GENERALIZED SRB MEASURES, PHYSICAL PROPERTIES, AND THERMODYNAMIC FORMALISM OF SMOOTH HYPERBOLIC SYSTEMS

SNIR BEN OVADIA

Abstract. We generalize the notion of SRB measures and characterize their existence, uniqueness, and ergodic, thermodynamic, and physical properties. We show that there exists a generalized SRB measure (GSRB for short) if and only if there exists some unstable leaf with a positive leaf volume for the set of hyperbolic points HWT(χ) (which are not necessarily Lyapunov regular). This condition is called the leaf condition. We show that the leaf condition also implies that the Gurevich pressure of the geometric potential is 0, and characterize all GSRBs as equilibrium states of the geometric potential, which gives the analogue to the entropy formula. Every finite GSRB is an SRB, and the finiteness of GSRBs is characterized by modes of recurrence of the geometric potential. We define a set of positively recurrent points, and characterize positive recurrence of the geometric potential by the leaf condition for the said points. We show the uniqueness of GSRBs on each ergodic homoclinic class, and that each ergodic component of a GSRB is a GSRB. In particular, this offers new proofs for the entropy formula and for the uniqueness of hyperbolic SRB measures, and for the fact that an ergodic component of a hyperbolic SRB measure is a hyperbolic SRB measure. We show physical properties for GSRBs (w.r.t. the ratio ergodic theorem, and by distributions). In our setup, M is a Riemannian, boundaryless, and compact manifold, with dim M ≥ 2; f ∈ Diff1+β(M), β > 0. These results offer an extension to the Viana conjecture, and serve as a partial answer to the Viana conjecture, and to its extension.

1. Introduction

1.1. Motivation and Background. An invariant ergodic measure is called physical if the set of all points which abide its time-forward ergodic theorem is a set of positive Riemannian volume in $M$ (often referred to as Lebesgue volume). The convention is that the events which are observable are events with a positive Lebesgue volume, as these are the events expected to be observed in a simulation, for example.

An SRB measure is a hyperbolic and invariant probability measure, such that given any measurable partition into unstable leaves—almost all of its conditional measures are absolutely continuous w.r.t. to the respective leaf’s Riemannian volume. SRB stands for Sinai, Ruelle and Bowen, due to their pioneering work in the context of Axiom A systems (see Sin68, Bow08, BR75).

It has been shown that ergodic SRB measures are physical w.r.t. Birkhoff’s ergodic theorem. This was first done by Pesin in Pes77 for volume preserving transformations, using Pesin’s absolute continuity theorem for the stable leaves foliation; this work was later extended by Katok and Strelcyn in KSLP86 who allowed singularities; and eventually shown by Pugh and Shub in the general case in PSS9 (see You02 for a more detailed review of the history of SRB measures and their motivation). Generally, physical measures on their own, by focusing on one trait, carry little information (see You02 for examples of physical measures which are not SRB). SRB measures, on the other hand, being hyperbolic and being considered the most compatible with the Riemannian volume when it is not preserved, display rich dynamics and geometric structure. They carry additional special properties and meaning (such as the entropy formula, see LS82, LY85).

In HY95, Hu and Young have shown an example of an “almost Anosov” system, where no SRB measure exists. This generates motivation to study a greater class of physical measures, which will describe the asymptotic behavior of observable events on a wider set of dynamical systems. Asymptotic behavior and ergodic theorems go hand in hand with recurrence and conservativity properties. This motivated the generalization of hyperbolic SRB and physical measures to include conservative (perhaps infinite) hyperbolic measures with absolutely continuous conditional measures (see Definition 6.2). We call such measures Generalized SRB measures, or GSRB for short. We show that GSRB measures are physical w.r.t. the ratio ergodic theorem (see Theorem 7.1), and display distributional physicality (see Theorem 7.2 and Theorem 7.9). In addition, we show that their existence implies thermodynamic properties, such as that the geometric potential is recurrent and has a Gurevich pressure 0, even when an SRB measure might not exist; and that GSRB measures are equilibrium states of the geometric potential (see §5, §6.4). We show that an ergodic homoclinic class admits at most one GSRB measure, and that it is ergodic, analogously to the result for SRB measures in RHRHTU11 (see Theorem 6.9). In particular, we offer new proofs for the entropy formula for hyperbolic SRB measures, for the uniqueness of hyperbolic SRB measures on ergodic homoclinic classes, and for the fact that an ergodic component of a hyperbolic SRB measure is a hyperbolic SRB measure.

Our work gives a sufficient and necessary condition for the existence of a GSRB measure, and a sufficient and necessary condition for the existence of a finite GSRB measure (i.e. a hyperbolic SRB measure). Both conditions are in the form of the leaf condition (i.e. the existence of an unstable leaf with a positive leaf volume for a set of points, see Definition 4.29), where the sets include points which display hyperbolic behavior, but are not restricted to be Lyapunov regular. The question of the existence of an SRB measure under an assumption of the form of a leaf condition, was raised to the author by Y. Pesin. This work, together with the example by Hu and Young, answers this question.

Our results hold for a compact, boundary-less and Riemannian manifold $M$ with $\dim M \geq 2$, and $f \in \text{Diff}^{1+\beta}(M)$, $\beta > 0$.

In CDP16, Climenhaga, Dolgopyat and Pesin have introduced the notion of a leaf condition, with a set of “effectively hyperbolic” points replacing our set of non-uniformly hyperbolic points. The conditions of effective hyperbolicity impose some uniform hyperbolic behavior only on the future of a set of points of positive Lebesgue measure. The restriction of the conditions to the future orbits of hyperbolic points makes the assumptions of effective hyperbolicity independent of the assumptions for non-uniform hyperbolicity. In this case, Climenhaga, Dolgopyat and Pesin show that if there exists a forward invariant set of positive Riemannian volume, which admits a measurable invariant family of stable and unstable cones, and the leaf condition is satisfied for an effectively hyperbolic subset of it, then there exists a hyperbolic SRB measure. Recently, in CLPT19, Climenhaga, Luzzatto and Pesin were able to show, using different methods than ours, a weaker version of Claim 6.5 in the two-dimensional setup. They assume the existence of a geometric
rectangle, with boundaries defined by the area between the stable and unstable leaves of two homoclinically related periodic hyperbolic points, such that it contains a set of non-uniformly hyperbolic points which return in a positive recurrent way to the geometric rectangle and to some Pesin level set; such that the saturation of their stable leaves has a positive Riemannian volume. In this case, they show that a hyperbolic SRB measure exists, and go further to show that when a hyperbolic SRB measure exists, this condition is satisfied. Their methods involve the construction of a Young tower, and are inherently two-dimensional, but they are able to construct the tower in a way which makes it a first-return tower for a power of \( f \) (which depends on the periods of the two periodic points which define the geometric rectangle). When omitting the restriction of the geometric rectangle and the positive recurrence to it, in the two-dimensional setup, their statement becomes similar to our Claim \( \text{Claim } 6.5 \) due to Pesin’s absolute continuity theorem.

Our results serve as a partial answer to the Viana conjecture in two senses, by both claiming that a more generic in some class of dynamical systems?

1.2. Notations.

(1) For every \( a, b \in \mathbb{R}, c \in \mathbb{R}^+ \), \( a = e^{\pm c} \cdot b \) means \( e^{-c} \cdot b \leq a \leq e^c \cdot b \), and \( a = b \pm c \) means \( b - c \leq a \leq b + c \).

(2) \( \forall a, b \in \mathbb{R}, a \wedge b := \min \{a, b\} \).

(3) For every topological Markov shift \( \Sigma \) which is induced by a graph \( \mathcal{G} := (V, E) \) (e.g. Theorem 5.2), for every finite admissible path \( (v_0, ..., v_l) \), \( v_i \in V, 0 \leq i \leq l \), a cylinder is a subsets of the form \([v_0, ..., v_l] = \{x \in \Sigma : u_{i+m} = v_i, \forall 0 \leq i \leq l \} \). When the \( m \) subscript is omitted, if not mentioned otherwise, \( m = 0 \) or \( m = -l \).

(4) TMS stands for a topological Markov shift.

(5) In our context, a Borel measure is conservative if it gives every wandering set a measure 0 (see Definition 6.1).

(6) Given two Borel measures \( \mu, \nu \) on a measure space \((X, \mathcal{B})\), we write \( \mu \ll \nu \) to mean “\( \mu \) is absolutely continuous w.r.t. \( \nu \)” (i.e. \( \forall E \in \mathcal{B}, \nu(E) = 0 \Rightarrow \mu(E) = 0 \)), and \( \mu \sim \nu \) to mean “\( \mu \) is equivalent to \( \nu \)” (i.e. \( \forall E \in \mathcal{B}, \nu(E) = 0 \Leftrightarrow \mu(E) = 0 \)).

1.3. Setup. Let \( M \) be a compact and Riemannian manifold, with no boundary, of dimension \( d = \dim M \geq 2 \). Let \( \beta > 0 \) be a positive constant, and \( f \in \text{Diff}^{1+\beta}(M) \) (i.e. \( f, f^{-1} \) are differentiable, and \( d f, d (f^{-1}) \) are \( \beta \)-Hölder continuous).

2. The Set of Hyperbolic Points HWT\( _\chi \)

The definition of \( \chi \)-hyperbolic points (\( \chi > 0 \)), in the context of Lyapunov regular points, is quite natural—considering all points with no zero Lyapunov exponents, with at least one positive exponent and one negative exponent, and with all exponents having absolute value greater than \( \chi \). The collection of points which display hyperbolic behavior can be a much bigger set than the Lyapunov regular points. We would like to consider a larger set of hyperbolic points, in order to study hyperbolicity on a bigger class of measures, which are not necessarily carried by Lyapunov regular points.

Definition 2.1.

(1)

\[
\chi - \text{summ} := \{x \in M : \exists \text{ a splitting } T_xM = H^s(x) \oplus H^u(x) \text{ s.t.} \prod_{\xi \in H^s(x), |\xi| = 1} \sum_{m=0}^{\infty} |d_x f^m \xi| e^{2 \chi m} < \infty, \prod_{\xi \in H^s(x), |\xi| = 1} \sum_{m=0}^{\infty} |d_x f^{-m} \xi| e^{2 \chi m} < \infty \}.
\]

\[\text{Although, their methods involve proving a refined shadowing theorem which one expects to extend to high dimensions.}\]
\((2)\) 
\[
\chi - \text{hyp} := \{ x \in M : \exists a \text{ splitting } T_x M = H^s(x) \oplus H^u(x) \text{ s.t. } \forall \xi_s \in H^s(x) \setminus \{0\}, \xi_u \in H^u(x) \setminus \{0\},
\]
\[
\limsup_{n \to \infty} \frac{1}{n} \log |d_x f^n \xi_s|, \limsup_{n \to \infty} \frac{1}{n} \log |d_x f^{-n} \xi_u| < -\chi.
\]
\((3)\) We define for each \(x \in \chi - \text{hyp}\),
\[
\chi(x) := -\max\{ \sup_{\xi_s \in H^s(x)} \limsup_{n \to \infty} \frac{1}{n} \log |d_x f^n \xi_s|, \sup_{\xi_u \in H^u(x)} \limsup_{n \to \infty} \frac{1}{n} \log |d_x f^{-n} \xi_u| \} > \chi.
\]
Notice that \(\chi - \text{hyp} \subseteq \chi - \text{summ}\).

**Theorem 2.2 (Pesin-Oseledec Reduction Theorem).** For each \(x \in \chi - \text{summ}\), write \(s(x) := \dim(H^s(x)), u(x) := \dim(H^u(x))\). For each such point \(x \in \chi - \text{summ}\), there exists an invertible linear map \(C_X(x) : \mathbb{R}^d \to T_x M\), which depends measurably on \(x\), such that \(C_X(x)[\mathbb{R}^s(x) \times \{0\}] = H^s(x), C_X(x)[\{0\} \times \mathbb{R}^u(x)] = H^u(x)\). \(C_X(\cdot)\) are chosen measurably on \(\chi - \text{summ}\), and the choice is unique up to a composition with an orthogonal mapping of the “stable” and of the “unstable” subspaces of the tangent space. In addition,
\[
C_X^{-1}(f(x)) \circ d_x f \circ C_X(x) = \left( \begin{array}{cc} D_s(x) & U(x) \\ 0 & D_u(x) \end{array} \right),
\]
where \(D_s(x), D_u(x)\) are square matrices of dimensions \(s(x), u(x)\) respectively, and \(\|D_s(x)\|, \|D_u^{-1}(x)\| \leq e^{-\chi}, \|D_u^{-1}(x)\|, \|D_u(x)\| \leq \kappa\) for some constant \(\kappa = \kappa(f, \chi) > 1\).

The Pesin-Oseledec reduction theorem has many different versions, which are suitable for different setups. We use the version which appears, with proof, in [BO18, Theorem 2.4].

\[\|C_X^{-1}(x)\|\] serves a measurement of the hyperbolicity of \(x\)- the greater the norm, the worse the hyperbolicity (i.e. slow contraction/expansion on stable/unstable spaces, or small angle between the stable and unstable spaces).

**Definition 2.3.** Let \(\epsilon > 0\), and let \(x \in \chi - \text{summ}\), then
\[
Q_\epsilon(x) := \max\{ Q \in \{ e^{\frac{\epsilon}{C_X^{-1}(x)}} \}_{i \in \mathbb{N}} : Q \leq \frac{1}{3\epsilon} \epsilon \log \| C_X^{-1}(x) \| \}
\]

\(Q_\epsilon(\cdot)\) depends only on the norm of \(C_X^{-1}(\cdot)\) (a Lyapunov norm on the tangent space of a point), which is indifferent to composition with orthogonal mappings of the “stable” and “unstable” subspaces.

**Definition 2.4.** A point \(x \in \chi - \text{summ}\) is called \(\epsilon\)-weakly temperable if
\[
\exists q_\epsilon : \{ f^n(x) \}_{n \in \mathbb{Z}} \to (0, \epsilon] \cap \{ e^{\frac{\epsilon}{4\chi}} \}_{i \in \mathbb{N}} \text{ s.t. } q_\epsilon \circ f^{\epsilon} \circ q_\epsilon^{-1} = e^{\pm \epsilon}, q(f^n(x)) \leq Q_\epsilon(f^n(x)), \forall n \in \mathbb{Z} \text{ and } \limsup_{n \to \pm \infty} q_\epsilon(f^n(x)) > 0.
\]
The set of all \(\epsilon\)-weakly temperable points is denoted by \(\epsilon\)-w.t.

**Definition 2.5.** Hyperbolic and Weakly Temperable points:

\((1)\) \(HWT_\chi := \chi - \text{summ} \cap \epsilon_\chi - \text{w.t.}, \text{ where } \epsilon_\chi > 0\) is given by [BO, Definition 3.1], and is a constant depending on \(M, f, \beta, \chi\).

\((2)\) From this point onward, in our context, a hyperbolic measure (which is not necessarily finite) is a measure carried by \(\bigcup_{\chi' > 0} HWT_{\chi'}\), and a \(\chi\)-hyperbolic measure is a measure carried by \(HWT_\chi\).

**Remark:** \(HWT_\chi\) carries all \(\chi\)-hyperbolic \(f\)-invariant probability measures; and \(HWT_\chi\) is defined canonically see [BO].

In the following parts of this paper, when \(\chi > 0\) is fixed, the subscript of \(\epsilon_\chi\) would be omitted to ease notation. In addition, we may assume \(\epsilon > 0\) is arbitrarily small, since the results of [BOT][BO] apply to all \(\epsilon \in (0, \epsilon_\chi]\), for a fixed \(\chi > 0\).
3. Preliminary Constructions

3.1. Symbolic Dynamics. Sarig first constructed a Markov partition for non-uniformly hyperbolic surface diffeomorphisms in [Sar13]. Later, we extended his results to manifolds of any dimension greater or equal to 2 in [BO18]. In [BO], we introduce the set $\text{WHT}_X$, which is defined canonically, and still consists of all recurrently-codable points (see Proposition 3.7) in the symbolic dynamics which were constructed in Sarig [Sar13] [BO18]. In the following section, we present an exposition of those results, which will be of use to us.

Definition 3.3. (Pesin-charts). Since $M$ is compact, $\exists r = r(M) > 0, \rho = \rho(M) > 0$ s.t. the exponential map $\exp_r : \{v \in T_x M : |v| \leq r\} \rightarrow B_r(x) = \{y \in M : d(x, y) < \rho\}$ is well defined and smooth. When $\epsilon \leq r$, the following is well defined since $C_{\chi}(\cdot)$ is a contraction (see [BO18 Lemma 2.9]):

1. $\psi_x^\epsilon := \exp_x \circ C_\chi(x) : \{v \in T_x M : |v| \leq \epsilon\} \rightarrow B_\epsilon(x)$, $\eta \in (0, Q_x(x)]$, is called a Pesin-chart.
2. A double Pesin-chart is an ordered couple $\psi_x^\epsilon, \psi_y^\epsilon : (\psi_x^\epsilon, \psi_y^\epsilon)$, where $\psi_x^\epsilon$ and $\psi_y^\epsilon$ are Pesin-charts.

Theorem 3.2. $\forall \chi > 0$ s.t. $\exists p \in \chi$-hyp a periodic hyperbolic point, $\exists$ a countable and locally-finite directed graph $G = (V, E)$ which induces a topological Markov shift $\Sigma := \{u \in V^\mathbb{Z} : (u_i, u_{i+1}) \in E, \forall i \in \mathbb{Z}\}$. $\Sigma$ admits a factor map $\pi : \Sigma \rightarrow M$ with the following properties:

1. $\sigma : \Sigma \rightarrow \Sigma, (\sigma u)_i := u_{i+1}, i \in \mathbb{Z}$ (the left-shift); $\pi \circ \sigma = f \circ \pi$.
2. $\pi$ is a Hölder continuous map w.r.t. to the metric $d(u, v) := \exp(- \min\{i \geq 0 : u_i \neq v_i\})$.
3. $\Sigma^\# := \{u \in \Sigma : \exists m_k, m_k \uparrow \infty s.t. u_m = m_m, u_{-m_k} = u_{-m_0}, \forall k \geq 0\}$. $\pi[\Sigma^\#]$ carries all $f$-invariant, $\chi$-hyperbolic probability measures.

This theorem is the content of [BO18 Theorem 3.13] and (similarly, the content of [Sar13 Theorem 4.16] when $d = 2$). $V$ is a collection of double Pesin-charts (see Definition 3.1), which is discrete. And we consider the modified construction that is introduced in [BO] Definition 3.1.

Definition 3.3. (1) $\forall u \in V, Z(u) := \pi[u] \cap \Sigma^\#$, $Z := \{Z(u) : u \in V\}$.
(2) $\mathcal{R}$ is a countable partition of $\bigcup_{u \in V} Z(u) = \pi[\Sigma^\#]$, s.t.
(a) $\mathcal{R}$ is a refinement of $Z$: $\forall Z \in Z, R \in \mathcal{R}, R \cap Z \neq \emptyset \Rightarrow R \subseteq Z$.
(b) The Markov property: $\forall R \in \mathcal{R}, \forall x, y \in R \exists z := [x, y]^R \in R$, s.t. $\forall i \geq 0, R(f^i(z)) = R(f^i(y)), R(f^{-i}(z)) = R(f^{-i}(x))$, where $R(t)$ is the unique partition member of $\mathcal{R}$ which contains $t$, for $t \in \pi[\Sigma^\#]$.
(c) $\forall R, S \in \mathcal{R}$, we say $R \rightarrow S$ if $R \cap f^{-1}[S] \neq \emptyset$, i.e. $\mathcal{E} = \{(R, S) \in \mathcal{R}^2 s.t. f^{-1}[S] \cap R \neq \emptyset\}$.
(d) $\Sigma := \{R \in \mathcal{R}^Z : R \rightarrow R_{i+1}, \forall i \in \mathbb{Z}\}$.

Remark: Given $Z$, such a refining partition as $\mathcal{R}$ exists by the Bowen-Sinai refinement, see [Sar13 § 11.1]. By property (2)(b), and since $\Sigma$ is locally-compact (see Theorem 3.2 local-finiteness of $\mathcal{G}$ implies local-compactness of $\Sigma$), $\Sigma$ is also locally-compact.

Definition 3.4. (1) $\Sigma^\# := \{R \in \Sigma : \exists m_k, m_k \uparrow \infty s.t. R_m = R_m, R_{-m_k} = R_{-m_0}, \forall k \geq 0\}$.
(2) Every two partition members $R, S \in \mathcal{R}$ are said to be affiliated if $\exists u, v \in V$ s.t. $R \subseteq Z(u), S \subseteq Z(v)$ and $Z(u) \cap Z(v) = \emptyset$ (this definition is due to O. Sarig. [Sar13 § 12.3]).

Claim 3.5 (Local finiteness of the cover $Z$). $\forall Z \in Z, \#\{Z' \in Z : Z' \cap Z \neq \emptyset\} < \infty$.

This claim is the content of [BO18 Theorem 5.2] (and similarly [Sar13 Theorem 10.2] when $d = 2$).

Remark: By Claim 3.5 and Definition 3.3(2)(b), it follows that every partition member of $\mathcal{R}$ has only a finite number of partition members affiliated to it.

---

3.1. i.e. hyperbolic measures with Lyapunov exponents greater than $\chi$ in absolute value.
4. Every $v \in V$ is a double Pesin-chart of the form $v = \psi_x^\epsilon \circ \psi_y^\epsilon$ with $0 < \psi_x^\epsilon \circ \psi_y^\epsilon \leq Q(x)$; and discreteness means that $\forall \eta > 0 : \#\{v \in V : v = \psi_x^\epsilon \circ \psi_y^\epsilon \circ \psi_z^\epsilon \circ \psi_w^\epsilon \circ \eta\} < \infty$. 

5
Theorem 3.6. Given $\hat{\Sigma}$ from Definition 3.3, there exists a factor map $\hat{\pi} : \hat{\Sigma} \to M$ s.t.
(1) $\hat{\pi}$ is Hölder continuous w.r.t. the metric $d(R, S) = \exp(-\min\{i \geq 0 : R_i \neq S_i \text{ or } R_{i-1} \neq S_{i-1}\})$.
(2) $f \circ \hat{\pi} = \hat{\pi} \circ \sigma$, where $\sigma$ denotes the left-shift on $\hat{\Sigma}$.
(3) $\hat{\pi}|_{\Sigma^\#}$ is finite-to-one.
(4) $\forall R \in \hat{\Sigma}$, $\hat{\pi}(R) \in \hat{R}_0$.
(5) $\hat{\pi}|_{\Sigma^\#}$ carries all $\chi$-hyperbolic invariant probability measures.

This theorem is the content of the main theorem of [BO18], Theorem 1.1 (and similarly the content of [Sar13, Theorem 1.3] when $d = 2$).

Proposition 3.7. $\hat{\pi}|_{\Sigma^\#} = \hat{\pi}|_{\Sigma^\#} = \bigcup R = HWT_\chi$.

This is the content of [BO18 Proposition 3.8, Corollary 3.9].

3.2. Maximal Dimension Unstable Leaves.

Definition 3.8. An unstable leaf (of $f$) in $M$, $V^u$, is a $(1 + \frac{c}{n})$-regular, embedded, open, Riemannian submanifold of $M$, such that $\forall x, y \in V^u$, $\limsup_{n \to \infty} \frac{1}{n} \log d(f^{-n}(x), f^{-n}(y)) < 0$. Similarly, a stable leaf is an unstable leaf of $f^{-1}$.

Definition 3.9. An unstable leaf is called an unstable leaf of maximal dimension, if it is not contained in any unstable leaf of a greater dimension.

Notice that if $x \in HWT_\chi$ belongs to an unstable leaf of maximal dimension $V^u$, then $\dim H^u(x) = \dim V^u$. It can be seen from the following claim.

Claim 3.10. $\forall u \in \Sigma$, there exists a maximal dimension unstable leaf $V^u(u)$, which depends only on $(u_i)_{i \leq 0}$, and a stable leaf $V^s(u)$, which depends only on $(u_i)_{i \geq 0}$, s.t. $\pi(u) = V^u(u) \cap V^s(u)$.

This is the content of [BO18 Proposition 3.12,Theorem 3.13, Proposition 4.4] (and similarly Sar13 Proposition 4.15,Theorem 4.16,Proposition 6.3] when $d = 2$). By construction, $V^s(u), V^u(u)$ are local, in the sense that they have finite (intrinsic) diameter.

Claim 3.11. $\forall u \in \Sigma$, $f(V^s(u)) \subset V^s(\sigma u)$, $f^{-1}[V^u(u)] \subset V^u(\sigma^{-1} u)$.

This is the content of [BO18 Proposition 3.12] (and similarly Sar13 Proposition 4.15] when $d = 2$).

3.3. Ergodic Homoclinic Classes and Maximal Irreducible Components.

Definition 3.12. Let $x \in HWT_\chi$, and let $u \in \Sigma^\#$ s.t. $\pi(u) = x$. The global stable (unstable) manifold of $x$ is $W^s(x) := \bigcup_{n \geq 0} f^{-n}[V^s(\sigma^n u)]$, $W^u(x) := \bigcup_{n \geq 0} f^n[V^u(\sigma^{-n} u)]$.

This definition is proper and is independent of the choice of $u$, for more details see [BO18 Definition 2.23,Definition 3.2].

Let $p$ be a periodic point in $\chi$ – summ, i.e. hyperbolic periodic point. Since $p$ is periodic, $\|C_\chi^{-1}(\cdot)\|$ is bounded along the orbit of $p$, and therefore $p \in HWT_\chi$.

Definition 3.13. The ergodic homoclinic class of $p$ is $H(p) := \{x \in HWT_\chi : W^u(x) \cap W^s(o(p)) \neq \emptyset, W^s(x) \cap W^u(o(p)) \neq \emptyset\}$, where $\cap$ denotes transverse intersections of full codimension, $o(p)$ is the (finite) orbit of $p$, and $W^s/u(\cdot)$ are the global stable and unstable manifolds of the point, respectively.

This notion was introduced in [RHRHTU11], with a set of Lyapunov regular points replacing $HWT_\chi$. Every ergodic conservative $\chi$-hyperbolic measure is carried by an ergodic homoclinic class of some periodic hyperbolic point.

Definition 3.14. Consider the Markov partition $\mathcal{R}$ from Definition 3.3
(1) Define $\sim \subset \mathcal{R} \times \mathcal{R}$ by $R \sim S \iff \exists n_{RS}, n_{SR} \in \mathbb{N}$ s.t. $R \overset{n_{RS}}{\to} S, S \overset{n_{SR}}{\to} R$, i.e. a path of length $n_{RS}$ connecting $R$ to $S$, and a path of length $n_{SR}$ connecting $S$ to $R$. The relation $\sim$ is transitive and symmetric. When restricted to $\{R \in \mathcal{R} : R \sim R\}$, it is also reflexive, and thus an equivalence relation. Denote the corresponding equivalence class of some representative $R \in \mathcal{R}$, $R \sim R$, by $\langle R \rangle$. 

(2) A maximal irreducible component in \( \hat{\Sigma} \), corresponding to \( R \in \mathcal{R} \) s.t. \( R \sim R \), is \( \{ R \in \hat{\Sigma} : R \in (R)^2 \} \).

**Proposition 3.15.** Let \( p \) be a periodic \( \chi \)-hyperbolic point. Then, there exists a maximal irreducible component, \( \hat{\Sigma} \subseteq \hat{\Sigma} \), s.t. \( \hat{\pi}(\hat{\Sigma}^\#) = H(p) \) modulo all conservative measures, where \( \hat{\Sigma}^\# := \{ u \in \hat{\Sigma} : \exists v, w \ s.t. \# \{ i > 0 : u_i = v \}, \# \{ i < 0 : u_i = w \} = \infty \} \).

This is the content of [BO, Theorem 4.10].

### 3.4. The Canonical Part of The Symbolic Space.

**Definition 3.16.**

\[
\hat{\Sigma}_L := \{(R_i)_{i \leq 0} \in \mathcal{R}^{-N} : \forall i \leq 0, R_{i-1} \rightarrow R_i \}, \quad \sigma_R : \hat{\Sigma}_L \rightarrow \hat{\Sigma}_L, \sigma_R((R_i)_{i \leq 0}) = (R_{i-1})_{i \leq 0}.
\]

Notice, \( \sigma_R \) is the right-shift, in opposed to the more commonly used left-shift. In order to prevent any confusion, we will always notate \( \sigma_R \) with a subscript \( R \) (for “right”), when considering the right-shift.

**Definition 3.17** (The canonical coding \( \hat{R}(\cdot) \)).

\[
\forall x \in \pi(\hat{\Sigma}^\#) = \bigcup \mathcal{R}, \ (\hat{R}(x))_i := R(f^i(x)), i \in \mathbb{Z}.
\]

One should notice that \( \hat{\pi}(\hat{R}(x)) = x, \hat{R}(x) \in \hat{\Sigma}^\circ \) (see Definition 3.20 for \( \hat{\Sigma}^\circ \)).

**Definition 3.18.**

\[
\forall R \in \hat{\Sigma}_L, \ W^u(R) := \bigcap_{j = 0}^{\infty} f^j[R_{-j}].
\]

This definition admits the following very important property.

**Corollary 3.19.** \( \forall R \in \hat{\Sigma}_L, \ f[W^u(R)] = \bigcup_{\sigma_R \hat{R} = R} W^u(S) \).

**Proof.** Since \( f \) is a diffeomorphism,

\[
f[W^u(R)] = f(\bigcap_{j = 0}^{\infty} f^j[R_{-j}]) = \bigcap_{j = 0}^{\infty} f^{j+1}[R_{-j}] = f(R_0) \cap \bigcap_{j = 1}^{\infty} f^{j+1}[R_{-j}]
\]

\[
= (\bigcup_{R_0 \rightarrow S} S) \cap f[R_0] \cap \bigcap_{j = 1}^{\infty} f^{j+1}[R_{-j}] = \bigcup_{R_0 \rightarrow S} (S \cap \bigcap_{j = 0}^{\infty} f^{j+1}[R_{-j}]) = \bigcup_{\sigma_R \hat{R} = R} W^u(S).
\]

where the transition from the top equation to the bottom one, is due to the fact that \( f[R_0] \subseteq \bigcup_{R_0 \rightarrow S} S \) by definition, whence \( f[R_0] = f[R_0] \cap \bigcup_{R_0 \rightarrow S} S \).

**Definition 3.20.**

\[
\hat{\Sigma}^\circ := \{ \hat{R} \in \hat{\Sigma} : \forall n \in \mathbb{Z}, f^n(\hat{R}) \in R_n \},
\]

\[
\hat{\Sigma}_L^\circ := \{ \hat{R} \in \hat{\Sigma}_L^\# : W^u(\hat{R}) \neq \emptyset \},
\]

where \( \hat{\Sigma}^\# := \{ (R_i)_{i \leq 0} : (R_i)_{i \in \mathbb{Z}} \in \hat{\Sigma}^\# \} \). We call \( \hat{\Sigma}^\circ, \hat{\Sigma}_L^\circ \) the canonical parts of the respective symbolic spaces. Notice that \( \hat{R}(\cdot) \) is the inverse of \( \hat{\pi}|_{\hat{\Sigma}^\circ} \).

**Remark:** One should notice that \( \hat{\Sigma}^\circ \subseteq \hat{\Sigma}^\#, \hat{\Sigma}_L^\circ \subseteq \hat{\Sigma}_L^\# \). This can be seen as follows: If \( \hat{R} \in \hat{\Sigma}^\circ \), then \( \hat{\pi}(\hat{R}) \in \bigcup \mathcal{R} = \pi(\hat{\Sigma}^\#) \). Take any \( \hat{u} \in \Sigma^\# \) s.t. \( \pi(\hat{u}) = \hat{\pi}(\hat{R}) \equiv x \), then \( Z(u_i) \supseteq R(f^i(x)), \forall i \in \mathbb{Z} \), whence by the local-finiteness of the refinement and the pigeonhole principle, \( \hat{R}(x) \in \hat{\Sigma}^\# \). In addition, since \( \hat{\Sigma}^\circ = \tau[\hat{\Sigma}^\circ] \) (where \( \tau \) is the projection to the non-positive coordinates), and \( \hat{\Sigma}_L^\# = \tau[\hat{\Sigma}^\#] \), we get \( \hat{\Sigma}_L^\circ \subseteq \hat{\Sigma}_L^\# \).

Next, since every admissible cylinder contains a point in \( \hat{\Sigma}^\circ \) (Sar13 Lemma 12.1), we get that \( \hat{\Sigma}^\circ \) is a dense invariant subset (Corollary 3.21 shows in addition that its image under \( \hat{\pi} \) covers the Markov partition elements). Thus, \( \hat{\Sigma}^\circ \) is dense \( \hat{\Sigma}_L \); and for every \( R, \hat{S} \in \hat{\Sigma}^\circ L \) s.t. \( \sigma_R \hat{S} = \hat{S} \) the Markov property tells us there is a point in \( W^u(\hat{\Sigma}^\circ) \) whence \( \hat{\Sigma}^\circ \) is also invariant.
Corollary 3.21.
\[ \tilde{\pi}^\circ = \tilde{\pi}^\# = \pi[\Sigma^\#] = \bigcup \mathcal{R}. \]

Proof. In the remark after Definition [§2.1] we saw that \( \hat{\Sigma}^\circ \subseteq \hat{\Sigma}^\# \). In addition, \( \pi[\Sigma^\#] \subseteq \tilde{\pi}^\circ \) because for any \( x \in \pi[\Sigma^\#] = \bigcup \mathcal{R} \), \( \mathcal{R}(x) \in \hat{\Sigma}^\circ \) and \( \tilde{\pi}(\mathcal{R}(x)) = x \). In total, by Proposition 3.7
\[ \tilde{\pi}^\circ \subseteq \tilde{\pi}^\# = \bigcup \mathcal{R} = \pi[\Sigma^\#] \subseteq \tilde{\pi}^\circ. \]

\[ \square \]

4. A Space of Absolutely Continuous Measures

4.1. Unstable Leaves and Absolutely Continuous Measures.

Lemma 4.1. If \( R_0 \to R_1 \), where \( R_0, R_1 \in \mathcal{R} \), and \( R_0 \subseteq Z(u_0) \), \( u_0 \in \mathcal{V} \) then \( \exists u_1 \in \mathcal{V} \) s.t. \( u_0 \to u_1 \) and \( R_1 \subseteq Z(u_1) \). Analogously, if \( R_0 \to R_1 \) and \( R_1 \subseteq Z(v_1) \), then \( \exists v_0 \in \mathcal{V} \) s.t. \( v_0 \to v_1 \) and \( R_0 \subseteq Z(v_0) \).

Proof. Let \( x \in f^{-1}[R_1] \cap R_0 \) (exists by definition since \( R_0 \to R_1 \)). By assumption, \( x \in Z(u_0) \), hence \( \exists \tilde{u}_1 \in \Sigma^\# \) s.t. \( \tilde{u}_0 = u_0 \) and \( \pi(\tilde{u}) = x \). Define \( u_1 := \tilde{u}_1 \) and \( f(x) = \pi(\tilde{u}_1) \). Hence \( f(x) \in R_1 \cap Z(\tilde{u}_1) = R_1 \cap Z(u_1) \). Since \( R_1 \cap Z(u_1) \neq \emptyset \), and \( R \) refines \( Z, R_1 \subseteq Z(u_1) \). The proof of the second part is similar. \[ \square \]

Definition 4.2. Given a chain \( \mathcal{R} \in \hat{\Sigma}_L \) we say a chain \( u \in \mathcal{V}^{\mathrm{lin}} \) covers the chain \( \mathcal{R} \) if \( u \) is admissible and \( R_i \subseteq Z(u_i) \) for all \( i \leq 0 \). We write \( u \pitchfork \mathcal{R} \).

By using Lemma 4.1 in succession, for every chain \( \mathcal{R} \in \hat{\Sigma}_L \), the collection of chains which cover \( \mathcal{R} \) is not empty.

Definition 4.3. Given \( R \in \mathcal{R} \), define \( W(R) := \bigcap \{ \psi_{\mathcal{R}_0} \{ R_{\mathcal{R}_0} (0) \} : \mathcal{R} \cup \mathcal{R} u_i = \psi_{\mathcal{R}_0} \{ R_{\mathcal{R}_0} (0) \}, R_0 = R \} = \bigcap \{ \psi_{\mathcal{R}_0} \{ R_{\mathcal{R}_0} (0) \} : Z(u) \supseteq R, u = \psi_{\mathcal{R}_0} \{ R_{\mathcal{R}_0} (0) \}, \} \), where \( R_{\mathcal{R}_0} (0) \) is the open \( \| \cdot \|_\infty \)-ball (box) around \( 0 \) of radius \( \rho_0 \).

Given a chain \( \mathcal{R} \in \hat{\Sigma}_L \), we define \( V^u(R) := W(R_0) \cap V^u(u) \) for some (any) \( u \pitchfork \mathcal{R} \).

The equality in the first part of the definition above is given by Lemma 4.1 since for every \( R \) s.t. \( R_0 = R \), and every \( u \) s.t. \( Z(u) \supseteq R, u \) can be extended to a chain \( u \) s.t. \( u \pitchfork \mathcal{R} \).

Lemma 4.4. Definition 4.3 is proper: \( V^u(R) \) is independent of the choice of \( u \).

Proof. By Claim 3.5 \( \forall \mathcal{R} \in \mathcal{R}, \{ u : Z(u) \supseteq R \} < \infty \). Therefore \( W(R_0) \) is well defined and is an open set. Assume \( u \in \mathcal{V} \) with \( u \pitchfork \mathcal{R} \), write \( u_i = \psi_{\mathcal{R}_i} \{ R_{\mathcal{R}_i} (0) \}, v_i = \psi_{\mathcal{R}_i} \{ R_{\mathcal{R}_i} (0) \}, i \leq 0 \). We show \( \forall i \leq 0, Z(u_i) \cap Z(v_i) \supseteq R_i \), hence \( \exists \tilde{u}_i \in \Sigma^\# \) s.t. \( \pi(\tilde{u}_i) = \pi(\tilde{u}_i) = z_i \) and \( \tilde{u}_i = u_i, \tilde{v}_i = v_i \). Therefore, by [BO18] Theorem 4.13, \( \psi_{\tilde{u}_i}^{-1} \circ \psi_{\tilde{v}_i} = O_{-i} + a_{-i} + \Delta_{-i} \), where \( O_{-i} \) is an orthogonal linear transformation, \( |a_{-i}| < 10^{-1}q_{-i}^a \land q_{-i}^u \) is a constant vector, and \( \Delta_{-i} : R_{-i} (0) \to \mathbb{R}^d \) is a differentiable map s.t. \( \Delta_{-i}(0) = 0 \) and \( \| d \Delta_{-i} \| \leq \frac{\rho_0}{10} \). In addition, the same theorem states that \( \frac{\rho_{-i}}{\rho_0} = e^{\frac{\rho_0}{\rho_0}} \). Take some \( z \in V^u(u) \cap W(R_0) \subseteq V^u(u) \cap \psi_{y_0} \{ R_{\mathcal{R}_0} (0) \} \), hence \( \forall i \geq 0, f^{-1}(z) \in \psi_{x_{-i}} \{ R_{\mathcal{R}_i} (0) \} \). One could check that the factors in the statements of [BO18] Proposition 2.21,Proposition 3.12(4) can be changed without affecting the proofs to say the following:
\[ V^u(u) = \{ x \in \psi_{y_0} \{ R_{\mathcal{R}_0} (0) \} : \forall i \geq 0, f^{-1}(z) \in \psi_{y_{-i}} \{ R_{\mathcal{R}_0} (0) \} \}. \]

Hence, \( z \in V^u(u) \) as well. So \( V^u(u) \cap W(R_0) \subseteq V^u(u) \cap W(R_0) \). By symmetry \( V^u(u) \cap W(R_0) = V^u(u) \cap W(R_0) \). \[ \square \]

Definition 4.5.
\[ \Sigma_L := \{ (u_i)_{i \leq 0} : u \in \Sigma \}. \]

Corollary 4.6. \( V^u(R) \) is an open submanifold of \( M \), and so it is equipped with its own induced (positive and finite) Riemannian volume measure.
Proof. Let some \( u \in \Sigma_L \) s.t. \( u \cap R \). By Definition 4.3, \( V^u(R) = V^u(u) \cap W(R_0) \). \( V^u(u) \) is an open submanifold (with a finite volume) of \( M \) by definition, and \( W(R_0) \) is a finite intersection of open subsets of \( M \) (recall Definition 4.3 and Definition 4.2(b)). The claim follows.

\[ \square \]

**Definition 4.7.** Let \( R \in \widehat{\Sigma}_L \), then \( \text{Vol}(V^u(R)) \in (0, \infty) \) denotes the volume of \( V^u(R) \) w.r.t. its induced leaf volume.

**Corollary 4.8.** For all \( R \in \widehat{\Sigma}_L \), \( V^u(R) = \bigcap \{ V^u(u) : u \cap R \} \).

Proof. \( \supseteq \): Recall, \( V^u(R) = \bigcap \{ \psi_{x_0}[R_{p_0}(0)] : Z(u) \supseteq R_0, u = \psi_{x_0}^{p_0} \} \cap V^u(u) \) for any \( u \) s.t. \( u \cap R \). Fix some \( u \) s.t. \( u \cap R \), and let \( z \in \bigcap \{ V^u(u) : u \cap R \} \). For each \( u \) s.t. \( Z(u) \supseteq R_0 \), use Lemma 4.1 in succession to extend \( u \) to a chain \( u \) s.t. \( u \cap R \) and \( u_0 = u \). Then, since \( V^u(u) \subseteq \psi_{x_0}[R_{p_0}(0)] \) for \( u_0 = \psi_{x_0}^{p_0} \), we get \( z \in \bigcap \{ \psi_{x_0}[R_{p_0}(0)] : Z(u) \supseteq R_0, u = \psi_{x_0}^{p_0} \} \). In addition, \( z \) is in \( V^u(u') \), whence \( z \in \bigcap \{ \psi_{x_0}[R_{p_0}(0)] : Z(u) \supseteq R_0, u = \psi_{x_0}^{p_0} \} \cap V^u(u') = V^u(R) \).

\( \subseteq \): If \( x \in V^u(R) \) and \( u \cap R \), then \( x \in V^u(u) \cap W(R_0) \) by definition. Hence \( x \in V^u(u) \). \( \square \)

**Corollary 4.9.** For all \( R \in \widehat{\Sigma}_L \), \( f[V^u(\sigma R)] \supseteq V^u(R) \).

Proof. By Corollary 4.8 \( V^u(R) = \bigcap \{ V^u(u) : u \cap R \} \). Therefore

\[
\begin{align}
\text{f}^{-1}[V^u(R)] &= \bigcap \{ \text{f}^{-1}[V^u(u)] : u \cap R \} \\
&\subseteq \bigcap \{ V^u(\sigma R u) : u \cap R \} \\
&\subseteq \bigcap \{ V^u(u) : u \cap R \} = V^u(\sigma R).
\end{align}
\]

The inclusion in line (3) is correct due to Lemma 4.1 \( \forall u \in \Sigma_L \), \( u \cap \sigma R \), there exists \( u \in \Sigma_L \) s.t. \( u \cap R \) and \( \sigma R u = u \) thus the intersection in line (2) is over a bigger collection of sets, and thus smaller. \( \square \)

Using Corollary 4.9 and Corollary 4.9, we are able to re-adapt a construction by Sinai \( \text{(Smi98)} \), and construct our family of absolutely continuous measures which we will call the natural measures.

**Theorem 4.10.** There exists a family of natural measures \( \{ m_{V^u(R)} \} \in \mathcal{E}_L \) s.t. \( \forall R \in \widehat{\Sigma}_L \) \( m_{V^u(R)} \) is a measure on \( V^u(R) \), and \( m_{V^u(\sigma R)} \circ \text{f}^{-1}[V^u(R)] = m_{V^u(R)} \cdot e^{\phi(R)} \), where \( \phi(R) := \lim_{n \to \infty} \frac{\text{Vol}(\text{f}^{-n}[V^u(R)])}{\text{Vol}(\text{f}^{-n}[V^u(\sigma R)])} \), \( \phi : \widehat{\Sigma}_L \to (-\infty, 0) \). In addition, \( m_{V^u(R)} \sim \lambda_{V^u(R)} \), \( d_m m_{V^u(R)} = e^{\phi(R)} \), where \( \lambda_{V^u(R)} \) is the normalized induced Riemannian leaf volume on \( V^u(R) \).

Proof. Fix \( R \in \widehat{\Sigma}_L \). By Corollary 4.9 \( \forall n \geq 0 \), \( f^{-n}[V^u(R)] \subseteq V^u(\sigma^n R) \). Denote by \( \lambda_n \) the normalized Riemannian leaf volume on \( f^{-n}[V^u(R)] \). Define \( \mu_n = \lambda_n \circ \text{f}^{-n} \). This is an absolutely continuous probability measure on \( V^u(R) \). Let \( \rho_n(y) := \frac{d\mu_n}{d\lambda_{V^u(R)}(y)}(y) = \text{Jac}(d_y f^{-n}|_{T_y V^u(R)}) \cdot \frac{\text{Vol}(V^u(R))}{\text{Vol}(f^{-n}[V^u(R)])} \). Define \( m \) as the Riemannian leaf volume on \( V^u(R) \) (not normalized). Then

\[
\rho_n(y) = \text{Jac}(d_y f^{-n}|_{T_y V^u(R)}) \cdot \frac{1}{\text{Jac}(d_y f^{-n}|_{T_y V^u(R)}) \text{dVol}(z)} \cdot \text{Vol}(V^u(R)).
\]

Define \( g_n(y) := \int_{V^u(R)} \frac{\text{Jac}(d_y f^{-n}|_{T_y V^u(R)})}{\text{Jac}(d_y f^{-n}|_{T_y V^u(R)})} \text{dVol}(z) \). Then

\[
\begin{align}
g_n(y) &= \int_{V^u(R)} \prod_{j=0}^{n-1} \frac{\text{Jac}(d_{f^{-j}(y)} f^{-1}|_{T_{f^{-j}(y)} V^u(R)})}{\text{Jac}(d_{f^{-j}(y)} f^{-1}|_{T_{f^{-j}(y)} V^u(R)})} \text{dVol}(z) \\
&= \int_{V^u(R)} \exp \left[ \sum_{j=0}^{n-1} \log \text{Jac}(d_{f^{-j}(y)} f^{-1}|_{T_{f^{-j}(y)} V^u(R)}) \right] \text{dVol}(z). \quad (4)
\end{align}
\]
Let \( z \in V^u(R) \). Thus by \([BO18\, Proposition\, 4.4(3)]\), for any \( n \geq 0 \), and \( \omega(f^{-n}(y)), \omega(f^{-n}(z)) \) any normalized volume forms on \( T_{f^{-n}(y)}f^{-n}[V^u(R)], T_{f^{-n}(z)}f^{-n}[V^u(R)] \) respectively,

\[
\forall m \geq 0, \quad \left| \log \left| d f_{-n}(y) f^{-n(m+n)} \omega(y) \right| - \log \left| d f_{-n}(z) f^{-n(m+n)} \omega(z) \right| \right| \leq e d(f^{-n}(y), f^{-n}(z))^\#. \tag{5}
\]

Let any \( u \in \Sigma_L, u_i = \psi_R \cdot p_i^r, i \leq 0 \) s.t. \( u \cap R \), then by the strong bound shown in the proof of \([Sar13\, Proposition\, 6.3(1)]\), \( e d(f^{-n}(y), f^{-n}(z))^\# \leq \epsilon(6(p_0^u e \beta)^8 \cdot e^{-\frac{4}{5}n}) \). Hence

\[
\sum_{j=0}^{n+m-1} \log \left| d f_{-j(z)} f^{-1}|T_{f^{-j(z)}}f^{-j}[V^u(R)] \right| - \log \left| d f_{-j(y)} f^{-1}|T_{f^{-j(y)}}f^{-j}[V^u(R)] \right|
\]

\[
= \sum_{j=n}^{n+m-1} \log \left| d f_{-j(z)} f^{-m}|T_{f^{-j(z)}}f^{-m}[V^u(R)] \right| - \log \left| d f_{-j(y)} f^{-m}|T_{f^{-j(y)}}f^{-m}[V^u(R)] \right|
\]

This bound is uniform in \( y, z \in V^u(R) \), thus \( \sum_{j=0}^{n} \log \left| d f_{-j(z)} f^{-1}|T_{f^{-j(z)}}f^{-j}[V^u(R)] \right| - \log \left| d f_{-j(y)} f^{-1}|T_{f^{-j(y)}}f^{-j}[V^u(R)] \right| \)

\[
g(y) := \lim_{n \to \infty} g_n(y) = \int_{V^u(R)} \lim_{n \to \infty} \prod_{j=0}^{n-1} \frac{\text{Jac}(d f_{-j(z)} f^{-1}|T_{f^{-j(z)}}f^{-j}[V^u(R)])}{\text{Jac}(d f_{-j(y)} f^{-1}|T_{f^{-j(y)}}f^{-j}[V^u(R)])} d\lambda(z). \tag{7}
\]

\( \rho = \frac{\text{Vol}(V^u(R))}{9} \), and by equation (6) (with \( n = 0 \)) and the remark after it, \( g = \text{Vol}(V^u(R)) e^{\pm \sqrt{v(R)^8}} = e^{\pm \epsilon} \), then \( \rho = e^{\pm \epsilon} \). Therefore, \( \rho_n \) uniformly \( \rho \), a continuous density. Define the measure on \( V^u(R) \):

\[
m_{V^u(R)}(A) = \int_A \rho d\lambda_{V^u(R)}. \]

Notice: To ease notations in what comes next we omit the restriction of the differential to the appropriate tangent space.

**Claim:** If \( A \subseteq f^{-1}[V^u(R)] \subseteq V^u(\sigma_R) \), then

\[
m_{V^u(\sigma_R)}(A) = \left( m_{V^u(R)} \circ f \right)(A) \cdot \left( m_{V^u(\sigma_R)} \circ f^{-1} \right)(V^u(R)).
\]

**Proof:** We start with the following definition, for \( \tilde{A} := f[A] \):

\[
m_{V^u(\sigma_R)} \circ f^{-1}(\tilde{A}) = \int_{f^{-1}[\tilde{A}]} \lim_{n \to \infty} \frac{\text{Jac}(dz f^{-n})}{\text{Vol}(f^{-n}[V^u(\sigma_R)])} \cdot \frac{d\lambda_{V^u(\sigma_R)}(z)}{\text{Vol}(V^u(\sigma_R))}
\]

\[
= \int_{\tilde{A}} \lim_{n \to \infty} \frac{\text{Jac}(dz f^{-n}) \cdot \text{Jac}(dz f^{-1})}{\text{Vol}(f^{-n-1}[V^u(R)])} d\lambda_{V^u(R)}(z) \cdot \lim_{n \to \infty} \frac{\text{Vol}(f^{-n-1}[V^u(R)])}{\text{Vol}(f^{-n}[V^u(\sigma_R)])}
\]

\[
= m_{V^u(\sigma_R)}(\tilde{A}) \cdot \lim_{n \to \infty} \frac{\text{Vol}(f^{-n-1}[V^u(R)])}{\text{Vol}(f^{-n}[V^u(\sigma_R)])}.
\]
where $\overline{m}_{V^*(s_\Sigma \mathcal{L})}, \overline{m}_{V^*(\mathcal{L})}$ are the un-normalized Riemannian volumes of the respective leaves; We could separate the second equation into two limits since their product is finite for a positive volume $\tilde{A}$, and since we additionally know that the limit on the left term exists and is finite for $\tilde{A}$ (whence the limit on the right term must exist and be finite as well).

Plugging in $\tilde{A} = V^u(\mathcal{L})$ yields $m_{V^*(s_\Sigma \mathcal{L})}(f^{-1}[V^u(\mathcal{L})]) = \lim_{n \to \infty} \frac{\text{Vol}(f^{-n-1}[V^u(\mathcal{L})])}{\text{Vol}(f^{-n}[V^u(s_\Sigma \mathcal{L})])}$. Substituting $\tilde{A} = f[A]$ gives the requested result. QED

**Definition 4.11.** For every $\mathcal{L} \in \hat{\Sigma}$, define the absolutely continuous probability measure $m_{V^*(\mathcal{L})}$ on $V^u(\mathcal{L})$ by Theorem 4.10. We call $\{m_{V^*(\mathcal{L})}\}_{\mathcal{L} \in \hat{\Sigma}}$ the family of natural measures.

We are now free to define the following space of absolutely continuous measures:

$$\forall \mathcal{L} \in \hat{\Sigma}, m_{\mathcal{L}} := 1_{V^u(\mathcal{L})} \cdot m_{V^*(\mathcal{L})}.$$  

($W^u(\mathcal{L})$ may be empty, and $m_{\mathcal{L}}$ may be the zero measure).

In what follows, we will mold the structure of a TMS onto our space of absolutely continuous measures, and will be able to use results in thermodynamic formalism in order to construct invariant measures with absolutely continuous conditional measures.

By Theorem 4.10 we get the following important property for the family of natural measures:

**Claim 4.12.** Given $\phi : \hat{\Sigma} \to (-\infty, 0]$ from the statement of Theorem 4.10 $\forall \mathcal{L} \in \hat{\Sigma}, m_{\mathcal{L}} \circ f^{-1} = \sum_{s_\Sigma \mathcal{L} \in R} e^{\phi(\mathcal{L})}m_S$.

**Proof.** The following is true by the definition of the natural measures, the property shown in Corollary 3.19 (i.e. $f[W^u(\mathcal{L})] = \bigcup_{s_\Sigma \mathcal{L} \in R} W^u(\mathcal{L})$) and Theorem 4.11. For any measurable $A \subseteq f[V^u(\mathcal{L})]$,

$$m_{\mathcal{L}} \circ f^{-1}(A) = m_{V^*(\mathcal{L})}(V^u(\mathcal{L}) \cap f^{-1}[A]) = m_{V^*(\mathcal{L})}(f^{-1} \bigcup_{\mathcal{L} \in \hat{\Sigma}} W^u(\mathcal{L}) \cap A) = \sum_{s_\Sigma \mathcal{L} \in R} e^{\phi(\mathcal{L})}m_{V^*(\mathcal{L})}(W^u(\mathcal{L}) \cap A) = \sum_{s_\Sigma \mathcal{L} \in R} e^{\phi(\mathcal{L})}m_{\mathcal{L}}(A),$$

where $m_{V^*(\mathcal{L})} \circ f^{-1}|_{W^u(\mathcal{L})} = e^{\phi(\mathcal{L})}$. $m_{V^*(\mathcal{L})} = \lim_{n \to \infty} \frac{\text{Vol}(f^{-n-1}[V^u(\mathcal{L})])}{\text{Vol}(f^{-n}[V^u(s_\Sigma \mathcal{L})])} \cdot m_{V^*(\mathcal{L})}$ for any $\mathcal{L}$ s.t. $s_\Sigma \mathcal{L} = \mathcal{L}$ by Theorem 4.10.

$\phi$ is sometimes being associated with the geometric potential, for reasons that will be more obvious in §3.

**Definition 4.13.** $M_f := \max_{\mathcal{L} \in \mathcal{M}} \{|\| dx f |, \| dx (f^{-1}) ||\|$.  

**Definition 4.14.** For every $x \in \mathcal{M}$ there is an open neighborhood $D$ of diameter less than $\rho$ and a smooth map $\Theta_D : T_x \mathcal{M} \to \bar{\mathbb{R}}^d$ s.t. :

1. $\Theta_D : T_x \mathcal{M} \to \bar{\mathbb{R}}^d$ is a linear isometry for every $x \in D$ .
2. Define $\nu_x := \Theta_D^{-1} \nu_x : \bar{\mathbb{R}}^d \to T_x \mathcal{M}$, then $(x, u) \mapsto (\exp_x \nu_x)(u)$ is smooth and Lipschitz on $D \times B_2(0)$ w.r.t. the metric $d(x, x') + |u - u'|$.
3. $x \mapsto \nu_x^{-1} \circ \exp_x$ is a Lipschitz map from $D$ to $C(\mathcal{D}, \bar{\mathbb{R}}^d) = \{C^0$-maps from $D$ to $\mathbb{R}^d\}$.

Let $D$ be a finite cover of $\mathcal{M}$ by such neighborhoods. Denote with $\varpi(D)$ the Lebesgue number of that cover: If $d(x, y) < \varpi(D)$ then $x$ and $y$ belong to the same $D$ for some $D$.  

4. $\exists E_0 = E_0(\mathcal{M})$ s.t. $\forall D \in \mathcal{D}, (x_1, u_1, v_1) \mapsto (\Theta_D \circ d_v \exp_{x_1}(\nu_{x_1}, u_1))$ is $E_0$-Lipschitz on $D \times B_2(0) \times B_2(0)$ w.r.t. the metric $d(x_1, x_2) + |u_1 - u_2| + |v_1 - v_2|.$

5. $\exists H_0 = H_0(\mathcal{M}, f)$ s.t. $\forall D, D_+ \in \mathcal{D}, \forall x, y, z \in D, s.t. f(x), f(y) \in D^+, f^{-1}(x), f^{-1}(z) \in D^-$, $||\Theta_D \circ d_x f^{-1}(\nu_x) - \Theta_D \circ d_y (f^{-1}(\nu_y)) ||, ||\Theta_D \circ d_x f^{-1} f_x - \Theta_D \circ d_y f^{-1} f_y || \leq H_0 \cdot d(x, y)^\beta.$

6. We assume w.l.o.g. that $\epsilon > 0$ is small enough, so $\sup \{|| d_v \exp_{x_1} - Id_{T_{x_1}} ||, || d_v \exp_{x_1} - Id_{T_{x_1}} || \leq \frac{\epsilon}{2}, \forall x \in \mathcal{M}$.

The following two definitions are due to Sarig in [Sar13 § 4.2, Definition 4.8] (the version here corresponds to the case $d \geq 2$ from [BOT18 Definition 3.1, Definition 3.2]). We use the notation ‘$u/s$’ to define both $u$-manifolds and $s$-manifolds, without having to write everything twice.
Definition 4.15. Let \( x \in \text{HWT}_\chi \), a \( u \)-manifold in \( \psi_x \) is a manifold \( V^u \subset M \) of the form
\[
V^u = \psi_x[(F^u_s(t_s(x)+1,...,t_d),...,F^u_s(t_s(x)+1,...,t_d),t_s(x)+1,...,t_d) : |t_s| \leq q],
\]
where \( 0 < q \leq Q_\varepsilon(x) \), and \( \vec{F}^u \) is a \( C^{1+\beta/3} \) function s.t. \( \max_{R_x(0)} |\vec{F}^u|_\infty \leq Q_\varepsilon(x) \).

Similarly we define an \( s \)-manifold in \( \psi_x \):
\[
V^s = \psi_x[(t_1,...,t_s(x),F^s_s(t_s(x)+1,...,t_d),...,F^s_s(t_s(x)+1,...,t_d)) : |t_s| \leq q],
\]
with the same requirements for \( \vec{F}^s \) and \( q \). We will use the superscript “u/s” in statements which apply to both the \( u \) case and the \( s \) case. The function \( \vec{F} = \vec{F}^{u/s} \) is called the representing function of \( V^{u/s} \) at \( \psi_x \).

The parameters of a \( u/s \)-manifold in \( \psi_x \) are:
- \( \alpha \)-parameter: \( \alpha(V^{u/s}) := \|d.\vec{F}\|_{\beta/3} := \max_{R_x(0)} \|d.\vec{F}\| + H\vec{O}_{\beta/3}(d.\vec{F}) \), where \( H\vec{O}_{\beta/3}(d.\vec{F}) := \max_{t_1,t_2 \in R_x(0)} \{\frac{|\vec{F}(t_1+t_2) - \vec{F}|}{|t_1-t_2|^{\beta/3}}\} \) and \( \|A\| := \sup_{v \neq 0} \frac{|A|_\infty}{|v|_\infty} \).
- \( \gamma \)-parameter: \( \gamma(V^{u/s}) := \|d_0 \vec{F}\| \)
- \( \varphi \)-parameter: \( \varphi(V^{u/s}) := |\vec{F}(0)|_\infty \)
- \( q \)-parameter: \( q(V^{u/s}) := q \)

A \( (u/s,\alpha,\gamma,\varphi,q) \)-manifold in \( \psi_x \) is a \( u/s \) manifold \( V^{u/s} \) in \( \psi_x \) whose parameters satisfy \( \alpha(V^{u/s}) \leq \alpha, \gamma(V^{u/s}) \leq \gamma, \varphi(V^{u/s}) \leq \varphi, q(V^{u/s}) \leq q \).

Notice that the dimensions of an \( s \) or \( u \) manifold in \( \psi_x \) depend on \( x \). Their sum is \( d \).

Definition 4.16. Suppose \( x \in \text{HWT}_\chi \) and \( 0 < p^s, p^u \leq Q_\varepsilon(x) \) (i.e. \( \psi^{p^s,p^u}_x \) is a double Pesin-chart). A \( u/s \)-admissible manifold in \( \psi^{p^s,p^u}_x \) is a \( (u/s,\alpha,\gamma,\varphi,q) \)-manifold in \( \psi_x \) s.t.
\[
\alpha \leq \frac{1}{2}, \gamma \leq \frac{1}{2}(p^u \wedge p^s)^{\beta/3}, \varphi \leq 10^{-3}(p^u \wedge p^s), \quad \text{and} \quad q = \begin{cases} p^u & \text{\( u \)-manifolds} \\ p^s & \text{\( s \)-manifolds} \end{cases}.
\]

Remark: Recall Claim 3.10 \( \forall \psi \in \Sigma \) there exist a maximal dimension stable leaf \( V^s(\psi) = V^s((u_i)_{i \leq 0}) \), and a maximal dimension unstable leaf \( V^u(\psi) = V^u((u_i)_{i \leq 0}) \); which is the content of \[BO18\] Proposition 3.12,Proposition 4.4] (and similarly \[Sar13\] Proposition 4.15,Proposition 6.3 when \( d = 2 \)). The construction in \[BO18\] Proposition 3.12] (and \[Sar13\] Proposition 4.15] when \( d = 2 \) in fact tells us that \( V^s(\psi) \) are \( V^u(\psi) \) are admissible stable and unstable manifolds in \( u_0 = \psi^{p^s_0,p^u_0}_x \), respectively.

Definition 4.17. Let \( \psi \) and \( \psi^u \) be \( u \)-admissible manifolds in \( \psi^{p^s,p^u}_x \), and Let \( F^u, G^u \) be their representing functions, respectively. Then,
\[
d_c^{CO}(V^u, W^u) := \max_{R_{p^u(0)}} |F^u - G^u|, \quad d_c^1(V^u, W^u) := \max_{R_{p^u(0)}} |F^u - G^u| + \max_{R_{p^u(0)}} \|dF^u - dG^u\|
\]
where \( R_{p^u(0)} := \{ u \in \text{R}^d : |u|_\infty \leq p^u \} \).

Definition 4.18. Let \( R, S \in \Sigma_L \) be two chains s.t. \( R_0 = S_0 \), then
\[
d_c(V^u(R), V^u(S)) := \max_{\text{w} \sim R, \text{w} \sim S, \text{w}_0 = \text{v}_0} \{d_c^{CO}(\text{w}(u), \text{v}(\text{w}))\}, \quad d_c^1(V^u(R), V^u(S)) := \max_{\text{w} \sim R, \text{w} \sim S, \text{w}_0 = \text{v}_0} \{d_c^1(\text{w}(u), \text{v}(\text{w}))\}
\]

The maximum is finite (and so the definition is proper), since \( \forall R \in \text{R} \), \( \# \{ u \in \mathcal{V} : Z(u) \supseteq R \} < \infty \), and \( \forall \text{w}, \text{v} \in \Sigma_L \) s.t. \( \text{w} \not\supseteq \text{v} \) and \( u_0 = v_0 = \psi^{p^s,p^u}_x \), \( u^v(u) = V^u(\text{w}) \), by \[BO18\] Proposition 4.15.]

Claim 4.19. \( \exists K > 0, \theta_0 \in (0,1) \) s.t. \( d(R, S) \leq e^{-n} \Rightarrow d_c(V^u(R), V^u(S)) \leq C \cdot \theta^n \), \( \forall n \geq 1 \).

Proof. Let \( u \in \mathcal{V} \) s.t. \( Z(u) \supseteq R_0 \supseteq S_0 \). Use Lemma 4.1 in succession to obtain an admissible sequence \( (u^-_{n+1},...,u^-_1,u^-) \) s.t. \( Z(u^-_i) \supseteq R_{i-1} \supseteq S_{i-1}, \forall i \leq i \leq n - 1 \). By continuing to use Lemma 4.1 in succession, separately, obtain two admissible chains \( \overline{w}_R(u), \overline{w}_S(u) \in \Sigma_L \cap [u] \) s.t. \( \overline{w}_R(u) \not\supseteq \overline{R}, \overline{w}_S(u) \not\supseteq \overline{S} \), and \( d(\overline{w}_R(u), \overline{w}_S(u)) \leq e^{-n} \). By \[BO18\] Proposition 4.15], \( \forall u' \in \Sigma_L \cap [u] \) s.t. \( u' \not\supseteq \overline{R} \), \( V^u(\overline{w}_R(u)) = V^u(u') \),
and similarly with $w_S(u)$. By [BO18 Proposition 3.12], $\exists K > 0, \theta \in (0,1)$ which depend on $\beta$ and $\chi$ s.t. $d_{C_1}(V^u(w_S(u)), V^v(w_S(u))) \leq K \cdot \theta^n$. Therefore,

$$d_{C_0}(V^u(R), V^v(S)) \leq d_{C_1}(V^u(R), V^v(S)) = \max_{u \in V(Z)(u) \geq R_0} \left\{ d_{C_1} \left( V^u(w_{\mathcal{A}}(u)), V^v(w_{\mathcal{A}}(u)) \right) \right\} \leq K \cdot \theta^n.$$

\[ \square \]

**Lemma 4.20.** Let $R, S \in \tilde{\Sigma}_L$ s.t. $d(R, S) = \epsilon^{-n}$, $n \geq 1$. Then, there exists a diffeomorphism $I : V^u(R) \to V^v(S)$, s.t. for $\beta := \frac{d_{\lambda u}(R)}{\lambda u v(R)}$, $\rho^S := \frac{d_{\lambda v}(S)}{\lambda u v(S)}$, $\exists \theta_2 \in (0,1)$ independent of $R, S$ s.t. $\| \beta - \rho \circ I \|_{\infty} \leq \epsilon \theta_2^2$, where $\lambda_{V^u(R)}, \lambda_{V^v(S)}$ are the normalized Riemannian volume on the respective leaf.

**Proof.** Let $u, v \in \Sigma_L$ s.t. $u \cap R, v \cap S, d(u, v) = \epsilon^{-n}$, and $d_{C_1}(V^u(R), V^v(S)) = d_{C_1}(V^u(u), V^v(v))$ (as constructed in Claim 4.19). Denote by $\tilde{F}^u$ and $\tilde{F}^v$ the representing functions of $V^u(v)$ and $V^v(u)$ respectively. Write $u = \dim V^u(R) = \dim V^v(S)$ (since $R_0 = S_0$).

**Part 0:** Write $\forall i \geq 0$, $u_{-i} = \psi^e_{-i, \nu_i}$, $v_{-i} = \psi^e_{-i, \nu_i}$, and recall that $u_{-i} = v_{-i}$ for all $i \leq n$ by assumption. Hence, $\psi_{u_0} = \psi_{v_0}$. In addition $R_0 = S_0$, thus $O := \psi^{-1}_0[W(R_0)]$ is an open subset of $\mathbb{R}^d$ for which $V^u(R) = (\psi_{x_0} \circ \tilde{F}^u)[O], V^v(S) = (\psi_{x_0} \circ \tilde{F}^v)[O]$ where $\tilde{F}^u \circ \tilde{F}^v(t) = (\tilde{F}^u(t), t)$. $I$ is defined in the following way: $\psi_{x_0}(F^u(t), t) \mapsto \psi_{x_0}(F^v(t), t)$. $I = \psi_{x_0} \circ \tilde{F}^u \circ \pi_u \circ \psi^{-1}_0$, where $\pi_u$ is the projection onto the last $u$ coordinates, and $\tilde{F}^u \circ \tilde{F}^v$ are diffeomorphism onto their images. So $I$ is a diffeomorphism. $I$ satisfies

$$d(I(x), y) \leq \| \psi_x \| \cdot d_{C_0}(F^u, F^v) \leq 2d_{C_0}(F^u, F^v). \tag{8}$$

Notice, the identity map $V^u(R)$ can be written as $Id = \psi_{x_0} \circ \tilde{F}^u \circ \pi_u \circ \psi^{-1}_0 : V^u(R) \to V^v(R)$. Hence, for all $z \in V^u(R)$:

$$\| \Theta D d_z I - \Theta D d_z Id \| = \| \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u \circ \pi_u \circ \psi^{-1}_0) - \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u \circ \pi_u \circ \psi^{-1}_0) \|
\leq \| \|C^{-1}_x(x_0)\| \cdot \| \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u - \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u) \|
\leq 2\|C^{-1}_x(x_0)\| \cdot \| \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u - \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u) \|$$

$$\leq 2\|C^{-1}_x(x_0)\| \cdot \| \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u - \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u) \|
\leq 2\|C^{-1}_x(x_0)\| \cdot \| \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u - \Theta D d_z (\psi_{x_0} \circ \tilde{F}^u) \|
\leq 8\|C^{-1}_x(x_0)\| \cdot d_{C_0}(V^u(R), V^v(S)), \tag{9}$$

where $t = \pi_u \psi^{-1}_0(z)$, and $\Theta D : TD \to \mathbb{R}^d$ is the local isometry as in Definition 4.11 s.t. $D$ is a neighborhood which contains $z, I(z)$. It follows that,

$$|\text{Jac}(d_z I) - 1| = |\text{Jac}(d_z I) - \text{Jac}(d_z Id)| \leq C_1 \| \Theta D d_z I - \Theta D d_z Id \| \leq 8C_1 \|C^{-1}_x(x_0)\| \cdot d_{C_0}(V^u(R), V^v(S)), \tag{10}$$

where $C_1$ is the Lipschitz constant for the absolute value of the determinant on the ball of $(d \times d)$-matrices with a bounded operator norm of $2M_f$. By [BO18 Proposition 3.12(5)], $d_{C_1}(V^u(u), V^v(v)) \leq K \theta^n$; and in addition, as detailed in the remark after [BO18 Definition 3.2], $d_{C_1}(V^u(u), V^v(v)) \leq 2(p_0)^{\frac{n}{d}} \cdot K \hat{\theta}^n$. Therefore,

$$d_{C_1}(V^u(R), V^v(S)) = d_{C_1}(V^u(u), V^v(v))
= d_{C_1}(V^u(u), V^v(v)) \cdot d_{C_1}(V^u(u), V^v(v)) \cdot K \hat{\theta}^n \leq 2(p_0)^{\frac{n}{d}} \cdot K \hat{\theta}^n. \tag{11}$$

Plugging this back in equation (10) gives, (for sufficiently small $\epsilon > 0$),

$$|\text{Jac}(d_z I) - 1| \leq 8C_1 \|C^{-1}_x(x_0)\| \cdot 2(p_0)^{\frac{n}{d}} \cdot K \hat{\theta}^n \leq \epsilon(p_0)^{\frac{n}{d}} \cdot \hat{\theta}^n, \tag{12}$$

where $\hat{\theta} := \theta \hat{\theta} \in (0,1)$, and $\hat{K} := \hat{K} \hat{\theta} > 0$.

\[ \footnote{Write $u = \dim V^u(R)$, and let $A, B$ be $u \times u$ matrices s.t. $|a_{ij} - b_{ij}| \leq \delta$ for all $i, j \leq u$. det $A = \sum_{\sigma \in S_u} \text{sgn}(\sigma) \prod_{i=1}^u a_{i\sigma(i)}$. Then $|\det A - \det B| \leq \sum_{\sigma \in S_u} \left| \prod_{i=1}^u b_{i\sigma(i)} - \prod_{i=1}^u a_{i\sigma(i)} \right| \leq |S_u| \cdot u \| B \|_F^{-1} \delta$. Take maximum over $u \leq d - 1$.} \]
Part 1: As in equation (4), given \( R \in \bar{S}_L \), let
\[
S_{m,z}^R(y) := \int_{V^u(R)} \exp \left( \sum_{k=0}^{n-1} \log \text{Jac}(d_{f-k}z \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(R)))}) - \log \text{Jac}(d_{f-k}y \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(R)))}) \right) \, \overline{m}_R(z),
\]
where \( \overline{m}_R \) is the induced Riemannian volume of \( V^u(R) \) (not normalized). We saw in Theorem 4.10 that for a fixed \( z \in V^u(R) \), the inner sum (denoted by \( S_{m,z}^R(y) \)) converges uniformly, to a limit denoted by \( S_{m}^R(y) \). Therefore, also uniformly in \( y, z \),
\[
|S_{m,z}^R(y) - S_{m}^R(y)| \leq e^{\frac{\beta}{2} (p_0^n \beta) \theta_3} e^{-\frac{\beta}{4} n} = e^{\frac{\beta}{2} (p_0^n \beta) \theta_3},
\]
where \( \theta_3 := e^{-\frac{\beta}{4} n} \in (0, 1) \).

Part 2:
\[
|g^R(y) - (g^S \circ I)(y)| \leq \left| \int_{V^u(R)} e^{S_{m,z}^R(y)} \overline{m}_R(z) - \int_{V^u(S)} e^{S_{m,z}^R(y)} \overline{m}_S(z) \right| \leq \left| \int_{V^u(R)} e^{S_{m,z}^R(y)} \overline{m}_R(z) - \int_{V^u(S)} e^{S_{m,z}^R(y)} \overline{m}_S(z) \right| \left( \text{Jac}(d_z I) \overline{m}_R(z) \right) \leq e^{\frac{\beta}{2} (p_0^n \beta) \theta_3} \text{Vol}(V^u(R)) \left( 2 \sup_{y,z \in V^u(R)} |S_{m,z}^R(y) - S_{m,z}^S(I(y))| + (p_0^n \beta) \theta_3 \right).
\]

Part 3: By [BL08, Lemma 2.15], \( \exists \omega_0 > 0 \) which depends only on \( M, f, \beta, \theta, \), s.t. \( \frac{\phi(f)}{\chi} = \omega_0 \). Let \( \kappa = \kappa(f, \chi) > 0 \) be the constant given by Theorem 2.2 Define,
\[
r := \log \left( \frac{\theta}{\omega_0 \beta + \nu + 1} \right) + 1,
\]
and notice that \( r > 1 \). For \( n \gg r \), define \( m = \lfloor \frac{n}{r} \rfloor \). Then,
\[
|S_{m}^R(y) - S_{m}^S(I(y))| \leq |S_{m,z}^R(y) - S_{m,z}^S(I(y))| + |S_{m,z}^R(y) - S_{m,z}^S(I(y))| + |S_{m,z}^S(I(y)) - S_{m,z}^S(I(y))|
\]
\[
(\text{eq. } 13) \leq 2e^{\frac{\beta}{2} (p_0^n \beta) \theta_3} \cdot \frac{\beta}{4} - 1 + \sum_{k=0}^{m} \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(R)))}) - \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(R)))}) + \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(S)))}) - \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(S)))})
\]
\[
\leq (p_0^n \beta) \cdot (\beta_3^{\frac{1}{2}})^n + \sum_{k=0}^{m} \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(R)))}) - \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(S)))}) + \sum_{k=0}^{m} \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(R)))}) - \log \text{Jac}(d_{f-k}(y) \cdot f^{-1}\vert_{T_{f-k}(y)(f^{-k}(V^u(S)))}).
\]
Part 4: We wish to bound the expressions of the form
\[ \log \text{Jac}(d_{f-k}(z)) - \log \text{Jac}(d_{f-k}(I(z))) \] for \( k \leq m \). Set \( I_k : V^u(\sigma^k_R) \rightarrow V^u(\sigma^k_S) \), \( \psi_{x,k} : F^g_{\sigma^k_R}(t), t \rightarrow \psi_{x,k}^T(\sigma^k_R(\psi_{x,k} t), t) \), where \( F^g_{\sigma^k_R}, F^g_{\sigma^k_S} \) are the representing functions of \( V^u(\sigma^k_R), V^u(\sigma^k_S) \) respectively (as in the definition of \( I \)). By Corollary \[ \text{f}^{-k}[V^u(R)] \subseteq V^u(\sigma^k_R), f^{-k}[V^u(S)] \subseteq V^u(\sigma^k_S). \]

We proceed to bound the first term. Consider the local isometries \( \Theta_{D_k} : T D_k \rightarrow \mathbb{R}^d, k \geq 0, \) as in Definition \[ \text{d}^{\text{local}} \) and the last line is by equation \( \text{[10]} \) and equation \( \text{[12]} \), applied to the shifted sequences \( \sigma^k_R, \sigma^k_S \). Then we get,

\[ |\text{Jac}(d_{f-k}(z)) - \text{Jac}(I_k(f_{k-1}(z)))| \leq C_1(4H_0 + 8M_f)e(p^u_k)^2 \tilde{\theta} \omega_0^{-k} \leq C_1(4H_0 + 8M_f)eQ \sigma_0^k \omega_0^{-k} \text{[15]} \]

we get,

\[ \text{Jac}(d_{f-k}(z)) = \exp(\pm\mathfrak{C}(2M_f)^d(4H_0 + 9M_f)e(p^u_k)^2 \tilde{\theta} \omega_0^{-k}) = \exp(\pm\mathfrak{C}Q \sigma_0^k \omega_0^{-k}) \text{[16]} \]

The last line is due to the choice of \( r \) in equation \( \text{[16]} \). We continue to bound the second term of equation \( \text{[18]} \). Define \( f_{x,x+1} := \psi_{x,A}^{-1} \circ f \circ \psi_{x,A} \). By \[ \text{[BO13]} \) Proposition 2.21,

\[ f_{x,x+1} = (D_x v_x + h_x(v_x, v_u), D_u v_u + h_u(v_x, v_u)) \]

for \( v_u = \pi_u \psi_{x,A}^{-1} \xi, v_x = \pi_x \psi_{x,A}^{-1} \xi, \) where \( \pi_x \) is the projection onto the \((d-u)\) first coordinates, \( \forall \xi \) tangent to \( \psi_{x,A} [R_{Q_{\xi}}(x)] \), where \( k^{-1} \leq ||D^{-1}_S||^{-1}, ||D_S|| \leq e^{-\epsilon} \) and \( e \leq ||D^{-1}_u||^{-1}, ||D_u|| \leq k, ||\partial(h_u, h_u)/(v_u, v_u)|| < e, \) and \( ||\partial(h_u, h_u)/(v_u, v_u)|| < e - \chi ||D^{-1}_u||^{-1} \).
\[
\frac{\partial \psi}{\partial x}\leq |v_1 - v_2|^{\beta/3} \text{ on } R_{Q_{\phi}}(x_0). \]
A similar statement holds for \(f_{x_{k+1}}^{-1}\). Notice, \(\kappa = \kappa(f, \chi) > 0\) was introduced before in Theorem 222. Then,
\[
|\psi_{x_k}^{-1}(I_k(f^{-k}(z))) - \psi_{x_k}^{-1}(f^{-k}(I(z)))| \leq |\psi_{x_k}^{-1}(I_k(f^{-k}(z))) - \psi_{x_k}^{-1}(f^{-k}(z))| + |\psi_{x_k}^{-1}(f^{-k}(z)) - \psi_{x_k}^{-1}(f^{-k}(I(z)))| \\
\leq (\kappa + \epsilon) d_{C^1}(V^{u}(u), V^{u}(v)) + d_{C^1}(V^{u}(\sigma^k_{\phi}u), V^{u}(\sigma^k_{\phi}v)) \\
\leq (\kappa + \epsilon) d_{C^1}(V^{u}(u), V^{u}(v)) + d_{C^1}(V^{u}(\sigma^k_{\phi}u), V^{u}(\sigma^k_{\phi}v)).
\]
By the estimates of equation (11) and equation (12), applied to the shifted sequences, we get \(\forall 0 \leq k \leq m\),
\[
d_{C^1}(V^{u}(\sigma^k_{\phi}u), V^{u}(\sigma^k_{\phi}v)) \leq (p^u_k)^\frac{\theta}{\epsilon} \theta_n^{k-\theta}\tag{20}
\]
In addition, by the admissibility of the chain \(u\) (or \(v\), \(p^u_k \leq \epsilon^k p^v_k\) (see [BO18 Definition 2.23]). Plugging this back in equation (21) yields,
\[
|\psi_{x_k}^{-1}(I_k(f^{-k}(z))) - \psi_{x_k}^{-1}(f^{-k}(I(z)))| \leq (\kappa + \epsilon) \theta_n^{k-\theta} (p^u_k)^\frac{\theta}{\epsilon} + (p^u_k)^\frac{\theta}{\epsilon} \theta_n^{k-\theta} \\
\leq \left( (\epsilon^k (\kappa + \epsilon)) m (\theta_n^{k-\theta}) (p^u_k)^\frac{\theta}{\epsilon} \right) \\
\leq \left( (\kappa + \epsilon) m (\theta_n^{k-\theta}) (p^u_k)^\frac{\theta}{\epsilon} \right) \leq 2(p^u_k)^\frac{\theta}{\epsilon} \theta^m.\tag{22}
\]
Define \(A_k : T_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u) \to T_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u)\), \(A_k \psi_{x_k}^{-1}(I_k(f^{-k}(z))) \psi_{x_k}\left( d_{\sigma^k_{\phi}u}(I_k(f^{-k}(I(z)))) F^{\sigma^k_{\phi}u} \right) = d^u_{x_k}\psi_{x_k}^{-1}(I_k(f^{-k}(I(z)))) F^{\sigma^k_{\phi}u} \). Then by equation (22), it can be shown similarly to equation 4, that
\[
\|\Theta_{D_k}Id_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u) - \Theta_{D_k} A_k\| \leq 2\|C^{-1}(x_k)\| \cdot (\text{Hölder} \cdot d.F^{\sigma^k_{\phi}u}) \cdot 2|\psi_{x_k}^{-1}(I_k(f^{-k}(z))) - \psi_{x_k}^{-1}(f^{-k}(I(z)))| \frac{\theta}{\epsilon} \\
+ 2|\psi_{x_k}^{-1}(I_k(f^{-k}(z))) - \psi_{x_k}^{-1}(f^{-k}(I(z)))| \cdot 2 \leq 8\|C^{-1}(x_k)\| \cdot (2p^u_k \theta^m) \frac{\theta}{\epsilon} \leq \epsilon^4 (\theta_n^{k-\theta})^m.
\]
Then,
\[
\|\Theta_{D_k} d_{f^{-k}(I(z))} f^{-1} - \Theta_{D_k} + d_{I_k(f^{-k}(z))} f^{-1} A_k\| \\
= \|\Theta_{D_k} d_{f^{-k}(I(z))} f^{-1} d_{I_k(f^{-k}(z))} \Theta_{D_k} d_{f^{-k}(I(z))} f^{-1} V^{u}(\sigma^k_{\phi}u) - \Theta_{D_k} A_k\| \\
\leq \|A_k\| \cdot \text{Hölder} \cdot d(f^{-k}(I(z)), I_k(f^{-k}(z)))^\beta + M \|\Theta_{D_k} d_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u) - \Theta_{D_k} A_k\| \\
\leq 2\text{Hölder} \cdot (2|\psi_{x_k}^{-1}(I_k(f^{-k}(z))) - \psi_{x_k}^{-1}(f^{-k}(I(z)))|)^\beta + M \epsilon^4 (\theta^m) \theta^m \leq \epsilon^3 (\theta^m).\tag{23}
\]
Therefore,
\[
\frac{\text{Jac}(d_{I_k(f^{-k}(z))})^{-1} |T_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u)|}{\text{Jac}(d_{I_k(f^{-k}(z))})^{-1} |T_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u)|} = \frac{\text{Jac}(d_{I_k(f^{-k}(z))})^{-1} A_k}{\text{Jac}(d_{I_k(f^{-k}(z))})^{-1}} \cdot \frac{1}{\text{Jac}(A_k)} = e^{\pm ((2M)^4 \epsilon^4 \epsilon^3 (\theta^m) + 2M^3 (\theta^m))}.\tag{17}
\]
Plugging this, together with equation (19), back in equation (18), yields
\[
\frac{\text{Jac}(d_{f^{-k}(I(z))})^{-1} |T_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u)|}{\text{Jac}(d_{f^{-k}(I(z))})^{-1} |T_{f^{-k}(I(z))} V^{u}(\sigma^k_{\phi}u)|} = \exp(\pm 2\epsilon^{2.5} (\theta^m)^m) = \exp(\pm 2\epsilon^{2.5} (\theta^m)^m) = \exp(\pm 2\epsilon^{2.5} (\theta^m)^m).
\]
Hence, by plugging this back in equation (17),
\[
|S_{\tilde{\phi}}^y(y) - S_{\tilde{\phi}}^y(I(z))| \leq (p^u_k)^\frac{\theta}{\epsilon} 2K_3 (\theta^m)^n \leq \frac{\epsilon^2}{2} \sum_{k=0}^m (\theta^m)^n \leq (p^u_k)^\frac{\theta}{\epsilon} 2K_3 (\theta^m)^n + \epsilon^2 n \cdot (\theta^m)^n \\
\leq \frac{\epsilon^2}{2} \cdot (\theta^m)^n + \frac{\epsilon^2}{2} \cdot (\theta^m)^n \text{ (for small enough } \epsilon) \leq \frac{\epsilon^2}{2} \cdot (\max(\theta^m_3, \theta^m_0)) \cdot (\theta^m)^n = \epsilon^2 \theta^m_3,\tag{23}
\]
where \(\theta_3 := \max(\theta^m_3, \theta^m_0, \tilde{\theta})\). Plugging this in equation (15) yields (for \(\epsilon\) sufficiently small),
\[
|g^L(y) - g^L \circ I(y)| \leq \epsilon^2 \text{Vol}(V^{u}(\tilde{R})) (2\epsilon^2 \theta_3^m + \epsilon (p^u_k)^\frac{\theta}{\epsilon} \theta^m) \leq \epsilon^2 \text{Vol}(V^{u}(\tilde{R})) \theta^m_3.\tag{23}
\]
Part 5: \[ |\text{Vol}(V^u(R)) - \text{Vol}(V^u(S))| = \int_O \text{Jac}(d_\epsilon(\psi_{x_0}) \tilde{F}^u) d\text{Leb}(t) - \int_O \text{Jac}(d_\epsilon(\psi_{x_0}) \tilde{F}^u) d\text{Leb}(t) \]
\[ \leq \int_O |\text{Jac}(d_\epsilon(\psi_{x_0}) \tilde{F}^u)) - \text{Jac}(d_\epsilon(\psi_{x_0}) \hat{F}^u))| d\text{Leb}(t) \]
\[ \leq \int_O C_1 ||\Theta_{D}d_\epsilon(\psi_{x_0}) \hat{F}^u) - \Theta_{D}d_\epsilon(\psi_{x_0}) \tilde{F}^u)|| d\text{Leb}(t), \]
where \( C_1 \) is the Lipschitz constant for the Jacobian operator (it is used properly here, since \( ||d_\epsilon(\psi_{x_0}) \tilde{F}^u)|| \leq 3 \)). In equation 21 we saw that \( ||\Theta_{D}d_\epsilon(\psi_{x_0}) \hat{F}^u) - \Theta_{D}d_\epsilon(\psi_{x_0}) \tilde{F}^u)|| \leq 4dC_1 (V^u(R), V^u(S)) \); hence \( |\text{Vol}(V^u(R)) - \text{Vol}(V^u(S))| \leq C_1 \cdot 4 \cdot 2K(p_0)^n \theta^n \). In addition, \( \text{Jac}(d_\epsilon(\psi_{x_0}) \hat{F}^u))^{-1} = \text{Jac}(d_\epsilon(\psi_{x_0}) \tilde{F}^u))^{-1} \leq 3 ||\chi^{-1}(x_0)|| \).

Therefore,
\[ \frac{|\text{Vol}(V^u(R)) - \text{Vol}(V^u(S))|}{\text{Vol}(V^u(R))} \leq \frac{\text{Leb}(O)8C_1 \hat{K}(p_0) \theta^n}{\text{Leb}(O)\frac{1}{3||\chi^{-1}(x_0)||}} \leq \epsilon \theta^n, \] (24)
when \( \epsilon \) is sufficiently small.
\[ \leq \text{Vol}(V^u(R)) \epsilon \theta^n \] (for small enough \( \epsilon \)). In particular,
\[ |\text{Vol}(V^u(R)) - \text{Vol}(V^u(S))| \leq \text{Vol}(V^u(R)) \cdot \epsilon \theta^n, \text{ and } \frac{\text{Vol}(V^u(S))}{\text{Vol}(V^u(R))} = e^{\pm \epsilon}. \] (25)

Part 6: Recall, \( g^R = e^{\pm \epsilon} \text{Vol}(V^u(R)) \) since \( g^R(y) = \int_{V^u(R)} e^{\frac{\text{Leb}(y)}{2}} d\text{m}_R(z) \) (and similarly for \( g^S \)). Hence
\[ ||g^R - g^S \circ I|| = \frac{||\text{Vol}(V^u(R)) - \text{Vol}(V^u(S))||}{g^S} \]
\[ \leq ||\text{Vol}(V^u(R))(g^R - g^S \circ I) + g^S(\text{Vol}(V^u(R)) - \text{Vol}(V^u(S)))|| \]
\[ \leq e^{2\epsilon} \frac{1}{\text{Vol}(V^u(S))} ||g^R - g^S \circ I|| + e^{3\epsilon} \frac{1}{\text{Vol}(V^u(R))} |\text{Vol}(V^u(R)) - \text{Vol}(V^u(S))| \]
\[ (\text{eq. } 23) \leq e^{2\epsilon} \frac{\text{Vol}(V^u(R))}{\text{Vol}(V^u(S))} \frac{1}{\text{Vol}(V^u(S))} \text{Vol}(V^u(R)) \theta^2 e^{3\epsilon} \frac{1}{\text{Vol}(V^u(R))} \text{Vol}(V^u(R)) e^{3\epsilon} \theta^n \]
\[ \leq \epsilon \cdot \sqrt{e^{2\epsilon} + e^{3\epsilon}} \theta^2 \leq \epsilon \theta^2 \] for small enough \( \epsilon \).

\[ \square \]

Claim 4.21. There exist \( n_0 \in \mathbb{N} \) and \( \theta_2 \in (0, 1) \), constants depending only on \( \chi, \beta, f \), such that for any \( n \geq n_0 \), \( |d_{\rho^R}(\tilde{S})| = e^{-n} \), then \( |\phi(R) - \phi(S)| \leq \sqrt{\theta_2^n} \). In addition, \( \phi \) has summable variations.

Proof. We define \( n_0 := \lceil r \rceil + 1 \), where \( r \) is a constant given by equation 13. We assume \( n \geq n_0 \). Recall the formula from the statement of Theorem 4.11
\[ e^{\phi(R)} = \lim_{m \to \infty} \frac{\text{Vol}(f^{-m} f^{-1} |V^u(R))|)}{\text{Vol}(f^{-m} |V^u(SR(R)))|} \]
\[ = \int_{f^{-1}|V^u(R)} \frac{d\text{m}_{\sigma_{SR}(R)}(y)}{g^{\sigma_{SR}(R)}(y)} = \int_{V^u(R)} \frac{d\text{m}_{\sigma_{SR}(R)}(y)}{g^{\sigma_{SR}(R)}(y)} \]
\[ f^{-1}(y), \]
where \( m_{\sigma_{SR}(R)} \) and \( m_{\sigma_{SR}(R)} \) are the induced Riemannian volumes of \( V^u(R) \) and \( V^u(SR(R)) \) respectively, the Jacobians refer to the Jacobians of the restriction of the differential to the tangent space to the domain of integration manifold, and \( g^{\sigma_{SR}(R)} \) is the continuous limit function as defined in equation 1, for \( V^u(SR(R)) \).

\[ ^7 \text{As defined in } [\text{Sar09}], \sum_{k=2}^{\infty} \text{var}_k(\phi) < \infty, \text{var}_k(\phi) = \sup\{\phi(R) - \phi(S) : d(R, S) \leq e^{-k}\}. \]
Assume \(d(R, S) = e^{-n}, n \geq 2\). Consider the maps \(I_1: V^u(R) \to V^u(S), I_2: V^u(\sigma R) \to V^u(\sigma S)\) as given by Lemma \([1,20]\). Then,
\[
e^{\phi(S)} = \int_{V^u(S)} \frac{\text{Jac}(d_y f^{-1}) d\mu_S(y')}{g^{\sigma} R \circ f^{-1}(y')} = \int_{V^u(S)} \frac{\text{Jac}(d_y I_1) \text{Jac}(d_y (I_1(y) f^{-1}) d\mu_R(y))}{g^{\sigma} R \circ f^{-1} \circ I_1(y)}.
\]
(26)
We now wish to bound the ratio between the integrands in the formulae of \(e^{\phi(S)}\) and \(e^{\phi(R)}\): by equation \([12]\), \(\text{Jac}(d_y I_1) = e^{\pm e^\theta_0}\) where \(\theta_0 \in (0, 1)\) is a constant depending only on \(\chi, \beta\). By equation \([19]\) (with \(m = k = 0\), \(\frac{\text{Jac}(d_y (I_1(y)) f^{-1})}{\text{Jac}(d_y f^{-1})} = e^{\pm e^\theta_0}\), where \(\theta_2 \in (0, 1)\) is a constant depending only on \(\chi, \beta, M, f\). We are therefore left to bound \(\frac{g^{\sigma} R \circ f^{-1} \circ I_1(y)}{g^{\sigma} R \circ f^{-1}(y')}\):
\[
|g^{\sigma} R(f^{-1}(y)) - g^{\sigma} R(f^{-1}(I_1(y)))| \leq |g^{\sigma} R(f^{-1}(y)) - g^{\sigma} R \circ I_2(f^{-1}(y))|
+ |g^{\sigma} R \circ I_2(f^{-1}(y)) - g^{\sigma} R(f^{-1}(I_1(y)))|
\leq e^{\phi} \text{Vol}(V^u(\sigma S)\theta_2^{-1} + |g^{\sigma} R \circ I_2(f^{-1}(y)) - g^{\sigma} R(f^{-1}(I_1(y)))|,
\]
where the last line is by equation \([23]\), and since all estimates with \(I_1\) hold with \(I_1 := I_1 : V^u(S) \to V^u(R)\). We continue to bound the second summand: denote \(t_1 = f^{-1} \circ I_1(y), t_2 = I_2 \circ f^{-1}(y)\). Denote \(V^u(\sigma S)\)
\[
S_{m,n}^\sigma(b) := \sum_{k=0}^{m-1} \log \text{Jac}(d_{f^{-k(a)})} f^{-1})|_{T_{f^{-k(a)}f^{-k}} V^u(\sigma S))| - \log \text{Jac}(d_{f^{-k(b)}f^{-1})|_{T_{f^{-k(b)}f^{-1}}| V^u(\sigma S))|}.
\]
Then,
\[
|g^{\sigma} R(t_2) - g^{\sigma} R(t_1)| = \lim_{m \to \infty} \int_{V^u(\sigma S)} |e^{S_{m,n}^\sigma(t_2)} - e^{S_{m,n}^\sigma(t_1)}| d\mu_{\sigma R}(z)
\leq \lim_{m \to \infty} \int_{V^u(\sigma S)} e^{S_{m,n}^\sigma(t_2)} - e^{S_{m,n}^\sigma(t_1)} - 1| d\mu_{\sigma R}(z)
= \lim_{m \to \infty} \int_{V^u(\sigma S)} e^{S_{m,n}^\sigma(t_2)} - e^{S_{m,n}^\sigma(t_1)} - 1| d\mu_{\sigma R}(z)
\leq e^\phi \text{Vol}(V^u(\sigma S)) \sup_m \frac{\text{Jac}(d_{f^{-m})|_{T_{f^{-m}} V^u(\sigma S)})}{\text{Jac}(d_{f^{-m})|_{T_{f^{-m}} V^u(\sigma S)})} - 1|,
\]
(28)
where by equation \([1]\) (with \(n = 0\), we get the uniform bound \(S_{m,n}^\sigma(b) = \pm \varepsilon\). In addition, equation \([1]\) (with \(n = 0\) also) yields the bound:
\[
\text{Jac}(d_{f^{-m})|_{T_{f^{-m}} V^u(\sigma S)}) = e^{\pm \varepsilon d(t_1, t_2)^{2}}.
\]
We wish to bound its exponent:
\[
d(t_1, t_2) = d(f^{-1}(I_1(y)), I_2(f^{-1}(y))) \leq d(f^{-1}(I_1(y)), f^{-1}(y)) + d(f^{-1}(y), I_2(f^{-1}(y))) \leq M f d(y, I_1(y)) + d(f^{-1}(y), I_2(f^{-1}(y)));
\]
equation \([3]\) bounds this by \(M f d(y, I_1(y))\); equations \([11]\) and \([12]\), \(d_{c^0}(V^u(\sigma R), V^u(\sigma S)), d_{c^0}(V^u(R), V^u(S)) \leq (\theta_0^2) \bar{\theta}^{-n-1}\). Thus, in total,
\[
|g^{\sigma} R(t_2) - g^{\sigma} R(t_1)| \leq 2 \left(\frac{e^\phi}{2} \text{Vol}(V^u(\sigma S)) \bar{\theta}^{-n-1} + \frac{e^\phi}{2} \text{Vol}(V^u(\sigma S)) \bar{\theta}^{-n-1}\right) \leq 2 \varepsilon^2 \text{Vol}(V^u(\sigma S)) \bar{\theta}^{-n-1}.
\]
Plugging this back in equation \([27]\) yields,
\[
|g^{\sigma} R(f^{-1}(y)) - g^{\sigma} R(f^{-1}(I_1(y)))| \leq 2 \varepsilon^2 \text{Vol}(V^u(\sigma S)) \bar{\theta}^{-n-1} + \varepsilon^2 \text{Vol}(V^u(\sigma S)) \bar{\theta}^{-n-1} \leq 2 \varepsilon^2 \text{Vol}(V^u(\sigma S)) \bar{\theta}^{-n-1}.
\]
Putting this together with the fact that \(g^{\sigma} R = e^{\pm e^\theta_0} \text{Vol}(V^u(\sigma S))\) (since \(S_{m,n}^\sigma(\cdot) = \pm \varepsilon, \forall z \in V^u(\sigma R)\)), gives us,
\[
\frac{g^{\sigma} R(f^{-1}(y))}{g^{\sigma} R(f^{-1}(I_1(y)))} = \exp(\pm 2 \varepsilon^2 \frac{1}{\theta_2} \theta_2^n) = \exp(\pm 2 \varepsilon^2 \theta_2^n),
\]
when \(\varepsilon\) is sufficiently small. Plugging this in equation \([26]\), together with the bound \(\frac{\text{Jac}(d_y (I_1) f^{-1})}{\text{Jac}(d_y f^{-1})} = e^{\pm \varepsilon^2 \theta_2^n}\) (by equation \([13]\)), and the bound \(\text{Jac}(d_y I_1) = e^{\pm e^\theta_0}\) (by equation \([12]\)), gives,
\[
\frac{e^{\phi(R)}(S)}{e^{\phi(S)}} = \exp(\pm(\theta_2^n + \varepsilon^2 \theta_2^n + \varepsilon^2 \theta_2^n)) = \exp(\varepsilon \sqrt{\theta_2^n})\) (for small enough \(\varepsilon\).
We are then left to show summable variations: for this it is enough to show that \(|\phi(R) - \phi(S)|\) is bounded uniformly whenever \(d(R, S) \leq e^{-2}\). Indeed,

\[
\phi(R) = \log \int_{f^{-1}[V^u(R)]} \frac{d\mu_{\mu(R)}(y)}{g^\sigma_y(R)(y)} = \log(e^\pm \Vol(f^{-1}[V^u(R)]) / \Vol(V^u(\sigma_R R))).
\]

By equation (28), whenever \(d(R, S) \leq e^{-2}\), \(\Vol(V^u(R)) = e^{\pm \epsilon} \Vol(V^u(S)), \Vol(V^u(\sigma_R R)) = e^{\pm \epsilon} \Vol(V^u(\sigma_R S))\). Therefore,

\[
|\phi(R) - \phi(S)| \leq 2\epsilon.
\]

**Corollary 4.22.** \(R \in \tilde{\Sigma}_L\), the function \(\rho^R = \frac{d\mu_{V^u(\sigma_R)}(x)}{d\mu_{V^u(x)}} : V^u(\sigma_R) \rightarrow [e^{-\epsilon}, e^\epsilon]\) is Hölder continuous, with a Hölder constant and exponent uniform in \(R\).

**Proof.** From equation (28) in Claim 4.21 and the three lines following it we get,

\[
|g^R(t) - g^R(s)| \leq e^{\epsilon} \Vol(V^u(\sigma_R))(2 \cdot e \cdot d(t, s)^{\frac{1}{2}}), \forall R \in \tilde{\Sigma}_L, t, s \in V^u(R).
\]

Hence \(\frac{\rho^R}{\Vol(V^u(\sigma_R))} = \frac{1}{\rho^R}\) is \((2e^{\epsilon}, \frac{1}{2})\)-Hölder continuous. Since \(\rho_R = e^{\pm \epsilon}\), \(\rho^R\) is \((2e^{\epsilon}, \frac{1}{4})\)-Hölder continuous. \(\square\)

**Definition 4.23.** We define the following Ruelle operator on \(C(\tilde{\Sigma}_L)\):

\[
(L_\phi \tilde{\psi})(R) := \sum_{\sigma_R S \in R} e^{\phi(S)} \tilde{\psi}(S).
\]

The sum has finitely many terms since \(\tilde{\Sigma}\) (and thus \(\tilde{\Sigma}_L\)) is locally-compact (see remark after Definition 3.3).

**Definition 4.24.** For any \(R \in \mathcal{R}\), define

\[
A_R := \bigcup \{V^s(S) : S \in \tilde{\Sigma}_R, S_0 = R\},
\]

where \(\tilde{\Sigma}_R := \{S \in \mathcal{R} : \bigcap_{i=0}^\infty f^{-i}[S] \neq \emptyset\}\), and for \(R \in \tilde{\Sigma}_R\), \(V^s(R) := W(R_0) \cap V^s(u)\) for some (any) \((u_i)_{i \geq 0} \in \mathcal{V}\) s.t. \(Z(u_i) \subseteq R_i \forall i \geq 0 (V^s(R)\) is well defined, similarly to Definition 4.3, by arguments analogous to those in Lemma 4.4).

This union is disjoint in the sense that for any two stable leaves, they either coincide or are disjoint, as they all span over the same window \(W(R)\) (recall Definition 4.3), and two stable leaves which span over the same window either coincide or are disjoint (see [BO18 Proposition 4.15], or [Sar13 Proposition 6.4] when \(d = 2\)).

**Claim 4.25.** \(\forall R \in \tilde{\Sigma}_L, m_R = 1_{\tilde{\Sigma}_L} \cdot m_{V^u(\sigma_R)}\).

**Proof.** Recall, \(m_R = \mathbb{1}_{W^s(\sigma_R)} \cdot m_{V^u(\sigma_R)}\), and we wish to show that \(W^u(\sigma_R) = V^u(\sigma_R) \cap A_{R_0}\). We start with the easy inclusion: let \(x \in W^u(\sigma_R)\), then \((R(x))_{i \geq 0} \in \tilde{\Sigma}_R\) and \(\{x\} = \{\tilde{\sigma}(R(x))\} = V^u(\sigma_R) \cap V^s((R(x))_{i \geq 0})\). Now for the other inclusion: let \(x \in V^u(\sigma_R) \cap A_{R_0}\), then \(x \in V^s(\sigma_R) S_0 \in \tilde{\Sigma}_R, S_0 = R_0\). Let \(y \in W^u(\sigma_R), z \in \bigcap_{i \geq 0} f^{-i}[S_i]\). One can easily check that then \(x\) must equal \([y, z]_{R_0}\) whence, by the Markov property, \((R(x))_{i \geq 0} = R\). Meaning \(x \in W^u(\sigma_R)\). \(\square\)

**Definition 4.26.** The extended space of absolutely continuous measures: \(\forall R \in \tilde{\Sigma}_L, \mu_R := 1_{\tilde{\Sigma}_L} \cdot m_{V^u(\sigma_R)}\), where by Claim 4.22 if \(R \in \tilde{\Sigma}_L\) then \(\mu_R = m_R\).

**Lemma 4.27.** \(\forall h \in C(M), \psi_h(R) := \mu_h(R)\) is continuous on \(\tilde{\Sigma}_L\).

**Proof.** Fixing some partition member \(T\), we consider the holonomy map along the stable leaves in \(A_T = \bigcup \{V^s(S) : \bigcap_{i \geq 0} f^{-i}[S] \neq \emptyset, S_0 = T\}\). \(\Gamma : V^s(S) \cap A_T \rightarrow V^u(R) \cap A_T, \Gamma R S \in \tilde{\Sigma}_L, R_0 = S_0 = T\). By Pesin’s absolute continuity theorem [BP07 Theorem 8.6.1], \(\|\text{Jac}(\Gamma) - 1\| \leq K_T \theta^n\) whenever \(d(R, S) \leq e^{-n}\), where \(\theta\) is as defined in Claim 4.19 and \(K_T\) is a positive constant depending on the partition member \(T\).
Here $\text{Jac}(\Gamma)$ refers to the Radon-Nikodym derivative of the mapping, and not the standard derivative (as it may not exist).

Let $h \in C(M)$, w.l.o.g. $\|h\| = 1$. $M$ is compact, whence $\epsilon_h(\delta) := \sup\{|h(x) - h(y)| : d(x, y) < \delta\} \xrightarrow{\delta \to 0} 0$. Assume $d(R, S) = e^{-n}, n \geq 1$. First, notice that if $x \in V^u(S) \cap A_T$, then $\exists \tilde{\epsilon} > 0$ such that $x \in \tilde{\epsilon}(S \cdot Q), \Gamma(x) = \tilde{\epsilon}(R \cdot Q)$, where $S \cdot Q, R \cdot Q$ are the respective concatenations of two one-sided chains which begin with the same symbol. In addition, $d(R, Q) = d(R, S) = e^{-n}$. Then by Claim 4.19 $d(x, \Gamma(x)) \leq 3d_{C_0}(V^u(R), V^u(S)) \leq 3C\theta^n$ where $\theta \in (0, 1), C > 0$ are constants and the factor of 3 comes from the Lipschitz bound of $R' \mapsto$ unique element of $\bigg\{V^u(R') \cap V^u(Q)\bigg\}, R' \in [T]\cap \bar{\Sigma}_L$ (see [BO18 Proposition 3.5(3)]).

Now recall the mapping $I : V^u(S) \to V^u(R)$ from Lemma 4.20.

**Step 1:** Assume $d(\Gamma(x), I(x)) \leq d(x, (I(x)) + d(x, \Gamma(x))$, and by claim 0 in Lemma 4.21 $d(x, I(x)) \leq 2d_{C_0}(V^u(R), V^u(S)) \leq 2C\theta^n$, whence in total $d(\Gamma(x), I(x)) \leq 4C\theta^n$.

**Step 2:** Recalling $m_{V^u(R)} = \frac{1}{\beta} \cdot m_{V^u(Q)}$, where $m_{V^u(Q)}$ is the induced Riemannian leaf volume of $V^u(R)$.

By part 4 in Lemma 4.21 $\|g_R \circ I - g_S\| = \epsilon_2 \frac{\text{Vol}(V^u(S))}{\beta_2} \|\| \theta_2 \in (0, 1)$ is a constant. Therefore

$$\frac{1}{\beta} \|g_R \circ I - \frac{1}{\beta} \| \leq \frac{1}{\beta} \|\| \leq \frac{\text{Vol}(V^u(S))}{\beta_2} \|\| \epsilon_2 \theta_2.$$  

By Theorem 1.10 $\|g\| \leq \frac{1}{\beta} \text{Vol}(V^u(Q)) e^{\pm \epsilon} \|\| \leq \frac{1}{\beta} \text{Vol}(V^u(S)) e^{\pm \epsilon}$. So in total $\frac{1}{\beta} \|g_R \circ I - \frac{1}{\beta} \| \leq \frac{1}{\beta} \text{Vol}(V^u(S)) e^{\pm \epsilon} \theta_2$. By part 5 of Lemma 4.20 $\frac{\text{Vol}(V^u(Q))}{\beta_2} = e^{\pm \epsilon}$ if $R_0 = S_0$; so define a constant $T_0 := \sup\{\frac{\text{Vol}(V^u(Q))}{\beta_2} : R = \frac{R_0}{S_0} = T\} \leq e^\epsilon \text{Vol}(V^u(S)) < \infty$. Whence $\|\|g_R \circ I - \frac{1}{\beta} \| \leq \frac{\text{Vol}(V^u(S))}{\beta_2} \|\| \leq C\text{tmp}(T) \epsilon_2 \epsilon_2 \theta_2 \leq C\text{tmp}(T) \epsilon_2 \theta_2$ for $\epsilon > 0$ small enough.

**Step 3:** By Corollary 4.22 $\rho^S(S) = \frac{\text{Vol}(V^u(S))}{g_S^2} \leq (2e^{3\epsilon}, \frac{\beta}{4})$ Hölder continuous. Therefore $\frac{1}{\beta}\rho^S$ is $(2e^{3\epsilon}, \frac{\beta}{4})$ Hölder continuous, whence $(C\text{tmp}(T)2e^{3\epsilon}, \frac{\beta}{4})$ Hölder continuous. Combining this with step 2 and 2 yields:

$$\frac{1}{\beta} \|g_R \circ I - \frac{1}{\beta} \| \leq \frac{1}{\beta} \|g_R \circ I - \frac{1}{\beta} \| \leq \frac{1}{\beta} \|g_R \circ I - \frac{1}{\beta} \| \leq \frac{\text{Vol}(V^u(S))}{\beta_2} \|\| \leq C\text{tmp}(T) \epsilon_2 \theta_2 + C\text{tmp}(T) \epsilon_2 \epsilon_2 \cdot d(\Gamma(x), I(x)) \frac{\beta}{4} \leq C\text{tmp}(T) \epsilon_2 \theta_2.$$  

where $\tilde{C}\text{tmp}(T)$ is a global constant of, and $\theta_2 \leq 2 < 1$. In addition, $\|h - h \circ \Gamma\| \leq \epsilon_h(d(x, \Gamma(x))) \leq \epsilon_h(3C\theta^n)$.

**Step 4:** $\Gamma$ is a bijection. So,

$$\int_{V^u(R) \cap A_T} h \frac{1}{g_R \circ I} d\tilde{m}_{V^u(R)} = \int_{V^u(S) \cap A_T} h \frac{1}{g_R \circ I} d\tilde{m}_{V^u(S)} = \int_{V^u(S) \cap A_T} h \circ (\Gamma) \frac{1}{g\circ \Gamma \circ \text{Jac}(\Gamma)} d\tilde{m}_{V^u(S)}$$  

$$= \int_{V^u(S) \cap A_T} h \frac{1}{g_R \circ I} d\tilde{m}_{V^u(S)} + \int_{V^u(S) \cap A_T} (\frac{h \circ \Gamma - h}{g_R \circ I} \text{Jac}(\Gamma) d\tilde{m}_{V^u(S)}$$  

$$+ \int_{V^u(S) \cap A_T} h \frac{1}{g_R \circ I} \text{Jac}(\Gamma) d\tilde{m}_{V^u(S)}$$  

$$= \int_{V^u(S) \cap A_T} h \frac{1}{g_R \circ I} \text{dVol}_{V^u(S)} + \epsilon(h(3C\theta^n)) + \|\text{Jac}(\Gamma)\| \|\text{Vol}(V^u(S))\| C\text{tmp}(T) \theta_2 + \|\text{Jac}(\Gamma) - 1\|,$$  

where the last transition used the bound we achieved in step 3. Thus,

$$\|\mu_R(h) - \mu_S(h)\| \leq \epsilon_h(3C\theta^n) + (1 + K_T) \|\text{Vol}(V^u(S))\| C\text{tmp}(T) \theta_2 + K_T \theta^n).$$
Therefore, \( \psi_h \) is uniformly-continuous on cylinders, and so it is continuous on \( \hat{\Sigma}_L \). \( \square \)

The following property is a crucial step in our construction:

**Proposition 4.28.** \( \forall h \in C(M), R \in \hat{\Sigma}_L, \mu_R(h \circ f) = \sum_{\sigma \in \hat{\Sigma}_L} \mu_{\hat{\Sigma}_L} = \mu_{\hat{\Sigma}_L} e^{\phi(h)} \).

**Proof.** Fix any \( h \in C(M) \). By Lemma 4.27, \( \psi_h(R) := \mu_R(h) \) and \( \psi_{h \circ f}(R) := \mu_{\hat{\Sigma}_L} \). By Claim 4.12 and Claim 4.29, \( \forall R \in \hat{\Sigma}_L, \psi_{h \circ f}(R) = \mu_{\hat{\Sigma}_L} \mu_{\hat{\Sigma}_L} \). By the remark after Definition 4.29, \( \hat{\Sigma}_L \) is dense in \( \hat{\Sigma}_L \). Therefore, by the continuity of \( L_o \) \( \phi \) is continuous and \( \hat{\Sigma} \) is locally-finite, \( \psi_{h \circ f}(R) = L_o \psi_h(R) \) for \( R \in \hat{\Sigma}_L \setminus \hat{\Sigma}_L \) as well. \( \square \)

4.3. The Leaf Condition.

**Definition 4.29.** We say that the leaf condition is satisfied, if there exists an unstable leaf of maximal dimension which gives \( \text{HWT}_x \) a positive leaf volume. We say that the leaf condition is satisfied for a measurable set \( A \in \mathcal{B} \), if there exists an unstable leaf of maximal dimension which gives \( A \) a positive leaf volume.

A notion of a similar “leaf condition” was introduced earlier by Climenhaga, Dolgopyat, and Pesin in [BP07].

**Definition 4.30.**

\[ \hat{\Sigma}^\# := \bigcup_{|S| \leq \Sigma} ([S] \cap \hat{\Sigma}_L^\#) \times ([S] \cap \hat{\Sigma}_L) \]

Notice, \( \hat{\Sigma}_L^\# \subseteq \hat{\Sigma}_L \subseteq \hat{\Sigma}^\# \).

**Lemma 4.31.** If there exists an unstable leaf of maximal dimension, \( V_u \), whose Riemannian volume gives \( \text{HWT}_x \) a positive measure, then there exist a maximal irreducible component \( \langle S \rangle^2 \cap \hat{\Sigma} \) and a periodic chain \( \hat{\Sigma} \in \hat{\Sigma}_L \cap \langle S \rangle \) s.t. \( \mu_{\hat{\Sigma}}(\hat{\Sigma}^\# \cap \langle S \rangle^2) > 0 \).

**Proof.** \( V_u \) gives a positive volume to \( \bigcup R \), which is a countable union. Therefore, \( \exists R \in \mathcal{R} \) s.t. \( V_u \cap R \) has a positive leaf volume in \( V_u \). Since \( \forall y \in R \cap V_u, \dim(V_u) = \dim(V_u(R)) \), \( \exists R \in \hat{\Sigma}_L \cap [R] \) s.t. \( m_{V_u(R)}(R) > 0 \). \( \forall x \in R, \exists S \in \mathcal{R} \) s.t. \( R(f^i(x)) = S \) for infinitely often \( i \geq 0 \). Therefore, because there is only a countable number of finite cylinders, \( \exists R \supseteq 2 \) and a cylinder \( \langle R, S_1, ..., S_{n-2}, S \rangle \) s.t. \( x \in R : R(x) \in \{R, S_1, ..., S_{n-2}, S\} \) \#(i : R(f^i(x)) = S) = \infty \) has a positive leaf volume in \( V_u(R) \). Let \( \hat{\Sigma} \) be the admission concatenation \( \hat{\Sigma} : (R, S_1, ..., S_{n-2}, S) \in \hat{\Sigma}_L \). Whence, \( V_u(R) \) gives a positive leaf volume to \( \{x \in R : \#(i \geq 0 : f^i(x)) = \infty \} \). Since \( S \) is a periodic symbol in the future of any of these points, \( \exists S \in \langle S \rangle \subset \hat{\Sigma}_L \) which is periodic.

The holonomy map along stable manifold leaves \( \Gamma: V_u(R) \cap \{x \in S : \#(i \geq 0 : f^i(x) = S) = \infty \} \rightarrow V_u(S) \) is defined by \( \Gamma(x) = \hat{\pi}((S_i)_{i \geq 0}, (R(f^i(x))_{i \geq 0})) \in \hat{\pi}(\hat{\Sigma}^\# \cap \langle S \rangle^2) \), where \( \cdot \) denotes an admissible concatenation of a negative chain to a positive chain. By Pesin’s absolute continuity theorem [BP07 Theorem 6.1], applied to the holonomy map \( \Gamma, m_{V_u(S)}(\Gamma[\{x \in S : \#(i \geq 0 : f^i(x) = S) = \infty \}]) > 0 \). Thus, \( \mu_{\hat{\Sigma}}(\hat{\Sigma}^\# \cap \langle S \rangle^2) > 0 \). \( \square \)

**Remark:**

1. Let \( \hat{\Sigma}^\pm \) be the periodic extension of \( \hat{\Sigma} \) to \( \hat{\Sigma} \), then \( p' := \hat{\pi}(\hat{\Sigma}^\pm) \) is a periodic point. It follows that \( H(p') \supseteq \hat{\pi}(\langle S \rangle^2 \cap \hat{\Sigma}^\#) \), whence \( \mu_{\hat{\Sigma}}(H(p')) > 0 \).

2. From this point on, we focus on one ergodic homoclinic class, and constructing a measure on it. By Lemma 4.32, we may restrict our attention to a maximal irreducible component, while all definitions and claims of 4.29 remain consistent. We therefore assume w.l.o.g. that \( \hat{\Sigma}_L, \hat{\Sigma} \) are irreducible. From now on, this assumption will go without mentioning. The recurrent properties and the Gureviich pressure which we discuss in the next subsection will be relevant to the maximal irreducible component to which we are restricted.
In this chapter we use the definitions of the Gurevich pressure, positive recurrence, and the “partition function” \( Z_n(\phi, R) := \sum_{S \in \hat{\Sigma}_L \cap [R, \sigma_R^n S]} e^{\sum_{k=0}^{n-1} \phi(\sigma_R^k S)} \) (this expression is finite since \( \hat{\Sigma}_L \) is locally compact). The Gurevich pressure of the potential \( \phi \) is defined as \( P_G(\phi) := \limsup_{n \to \infty} \frac{1}{n} \log Z_n(\phi, R) \in (-\infty, \infty) \), and when \( \hat{\Sigma}_L \) is topologically mixing, the limit exists and is independent of the choice of the symbol \( R \) (see [Sar09 Proposition 3.2] for proof). We say that the potential \( \phi \) is recurrent if \( \sum_{n \geq 1} e^{-nP_G(\phi)} Z_n(\phi, R) = \infty \) for some symbol (in fact the finiteness of this expression is independent of the choice of \( R \), as can be seen in [Sar09 Corollary 3.1]). We say that the potential \( \phi \) is positive-recurrent if it is recurrent, and \( \sum_{n \geq 1} n \cdot e^{-n P_G(\phi)} \sum_{S \in \hat{\Sigma}_L \cap [R, \sigma_R^n S]} e^{\sum_{k=0}^{n-1} \phi(\sigma_R^k S)} < \infty \) for some (any) symbol \( R \). For more details, see [Sar09 § 3.1.3]. Sarig developed an extensive theory for such setups where the potential is recurrent. For a detailed review of his theory, see [Sar09].

**Definition 5.1.** The Geometric potential:

\[ \varphi : \hat{\Sigma} \to [-d \cdot \log M_f, d \cdot \log M_f], \varphi(R) := -\log \text{Jac}(d\hat{\pi}_f|_\mathcal{T}_{\hat{\Sigma}} \cap \mathcal{V}^u(R)). \]

**Theorem 5.2.** \( P_G(\phi) \leq 0 \).

**Proof.** Let \( \phi_n := \sum_{k=0}^{n} \phi \circ \sigma_R^k, n \geq 0 \). Notice:

\[ e^{\phi_n(R)} \cdot m_{V^u(R)} = m_{V^u(\sigma_R^n R)} \circ f^{-1}|_{V^u(R)}, \]

\[ \Rightarrow e^{\phi_n(R)} \cdot m_{V^u(R)} = m_{V^u(\sigma_R^n R)} \circ f^{-1}|_{V^u(R)}, \]

\[ \Rightarrow e^{\phi_n(R)} = m_{V^u(R)}(f^{-n}|_{V^u(R)}), \text{ if } \sigma_R^n R = R. \]

Define \( E : P_{n,L} \leftrightarrow P_n \) as the natural association between the \( n \)-periodic points in \( \hat{\Sigma}_L \) and the \( n \)-periodic points in \( \hat{\Sigma} \). Define \( \Delta_n(R) := \phi_n(R) - \varphi_n(E(R)) \), where \( \varphi_n(S) := \sum_{k=0}^{n} \varphi(\sigma^{-k} S) \).

**Part 1:** \( \Delta_n|_{P_{n,L}}(\cdot) \) is bounded uniformly in \( n \).

**Proof:** Let some \( R \in P_{n,L} \), and write \( x := \hat{\pi}(E(R)) \). Denote by \( \lambda \) the (non-normalized) Riemannian leaf volume on \( V^u(R) \).

\[ e^{\Delta_n(R)} = m_{V^u(R)}(f^{-n}|_{V^u(R)}) \cdot \frac{1}{\text{Jac}(d_x f^{-n}|_{\mathcal{T}_{\mathcal{V}^u(R)}})} \]

\[ = \int_{f^{-n}|_{V^u(R)}} (g^R \text{ is the limit function defined in equation (7)}) \]

\[ = \int_{V^u(R)} \frac{1}{g^R(f^{-n}(t))} \cdot \frac{\text{Jac}(d_x f^{-n}|_{\mathcal{T}_{\mathcal{V}^u(R)}})}{\text{Jac}(d_x f^{-n}|_{\mathcal{T}_{\mathcal{V}^u(R)}})} \]

Recall that by Theorem 4.10 \( g^R = \text{Vol}(V^u(R))e^{\pm \epsilon} \), and by equation 5 (with \( n = 0 \)), \( \frac{\text{Jac}(d_x f^{-n}|_{\mathcal{T}_{\mathcal{V}^u(R)}})}{\text{Jac}(d_x f^{-n}|_{\mathcal{T}_{\mathcal{V}^u(R)}})} = e^{\pm \epsilon}. \) Whence \( e^{\Delta_n(R)} = e^{\pm 2 \epsilon}, \) and therefore \( |\Delta_n| \leq 2 \epsilon. \) QED

**Part 2:** By [BOL18 Proposition 6.1], and the regularity of \( f, \varphi \) is Hölder continuous. Therefore, by Sinai’s theorem (in its version for countable Markov shifts, as in [Dac13]), there exists a potential \( \varphi^- : \hat{\Sigma} \to \mathbb{R} \), which is bounded on cylinders, and such that \( (R_i = S_i, \forall i \leq 0) \Rightarrow \varphi^-(R) = \varphi^-(S) \); and there exists a bounded and uniformly continuous function \( A : \hat{\Sigma} \to \mathbb{R} \) such that

\[ \varphi = \varphi^- + A \circ \sigma^{-1} - A. \]

In this case we say that \( \varphi - \varphi^- \) is a coboundary. It follows that,

\[ \|\varphi_n - \varphi_n^t\|_\infty \leq 2\|A\|_\infty. \]
\( \varphi^- \) can be naturally identified with a potential on \( \hat{\Sigma}_L \), s.t. \( \| \phi_n - \varphi_n^- \|_{p_n, \infty} \leq 2(\|A\|_{\infty} + \epsilon) < \infty, \forall n \geq 0. \)

**Part 3:** Fix some symbol \( R. \) One should notice that since \( A, \varphi \) are bounded, so must \( \varphi^- \) be; whence the variational principle (see [Sar09, Theorem 4.4]) is applicable to it.

\[
P_G(\phi) = \limsup \frac{1}{n} \log Z_n(\phi, R) = \limsup \frac{1}{n} \log Z_n(\varphi^-, R)
\]

\[
= \sup \{ h_v(\sigma) + \int \varphi^- d\nu : \nu \text{ is an inv. prob. on } \hat{\Sigma}_L \} \tag{\text{: variational principle}}
\]

\[
\overset{(1)}{=} \sup \{ h_{\nu^\pm}(\sigma^{-1}) + \int \varphi^- d\nu^\pm : \nu^\pm \text{ is an inv. prob. on } \hat{\Sigma} \}
\]

\[
= \sup \{ h_{\nu^\pm}(\sigma^{-1}) + \int \varphi d\nu^\pm : \nu^\pm \text{ is an inv. prob. on } \hat{\Sigma} \} \overset{(2)}{\leq} 0 \tag{\text{, } \varphi^- - \varphi \text{ is a coboundary}.
\]

(1) is due to the entropy preserving natural bijection between shift invariant measures on \( \hat{\Sigma} \) and on \( \hat{\Sigma}_L \).

**Proposition 5.3.** \( \psi : \hat{\Sigma} \to \mathbb{R}^+ \cup \{0\}, \psi(R) := \mu_R(1) \) is a non-negative continuous eigenfunction of \( L_\phi \) with eigenvalue 1. If there exists a chain \( R \in \hat{\Sigma}_L \) s.t. \( \mu_R(1) > 0 \), then \( \psi \) is also positive.

**Proof.** By Lemma \[\boxed{127}\] \( \psi \) is continuous. If there exists a chain \( R \in \hat{\Sigma}_L \) s.t. \( \mu_R(1) > 0 \), then by continuity, \( \exists n_R \text{ s.t. } d(R, S) \leq e^{-n_R} \Rightarrow \psi(S) > 0 \). This in turn means that \( \forall m \geq 0, \psi(\sigma^m_R S) > 0 \), since \( L_\phi \psi = \psi \) (by Proposition \[\boxed{128}\]). By irreducibility, \( \forall S \in \hat{\Sigma}_L, \exists \nu \in \hat{\Sigma}_L \text{ s.t. } d(S, R) \leq e^{-n_R}, \) and \( \exists m_S \geq 0 \text{ s.t. } \sigma^m_R S = S \). Therefore \( \psi(S) > 0 \), and it follows that \( \psi \) is positive everywhere.

**Theorem 5.4.** If \( \exists R \in \hat{\Sigma}_L \text{ s.t. } \mu_R(1) > 0 \), then \( P_G(\phi) = 0 \) and \( \phi \) is recurrent.

**Proof.** By Theorem \[\boxed{5.2} \] \( P_G(\phi) \leq 0 \). Therefore, it is enough to show \( \sum_{n \geq 1} Z_n(\phi, R) = \infty \) for some symbol \( R \). In particular, the topological pressure of the geometric potential is 0, and \( \varphi^- \) is recurrent. We assume w.l.o.g. that \( \mu_R(\bigcup \{ V^*(S) : S \in \hat{\Sigma}_R \cap [R_0], \# \{ i \geq 0 : S_i = R_0 \} = \infty \} ) > 0 \).

Define \( A_n := \bigcup_{W=R_0,W_1,...,W_{n-1},R_0} f^{-n}[V^*(R,W)] \), where the “\( \cdot \)” product denotes an admissible concatenation. Notice, \( V^*(R) \cap \bigcup \{ V^*(S) : S \in \hat{\Sigma}_R \cap [R_0], \# \{ i \geq 0 : S_i = R_0 \} = \infty \} \subseteq \limsup A_n = \bigcap_{n=1}^{\infty} \bigcup_{n=1}^{\infty} A_n \) naturally by the coding of each point in the LHS set. It follows that \( \mu_R(\limsup A_n) > 0 \), and in particular, \( m_{V^*(R)}(\limsup A_n) > 0 \).  

\[
\sum_{n \geq 1} m_{V^*(R)}(A_n) \leq \sum_{n \geq 1} \sum_{W=R_0,W_1,...,W_{n-1},R_0} m_{V^*(R)}(f^{-n}[V^*(R,W)]) \leq \sum_{n \geq 1} \sum_{W=R_0,W_1,...,W_{n-1},R_0} e^{\phi_n(R,W)} = \sum_{n \geq 1} \sum_{W=R_0,W_1,...,W_{n-1},R_0} e^{\phi_n(R,W)}
\]

where the last equality is by Theorem \[\boxed{1.10}\]. For every \( n \geq 1 \), for every \( W = R_0,W_1,...,W_{n-1},R_0, \) write \( R_\bar{W} \) for the periodic concatenation of \( W \) to itself. It follows that \( d(R,W,\bar{W}) \leq e^{-n} \). Therefore, by Claim \[\boxed{1.21}\] and since \( \phi \) is bounded on \( [R_0] \), \( C \supset 0 > 0, n_0 \in \mathbb{N} \text{ s.t. } \forall n \geq n_0, e^{\phi_n(R,W)} = C^{\pm 1} e^{\phi_n(R,W)} \). We get,

\[
\sum_{n \geq 1} m_{V^*(R)}(A_n) \leq \sum_{n \geq 1} \sum_{W=R_0,W_1,...,W_{n-1},R_0} e^{\phi_n(R,W)} = C^{\pm 1} \sum_{n \geq 1} Z_n(\phi, R_0).
\]

\[8\]Every \( S \in \hat{\Sigma}_L \) has some symbol recurring infinitely often in the future; then for some symbol \( S \), the set of all points which return to \( S \) infinitely often in \( A_{\phi_n} \cap V^*(R) \) has a positive measure. There are only countably many cylinders which begin in \( R_0 \), and end in \( S \), therefore, there is some cylinder \( [R_0,a_1,...,a_{n-2},S] \) s.t. \( \bigcup \{ V^*(S) : S \in \hat{\Sigma}_L \cap [R_0,a_1,...,a_{n-2},S], \# \{ i \geq 0 : S_i = S \} = \infty \} \) has a positive leaf volume in \( V^*(R) \). Therefore, the admissible concatenation \( \bar{R} := \bar{R}_0 (R_0,a_1,...,a_{n-2},S) \in \hat{\Sigma}_L \) has the property that \( \mu_{\bar{R}}(\bigcup \{ V^*(S) : S \in \hat{\Sigma}_L \cap [S], \# \{ i \geq 0 : S_i = S \} = \infty \}) > 0 \).

\[9\]By equation \[\boxed{50}\], \( \phi \) is bounded on cylinders of length 2, and there are only finitely many such cylinders contained in \( [R_0] \) by the local-compactness of \( \hat{\Sigma}_L \).
6. Existence, Uniqueness and The Generalized Entropy Formula

6.1. Generalizing the notion of an SRB measure.

**Definition 6.1.** Let \( (X, \mathcal{B}', \nu) \) be a measure space. Let \( T : X \rightarrow X \) be a measurable transformation.

1. A measurable set \( W \in \mathcal{B}' \) is called wandering if \( \{T^{-n}[W]\}_{n \geq 0} \) are pairwise disjoint.
2. \( \nu \) is called conservative if \( \nu \) gives every wandering set a measure 0.
3. \( \nu \) is called non-singular if \( \nu \sim \nu \circ T^{-1} \). In this case, \( (X, \mathcal{B}', \nu, T) \) is said to be a non-singular transformation.

Halmos’ recurrence theorem ([Aar97, §1.1.1]) states that if \( (X, \mathcal{B}', \nu, T) \) is a non-singular transformation, then \( \nu \) is conservative if and only if \( \sum_{n\geq 0} \chi_{\nu^{-1}T^n} = \infty \) \( \nu \)-a.e. on \( E \) for every \( E \in \mathcal{B}' \) s.t. \( \nu(E) > 0 \) (i.e. the Poincaré recurrence theorem holds: in every positive measure set, almost every point returns to it infinitely many times). It follows that every invariant probability measure is conservative by the Poincaré recurrence theorem. We work in the context of non-singular transformations, and use the characterization of conservativity by Halmos as the definition. Notice that if \( (X, \mathcal{B}', \nu, T) \) is an invertible transformation, then any wandering set for \( T \) is a wandering set for \( T^{-1} \).

**Definition 6.2.** A generalized SRB measure (GSRB in short) is a Borel measure on \( M \) such that:

1. It is a conservative, invariant, \( \chi \)-hyperbolic measure (perhaps infinite, see Definition 2.3) for some \( \chi > 0 \); which is finite on regular sets (sets of bounded hyperbolicity, see [BP07, §2.2]).
2. It has absolutely continuous conditional measures w.r.t. any measurable partition subordinate to the lamination of maximal dimension unstable leaves (recall Definition 3.9) of any measurable subset of finite measure.

A finite GSRB measure is called an SRB measure.

6.2. Existence.

**Theorem 6.3.** If there exists a maximal dimension unstable leaf \( V' \), which gives HWT\( _\chi \) a positive leaf volume (for some \( \chi > 0 \)), then there exists a hyperbolic periodic point \( q \), s.t. \( H(q) \) carries an ergodic GSRB \( \mu \). \( \mu \) is an SRB measure if and only if \( \phi \) is positive recurrent.

**Proof.** By Lemma 5.4 we may assume w.l.o.g. that \( \hat{\Sigma}_L \) is irreducible, and that there exists a periodic chain \( \tilde{R} \subseteq \hat{\Sigma}_L \) s.t. \( \mu(\tilde{R}) > 0 \). Then, by Theorem 5.3 \( P_G(\phi) = 0 \) and \( \phi \) is recurrent. By [Sar09, Theorem 3.4], \( \Sigma_L \) is a unique (up to normalization) \( \phi \)-invariant measure on \( \hat{\Sigma}_L \), \( p \) (that is, \( L^*_\phi p = e^{P_G(\phi)} p = p \), where \( L^*_\phi \) is the dual operator of \( L_\phi \)); and \( p \) is ergodic, conservative, non-singular, and finite on cylinders. Define

\[
\mu := \int_{\hat{\Sigma}_L} \mu_{\tilde{R}} dp(\tilde{R}),
\]

where \( \{\mu_{\tilde{R}}\}_{\tilde{R} \in \hat{\Sigma}_L} \) is the extended space of absolutely continuous measures (see Definition 4.20). \( \mu \) is not the zero measure, since \( \mu(1) = \int \mu_{\tilde{R}}(1) dp = \int \psi(\tilde{R}) dp \), where \( \psi \) is a continuous positive function (see Proposition 6.3); whence \( \mu(1) > 0 \).

**Claim 1:** \( \mu \circ f^{-1} = \mu \).

**Proof:** By Proposition 4.28 \( \mu_{\tilde{R}} \circ f^{-1} = \sum_{\beta : \beta \leq \tilde{R}} e^{\phi(\beta)} \mu_{\beta} \), whence \( \mu \circ f^{-1} = \int \mu_{\tilde{R}} \circ f^{-1} dp = \int \sum_{\beta : \beta \leq \tilde{R}} e^{\phi(\beta)} \mu_{\beta} dp = \int \mu_{\tilde{R}} dp = \mu \).

---

\(^{10}\)Every subset of HWT\( _\chi \) of bounded hyperbolicity (i.e. a level set) can be covered by a finite number of members of \( \mathcal{R} \), and every partition member is contained in a level set. This can be seen immediately by [BO18, Proposition 4.4(2)].

\(^{11}\)It is well defined due to Rokhlin’s disintegration theorem.

\(^{12}\)The condition of topological mixing can be assumed w.l.o.g. to be satisfied, using the Spectral Decomposition theorem (see [Sar15, Theorem 2.5]), and composing our measure as a uniform average over the measures corresponding to the mixing components of the decomposition.
where the last transition is by the \( \phi \)-conformalism of \( p \), and the fact that \( P_G(\phi) = 0 \).

Claim 2: \( \mu \) is finite iff \( \phi \) is positive-recurrent.

Proof: As in the beginning of the proof, write \( \mu(1) = p(\psi) \), where \( \psi \) is a positive continuous eigenfunction of \( L_\phi \) with eigenvalue 1. Then \( \psi \) must be the unique (up to normalization) harmonic function associated with \( p \) (see [Sar09 Theorem 3.4],[Sar01 Theorem 1]). Then, by [Sar09 Proposition 3.5], \( p(\psi) < \infty \) iff \( \phi \) is positive-recurrent.

Claim 3: \( \mu \) is conservative. The first set in the list below also shows that \( \mu \) is finite on regular sets.

Proof: Let \( A \subseteq M \) be a measurable set s.t. \( \mu(A) > 0 \). Write \( R = \{ R_i \}_{i \in \mathbb{N}, k_i := \cup \{ V^n(R) \cap A_{\mu(i)} : R \in [R(i)] \} \subseteq \Sigma_L^\# \}. \) It is clear that \( \mu \) is carried by \( \bigcup_{i \geq 0} k_i \), since \( p \) is conservative and carried by \( \Sigma_L^\# \). We show the following three steps to complete the proof:

1. \( \forall i \in \mathbb{N}, \mu(k_i) < \infty \) if \( \text{if } S \neq A \cap k_i \) then \( R_0 = R(i) \) and \( (V^n(R) \cap A_{\mu(i)}) \cap (V^n(S) \cap A_{\mu(0)}) \neq \emptyset \), then \( \exists x \) s.t. \( x = \pi(R_0) = \pi(S_0) \) where \( \pi(S) \in \Sigma^\# \) and \( S_0 = S_0, R_0 = R(i) \). Therefore, \( S_0 \in \{ S \subseteq Z(v) : Z(u) \cap Z(v) \neq \emptyset \} \). Then, this collection is finite by the local finiteness of \( Z \) and its refinement.
2. \( \forall i \geq 0, p\text{-a.e. } R \subseteq [R(i)] \) returns to it infinitely often with iterations of \( \sigma_R \) since \( p \) is conservative. For any such chain and \( n \geq 0 \), \( f^{-n}([V^n(R) \cap A_{\mu(0)}] \subseteq [V^n(\sigma^n_R)] \cap A_{\mu(n)} \} \). Therefore, \( \mu(k_i) = \int_{[S \subseteq Z(v) : Z(u) \cap Z(v) \neq \emptyset]} p([S]) < \infty \).
3. \( \forall i \geq 0, p\text{-a.e. } x \in A \cap k_i \) then \( f^{-n}(x) \in A \cap k_i \). For every \( i \geq 0 \), \( p\text{-a.e. } R \subseteq [R(i)] \) returns to it infinitely often with iterations of \( f^{-1} \). The first return map to \( k_i, \mathcal{F} \), is well defined. If \( \mu(k_i \cap A) > 0 \), then \( \mu(k_i) : \mu(k_i) = \frac{\mu(k_i)}{\mu(k_i)} \) is \( \mathcal{F} \)-invariant, and finite by the first step. Therefore, by the Poincaré recurrence theorem, \( p\text{-a.e. } k_i \cap A \) returns to \( k_i \cap A \) infinitely often with iterations of \( f^{-1} \).

Claim 4: \( \mu \) is carried by \( H(q) \subseteq \text{HWT}_X \), where \( q \) is a hyperbolic periodic point.

Proof: Since \( p \) is conservative, \( \mu \) is carried by a union of sets which carry \( \{ R \} \subseteq \Sigma_L^\# \). Each such measure is carried by \( V^n(R) \cap A_{\mu(0)} \subseteq \Sigma \). Let \( R' \subseteq \Sigma \) is a periodic chain, and define \( q := \pi(R') \). Then, by irreducibility, \( \pi(\Sigma^\#) \subseteq H(q) \).

Claim 5: \( \mu \) is ergodic.

Proof: It follows directly from Theorem 6.3 below, since \( p \) is ergodic.

6.3 Positive Recurrence, and Finiteness. In Theorem 5.3 we saw that the leaf condition implies the existence of a GSRB, and that it is finite if and only if the geometric potential is positive recurrent. We now offer a more refined condition to characterize when is \( \phi \) positive recurrent.

Definition 6.4. The points \( \text{HWT}^{PR}_X := \{ x \in \text{HWT}_X : \exists \tau_x > 1 \text{ s.t. } \limsup_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} 1_{||C^{-1}_x(\cdot) \leq r_x||} \circ f^k(x) > 0 \} \) are called the positively recurrent points in \( \text{HWT}_X \).

Claim 6.5. There exists a finite \( \chi \)-hyperbolic GSRB if and only if the leaf condition is satisfied for \( \text{HWT}^{PR}_X \).

Proof: If there exists a finite \( \chi \)-hyperbolic GSRB (i.e. an SRB), then the leaf condition is satisfied trivially for \( \text{HWT}^{PR}_X \). Then assume that the leaf condition is satisfied by \( \text{HWT}^{PR}_X \subseteq \text{HWT}_X \). Let \( x \in \text{HWT}^{PR}_X \), then by the finiteness of \( \{ R \in R : \inf \{ ||C^{-1}(y)|| : y \in R \} \leq r_x \} \), there must be some symbol \( R_x \) s.t. \( \limsup_{n} \frac{1}{n} \sum_{k=0}^{n-1} 1_{R_x} \circ f^k(x) > 0 \). Therefore, there exists \( R \in R \) s.t. the leaf condition is satisfied for

\[ 13 \text{If } x = \pi(R, S), \text{where the dot means an admissible concatenation, and } S \subseteq R, \text{then } f^{-n}(x) = \pi((S)^k R : ((R_{n-1}, ..., R_0) \cdot S)) \] and \( (R_{-n}, ..., R_0) \cdot S \subseteq S_R \) (by the Markov property); in addition \( R \subseteq \Sigma_L^\# \Rightarrow \pi(R) \subseteq \Sigma_L^\#. \]
\( \{ x \in R : \limsup \frac{1}{N} \sum_{k=0}^{\sigma f(x)} \phi \in f^{-1}(R) \} \). Whence, \( \exists \mathcal{R}' \in \Sigma^\# \cap [R] \) s.t. \( \mu_{\mathcal{R}'}(\{ x \in R : \limsup \frac{1}{N} \sum_{k=0}^{\sigma f(x)} \phi \in f^{-1}(R) \}) \). Let \( \mathcal{R} \in \langle R \rangle \) and let \( \Gamma_{\mathcal{R}} : V^u(\mathcal{R}) \cap A_{\mathcal{R}} \rightarrow V^u(\mathcal{R}) \cap A_{\mathcal{R}} \) be the holonomy map along the stable leaves in \( A_{\mathcal{R}} \). Then, \( \forall x \in V^u(\mathcal{R}) \cap A_{\mathcal{R}} \cap \{ x \in R : \limsup \frac{1}{N} \sum_{k=0}^{\sigma f(x)} \phi \in f^{-1}(R) \} \), \( \Gamma_{\mathcal{R}}(x) \) has a coding in \( \Sigma^\# \) with the same future as \( x \). By [B01, Proposition 4.8],

Therefore, \( \limsup_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{[C^{-1}(\cdot)]} \circ \rho_k \Gamma_{\mathcal{R}}(x) > 0 \), whence \( \Gamma_{\mathcal{R}}(x) \) is in \( HWT_{\chi} \). By Pesin's absolute continuity theorem [BP07, Theorem 6.1.1], \( \Gamma_{\mathcal{R}} \) maps a positive leaf volume set to a positive leaf volume set. Then,

\[ \forall \mathcal{R} \in \Sigma^\# \cap \langle R \rangle \cap N, \mu_{\mathcal{R}}(HWT_{\chi}^p) > 0. \] (32)

We may now continue to carry out the construction as in Theorem 6.3 and get a GSRB, \( \mu = \int_{\Sigma} \mu_d \), where \( \forall \mathcal{R} \in \Sigma^\# \), \( \mu_{\mathcal{R}} \) is carried by \( V^u(\mathcal{R}) \cap A_{\mathcal{R}} \); and \( p \) gives a positive measure to every cylinder by [Sar09, Claim 3.5, pg. 76]. Thus, together with equation (32), it follows that \( \mu(HWT_{\chi}^p) > 0 \). Therefore, \( \exists \mathcal{N} \in \mathbb{N} \) s.t. \( \mu(\limsup_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{[C^{-1}(\cdot)]} \circ \rho_k \Gamma_{\mathcal{R}}(x) > 0 \) (while \( \mu(\limsup_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{[C^{-1}(\cdot)]} \circ \rho_k \Gamma_{\mathcal{R}}(x) \) is carried by \( \mathcal{R} \)).

By the ratio ergodic theorem (see Theorem 4.1), \( \forall M \in \mathbb{N} \), \( \limsup_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{[C^{-1}(\cdot)]} \circ \rho_k \Gamma_{\mathcal{R}}(x) \to 0 \).

Therefore \( \mu \) is finite.

The following characterization (together with the uniqueness, which is proved in Theorem 6.3 below, and the fact that \( P_C(\phi) = 0 \), see Theorem 5.4, serves as an analogue to the entropy formula. It shows that every GSRB is the pull-back of the unique (up to scaling) equilibrium state of the geometric potential \( \phi \) on a corresponding maximal irreducible component. This coincides with the celebrated result of Ledrappier and Strelcyn in [LS92], and the Margulis-Ruelle inequality for hyperbolic SBR measures. The characterization of GRPF measures (i.e. \( \psi \cdot p \) in our context) by a variational principle is due to Sarig, in [Sar11]. Sarig proved that (in our context, where \( P_C(\phi) = 0 \) for every conservative and invariant measure which is finite on cylinders, \( m, \int_{\Sigma^\#} \langle I_m + \phi + \log \psi - \log \psi \rangle \leq 0 \) where \( I_m \) is the information function of \( m \) w.r.t. the partition by cylinders; and equality holds if and only if \( m \propto \psi \cdot p \).

Theorem 6.6. Under the assumptions of Theorem 6.3, the measure \( \mu \) which is given in its statement, is proportional to \( \psi \cdot p \circ \hat{\pi}^{-1} \), where \( \psi \cdot p \) is the unique shift-invariant extension of \( \psi \) to \( \hat{\Sigma} \) such that \( \psi \cdot p \circ \sigma = \psi \cdot p \) (\( \tau \) is the projection to the non-positive coordinates, \( \psi \) is the unique continuous and positive \( \phi \)-harmonic function on \( \hat{\Sigma} \), i.e. \( L_\phi \psi = e^{P_C(\phi)} \psi = \psi \), and \( p \) is the unique \( \phi \)-conformal measure on \( \hat{\Sigma} \), i.e. \( L_\phi^* p = e^{P_C(\phi)} p = p \), where \( L_\phi^* \) is the dual operator of \( L_\phi \).

Proof. As argued in claim 1 of Theorem 6.3, \( \mu_{\mathcal{R}}(1) = \psi(\mathcal{R}) \) by the uniqueness of the continuous and positive \( \phi \)-harmonic function on \( \hat{\Sigma} \) (\( \psi \) is only determined up to scaling, so we choose the version \( \psi(\mathcal{R}) = \mu_{\mathcal{R}}(1) \)). Write \( \forall \mathcal{R} \in \Sigma^\# \), \( p_{\mathcal{R}} := \frac{\mu_{\mathcal{R}}}{\mu} \), a probability measure on \( V^u(\mathcal{R}) \), which is absolutely continuous w.r.t. its leaf volume. One can check easily that \( \psi \cdot p \) must indeed be invariant. Then,

\[ \mu = \int_{\Sigma} \mu \, dp = \int_{\Sigma} \int_{\mathcal{R}} p_{\mathcal{R}}(\psi \cdot p) \, dp_{\mathcal{R}} = \int_{\mathcal{R}} \psi \cdot p \, dp_{\mathcal{R}}. \]

Notice that \( \forall \mathcal{R} \in \Sigma, p_{\mathcal{R}} \left( \left\{ x \in M : \mathcal{R} \in \tau^{-1}[\{ x \}] \right\} \right) = 0 \). Then, for every measurable \( E \in \mathcal{B} \), where \( \mathcal{B} \) is the Borel \( \sigma \)-algebra of \( M \),

\[ \mu(E) = \int_{\mathcal{R}} \int_{\mathcal{R}} \chi_{\mathcal{R}}(E) \, dp_{\mathcal{R}} \, dp_{\mathcal{R}} = \int_{\mathcal{R}} p_{\mathcal{R}}(\psi \cdot p \, \psi \cdot p) \leq \int_{\mathcal{R}} \psi \cdot p \, \psi \cdot p \leq \int_{\mathcal{R}} \psi \cdot p \, \psi \cdot p = \int_{\mathcal{R}} \psi \cdot p \circ \hat{\pi}^{-1}(E). \]

Now, since \( p \) is conservative and ergodic (and \( \sigma \)-finite), so must \( \psi \cdot p \) be, and so also \( \hat{\psi} \cdot p \), and in turn also \( \psi \cdot p \circ \hat{\pi}^{-1} \). In claim 3 of Theorem 6.3 we have seen that \( \mu \) is conservative (and \( \sigma \)-finite). So \( \mu \) is an invariant.

\footnote{Recall Part 2 in Theorem 4.3 for the relation between \( \phi \) and \( \psi \).

\footnote{\( \psi \) and \( p \) are unique up to scaling, but we choose the version of \( \psi \) which corresponds to \( R \mapsto \mu_{\mathcal{R}}(1) \), and the version of \( p \) which corresponds to \( \mu = \int_{\Sigma} \mu \, dp \).}
conservative, \(\sigma\)-finite measure, dominated by an ergodic, invariant, conservative, \(\sigma\)-finite measure \(\hat{\psi} \cdot p \circ \hat{\pi}^{-1}\), whence \(\mu \propto \hat{\psi} \cdot p \circ \hat{\pi}^{-1}\) (with a proportion constant less or equal to 1).

\[\square\]

6.5. Uniqueness and Ergodic Components.

**Definition 6.7.** Consider the Markov partition \(\mathcal{R}\) from Definition 3.3. Let \(R \in \mathcal{R}\). Recall the relation \(\sim\) from Definition 3.14.

1. \((R) := \{S \in \mathcal{R} : R \sim S\}\).
2. \(R^\uparrow := \{x \in \mathcal{R} : \forall i \in \mathbb{Z}, R(f^i(x)) \sim R\}\), is the recurrent part of the partition element \(R\).
3. \(\Lambda(R) := \bigcup_{S \in (R)} S^\downarrow\), is called an irreducible Markov partition.

Notice that every conservative measure is carried by a disjoint union of irreducible Markov partitions, since every point which returns to its partition element infinitely often in the past and in the future, lies in the recurrent part of its partition element. There could be at most countably many different irreducible Markov partitions.

Every irreducible Markov partition is an invariant set. For every GSRB \(\nu\),

\[\nu = \sum_{\text{irreducible Markov partition } \Lambda(R)} \mathbb{1}_{\Lambda(R)} \cdot \nu.\]

Each summand is by definition a GSRB as well.

The next lemma shows that there could be at most countably many ergodic GSRBs, and that every ergodic component of a GSRB is a GSRB.

**Lemma 6.8.** Let \(\nu\) be a GSRB, carried by an irreducible Markov partition \(\Lambda(R)\). Then \(\nu\) is ergodic.

**Proof.** The assumptions of this lemma imply that the leaf condition is satisfied for \(\hat{\Sigma}^0 \cap \langle R \rangle^\mathbb{Z}\) and a GSRB \(\mu\) can be constructed as in Theorem 6.3 with the maximal irreducible component \((R)^{-N} \cap \hat{\Sigma}_L\). We show that \(\nu \propto \mu\), and in particular ergodicity would follow. w.l.o.g. \(\nu(R) > 0\). We write \(\hat{\Sigma}_L\) instead of \((R)^{-N} \cap \hat{\Sigma}_L\) to ease notation. In this lemma, we say a point \(x\) is “generic” for a countable collection of integrable functions if for every function in the collection, the limit in the ratio ergodic theorem exists for \(x\) for both \(f\) and \(f\cdot\), and these limits coincide (see Theorem 7.1). The set of generic points carries every invariant, conservative, \(\sigma\)-finite measure by the ergodic decomposition of such measures (see [Aar97, Theorem 2.2.9]). We say that a point is \(\mu\)-generic for a countable collection of integrable functions, if it is generic, and its corresponding limits abide the law of \(\mu\).

Let \(g \in C^+(\hat{\pi}([R]))\). By [Mic01], we may assume w.l.o.g. that \(g\) is locally-Lipschitz continuous, and so, since \(\hat{\pi}([R])\) is compact, also Lipschitz continuous. Set \(\mathcal{F} := \{g \cdot \mathbb{1}_{\hat{\pi}([R])}, g \cdot \mathbb{1}_{R}, \mathbb{1}_{\hat{\pi}([R])}, \mathbb{1}_{\{S : S\text{ is affiliated to }R\}}\}\).

Disintegrate \(\nu|_R\) by \(\{W^u(R)\} \cap \Sigma_L \cap [R]\). There exists \(R \in \hat{\Sigma}_L \cap [R]\) s.t. \(m_{W^u(R)}(A_R \cap \{x \in \mathcal{R} : x \text{ is generic for } \mathcal{F}\}) > 0\). Since \(p\) gives a positive measure to every cylinder ([Sar92] Claim 3.5, pg. 76), there exists \(R' \in \hat{\Sigma}_L\) s.t. \(\mu_{R'}(\{x \in \mathcal{R} : x \text{ is } \mu\text{-generic for } \mathcal{F}\}) = \psi(R)\). Then by Pesin’s absolute continuity theorem for the holonomy map \(\Gamma : V^u(R) \cap A_R \rightarrow V^u(R') \cap A_R\) ([BP07] Theorem 8.6.1) \(\mu_{R'}(\Gamma([x \in W^u(R) : x \text{ is generic for } \mathcal{F}])) > 0\). Then, there exist \(x \in W^u(R), y \in V^u(R) \cap A_R\) s.t. \(y = \Gamma(x)\), and \(x\) is \(\nu\)-generic for \(\mathcal{F}\) and \(y\) is \(\mu\)-generic for \(\mathcal{F}\).

Write \(R^\uparrow = (R(f(x)))_{x \geq 0} \in \hat{\Sigma}_R\), then \(y = \hat{\pi}(R' \uparrow)\); and \(\forall k \geq 0\) s.t. \(f^k(x) \in R, f^k(y) \in \hat{\pi}([R])\). Therefore, the following properties hold for all \(n \geq 1\):

- \(C := \sum_{k \geq 0} \|g \circ f^k(x) - g \circ f^k(y)\| < \infty\).
- \(\lim_{t \to \infty} \sum_{k=0}^{t-1} \mathbb{1}_{\hat{\pi}([R])} \circ f^k(y) = \infty\).
Therefore, \( \forall n \geq 1, \)

\[
\frac{\mu(g \cdot 1_{\overline{[R]}})}{\mu(\overline{[R]})} = \lim_{n \to \infty} \frac{\sum_{k=0}^{n-1} 1_{\overline{[R]}} \circ f^k(g)}{\sum_{k=0}^{n-1} 1_{\overline{[R]}} \circ f^k(y)} = \lim_{n \to \infty} \frac{\sum_{k=0}^{n-1} (g \cdot 1_R) \circ f^k(x)}{\nu(\bigcup_{S: S \text{ is affiliated to } R} f^k(x))}.
\]

This is in fact true for \( \forall g \in C_+(\overline{[R]}) \) (i.e. positive and continuous). Then, for every ergodic component of \( \nu, \nu, \text{ s.t. } \nu(R) > 0, 1_{\overline{[R]}} \cdot \nu \gg 1_R \cdot \nu \). Now, since \( \mu \) is ergodic, conservative, and gives \( \overline{[R]} \) a positive measure, \( \overline{\Sigma} = \bigcup_{g \in \mathbb{Z}} f^g(\overline{[R]}) \pmod{\mu} \). \( \mu \) is ergodic and both \( \mu \) and \( \nu \) are invariant; therefore \( \mu \) c.e. every ergodic component of \( \nu \) which gives \( R \) a positive measure; but \( R \) was chosen arbitrarily s.t. \( \nu(R) > 0 \), then \( \mu \) c.e. every ergodic component of \( \nu \). Whence \( \mu \propto \nu \).

\[\square\]

**Theorem 6.9** (Uniqueness). *Every ergodic homoclinic class \( H(p') \) of a hyperbolic periodic point \( p' \) carries at most one GSRB, up to scaling.*

**Proof.** If \( H(p') \) does not carry any GSRB measure, we are done; then we assume otherwise. Let \( \overline{\Sigma} \) be the maximal irreducible component constructed in Proposition \[8,10\] s.t. \( \overline{\Sigma} = H(p') \pmod{\text{all GSRB measures}} \) (since GSRB measures are conservative by definition). Then the leaf condition is satisfied for \( \overline{\Sigma} = H(p') \pmod{\text{all GSRB measures}} \). Thus, it follows that there exists a cylinder \( [R] \subseteq \overline{\Sigma}_L \) and a chain \( \overline{R} \in \overline{\Sigma}_L \cap [R] \), s.t. equation \[31\] is satisfied with \( A_n := \bigcup (\overline{R}) \cap [R] \), and \( m_{\overline{R}}^{g_1} = \overline{R} \cap [R] \). Thus, as in Theorem \[6.4\], \( \phi : \overline{\Sigma}_L \to (-\infty, 0) \) is recurrent and \( P_{\overline{R}}(\phi) = 0 \) on \( \overline{\Sigma}_L \). Let \( h, q \) be the \( \phi \)-harmonic function and \( \phi \)-conformal measure on \( \overline{\Sigma}_L \) (up to scaling), respectively. Let \( m := \overline{h} \cdot q \) be the unique invariant extension of \( h \cdot q \) to \( \overline{\Sigma} \). It follows that since \( \phi : \overline{\Sigma}_L \to (-\infty, 0) \) is recurrent, \( h \cdot q \) is conservative and ergodic, and so is \( m \). By Lemma \[6.8\], every ergodic component of a GSRB on \( H(p') \) is a GSRB carried by an irreducible Markov partition which satisfies the leaf condition. Let \( \Lambda_{\{R\}} \subseteq H(p') \) be such an irreducible Markov partition. By the proof of Lemma \[6.8\], every ergodic component which is carried by \( \Lambda_{\{R\}} \) is proportional to the GSRB constructed in Theorem \[6.3\] corresponding to the maximal irreducible component \( \overline{\Sigma}_L \cap [R]^{\geq 0} \). Then, we may assume w.l.o.g. that every GSRB on \( H(p') \) is proportional to a GSRB as constructed in Theorem \[6.3\] since proving that each such measure is proportional to \( m \circ (\overline{\pi}^{\gamma})^{-1} \) would be sufficient. Let \( \mu \) be an ergodic GSRB carried by \( \Lambda_{\{R\}} \subseteq H(p') \), write \( \overline{\Sigma} \) for short instead of \( \overline{\Sigma} \cap [R]^{\geq 0} \), and write \( \overline{\pi} := \overline{\pi}|_{\overline{\Sigma}} \). Fix \( \{S \} \in \overline{\Sigma} \) s.t. \( \mu(\overline{\Sigma} \cap \overline{\Sigma}^\#) > 0 \).

**Step 1:** Let \( \{S, \ldots, S\} \subseteq \{S\} \) be a cylinder of length \( n \). Whence, by definition of the extension \( \overline{h} \cdot q \),

\[
\overline{m}([S, \ldots, S]) = (h \cdot q)(\overline{1}_{[S, \ldots, S]} = C_S^{\overline{1}} q(\overline{1}_{[S, \ldots, S]} = C_S^{\overline{1}} q(L_{\overline{h}}^{\overline{1}}(S, [S, \ldots, S])),
\]

where \( C_S := \max_{g \in [S]} (h(\overline{1}_{S})) \). One should notice that \( (L_{\overline{h}}^{\overline{1}}(S, [S, \ldots, S])) = e^{\overline{h} \cdot q}(\overline{S}, [S, \ldots, S]) \) for all \( \overline{S} \in \{S\} \) and outside \( \{S\} \), where the “...” product denotes an admissible concatenation. By Claim \[4.21\],

\[\text{28}\]
\(C^{\pm 1} e^{\phi_a(\Sigma(S,...,S))}\), where \(C \geq 1\) depends on \(S\) alone, and \(\Sigma(S,...,S)\) is the periodic extension of \((S,...,S)\) to \(\tilde{\Sigma}_L\).

So,

\[
m([S,...,S]) = (C_S \cdot C^{\pm 1} e^{\phi_a(\Sigma(S,...,S))}).
\]

Notice, if \(\forall\) admissible periodic cylinder of the form \([S,...,S]\), \(\mu\) gives \(\pi\) \([S,...,S] \cap \tilde{\Sigma}^\#\) a measure dominated by \(e^{\phi_a(\Sigma(S,...,S))}\), then \(\mu\) is dominated by \(m \circ \pi^{-1}\), since both measures are carried by \(\pi[\tilde{\Sigma}^\#]\). Thus, since both \(m \circ \pi^{-1}\) and \(\sigma\)-finite, it would follow that \(\mu \propto m \circ \pi^{-1}\). Our aim is therefore to show that \(\mu\) gives \(\pi\) \([S,...,S] \cap \tilde{\Sigma}^\#\) a measure dominated by \(e^{\phi_a(\Sigma(S,...,S))}\).

**Step 2:** Fix a symbol \(a \in \langle R \rangle\) s.t. \(\int_{[a]} \mu_{[a]}(\pi) [S,...,S] \cap \tilde{\Sigma}^\# \) dp > 0 (in particular \(a\) is affiliated to \(S\), and so there are finitely many such symbols, with a multiplicity bound depending on \(S\)).

Let \(R \in \tilde{\Sigma}_L^\# \cap [a]\), and assume \(\mu_{[a]}(\pi) [S,...,S] \cap \tilde{\Sigma}^\# \) > 0 (the cylinder \([S,...,S]\) has its zeroth coordinate at the right-most entry). Then \(\exists S \in \tilde{\Sigma}_L^\# \cap [S,...,S]\) s.t. \(f^{-n}([V^u(S)] \cap V^u(R)) \neq \emptyset\) (where \(n\) is the length of \([S,...,S]\)). Each unstable leaf is of diameter (in its inner induced metric) less than \(\pm \pi\).

Let \(\pi = \tilde{\Sigma}^\# \cap \Sigma^\#\). Each unstable leaf is of diameter (in its inner induced metric) less than \(\pm \pi\). Thus, since leaf distances shrink, and the leaf contracts, asymptotically. Then, \(\forall k \geq 0\), \(\text{diam}(f^{-k}([V^u(R)]) \leq e^{-\frac{k}{2}}\pi\), in its intrinsic metric. All points of \(V^u(R) \cap A_n\) lie within a ball in \(V^u(R)\), which is separated from the boundary of \(V^u(R)\) by at least \(\frac{1}{2}\text{diam}(V^u(R))\) (see [BO13 Proposition 3.5]). In addition, \(\sup_{a \in [a]} \text{diam}(V^u(S_r)) \leq e^{-\frac{k}{2}}\pi\). It follows that there exists some \(n_{S,a}\) s.t. if \(n \geq n_{S,a}\), then \(\mu_{[a]}(\pi) [S,...,S] \cap \tilde{\Sigma}^\# \) > 0, then \(f^{-n}([V^u(S)]) \subseteq V^u(R)\). In fact, since \(a\) belongs to the finite collection of symbols affiliated to \(S\), we can choose \(n_{S,a}\) large enough so it depends only on \(S\), and denote it by \(n_S\).

**Step 3:** Fix any \(x_0 \in V^u(R) \cap \pi [[S] \cap \tilde{\Sigma}^\#]\), and fix any \(S_R \in \pi [[S] \cap \tilde{\Sigma}^\#]\). \(S_R\) has an extension in \(\pi^{-1}[[x_0]] \cap \tilde{\Sigma}^\#\). Then, for any \(x \in V^u(R) \cap \pi [S] \cap \tilde{\Sigma}^\#\), there exists a coding \(S_x \in \tilde{\Sigma}^\# \cap [S]\) where \((S_x)_i = (S_R)_i\), \(\forall i \leq 0\): This is true since each such \(x\) can be coded by a chain in \(\tilde{\Sigma}^\# \cap [S]\), and the concatenation of its positive coordinates with \(S_R\) would be admissible (since \(S_R \in \tilde{\Sigma}^\# \cap [S]\)); and by the fact that the new chain also shadows \(x\), it follows that it must code it.

**Step 4:** Let \(\lambda_{V^u(S_R)}\) be the induced Riemannian volume of \(V^u(S_R)\). By part 5 in Lemma [20] \(\sup_{a \in [a]} \text{Vol}(V^u(S'_a)) \leq e^{\epsilon}\). By Theorem [10] \(\frac{d\lambda_{V^u(S'_a)}}{d\lambda_{V^u(S_R)}} = e^{\pm \epsilon}\). Therefore,

\[
\mu_{[a]}(\pi) [S,...,S] \cap \tilde{\Sigma}^\# \leq m_{V^u(R)}\left(f^{-n}([V^u(S_R) \cdot (S,...,S)])\right) \leq \frac{e^{\epsilon}}{\text{Vol}(V^u(R))}\lambda_{V^u(R)}\left(f^{-n}([V^u(S_R) \cdot (S,...,S)])\right)
\]

\[
= \frac{e^{\epsilon}}{\text{Vol}(V^u(R))}\lambda_{V^u(S_R)}\left(f^{-n}([V^u(S'_a) \cdot (S,...,S)])\right)
\]

\[
\leq \frac{e^{\epsilon}}{\text{Vol}(V^u(R))}m_{V^u(S'_a)}\left(f^{-n}([V^u(S'_a) \cdot (S,...,S)])\right) \leq C'_S \cdot m_{V^u(S'_a)}\left(f^{-n}([V^u(S'_a) \cdot (S,...,S)])\right)
\]

\[
= C'_S \cdot e^{\phi_a(S(S,...,S))} \leq C \cdot e^{\phi_a(S(S,...,S))},
\]

where \(C'_S := \max_a \text{ affiliated to } S \text{ Vol}(V^u(R))\), and the last inequality is by step 1. Therefore,

\[
\mu(\pi) [S,...,S] \cap \tilde{\Sigma}^\# = \sum_{a \text{ affiliated to } S} \int_{[a]} \mu_{[a]}(\pi) [S,...,S] \cap \tilde{\Sigma}^\# dp \leq \sum_{a \text{ affiliated to } S} p([a]) \cdot (CC'_S) e^{\phi_a(S(S,...,S))}.
\]

Set \(\tilde{C}_S := \sum_{a \text{ affiliated to } S} p([a]) \cdot (CC'_S)\).

---

17 For every two chains, \(R^{(1)}, R^{(2)} \in [a]\), one can use the map \(I : V^u(R^{(1)}) \rightarrow V^u(R^{(2)})\) from Lemma [20] and compose it with every path in \(V^u(R^{(1)})\) to get a path in \(V^u(R^{(2)})\). Then, using equation [3] to bound the Jacobian of \(I\), the estimation for the path length follows.
Step 5: So in total,
\[ m \circ \tilde{\pi}^{-1} \left( \tilde{\pi} \left( \left[ S, ..., S \right] \cap \tilde{\Sigma}^\# \right) \right) \geq m \left( \left[ S, ..., S \right] \right) \geq (C_S C)^{-1} e^{\phi_n \left( \left[ C_S \left( S, ..., S \right) \right] \right)} \geq (C_S C \cdot \tilde{C}_S)^{-1} \mu \left( \tilde{\pi} \left( \left[ S, ..., S \right] \cap \tilde{\Sigma}^\# \right) \right). \]

S was chosen arbitrarily s.t. \( \mu \left( \left[ S \right] \cap \tilde{\Sigma}^\# \right) > 0 \) \( (m \circ \tilde{\pi}^{-1} \) gives a positive measure to each cylinder by \cite{Sar09} Claim 3.5, pg. 76), and the bound for all cylinder estimations depends only on S. Then, \( \mu \ll m \circ \tilde{\pi}^{-1} \), and so \( \mu \propto m \circ \tilde{\pi}^{-1} \). It follows that every GSRB carried by \( H(y') \) is proportional to \( m \circ \tilde{\pi}^{-1} \), and so all are proportional to each other.

7. Ergodic Theorems and Physical Properties

Recall \cite{Pes77} an invariant ergodic measure is called physical if the set of all points which abide its time-forward ergodic theorem is a set of positive Lebesgue volume. When a GSRB is finite (in particular it is an SRB measure), it has been shown it is also physical w.r.t. Birkhoff’s ergodic theorem (see \cite{Pes77, KSLP80, PS89}).

The sketch of proof using the Absolute Continuity theorem is as follows: When \( \mu \) is an SRB measure, \( \mu \)-a.e. point is hyperbolic and \( \mu \)-regular w.r.t. to the pointwise ergodic theorem. By the disintegration of \( \mu \) into absolutely continuous measures, there is some unstable leaf, with a positive leaf volume for \( \mu \)-regular points which are hyperbolic points. Consider all local stable leaves which go through these points— they demonstrate the same future behavior as the regular points, by the forward contraction of stable leaves. Using the disintegration of the Lebesgue measure by a partition of transversals to the local stable leaves, and Pesin’s absolute continuity theorem, it follows that the union of all the local stable leaves of the \( \mu \)-regular points must have a positive Riemannian volume.

7.1. The Physical Properties of an Infinite GSRB. The motivation for the definition of physical measures is as follows: assume \( M \) is a phase-space of some chaotic physical system. Given a macroscopic quantity of the system which we can measure, we would like for a random initial condition to have a positive probability to have its orbit encoding information about the average of the macroscopic quantity over the whole phase-space. That is, averaging the time series of measurements of the macroscopic quantity, would reveal information about the average of the quantity over the whole phase-space (w.r.t. our physical measure). Subsets of the phase-space with a positive Riemannian volume, are what we assume by convention to have a positive probability to be observed in a simulation or an experiment. A physical measure describes the asymptotic behavior of such a set, or event. Macroscopic quantities (e.g. pressure, temperature, etc.) are not sensitive to a small change in the condition of a small amount of particles, and are conventionally assumed to be continuous (as assumed when discussing physicality of SRB measures). These concepts in mind motivated the study of physicality in the following sense for infinite measures as well.

**Theorem 7.1** (The Ratio Ergodic Theorem). Let \( (X, \mathcal{B}, \mu, T) \) be a \( \sigma \)-finite measure preserving transformation, and assume that \( \mu \) is conservative. Then for \( \mu \)-a.e. \( x \in X \), \( \forall g, h \in L^1(\mu) \) s.t. \( h \geq 0 \) and \( \int h \, d\mu > 0 \),

\[
\lim_{n \to \pm \infty} \frac{\sum_{k=0}^{n} g \circ T^k(x)}{\sum_{k=0}^{n} h \circ T^k(x)} = \left( \frac{\int g \, d\mu}{\int h \, d\mu} \right).
\]

This theorem is due to E. Hopf, and an elegant proof in English can be found in \cite{Zwe04}.

**Theorem 7.2.** Assume there exists an unstable leaf with a positive leaf volume for \( HWT_{\chi} \), and let \( \mu \) be the ergodic GSRB which we constructed in Theorem 7.3. Then,

\( \forall g, h \in C(M) \cap L^1(\mu) \) s.t. \( h \geq 0 \), \( \int h \, d\mu > 0 \),

\[
\text{Vol} \left\{ x \in M : \lim_{n \to \infty} \frac{\sum_{k=0}^{n} g \circ f^k(x)}{\sum_{k=0}^{n} h \circ f^k(x)} = \left( \frac{\int g \, d\mu}{\int h \, d\mu} \right) \right\} > 0,
\]

where \( \text{Vol} \) denotes the Riemannian volume of \( M \).
Proof.

Step 0: Let $g, h \in C(M) \cap L^1(\mu)$ be any two functions s.t. $h \geq 0$, $\mu(h) > 0$. $\mu$ is an ergodic, conservative and invariant measure. Let $X$ be the set of all points in $\bigcup \{V^u(R) \cap A_{R_0} : R \in \hat{\Sigma}^\# \}$ which are generic w.r.t. the ratio ergodic theorem of $\mu$ for $g, h$.

$$X' := \bigcup \{V^u(S) : S \in \hat{\Sigma}^\#, \hat{\pi}(S) \in X \}.$$  \hfill (33)

It is clear that $\exists R \in \hat{\Sigma}^\#$ s.t. $\mu_{\hat{R}}(X') = \mu_{\hat{R}}(1) > 0$, therefore, by Pesin’s absolute continuity theorem, $X'$ has a positive Riemannian volume. We wish to prove that the ratio ergodic theorem limit holds for every point in $X'$.

Step 1: We start by assuming that $g, h$ are Lipschitz functions. Let $y \in X'$, and write $x := \hat{\pi}(S)$ for a chain $S \in \hat{\Sigma}^\#$ s.t. $\hat{\pi}(S) \in X$ and $y \in V^u(S)$.

Since $x$ and $y$ belong to the same local stable manifold, their orbits converge exponentially fast. Whence, since $h$ is Lipschitz, $\sum_{k=0}^{\infty} h(f^k(y)) < \infty$. In addition, since $\mu$ is infinite and conservative, and $\int hd\mu > 0$, $\lim_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} h(f^k(x)) = \infty$ (recall Definition 6.1). We therefore get $\lim_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n-1} h(f^k(y)) = \infty$ as well. Similarly, $\sum_{k=0}^{\infty} |g(f^k(y)) - g(f^k(x))| < \infty$. Whence,

$$\sum_{k=0}^{n} g \circ f^k(y) - \sum_{k=0}^{n} g \circ f^k(x) \leq \left(1 + \sum_{k=0}^{n} h(f^k(y)) - \sum_{k=0}^{n} h(f^k(x)) \right) \left(1 + \sum_{k=0}^{n} h \circ f^k(y) - \sum_{k=0}^{n} h \circ f^k(x) \right) \sum_{k=0}^{n} g \circ f^k(y) \sum_{k=0}^{n} h \circ f^k(x).$$

$$= \left(\int \frac{gd\mu}{hd\mu} + o(1) \right) \left(1 + O(1) \cdot o(1) \right) \left(1 \cdot o(1) \right) \frac{\int gd\mu}{n \to \infty} \frac{\int h \cdot d\mu}{n \to \infty}.$$  \hfill (34)

Step 2: Now, back to only assuming that $g, h$ lie in $C(M)$, and are not necessarily Lipschitz continuous. It is enough to assume that $g \geq 0$, by the linearity of the limit, and the fact that every integrable continuous function can be written as the difference of two continuous, integrable and non-negative functions. $\log g \in C([g^{-1}([0, \infty)))$. $g^{-1}([0, \infty))$ is an open set, and clearly a metric subspace of $M$. By [Mic01], $\log g$ can be approximated on $g^{-1}([0, \infty))$ uniformly by locally-Lipschitz functions. Fix $\delta > 0$, and let $\log \tilde{g}^\delta$ be a locally-Lipschitz function on $g^{-1}([0, \infty))$ s.t. $\sup_{y \in g^{-1}([0, \infty))} |\log g - \log \tilde{g}^\delta| \leq \delta$. Then $\tilde{g}^\delta$ is a locally-Lipschitz function on $g^{-1}([0, \infty))$, s.t. $\lim_{t \to \delta} g^{-1}([0, \infty)] \tilde{g}^\delta(t) = 0$, and $\tilde{g}^\delta_{|g^{-1}([0, \infty))} = e^\delta$. Write $g^\delta := 1_{g^{-1}([0, \infty))} \cdot \tilde{g}^\delta$, then $g^\delta$ is a locally-Lipschitz function on all of the compact manifold $M$. Thus, $g^\delta$ is Lipschitz on $M$. In addition, by the definition of $g^\delta$, $\frac{d}{dt} g^\delta = e^\delta$ (0 set to be 1). Define $h^\delta$ analogously; and conclude $\frac{d}{dt} h^\delta = e^\delta$ as well. In particular, it follows that $g^\delta, h^\delta \in L^1(\mu)$ and $\int hd\mu > 0$. Let $\delta_n \downarrow 0$, and choose $X$ s.t. each point in $X$ is generic for $(g^{\delta_n}, h^{\delta_n})$, $\forall n \geq 0$ (it is still a full $\mu$-measure set). Let $\delta \in \{\delta_n\}_{n \geq 0}$. So, $\forall y \in X'$,

$$e^{\pm 2\delta} \sum_{k=0}^{n} g \circ f^k(y) = \sum_{k=0}^{n} h \circ f^k(y) \; \mu(g^\delta) = \frac{\mu(g)}{\mu(h)} e^{\pm 2\delta}.$$  \hfill (35)

Thus, since $\delta$ was arbitrary,

$$\sum_{k=0}^{n} g \circ f^k(y) \; n \to \infty \frac{\mu(g)}{\mu(h)}.$$  \hfill (36)

\[ \square \]

Corollary 7.3. Under the assumptions of Theorem 7.2 above,

$$\inf_{g, h \in C(M) \cap L^1(\mu) : h \geq 0, \mu(h) > 0} \text{Vol} \left\{ x \in M : \frac{\sum_{k=0}^{n} g \circ f^k(x)}{\sum_{k=0}^{n} h \circ f^k(x)} \to \int \frac{g \cdot d\mu}{h \cdot d\mu} \right\} > 0.$$  \hfill (37)

Proof. Fix $[R'] \subset \hat{\Sigma}^\#, [R'] \subset [R]$. Since $\mu = \int \frac{g \cdot d\mu}{h \cdot d\mu}$ is conservative, and $p$ gives all cylinders a positive measure, $\forall g, h \in C(M) \cap L^1(\mu)$ s.t. $h \geq 0, \mu(h) > 0$, $\exists R \in [R']$ s.t. $\mu_R \left\{ x \in M : \frac{\sum_{k=0}^{n} g \circ f^k(x)}{\sum_{k=0}^{n} h \circ f^k(x)} \to \int \frac{g \cdot d\mu}{h \cdot d\mu} \right\} = \mu_R(1)$. In Theorem 7.2 we show that for $\mu_R$-a.e. $x \in V^u(\hat{R}) \cap A_{R'}$, for every $y \in V^u(S)$ (where $S \in [R'] \cap \hat{\Sigma}^\#$ s.t. $\hat{\pi}(S) = x$), $\frac{\sum_{k=0}^{n} g \circ f^k(y)}{\sum_{k=0}^{n} h \circ f^k(y)} \to \frac{\int g \cdot d\mu}{\int h \cdot d\mu}$. Thus, by Pesin’s absolute continuity theorem (since $\mu_R = 1_{A_{R'}} \cdot m_{V^u(S)}$, $\mu_R = 1_{A_{R'}} \cdot m_{V^u(S)}$, and $m_{V^u(S)}$, $m_{V^u(S)}$ are equivalent to their respective leaf’s
volume), for $\mu_H$-a.e. $x' \in V^u(R') \cap A_{R'}$, for every $y' \in V^s(S')$ (where $S' \in [R'] \cap S^\emptyset$ s.t. $\hat{\pi}(S') = x'$),

$$\sum_{k=0}^N g^{f^k(y')} - \sum_{k=0}^N h^{f^k(y')} \xrightarrow{n \to \infty} \int_{h^0} f_{\hat{h}^0}.$$ 

Therefore, applying Pesin’s absolute continuity theorem to the global stable foliation through a full leaf volume subset of $V^u(R') \cap A_{R'}$, gives a positive Riemannian volume set of points, with a volume bound uniform in $g, h$. In fact, the same bound holds for any countable collection of pairs of functions in $C(M) \cap L^1(\mu)$.

7.2. Physical Measurements. This subsection, and Proposition 2.8 in it, were aimed to show that the physicality of an infinite GSRB is not a null property, even in cases where it is difficult to check if $C(M) \cap L^1(\mu) \neq \emptyset$, where $\mu$ is an infinite GSRB.

Lemma 7.4. Let $z \in HWT_{\chi}$ and let $x \in W^u(z) \cap HWT_{\chi}$. Let $r > 1$ s.t. $\exists m_k \uparrow \infty$ s.t. $\|C^{-1}_\chi(f^{-m}(x))\| \leq r$. Then $\forall k \geq 0$, $\exists \eta$ an invertible linear map $\eta^{(m)} : H^s(f^{-m}(x)) \to H^s(f^{-m}(z))$ s.t. $\exists C = C(x, y) > 0$, $\gamma = \gamma(x, y) \in (0, 1)$, s.t. $\|\eta_m\|, (\|\eta_m\|^{-1}) = e^{O(e^{-\frac{C}{r}})},$ and $\forall \xi \in H^s(f^{-n}(x)), |\xi| = 1,$ if $m_k \leq m \leq m_{k+1},$

$$\frac{S(f^{-m}(x), \xi)}{S(f^{-m}(z), \eta_m(\xi))} = e^{\pm C\gamma_k}.$$ 

A similar claim holds for $x \in W^s(z) \cap HWT_{\chi}$. The constants in the big $O$ depend on $x$ and $z$.

Proof. First notice that $\dim H^s(x) = \dim H^s(z) = s(z)$, and a linear bijection can be defined. Since $z \in HWT_{\chi}$, by [Sar13, Lemma 4.6],

$$p_n^u := \max\{t \in \{e^{-\frac{t}{\eta}}\}_{t \geq 0} : e^{-Nt} \leq Q_\epsilon(f^{n-N}(z)), \forall N \geq 0\},$$

$$p_n^s := \max\{t \in \{e^{-\frac{t}{\eta}}\}_{t \geq 0} : e^{-Nt} \leq Q_\epsilon(f^{n+\eta}(z)), \forall N \geq 0\}, \quad \underline{w} := \{\psi^{p_n^u, p_n^s}_{f^{-n}(z)}\}_{n \in \mathbb{Z}},$$

(36) are well defined, and the map $\underline{w}$ is admissible. The formulae for $p_n^u, p_n^s$ are due to F. Ledrappier. We may assume w.l.o.g. that $x \in V^s(u)$. Let $P_s : \mathbb{R}^d \to \mathbb{R}^s(x)$ be the projection to the $s(z)$ first coordinates. $V^s(R(x))$ is a $C^1 + \dot{\theta}$-smooth manifold which intersects $V^u(u)$ transversely. Therefore, there exists a number of iterations, $\tilde{n}$, such that $P_s \circ \psi^u_{f^{-n}(z)} \circ f^{-\tilde{n}} \circ \psi_{z}^{-1}(V^s(R(x)))$ covers the domain in the chart $\psi^{p_n^u, p_n^s}_{f^{-n}(z)}$. Let $V^u(f^{-\tilde{n}-m}(x))$ be the part of $W^s(f^{-\tilde{n}-m}(x))$ which contains $f^{-\tilde{n}-m}(x)$ and spans over the chart $\psi^{p_n^u, p_n^s}_{f^{-\tilde{n}-m}(z)}$. Assume w.l.o.g. that $\tilde{n} = 0$. Denote the function representing the graph of $V^s(\sigma^{-k}u)$ by $F_k$, and the function representing the graph of $V^s(f^{-k}(x))$ by $G_k, k \geq 0$. By [BO18], Proposition 3.8, $\forall m \geq 0, \|dG_m - dF_m\| \leq O(e^{-\frac{C}{m}})$. Let $\xi \in H^s(x)$ s.t. $|d_x(f^{-1})\xi| = 1$. $\xi = \psi_{\xi}(u, d_{P_0\psi_{z}^{-1}(x)}G_0u)$ for some $u \in \mathbb{R}^s(x)$. Define $\eta = \eta(\xi) := d_0\psi_{z}(u, 0) \in H^s(z)$.

Step 0: Let $D \ni x$ be a small neighborhood, and $\Theta_D : TD \to \mathbb{R}^d$ a local isometry as in Definition 4.14 Then,

$$\left| |d_x(f^{-1})\xi| - |d_z(f^{-1})\eta| \right| = |d_x(f^{-1})d_{\psi_{z}^{-1}(x)}\psi_{z}(u, d_{P_0\psi_{z}^{-1}(x)}G_0u)| - |d_z(f^{-1})d_0\psi_{z}(u, 0)| \leq H_0 \cdot d(x, z) \beta \cdot |\xi| + M_f |\Theta_D \circ d_{\psi_{z}^{-1}(x)}\psi_{z}(u, d_{P_0\psi_{z}^{-1}(x)}G_0u) - \Theta_D \circ d_0\psi_{z}(u, 0)| \leq H_0 M_f \cdot d(x, z) \beta$$

$$+ E_0 M_f \left( d(x, z) + |\psi_{z}^{-1}(x) - 0| + |u| \cdot \left( \frac{1}{2} |\psi_{z}^{-1}(x) - 0|^{\frac{3}{2}} + \|dF_0 - dG_0\|_{\infty} \right) \right) \leq 8M_f^2 (E_0 + H_0) \cdot \|C^{-1}_\chi(z)\|^2 \left( d(x, z) \frac{3}{2} + \|dF_0 - dG_0\|_{\infty} \right) = O \left( \|C^{-1}_\chi(z)\|^2 \left( d(x, z) \frac{3}{2} + \|dF_0 - dG_0\|_{\infty} \right) \right).$$

Then,

$$|d_x(f^{-1})\xi|^2 - |d_z(f^{-1})\eta|^2 = O \left( \|C^{-1}_\chi(z)\|^2 \left( d(x, z) \frac{3}{2} + \|dF_0 - dG_0\|_{\infty} \right) \right).$$

32
Similarly, one gets that for $m \geq 0$, $\forall \xi_m \in H^s(f^{-m}(x))$ s.t. $|d_{f^{-m}(x)}(f^{-1})\xi_m| = 1$,

$$\left|d_{f^{-m}(z)}(f^{-1})\xi_m|^2 - |d_{f^{-m}(z)}(f^{-1})\eta_m(\xi_m)|^2 \right| = O\left( \left\| C^{-1}_\chi(f^{-m}(z)) \right\|^2 \left( d(f^{-m}(x), f^{-m}(z))^2 + \left\| dF_{f^m} - dG_m \right\|_{\infty} \right) \right) = O\left( e^{-\frac{8m}{9}} \right),$$  

(37)

where $\eta_m(\xi_m) := d\psi_{f^{-m}(z)}(u_m, 0) \in H^s(f^{-m}(z))$ when $\xi_m = d_{\psi_{f^{-m}(z)}}(f^{-m}(z))u_m, d_{\psi_{f^{-m}(z)}}(f^{-m}(z))G_mu_m$ for some $u_m \in \mathbb{R}^s$; $\eta_m : H^s(f^{-m}(x)) \rightarrow H^s(f^{-m}(z))$ are linear and invertible.

Step 1: Define $\rho := \max\left( \frac{\langle s(x, \xi) \rangle_{S(x, \eta)}}{\langle s(x, \xi) \rangle_{S(x, \eta)}} \right)$. Let $0 < \delta := (\log \rho)^2$. Assume w.l.o.g. that $|d_x(f^{-1})\xi|^2 - |d_z(f^{-1})\eta|^2| \leq \delta$.

$$S^2(f^{-1}(x), d_x(f^{-1})\xi) = \sum_{m=0}^{\infty} |d_{f^{-1}(z)}(f^{-1})\xi|^2 e^{2\chi_m} = S^2(\xi, \xi)e^{2\chi} + 2|d_x(f^{-1})\xi|^2$$

$$\leq \rho^2 e^{2\chi} S^2(\xi, \eta) + 2|d_x(f^{-1})\xi|^2.$$  

$$S^2(f^{-1}(z), d_z(f^{-1})\eta) = \sum_{m=0}^{\infty} |d_{f^{-1}(z)}(f^{-1})\eta|^2 e^{2\chi_m} = S^2(\eta, \eta)e^{2\chi} + 2|d_z(f^{-1})\eta|^2.$$  

Then,

$$\frac{S^2(f^{-1}(x), d_x(f^{-1})\xi)}{S^2(f^{-1}(z), d_z(f^{-1})\eta)} \leq \frac{\rho^2 e^{2\chi} S^2(\xi, \eta) + 2|d_x(f^{-1})\xi|^2}{S^2(f^{-1}(z), d_z(f^{-1})\eta)} = \rho^2 - \frac{2(\rho^2 - 1)|d_x(f^{-1})\xi|^2}{S^2(f^{-1}(z), d_z(f^{-1})\eta)}.$$  

(38)

Now, since $\rho \geq e^{\sqrt{\delta}}$, then $\rho^2 - 1 \geq 2\sqrt{\delta}$, and so $\rho^2 - 1)|d_x(f^{-1})\xi|^2 \leq (\rho^2 - 1)(1-\delta) - \delta \geq (\rho^2 - 1)(1-\delta) - 2\sqrt{\delta} \geq (\rho^2 - 1)(1-\delta - \frac{4}{\sqrt{\delta}}) \geq (\rho^2 - 1)(1-\delta - \frac{4}{\sqrt{\delta}}) \geq (\rho^2 - 1)(1-\frac{4}{\sqrt{\delta}}) \geq (\rho^2 - 1)e^{-2\sqrt{\delta}},$

for small enough $\delta \in (0, 1)$. We then get that all together,

$$\frac{S^2(f^{-1}(x), d_x(f^{-1})\xi)}{S^2(f^{-1}(z), d_z(f^{-1})\eta)} \leq e^{2\chi} \frac{1 - \frac{2(1 - \frac{1}{\rho^2})e^{-2\sqrt{\delta}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}} \leq e^{2\chi} \frac{1 - \frac{2(1 - \frac{1}{e^{2\sqrt{\delta}}})e^{-2\sqrt{\delta}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}} \leq e^{2\chi} \frac{1 - \frac{2\sqrt{\delta}e^{-2\sqrt{\delta}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}} \leq e^{2\chi} \frac{1 - \frac{\log \rho}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}}}{\left\| C^{-1}_\chi(f^{-1}(z)) \right\|_{\infty}}.$$  

(39)

A lower bound is derived similarly. Define $\rho_m := \max\left\{ \frac{S(f^{-m}(x), \xi)_m}{S(f^{-m}(z), \eta_m(\xi)_m)}, \frac{S(f^{-m}(z), \eta_m(\xi)_m)}{S(f^{-m}(z), \eta_m(\xi)_m)} \right\}$, where $\xi_m := d_{f^{-m-1}(x)}(f^{-1}, d_{f^{-m-1}(z)}(f^{-1})\xi_m)$.

Step 2: $\forall m \geq 0$ s.t. $(\log \rho_m)^2 < |d_{f^{-m}(x)}(f^{-1})\xi_m|^2 - |d_{f^{-m}(z)}(f^{-1})\eta_m|^2 |$, by equation (37), we get that $\rho_m := e^{O(e^{-\frac{\theta m}{\theta}})}$, where $\xi_m := d_{f^{-m-1}(x)}(f^{-1}, d_{f^{-m-1}(z)}(f^{-1})\xi_m)$. Then we may assume w.l.o.g. that all $m \geq 0$ are not as such, and carry out step 1. It follows that $\rho_m$ keep improving, and for a subsequence $m_k \uparrow \infty$ and a constant $r > 1$ s.t. $\left\| C^{-1}_\chi(f^{-m_k}(z)) \right\| \leq r,$

$$\rho_{m_k + 1} \leq \rho_{m_k}(1 - \frac{\log \rho_{m_k}}{r}) = e^{\lambda_{m_k}}(1 - \frac{\lambda_{m_k}}{r}) \leq e^{\lambda_{m_k}} \frac{\rho_{m_k}}{r} = e^{\lambda_{m_k}} e^{-\frac{\lambda_{m_k}}{r}} \leq \cdots \leq (e^{\lambda_{m_0}}(1 - \frac{1}{r}))^k = e^{O\left(1 - \frac{1}{r}\right)^k},$$  

(40)

where $\rho_m := e^{\lambda_m}$. The big $O$ constants in equation (37) depend on $x, y$, but they do not depend on $\xi$.

We are left to bound $\left\| \eta(\xi) \right\|, \left\| \eta(\xi)^{-1} \right\|$. Write $\xi_m = d_{\psi_{f^{-m}(z)}}(f^{-m}(x))d_{\psi_{f^{-m}(z)}}(f^{-m}(x))G_mu_m$, then $|u_m| \leq \left\| C^{-1}_\chi(f^{-m}(z)) \right\| \cdot \left\| \eta_m(\xi) \right\|$. Let $D_m \ni f^{-m}(z), f^{-m}(x)$ be a small neighborhood, and $\Theta_{D_m}$:
$TD_m \to \mathbb{R}^d$ a local isometry as in Definition 4.14 Then,

$$|\xi_m| = |d_{D_m}^{-1}(f_m(z)) \psi f_m(z) \left( d_{P_x \psi f_m(z)} \frac{u_m}{(f_m(z))} G_m u_m \right)|$$

$$= |\eta_m(\xi_m)| \pm \left( 2 \| \Theta D_m d_{D_m}^{-1}(f_m(z)) \psi f_m(z) - \Theta D_m d_0 \psi f_m(z) \| \cdot (1 + \| d G_m \|) |u_m| + \| d_0 \psi f_m(z) \| \cdot \| d G_m \| |u_m| \right)$$

$$= |\eta_m(\xi_m)| \pm |\eta_m(\xi_m)||C^{-1} \cdot (f_m(z))| \cdot \left( 3\| C^{-1} \cdot (f_m(z)) \| \cdot E_0 |\psi f_m(z) -(f_m(z)) - 0| + 2 \cdot \frac{1}{2} |\psi f_m(z)(f_m(z)) - 0| \right)$$

$$= |\eta_m(\xi_m)| e^{O(e^{-\frac{2\beta}{m}})}.$$  \hspace{1cm} (41)

\qed

**Lemma 7.5.** Let $x \in \text{HWT}_x$, and let $y \in V^s(\mathbb{R}(x))$. Then \( \forall n \geq 0 \exists \text{an invertible linear map } \eta^{(n)} : H^s(f^n(y)) \to H^s(f^n(x)) \text{ s.t. } \| \eta^{(n)} \| , \| (\eta^{(n)})^{-1} \| = e^{O(e^{-\frac{2\beta}{m}})} \), and \( \forall \xi \in H^s(f^n(y)) , |\xi| = 1 \),

$$\frac{S(f^n(y), \xi)}{S(f^n(x), \eta^{(n)}(\xi))} = e^{O(e^{-\frac{2\beta}{m}})}.$$

A similar claim holds for $V^u(\mathbb{R}(x))$.

**Proof.** First, notice that $s(x) = \dim H^s(x) = \dim H^s(y)$, so invertible linear maps can be defined. As in equation [35], let $y := \{ \psi_{f^n(x)} \}_{n \in \mathbb{Z}}$ be an admissible chain. Let $F_n$ be the function representing the graph of the admissible manifold $V^s(\sigma^n y)$ in $\psi_{f^n(x)}$. Let $\xi \in H^s(y)$, $|\xi| = 1$.

Define, $\forall n \geq 0, \eta^{(n)} : H^s(f^n(y)) \to H^s(f^n(x))$, $\eta_n = \eta^{(n)}(d_y f^n \xi) := C_x(f^n(x)) \circ P_x \circ d_y f^n \xi$. Then, $| u_n | \leq \| C^{-1} \cdot (f^n(x)) \| \cdot |\eta_n|$. Let $D_n \ni f^n(y), f^n(x)$ be a small neighborhood, and $\Theta_{D_n} : TD_n \to \mathbb{R}^d$ a local isometry as in Definition 4.14 Then,

$$|d_y f^n \xi| = |d_{\psi f^n(x)}(f^n(y)) \psi f^n(x) \left( d_{P_x \psi f^n(x)} \frac{u_n}{(f^n(y))} F_n u_n \right)|$$

$$= |\eta_n| \pm \left( 2 \| \Theta D_n d_{D_n}^{-1}(f^n(y)) \psi f^n(x) - \Theta D_n d_0 \psi f^n(x) \| \cdot (1 + \| d F_n \|) |u_n| + \| d_0 \psi f^n(x) \| \cdot \| d F_n \| |u_n| \right)$$

$$= |\eta_n| \pm |\eta_n||C^{-1}(f^n(x))| \cdot \left( 3\| C^{-1}(f^n(x)) \| \cdot E_0 |\psi^{-1}(f^n(x)) - 0| + 2 \cdot \frac{1}{2} |\psi^{-1}(f^n(x))(f^n(y)) - 0| \right)$$

$$= |\eta_n| e^{O(e^{-\frac{2\beta}{m}})}.$$  \hspace{1cm} (42)

In addition,
\[
\frac{\|d_y f\xi\|}{\|d_x f\eta\|} = \frac{|d_{\psi^{-1}_{f(x)}(y)} \psi f(x) d_{P_{\psi^{-1}_{f(x)}(y)} F_1 u_{1}}|}{|d_0 \psi f(x) (u_1 0)|} \\
= 1 \pm \left( \left| \left( \Theta_D d_{\psi^{-1}_{f(x)}(y)} \psi f(x) - \Theta_D d_{0} \psi f(x) \right) \left( u_1 0 \right) \right| \\
+ \left| \left( \Theta_D d_{\psi^{-1}_{f(x)}(y)} \psi f(x) - \Theta_D d_{0} \psi f(x) \right) \left( u_1 0 \right) \right| \right) \\
= 1 \pm \left( E_0 |\psi^{-1}_{f(x)}(y)| - 0 \cdot ||C^{-1}_x(f(x))|| + 2||C^{-1}_x(f(x))|| \cdot \frac{1}{2} |\psi^{-1}_{f(x)}(y)| - 0| \right) \\
= 1 \pm 2E_0 ||C^{-1}_x(f(x))|| \cdot |\psi^{-1}_{f(x)}(y) - \psi^{-1}_{f(x)}(y)| \cdot 2 = 1 \pm 4E_0 ||C^{-1}_x(f(x))|| \cdot d(f(x), f(y)) \tilde{\beta} \\
= 1 \pm \frac{1}{4} d(f(x), f(y))^2 = e^{\pm d(f(x), f(y))^2}. 
\]

Whence, together with equation (42), \[|d_{f^m(x)} f f^{(m)}(y) \xi| = e^{\pm d(f(x), f(y))^2}. \] The bounds in equation (43) in fact apply \(\forall n \geq 0, \) so \(\forall \xi_n \in H^s(f^m(y)), \)

\[|d_{f^m(\xi)} f^{(m)}(y) \xi| = e^{\pm d(f(x), f(y))^2}. \]

These commuting relations admit the following property \(\forall m \geq 0 \) and \(\xi \in H^s(f^m(y)), \)

\[|d_{f^m(x)} f^{(m)}(y) \xi| = |d_{f^{m+1}(x)} f \cdot d_{f^m(x)} f^{(m)} \xi| \]

Proof. By Lemma 7.4 and Lemma 7.5. \(\exists C \in H \) such that \(\forall k \geq 0 \) and \(\forall \xi_n \in H^s(f^m(y)), \xi_n \in H^u(f^m(y)), \) \(S^2(f^m(x), \eta \xi_n) = e^{\pm C \xi^k} S^2(f^m(y), \xi_n) + U^2(f^m(x), \eta \xi_n) + U^2(f^m(y), \xi_n). \) Then, \(S^2(f^m(x), \eta \xi_n) + U^2(f^m(x), \eta \xi_n) \leq e^{C \xi^k} (S^2(f^m(y), \xi_n) + U^2(f^m(y), \xi_n)) \]

\[\leq \|C^{-1}_x(f^m(y))\|^2 \cdot e^{C \xi^k} \xi^2_n + \xi^2_n. \]
Now, denote by $F^s_n$ and $F^u_n$ the representing functions of $V^s(f^n(x))$ and $V^u(f^n(x))$ (respectively), in the chart $\psi^p_{n,y}$, where $p^s_n, p^u_n$ are given by the formulae in equation (36).

$$\left\| \xi_s^+ + \xi_u^+ \right\| \leq \left| \eta(n) \xi_s^+ + \eta(n) \xi_u^+ \right| + \left| \text{Lip}(d, \psi_{f^n(x)} \cdot |\psi_{f^n(x)}^{-1}(f^n(y))| \cdot \left| \left( u^s_n, u^u_n \right) \right| + 2 \cdot \frac{1}{2} |\psi_{f^n(x)}^{-1}(f^n(y))|^3 \right|

\leq 1 + 6 \|C^{-1}\| (f^n(x)) \cdot d(f^n(x), f^n(y)) \frac{f}{f} \cdot \left| \left( u^s_n, u^u_n \right) \right| \leq 1 + 24 \|C^{-1}\| (f^n(x)) \| d(f^n(x), f^n(y)) \frac{f}{f} \| \leq 1 + 24 C^2 \cdot \varepsilon^{-\left(\frac{1}{2} - 2\varepsilon\right)n} \leq C \cdot \varepsilon^{\delta n},$$

where $C = C(x) > 0$ is given by the $\varepsilon$-weak temperability of $x$ s.t. $\forall n \geq 0 \|C^{-1}\| (f^n(x)) \leq C \cdot \varepsilon^{\delta n}$. Plugging this back in equation (16) yields,

$$\|C^{-1}\| (f^n(x)) \leq C \cdot \varepsilon^{\delta n},$$

where $\tau := \max(\gamma, e^{-\delta \frac{n}{n}})$. Whence, by symmetry, $\|C^{-1}\| (f^n(0)) = e^{O(\tau^k)}$.

**Definition 7.7.** Let $\mu$ be an invariant, $\sigma$-finite, and conservative Borel measure. A collection of $\mu$-integrable functions, $A$, is called a collection of physical measurements for $\mu$, if $\forall g, h \in A$ s.t. $h \geq 0$ and $\int h \, d\mu > 0$,

$$\text{Vol} \left( \left\{ x \in M : \sum_{k=0}^{n} g \circ f^k(x) \rightarrow \frac{\int g \, d\mu}{\int h \, d\mu} \right\} \right) > 0.$$

**Proposition 7.8.** Let $\mu$ be ergodic GSRB. Then there exists a countable dense set $A \subseteq L^1(\mu)$ such that each function in $A$ has a natural version- i.e. when restricted to each global stable leaf, it is either Lipschitz continuous or identically 0, modulo the leaf volume. Furthermore, the collection of these versions is a collection of physical measurements for $\mu$.

**Proof.** Let $g \in L^1(\mu)$, and let $\delta > 0$. $\exists r_0 > 0$ s.t. $\forall n \geq r_0, \|C^{-1}\| (f^n) \cdot g - g \|L^1(\mu) \leq \delta$. Denote $\omega_n(x) := \begin{cases} 1, & \|C^{-1}\| (f^n) \leq n, \\ 1 - (\|C^{-1}\| (f^n) - n), & n \leq \|C^{-1}\| (f^n) \leq n + 1, \\ 0, & \|C^{-1}\| (f^n) \geq n + 1. \end{cases}$

The measure $\omega_n \cdot \mu$ is finite, and so $\exists g_n \in \text{Lip}(M)$ s.t. $(\omega_n \cdot \mu)(g_n - g) \leq \frac{\delta}{2}$. It follows that $\|g_n \cdot \omega_n - g \|L^1(\mu) \leq \delta$. Since Lip($M$) is separable, there exists a countable dense set $F \subseteq \text{Lip}(M)$. Then $A := \{ g \cdot \omega_n \}_{n \geq 1, g \in F}$ is a countable collection of $\mu$-integrable functions which is dense in $L^1(\mu)$.

The functions in $A$ are defined on HWT; we wish to show that each function in $A$ has a natural version, s.t. on each global stable leaf, which is either Lipschitz continuous (a.e. w.r.t. the leaf volume), or identically 0. Furthermore, we show that the collection of these versions satisfies is a collection of physical measurements for $\mu$. In particular, this shows that the physicality of a GSRB is not a null property in cases where it is difficult to check if $C(M) \cap L^1(\mu)$ is not empty.

We say a point $x$ is $\mu$-generic w.r.t. $A$ if it is a generic point of $\mu$ by the ratio ergodic theorem, for every two functions $g, h \in A$ (where the function in the denominator is non-negative and has a positive integral). Write $\mathcal{X} := \{ \text{all } \mu\text{-generic points w.r.t. } A \}$. Let $\mathcal{R} \in \Sigma^L_\#$ s.t. $\mu_{\mathcal{R}}(\mathcal{X}) = \mu_{\mathcal{H}}(1)$. The Riemannian volume $\text{Leb}(\mathcal{X}) = 0$, otherwise physicality follows trivially, thus for $\mu_{\mathcal{R}}$-a.e. $x \in V^s(\mathcal{R}) \cap A_{\mathcal{R}} \cap \mathcal{X}$, $\lambda_{\mathcal{V}^s(\mathcal{R})}(\mathcal{X}) = 0$, where $\lambda_{\mathcal{V}^s(\mathcal{R})}$ is the induced Riemannian leaf volume of $V^s(\mathcal{R}(x))$. We therefore assume w.l.o.g. that $\forall x \in V^s(\mathcal{R}) \cap A_{\mathcal{R}} \cap \mathcal{X}$, $\lambda_{\mathcal{V}^s(\mathcal{R})}(\mathcal{X}) = 0$.

The following part of the construction involves a transfinite recursion, and so the axiom of choice. Let $g \in A$. We wish to construct a version of $g$, denoted $g^*$; such that for any $h \in A$ s.t. $h \geq 0$ and $\int h \, d\mu > 0$, $\{ g^*, h^* \}$ are a collection of physical measurements. Write $g = \hat{g} \cdot \omega_N$, where $\hat{g} \in \text{Lip}(M)$ and $N \in N$, and fix
Next, the transfinite recursion is defined in the same way for the successor case and the limit case: Assume $W$ is defined on $\forall \alpha \exists x \in V(\alpha) \cap A_\alpha \cap \mathcal{X}$, denote $p_s(x) := \min\{m' \geq 1: \exists 0 \leq n < m' \text{ s.t. } f^{m'}(x_0) \in W_s(f^n(x_0))\}$, and if the minimum is over an empty set, define $p_s(x) := \infty$. Define, $\forall 0 \leq n \leq p_s(x_0) - 1$, $g'_n|_{W^n(x_0)}(y) := \begin{cases} \frac{\hat{g}(y)\omega_N(f^n(x_0))}{\hat{g}(y)\omega_N(y)}, & y \notin HWT_x, \\ \frac{\hat{g}(y)\omega_N(f^n(y))}{\hat{g}(y)\omega_N(y)}, & y \in HWT_x. \end{cases}$

We continue this way by transfinite recursion until we exhaust all of $V(\alpha) \cap A_\alpha \cap \mathcal{X}$, and $g'$ is defined on the forward-orbits of all points $V(\alpha) \cap A_\alpha \cap \mathcal{X}$. $g'$ and $g$ differ from each other by at most a subset of $M \setminus HWT_x$, which is a $\mu$-null set. Therefore $g'$ is $\mu$-integrable, and $\int g'd\mu = \int gd\mu$.

It remains to prove physicality: Let $g, h \in A$ s.t. $h \geq 0$, $\int hd\mu > 0$ and $h = \hat{h}\omega_N$, $g = \hat{g}\omega_N$, where $\hat{h}, \hat{g} \in \text{Lip}(M), N, N' \in \mathbb{N}$; and assume w.l.o.g. that $N \leq N'$. $\forall x \in V(\alpha) \cap A_\alpha \cap \mathcal{X}$, $\forall y \in V(\alpha)$, we divide into two steps:

(1) if $y \in HWT_x$, then $\sum_{n \geq 0} |g'(f^n(y)) - g'(f^n(x))| < \infty$, $\sum_{n \geq 0} |h'(f^n(y)) - h'(f^n(x))| < \infty$, by Corollary 7.6.

(2) if $y \notin HWT_x$, then by the transfinite construction, $g'(f^n(y)) = \hat{g}(f^n(y))\omega_N(f^n(y'))$ with $y' \in HWT_x$, and so $g' \in W^x(x)$. Then $\sum_{n \geq 0} |g'(f^n(y)) - g'(f^n(y'))| < \infty$, $\sum_{n \geq 0} |h'(f^n(y)) - h'(f^n(x))| < \infty$ (as in step 1), and so $\sum_{n \geq 0} |g'(f^n(y)) - g'(f^n(x))| < \infty$. Similarly, $\sum_{n \geq 0} |h'(f^n(y)) - h'(f^n(x))| < \infty$.

By equation (31), this is sufficient to conclude that $\frac{\sum_{k=0}^n g'(f^k(y))}{\sum_{k=0}^n h'(f^k(y))} \xrightarrow{n \to \infty} \frac{\int g'd\mu}{\int h'd\mu}$ as in Corollary 7.3. $\exists C > 0$ s.t. $\forall g, h \in A$ s.t. $h \geq 0, \int hd\mu > 0, \text{Vol}\left\{ y \in M : \frac{\sum_{k=0}^n g'(f^k(y))}{\sum_{k=0}^n h'(f^k(y))} \xrightarrow{n \to \infty} \frac{g'd\mu}{h'd\mu} \right\} \geq C$. □

7.3. Distributional Physicality

When given a finite ergodic invariant measure $\mu$, physicality is the property of having a positive probability (w.r.t. the Riemannian volume) for an initial condition to be future-generic for continuous macroscopic quantities of the system, i.e.

$$\text{Vol}\left\{ x \in M : \forall g \in C(M), \frac{1}{n} \sum_{k=0}^{n-1} g \circ f^k(x) \xrightarrow{n \to \infty} \int g d\mu \right\} > 0.$$ \hspace{1cm}

When $\mu$ is infinite, and Birkhoff’s ergodic theorem does not apply anymore, one approach to physicality is by the ratio ergodic theorem, as done so far in §7.2 (see Theorem 7.2 and Proposition 7.3). The ratio ergodic theorem is relative, meaning we normalize the time-series of one function, by the time-series of another. When $\mu$ is infinite, may it be conservative and $\sigma$-finite, Aaronson had shown in [Aar77] that no absolute version of the ratio ergodic theorem can exist for even a single function. That is, $\forall \{b_n\}_{n \geq 0} \subseteq \mathbb{N}, \forall g \in L^1(\mu)$ s.t. $g \geq 0$ and $\int g d\mu > 0$,

$$\limsup_{n \to \infty} \frac{1}{b_n} \sum_{k=0}^{n-1} g \circ f^k = \infty \text{ a.e.},$$ \hspace{1cm} or $$\liminf_{n \to \infty} \frac{1}{b_n} \sum_{k=0}^{n-1} g \circ f^k = \infty \text{ a.e.} \text{ (or both).}$$

Therefore, even though we cannot ask for a stronger (absolute) notion of point-wise physicality, we can consider another natural approach to physicality. When recalling the original motivation of physicality, it seems natural to consider a cluster, or distribution, of initial conditions, w.r.t. the Riemannian volume. This leads us to the following theorem.
Theorem 7.9. Let $\mu$ be an ergodic GSRB, and denote by $\text{Vol}$ the Riemannian volume of $M$. There exist $\rho \in L^1(\text{Vol})$ and a sequence $a_n \xrightarrow{n \to \infty} \infty$, which depend on $\mu$, s.t. $\rho \cdot \text{Vol}$ is a probability and $\forall g \in C(M) \cap L^1(\mu)$,

\[
(\rho \cdot \text{Vol}) \left( \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k \right) \xrightarrow{n \to \infty} \int g \mu.
\]

The statement also holds with the collection of physical measurements from Proposition 7.8 A, replacing $L^1(\mu) \cap C(M)$.

This theorem is a consequence of a property which is not generally true for all $\sigma$-finite, conservative, ergodic measures. It is called point-wise dual ergodicity (see equation (47)), and it holds for the conformal measures of Hölder continuous potentials on a locally-compact TMS. However, we will see that this property can be used with GSRBs, by their unique relation with the conformal measure of the geometric potential.

Proof. Assume that there exists an unstable leaf with a positive leaf volume for HWT$_x$, and let $\mu$ be the GSRB constructed in Theorem 6.3. Write $\mu = \int_{\hat{\Sigma}} \mu_R dp$ where $\hat{\Sigma}$ is an irreducible TMS and $p$ is the conformal measure of the (recurrent) geometric potential $\phi$.

Fix a cylinder $[R] \subseteq \hat{\Sigma}_L$, and a chain $R \in \hat{\Sigma}_L \cap [R]$. Let $g \in L^1(\mu) \cap C(M)$, and let $L$ be its Lipschitz constant. Define $\psi_g(\Sigma) := \mu_g(\Sigma), \forall \Sigma \in \hat{\Sigma}_L$. Then, by definition, $\int \psi_g dp = \int g \mu$, and so $\int |\psi_g| dp \leq \int |g| dp = \int |g| d\mu < \infty$. By [Sar09, Proposition 3], $p$ is point-wise dual ergodic, i.e.

$$\exists \text{ a sequence } a_n \to \infty \text{ s.t. } \forall \psi' \in L^1(p), \text{ for } p\text{-a.e. } \Sigma \in \hat{\Sigma}_L, \frac{1}{a_n} \sum_{k=0}^{n-1} (L^k g \psi')(\Sigma) \xrightarrow{n \to \infty} \psi_1(\Sigma) \cdot \int \psi' dp.$$ (47)

Notice that $\frac{1}{a_n} \sum_{k=0}^{n-1} (L^k g \psi')(\Sigma) = \mu_g(\frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k)$, by Proposition 4.28. Thus, since $p$ gives a positive measure to every cylinder ([Sar09, Claim 3.5, pg. 76]), we get that there exist $\{R^{(m)}\}_{m \geq 0} \subseteq [R]$ s.t. $d(R_m^{(m)}, R) \leq e^{-m}$, and $\forall m \geq 0$,

$$\mu(R^{(m)}) \left( \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k \right) \xrightarrow{n \to \infty} \psi_1(R^{(m)}) \cdot \int \psi_g dp = \mu(R^{(m)}) \cdot 1 \cdot \int g \mu.$$  

Part 1: Let $\Gamma_m : V^n(R^{(m)}) \cap A_R \to V^n(R) \cap A_R$ be the holonomy map along the stable leaves of $A_R$. By Pesin’s absolute continuity theorem ([BP07, Theorem 8.6.1], $\|\text{Jac}(\Gamma_m) - 1\| \leq K_R \theta^m$), where $\theta$ is as defined in Claim 4.11, and $K_R$ is a positive constant depending on the partition member $R$. Recall, $\mu_R = \frac{1}{A_R} \cdot \nu_{V^n(R)}$, and $m_{V^n(R)} = \frac{1}{A_R} \cdot \lambda_{V^n(R)}$, where $\lambda_{V^n(R)}$ is the induced Riemannian leaf volume of $V^n(R)$. Write $G_n := \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k$. 

\[\text{[8]Here } \text{Jac}(\Gamma_m) \text{ refers to the Radon-Nikodym derivative of the mapping, and not the standard derivative (as it may not exist).}\]
\[
\int_{V^u(R) \cap A_R} G_n \frac{1}{g_{\mu_R}} d\lambda_{V^u(R)} = \int_{\Gamma_m[V^u(R)] \cap A_R} G_n \frac{1}{g_{\mu_R}} d\lambda_{V^u(R)} = \int_{V^u(R) \cap A_R} (G_n \circ \Gamma_m - G_n) \frac{1}{g_{\mu_R} \circ \Gamma_m} \text{Jac}(\Gamma_m) d\lambda_{V^u(R)}.
\]

Thus, in total, \( \limsup_{n \to \infty} \mu_R(G_n) \leq 1 \cdot \mu_R(1) \) Therefore, \( \forall m \geq 0, \)

\[
\limsup_{n \to \infty} \mu_R(G_n) \leq \frac{1}{\mu_R(1)} \mu(g) + \frac{\mu(g)}{\mu_R(1)} \left( \| \text{Jac}(\Gamma_m) \| \| \frac{g_{\mu_R}}{g_{\mu_R} \circ \Gamma_m} - 1 \| + \| \text{Jac}(\Gamma_m) - 1 \| \right) .
\]

Since \( R^k \mapsto \mu_R(1) \) is continuous on \( [R], \mu_R(1) \xrightarrow{m \to \infty} \mu_R(1) \). Therefore, by step 3 in Lemma [4.27], and since \( \| \text{Jac}(\Gamma_m) - 1 \| \leq K_R \theta^m \),

\[
\frac{\mu(g)}{\mu_R(1)} \left( \| \text{Jac}(\Gamma_m) \| \| \frac{g_{\mu_R}}{g_{\mu_R} \circ \Gamma_m} - 1 \| + \| \text{Jac}(\Gamma_m) - 1 \| \right) \xrightarrow{m \to \infty} 0.
\]

Thus, in total, \( \limsup_{n \to \infty} \mu_R(G_n) \leq \frac{1}{\mu_R(1)} \mu(g) \). Similarly, \( \liminf_{n \to \infty} \mu_R(G_n) \geq \frac{1}{\mu_R(1)} \mu(g) \), and so \( \mu_R(G_n) \xrightarrow{n \to \infty} \frac{1}{\mu_R(1)} \mu(g) \).

Part 2: Define the probability \( \nu := \int f_{V^u(R)}(R_{(x)}) d\mu_R(x) \), where \( R_{(x)} \) is the normalized induced Riemannian leaf volume of \( V^u(R(x)) \); Thus, by Pesin's absolute continuity theorem, and since \( \mu_R \ll \lambda_{V^u(R)}, \nu \ll \alpha \).

\( \forall x \in V^u(R) \cap A_R, y \in V^u(R(x)) \), since \( g \) is \( L \)-Lipschitz, \( |g \circ f^k(x) - g \circ f^k(y)| \leq L \cdot e^{-\frac{\delta}{k}}, \forall k \geq 0 \). Then,

\[
(\rho \cdot \text{Vol}) \left( \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k \right) = \nu(\frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k) = \frac{1}{\mu_R(1)} \int \lambda_{V^u(R(x))} \left( \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k \right) d\mu_R
\]

\[
= \frac{1}{\mu_R(1)} \int \left( \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k + \frac{1}{a_n} \sum_{k=0}^{n-1} e^{-\frac{\delta}{k}} \right) d\mu_R
\]

\[
= \frac{1}{\mu_R(1)} \mu_R \left( \frac{1}{a_n} \sum_{k=0}^{n-1} g \circ f^k \right) + O(\frac{1}{a_n} \xrightarrow{n \to \infty} \int g d\mu).
\]

Part 3: Now, given \( g \in C(M) \cap L^1(\mu) \) (w.l.o.g. \( g \geq 0 \)), by [HUSE], \( \forall \delta > 0 \exists g^{(\delta)} \in \text{Lip}(M) \) s.t. \( g^{(\delta)} = e^{\pm \delta} g; \) whence \( g^{(\delta)} \) satisfies the assumptions for parts 1 and 2. As in equation [33], this is sufficient.

---

\textsuperscript{19} By [BOTS] Proposition 4.4, \( d(f^k(x), f^k(y)) \leq e^{-\frac{\delta}{k}} \forall k \geq 0 \).
Part 4: Let $\mathcal{A}$ be the countable collection of physical measurements from Proposition 7.8. Then a chain $R \in \hat{\Sigma}_L$ can be chosen to be generic (w.r.t. the point-wise dual ergodic theorem) for all $\{\psi_g\}_{g \in \mathcal{A}}$. Then we may skip part 1, and carry out parts 2 and 3; the estimations apply.
