are the corresponding infinite upper triangular matrices.
Proof of Theorem 1.13. From Theorem 1.9, Proposition 4.9, and Example 4.10

\[
\left| L_i(C^m_j) \right| = \left| L_iC^m[j] \right| = \left| (E_i \circ L^o_m \circ L^o_+) [j] \right|
\]
\[
= \left| (E_i \circ L^o_+) [j] \right|^m \left| (E_i \circ E_+)[j] \right| = (Sc)^m S.
\]

Similarly from Theorem 1.11, Proposition 4.9, and Example 4.10

\[
\left| L_i(S^m_j) \right| = \left| L_iS^m[j] \right| = \left| (E_i \circ L^o_m) [j] \right|
\]
\[
= \left| (E_i \circ L^o_+) [j] \right|^m = (Sc)^m.
\]

\qed
