MICROSCOPIC DERIVATION OF TIME-DEPENDENT POINT INTERACTIONS

RAFFAELE CARLONE, MICHELE CORREGGI, MARCO FALCONI, AND MARCO OLIVIERI

ABSTRACT. We study the dynamics of the three-dimensional Fröhlich polaron – a quantum particle coupled to a bosonic field – in the quasi-classical regime, i.e., when the field is very intense and the corresponding degrees of freedom can be treated semiclassically. We prove that in such a regime the effective dynamics for the quantum particles is approximated by the one generated by a time-dependent point interaction, i.e., a singular time-dependent perturbation of the Laplacian supported in a point. As a byproduct, we also show that the unitary dynamics of a time-dependent point interaction can be approximated in strong operator topology by the one generated by time-dependent Schrödinger operators with suitably rescaled regular potentials.

1. Introduction and Main Results

Point interactions, also called zero-range interactions or Fermi pseudo-potentials (see [AGH-KH] for an extensive review of the topic) have been widely studied in mathematical physics as solvable models for realistic quantum systems. By formally replacing a typically complicated interaction potential with a sum of singular distributions (Dirac deltas) supported at isolated points or on curves or surfaces, one aims at summing up all the features of the interaction in a minimal number of physical parameters (e.g., scattering length, effective range, . . . ). The models obtained by this approximation are almost exactly solvable, while the salient physical features of the original systems should be retained in the procedure. Often, however, there is no conclusive evidence of the latter assertion: despite being known that point interactions can be approximated by suitable rescaled potentials, it is not clear whether they can be derived from realistic models, in suitable physical regimes.

In this paper we would like to derive a class of zero-range models as the effective description of physical systems, with such effective description originating from a well-defined approximation that we call quasi-classical limit (see [CF, CFO] and references therein). This should clarify the importance of zero-range models in mathematical and theoretical investigations. As a by-product, we also prove that there exist lattice field quantum states in which a polaron is completely ionized (this is discussed in more detail below).

The class of zero-range models considered is the one of so-called time-dependent point interactions: solvable models with singular potentials whose “strength” changes in time. They are typically useful to investigate the ionization of a bound state by the action of a time-dependent localized interaction. In the zero-range approximation one studies the formal Hamiltonian

$$-\Delta + \mu(t)\delta(x)$$

in $L^2(\mathbb{R}^d)$, and the system is assumed to be in a bound state at initial time, e.g., in the ground state, and the asymptotic probability of ionization is computed [CDFM, CD2] (see also [CCL] and [CD1] for the one-dimensional version of the same model and other time-dependent singular perturbations, respectively). As already discussed, the question whether such a minimal model does describe any physically relevant system as, for instance, a quantum particle interacting with a laser, is still an open question and precisely the one that we address in this paper.

We prove that time-dependent point interactions can indeed be derived from the microscopic dynamics of a quantum particle (Fröhlich polaron) interacting with a bosonic scalar quantum field (phonon or Bose field), in suitable configurations in which the field is very intense, and the average number of carriers is much larger than one. Here, the reference scale is the value of the commutator.
between creation and annihilation operators of the field, which is set equal to one in the considered units. Equivalently, it is more convenient to set
\[ [a_\varepsilon(x), a_\varepsilon(x)] = \varepsilon \delta(x - y), \]  
and to take the limit
\[ \varepsilon \to 0. \]  

Here \( a(x) \) and \( a^\dagger(x) \), \( x \in \mathbb{R}^3 \), are the usual operator-valued distributions associated to the annihilation and creation of field carriers. The limit \( \varepsilon \to 0 \) is precisely the aforementioned quasi-classical limit. In the case of the Fröhlich polaron such a limit is known to be equivalent, at least in the stationary picture, to the so-called strong coupling regime (see §1.1 below), i.e., when the coupling between the particles and Bose field is large. The strong coupling dynamics is slightly different from the one considered here, because the field is frozen to leading order.

The Fröhlich polaron was originally introduced in [Fr] to model the interaction between one or more electrons with a crystal of nuclei, vibrating around the rest positions on the lattice crystal, but, more recently, has been widely used in physics (also under the name of Bose polaron) as an effective model to describe the behavior of an impurity in a Bose-Einstein condensate (see, e.g., [GD] for a review of the topic). The model can also be concretely realized in the lab [Ho et al.], by immersing a Cs impurity in a Rb condensate. Typically, the polaron is studied in three dimensions, but lower dimensional models may also be of a certain interest from the physical point of view [GAD]. For instance, one-dimensional tight-binding models are known to well-approximate the motion of electrons in organic semiconductors [DeF et al.]. Furthermore, in this investigations the phonon degrees of freedom are typically treated classically, as in the ideal quasi-classical limit described above.

When the limit \( \varepsilon \to 0 \) is taken, the bosonic field becomes a classical field, whose dynamics \textit{a priori} would depend on both its initial configuration and the coupling with the particle. We are going to scale the coupling in such a way that the classical field evolves freely in the limit, while the particle effective dynamics is generated by an effective time-dependent interaction which is time-periodic and point-like at the origin, i.e., it is the rigorous counterpart of (1.1). Physically speaking, the quasi-classical limit we are considering is such that there is no back-reaction of the particle on the classical field.

Mathematically the dimensions lower than three are easier to deal with, therefore we prefer to focus on a three-dimensional model; our techniques can be easily adapted to study one and two dimensional systems. Notice that, since we derive a time-dependent point interaction from the polaron Hamiltonian and the former model shows complete asymptotic ionization [CDFM, Thm. 4.4], we also prove that there exist quantum field configurations that yield complete ionization of the polaron (compare with [To]). Let us stress that our model is at zero-temperature, and the ionization is due to the field configuration only; a discussion of temperature-induced ionization for polaron systems can also be found in the physical literature (see, e.g., [HP]).

In the next §1.1 and 1.2 we describe our setting in more detail, introducing the microscopic system and the effective point interaction model, respectively. The convergence of the dynamics is discussed in §1.4, where we also state a technical result about the approximation of the dynamics generated by a time-dependent point interaction by means of the dynamics generated by the corresponding approximating regular potentials.

Let us conclude this section by fixing some basic notations. We use the convention of denoting by calligraphic letters all the quantities referring to the effective model, e.g., \( U_{\text{eff}} \) and \( H_{\text{eff}} \) denote the effective dynamics and generator, respectively, while regular letters (e.g., \( U_\varepsilon \) and \( H_\varepsilon \)) are attached to the microscopic counterparts, i.e., to the operators acting on the full particle-field Hilbert space. Bold letters denotes vectors (\( x \)), while italic roman letters are used for scalar quantities. When there is no risk of confusion, we use the corresponding italic letter (\( x \)) to denote the modulus of a vector (\( x \)). Concerning operators and quadratic forms, we denote by \( \mathcal{D}(A) \) and \( \mathcal{D}[A] \) the operator and form domains, respectively.
1.1. Microscopic model. As anticipated, we want to investigate the quasi-classical limit of a system composed of a quantum spinless particle interacting with a bosonic field. For the sake of concreteness, we consider the interaction with a phonon lattice field, the so-called Fröhlich polaron model [FG], although other models might be considered as well.

The Hilbert space of microscopic states is thus $\mathcal{H} := L^2(\mathbb{R}^3) \otimes \Gamma_s(\mathcal{F})$, where the single excitation (phonon) space is $\mathcal{F} = L^2(\mathbb{R}^3)$, and $\Gamma_s$ stands for the symmetric Fock space. The Hamiltonian of the full system reads

$$ H_\varepsilon = H_0 + H_I = (−Δ + W_\sigma(x)) \otimes 1 + \frac{1}{\varepsilon} \left(1 \otimes d\Gamma_\varepsilon(1)\right) + a_\varepsilon(\lambda_x) + a_\varepsilon^\dagger(\lambda_x), $$

where $1$ stands for the identity operator on either $L^2(\mathbb{R}^3)$ or $\Gamma_s(\mathcal{F})$, and $H_0 = −Δ \otimes 1 + \frac{1}{\varepsilon} 1 \otimes d\Gamma_\varepsilon(1)$. The particle’s potential $W_\sigma \in C^\infty_0(\mathbb{R}^3)$ is meant an approximation of a stationary point interaction, see [1.3] and Definition 1.5 for additional details. We have used the $\varepsilon$-dependent representation of the canonical commutation relations for the creation and annihilation operators $a_\varepsilon$ and $a_\varepsilon^\dagger$, i.e.,

$$ [a_\varepsilon(\xi), a_\varepsilon^\dagger(\eta)] = \varepsilon \langle \xi | \eta \rangle_{\mathcal{F}}. $$

The form factor $\lambda_x$ has the explicit form

$$ \lambda_x(k) = \frac{e^{ik \cdot x}}{k}. $$

The commutation relations (1.5) can be thought of as a quasi-classical rescaling of the usual relations; such rescaling is convenient to investigate the regime $\langle a^\dagger a \rangle \gg [a, a^\dagger] = 1$, where $a^\dagger$ are the usual creation and annihilation operators. In fact, one can set $a_\varepsilon^\dagger := \sqrt{\varepsilon}a^\dagger$, from which (1.5) follows. Moreover, given any self-adjoint one-particle operator $h$ on $\mathcal{F}$,

$$ d\Gamma_\varepsilon(h) = \varepsilon d\Gamma(h), $$

where the former is written w.r.t. $a_\varepsilon^\#$ and the latter w.r.t. $a^\#$. The parameter $\varepsilon$ is the quasi-classical parameter that describes the energy scale of the macroscopic phonon field, which is of order $O(\varepsilon^{-1})$, and is assumed to be small, i.e., $\varepsilon \ll 1$. This corresponds to high field energies, due to the presence of a large number of excitations.

It is worth noting that in the Fröhlich polaron the quasi-classical limit is equivalent in the stationary setting, up to a suitable rescaling of time and lengths, to the strong-coupling regime. We refer to [GrWg, FS, FG, Gr, LT] for further details on the strongly coupled polaron. Note, however, that here we are studying the dynamics of the polaron and the usual strong coupling regime would lead to a different field energy (no $\varepsilon^{-1}$ prefactor) and, in turn, to a field which is frozen to leading order.

Since for any $x \in \mathbb{R}^3$, $\lambda_x \notin \mathcal{F}$, $H_\varepsilon$ can be written explicitly as the above sum only as a quadratic form, acting on the form domain of the non-interacting part $\mathcal{D}[H_0]$ (see, e.g., [LT, FS, Fa3, GrWg]). The form $\langle \cdot | H_\varepsilon \cdot \rangle_{\mathcal{H}}$ is closed and bounded from below on $\mathcal{D}[H_0]$, and therefore $H_\varepsilon$ can be defined as a self-adjoint operator on a suitable dense domain $\mathcal{D}(H_\varepsilon) \subset \mathcal{D}[H_0]$. Moreover, $H^2(\mathbb{R}^3) \otimes \mathcal{D}(d\Gamma_\varepsilon(1)^{1/2})$ is dense in $\mathcal{H}$ and contained in the form domain $\mathcal{D}[H_0]$.

1.2. Effective dynamics. As anticipated above, we want to derive an effective dynamics generated by the formal operator (1.1), i.e., $−Δ + "\mu(t)\delta(x)"$. In two or three dimensions the rigorous definition of the self-adjoint counterpart of this formal expression is not straightforward: one can not simply consider the corresponding energy form and investigate his closedness, as it is done in one dimension. The typical way to address this question (see, e.g., [AGK, KH]) is to consider the operator $−Δ$ restricted to functions vanishing at the origin and classify its self-adjoint extensions, which form a one-parameter family of operators $\{\mathcal{H}_\beta, \beta \in \mathbb{R}\}$, given by

$$ \mathcal{H}_\beta \psi = −Δ\phi, $$

$$ \mathcal{D}(\mathcal{H}_\beta) = \left\{ \psi \in L^2(\mathbb{R}^3) \mid \psi = \phi + \frac{q}{4\pi}x, \phi \in H^2_{\text{loc}}(\mathbb{R}^3), \Delta\phi \in L^2(\mathbb{R}^3), q \in \mathbb{C}, \phi(0) = \beta q \right\}. $$

The spin can be easily added to the picture, however since it would make the notations more cumbersome, we avoid it. Similarly, we can include more quantum particles in the model and possibly some interaction or a trapping potential, but similarly we consider the simplest model for the sake of clarity.
The interaction is thus encoded into the boundary condition $\phi(0) = \beta q$, which has to be satisfied by any function in $\mathcal{D}(\mathcal{H}_\beta)$. The action of $\mathcal{H}_\beta$ on the other hand coincides with the one of $-\Delta$, although on the regular part of the wave function $\phi$. In particular, if $\phi(0) = 0$, it is immediate to verify that $\mathcal{H}_\beta \phi = -\Delta \phi$ and, in this respect, $\mathcal{H}_\beta$ defines a self-adjoint realization of the formal expression $-\Delta + \mu \delta(x)$. However, it is important to remark that the meaning of the parameter $\beta$ in (1.8) is not the strength of the interaction but it is rather proportional to the scattering length, so that for instance the free operator $-\Delta$ corresponds to $\beta = +\infty$.

As already discussed, our main goal is thus to prove a rigorous derivation of the effective particle dynamics generated by the time-dependent operator $\mathcal{H}_{\beta(t)}$, with $\beta(t)$ a periodic function. The existence of such a dynamics has already been studied in the literature [SY] (see also [CCF, CFT] for further details) and it is known that, under minimal regularity assumptions on $\beta(t)$, i.e. $\beta(t) \in L^\infty(\mathbb{R})$, there exists a two-parameter unitary group $\mathcal{U}_{\text{eff}}(t, s)$, $t, s \in \mathbb{R}$, which is generated by $\mathcal{H}_{\beta(t)}$: for any $s \in \mathbb{R}$ and any $\psi \in \mathcal{D}(\mathcal{H}_{\beta(s)})$,

$$\lim_{\hbar \to 0} \frac{i}{\hbar} (\mathcal{U}_{\text{eff}}(s + h, s) - I) \psi = \mathcal{H}_{\beta(s)} \psi. \quad (1.9)$$

In fact, the time-evolution generated by $\mathcal{H}_{\beta(t)}$ can be explicitly characterized: for any $\psi_s \in H^1_0(\mathbb{R}^3 \setminus \{0\})$,

$$\psi_t(x) := (\mathcal{U}_{\text{eff}}(t, s) \psi_s)(x) = (U_0(t-s) \psi_s)(x) + i \int_s^t d\tau U_0(t-\tau; x) q(\tau), \quad (1.10)$$

where we have denoted by $U_0(t)$ the unitary time-evolution generated by $\mathcal{H}_0 = -\Delta$, and by $U_0(t; x)$ the corresponding integral kernel, which reads

$$U_0(t; x) := \frac{1}{(4\pi i t)^{3/2}} \exp \left\{ \frac{ix^2}{4t} \right\}. \quad (1.11)$$

The charge $q(t) \in \mathbb{C}$ solves the Volterra-type integral equation

$$q(t) + 4\sqrt{\pi i} \int_s^t d\tau \frac{\beta(\tau) q(\tau)}{\sqrt{t-\tau}} = 4\sqrt{\pi i} \int_s^t d\tau \frac{1}{\sqrt{t-\tau}} (U_0(\tau - s) \psi_s)(0), \quad (1.12)$$

and, in fact, is the unique solution of such an equation in the space of continuous functions. Notice that it is easy to verify heuristically that (1.10) solves the time-dependent Schrödinger equation, since

$$i \partial_t \psi_t = -\Delta \left( \psi_t - \frac{q(t)}{4\pi x} \right),$$

while it is much harder to derive the charge equation (1.12), which is related to the boundary condition in (1.8). The evolution $\mathcal{U}_{\text{eff}}$ can be expressed as in (1.10) for any $\psi_s$ vanishing around the origin, but it can be extended to any state in $L^2(\mathbb{R}^3)$ by density.

1.3. The stationary part of the point interaction. The quantum particle is subjected, in the microscopic model defined by $H_\varepsilon$, to an external smooth and compactly supported potential $\mathcal{W}_\sigma$, approximating a stationary point interaction. Let us discuss and motivate the presence of such potential. First of all, let us remark that the small parameter $\sigma$, describing the convergence to a point interaction, will be chosen as a suitable function of $\varepsilon$. This is however not necessary, and one could consider the limit $\varepsilon \to 0$ before, and only then remove the regularization given by $\sigma$.

The introduction of $\mathcal{W}_\sigma$ in the model is motivated as follows. The quasi-classical scaling of the field, and in particular the presence of the factor $\frac{1}{\varepsilon}$ in front of the free field part, yield a prescribed time-dependence for the quasi-classical generated effective potential. In describing a time-dependent point interaction, however, there is a contribution due to a stationary part (corresponding to the one appearing on the right hand side of Eq. (1.27) below). Such stationary part does not satisfy the equation governing the time dependence yielded by the quasi-classical field, and therefore it cannot originate from the particle-field interaction under study. It can, however, be originated by the interaction with another bosonic force-carrying field. Physically, a realistic situation would be that of a system in which a single force-carrying field behaves differently
at different frequencies: the free energy of a set of frequencies scales with a quasi-classical factor \( \frac{1}{\varepsilon} \), and the other set with a factor 1.

From a mathematical standpoint, the microscopic Hamiltonian describing the coupling with an additional field (or with the other set of frequencies) would be of the following form:

\[
H_\varepsilon = -\Delta \otimes 1 \otimes 1 + \frac{1}{\varepsilon} \left( 1 \otimes d\Gamma^{(a)}(1) \otimes 1 \right) + 1 \otimes 1 \otimes d\Gamma^{(b)}(1) + a_\varepsilon(\lambda_\varepsilon) + a^\dagger_\varepsilon(\lambda_\varepsilon)
\]

\[
+ b_\varepsilon(\lambda_\varepsilon) + b^\dagger_\varepsilon(\lambda_\varepsilon)
\]

where \( b^\dagger_\varepsilon \) are the quasi-classical creation and annihilation operators corresponding to the other field. Let us remark that in this case, there is no additional external potential acting on the particle (as expected), but apart from that the structure of the Hamiltonian is very similar to the one given by Eq. (1.4). In fact, the analysis in this case would carry out in a manner perfectly analogous to the one given below. Therefore, for the sake of a clearer exposition, we decided to present the result in the case in which the action of the additional field is directly given by the potential \( W_\sigma \). A precise definition of the latter, and of the properties that it should satisfy to be an approximation of a stationary point interaction are given in Eq. (1.25) and Definition 1.5 below.

1.4. Main results. We now describe in more detail the quasi-classical regime. Let \( \mathcal{B} \in \mathcal{B}(L^2(\mathbb{R}^3)) \) be a bounded observable associated to the particle. The Heisenberg evolution of \( \mathcal{B} \) in the microscopic dynamics is given by

\[
B_\varepsilon(t, s) = e^{iH_\varepsilon(t-s)\mathcal{B}} \otimes 1 e^{-iH_\varepsilon(t-s)}.
\]

Since the microscopic system describes an interaction between the particle and the phonon field, for almost all \( t \in \mathbb{R} \), \( B_\varepsilon(t, s) \big|_{\Gamma_\varepsilon(\mathcal{B})} \neq 1 \), thus acting non-trivially on the field. However, since we are interested on a description of the subsystem consisting of the particle alone, let us take the partial expectation of \( B_\varepsilon(t, s) \) with respect to some initial state of the field \( \Psi_\varepsilon \in \Gamma_\varepsilon(\mathcal{H}) \) at time \( s \) (to be fixed later):

\[
\mathcal{B}_\varepsilon(t, s) := \langle \Psi_\varepsilon | B_\varepsilon(t, s) | \Psi_\varepsilon \rangle_{\Gamma_\varepsilon(\mathcal{B})} = \langle e^{-iH_\varepsilon(t-s)} \Psi_\varepsilon | \mathcal{B} \otimes 1 e^{-iH_\varepsilon(t-s)} \Psi_\varepsilon \rangle_{\Gamma_\varepsilon(\mathcal{B})} \in \mathcal{B}(L^2(\mathbb{R}^3)).
\]

Our main goal is thus to prove that in the quasi-classical limit \( \varepsilon \to 0 \), \( \mathcal{B}_\varepsilon(t, s) \) converges to \( \mathcal{B}(t, s) \) in some topology (that turns out to be at most the strong operator topology), the latter being defined as

\[
\mathcal{B}(t, s) := \mathcal{U}_{\text{eff}}(t, s) \mathcal{B} \mathcal{U}_{\text{eff}}(t, s),
\]

where the two-parameter unitary group \( \mathcal{U}_{\text{eff}}(t, s) \) is defined in §1.2. In other words, the effective quasi-classical evolution of the particle is, whenever the field is in a suitable microscopic state described by \( \Psi_\varepsilon \), generated by the time-dependent point interaction Hamiltonian \( H_\beta(\cdot) \). The expression (1.16) does not hold true for any choice of the field state \( \Psi_\varepsilon \), but only for a restricted class of vectors; the relevant example on which we focus our attention is a time-dependent coherent state of the form

\[
\Xi_{\varepsilon,s} := W_\varepsilon \left( \frac{\alpha_\varepsilon(s)}{\varepsilon} \right) \Omega,
\]

where

\[
W_\varepsilon(\xi) = e^{i(\alpha(\xi) + a^\dagger(\xi))}
\]

is the Weyl operator and \( \Omega \) is the \( \varepsilon \)-independent coherent vector. Our proof takes advantage of the convenient coherent structure of \( \Xi_{\varepsilon,s} \). The function \( \alpha_\varepsilon \in \mathcal{H} \) is chosen of the following form:

\[
\alpha_\varepsilon(k;s) = c_\varepsilon \sigma_\varepsilon k \hat{W} (\sigma_\varepsilon k),
\]

where \( \hat{W} \in C^\infty_0(\mathbb{R}^3) \) is the potential already introduced before, that is resonant in the sense of Definition 1.5 and \( \hat{W} \) stands for its Fourier transform, \( c_\varepsilon \) is a \( \varepsilon \)-uniformly bounded constant

\[
c_\varepsilon = \beta \sigma_\varepsilon + o(\sigma_\varepsilon),
\]

The analysis can be easily extended to suitable unbounded observables, but we restrict the discussion to bounded operators for the sake of simplicity.
and $\sigma_\varepsilon > 0$ is such that
\[ \varepsilon^{1/6} \ll \sigma_\varepsilon \ll 1. \]  
(1.21)

We can now state our main result:

**Theorem 1.1 (Effective dynamics).**

Let $\mathcal{B}$ be a bounded operator on $L^2(\mathbb{R}^3)$. Let also $\mathcal{B}_\varepsilon(t, s)$ and $\mathcal{B}(t, s)$ be defined as in (1.15) and (1.16), respectively. If the field is in the coherent state (1.17) at time $s \in \mathbb{R}$, then, for any $t \in \mathbb{R}$,
\[ \mathcal{B}_\varepsilon(t, s) \xrightarrow[\varepsilon \to 0]{\mathcal{B}(t, s) = \mathcal{U}_{\text{eff}}^{\dagger}(t, s) \mathcal{B} \mathcal{U}_{\text{eff}}(t, s),} \]
where $\mathcal{U}_{\text{eff}}$ is the dynamics generated by $\mathcal{H}_{\beta(t)}$, with
\[ \beta(t) = 2\beta \cos(t - s). \]  
(1.23)

**Remark 1.2 (Initial state).**

The choice of the initial state $\Xi_{\varepsilon, s}$ is crucial for the derivation of the effective dynamics. Let us stress that $\Xi_{\varepsilon, s}$ depends on $\varepsilon$ through the phonon field (of order $\sqrt{\varepsilon}$), through the factor $\varepsilon^{-1}$ in the argument, and additionally through $\alpha_\varepsilon$. This latter $\varepsilon$-dependence, that is new compared to other situations in which coherent states are used to investigate quasi- and semi-classical limits (see, e.g., [He, GV2, GV1, GNV, RS, Fa2]), is chosen so that the effective potential becomes singular in the limit, due to the $\sigma$-scaling: in the language of semiclassical analysis, $\Xi_{\varepsilon, s}$ converges to an additive but not $\sigma$-additive cylindrical Wigner measure on the classical space of fields (see [Fa1, Fa5] for additional details on cylindrical Wigner measures).

**Remark 1.3 (Field dynamics).**

The effective dynamics $\mathcal{U}_{\text{eff}}$ of the particle is time-dependent in the quasi-classical regime, although the original microscopic dynamics $U_{\varepsilon}$ generated by $H_{\varepsilon}$ is time-independent. The reason is clearly the interaction particle-field, which produces an entanglement of any initial product state, and additionally through $\alpha_\varepsilon$. This latter $\varepsilon$-dependence, that is new compared to other situations in which coherent states are used to investigate quasi- and semi-classical limits (see, e.g., [He, GV2, GV1, GNV, RS, Fa2]), is chosen so that the effective potential becomes singular in the limit, due to the $\sigma$-scaling: in the language of semiclassical analysis, $\Xi_{\varepsilon, s}$ converges to an additive but not $\sigma$-additive cylindrical Wigner measure on the classical space of fields (see [Fa1, Fa5] for additional details on cylindrical Wigner measures).

**Remark 1.4 (Heisenberg evolution).**

The convergence proven in (1.22) implies by duality that the effective Schrödinger dynamics on states in $L^2(\mathbb{R}^3)$ is also given by the two-parameter unitary group $\mathcal{U}_{\text{eff}}(t, s)$: in the limit $\varepsilon \to 0$, a state $\psi \in L^2(\mathbb{R}^3)$ at time $s$ is mapped to $\mathcal{U}_{\text{eff}}(t, s)\psi$ at time $t$.

An important step in the proof of the main Theorem above is the approximation of the effective dynamics $\mathcal{U}_{\text{eff}}$ by the one generated by Schrödinger operators with rescaled smooth potentials. It is indeed very well known that a point interaction Hamiltonian can be obtained as the strong resolvent limit of a sequence of operators with rescaled smooth potentials: let $\mathcal{W} \in C^\infty_0(\mathbb{R}^3)$ and let $0 < \sigma \ll 1$; set
\[ \mathcal{W}_\sigma(x) := \frac{\nu(\sigma)}{\sigma^2} \mathcal{W}(x/\sigma), \]  
(1.25)
and
\[ \mathcal{K}_{\beta, \sigma} := -\Delta + \mathcal{W}_\sigma(x), \]  
(1.26)
which is obviously self-adjoint on $H^2(\mathbb{R}^3)$. In order to generate a point interaction, it is well-known that a zero-energy resonance must be present. Therefore, we formulate the following

**Definition 1.5 (Resonant potential).**

Let $\mathcal{W} \in C^\infty_0(\mathbb{R}^3)$. We say that $\mathcal{W}$ is resonant, if
\[ -1 \text{ is a simple eigenvalue of } \text{sgn}(\mathcal{W})|\mathcal{W}|^{1/2}(-\Delta)^{-1}|\mathcal{W}|^{1/2} \text{ with eigenvector } \phi \in L^2(\mathbb{R}^3); \]  

\[ \mathcal{K}_{\beta, \sigma} : \mathcal{W}_\sigma(x), \]  
(1.26)
The idea is to split the interval $[s,t]$ into smaller intervals and replace in each of them the evolved state still satisfies the boundary condition in (1.8) and therefore belongs to $\mathcal{H}_\beta$, $\nu(\sigma) = 1 + \beta\sigma + o(\sigma)$, for some $\beta \in \mathbb{R}$, then [AGH-KH] Thm. 1.2.5

\[ \mathcal{K}_{\beta,\sigma} \xrightarrow{\| \cdot \| - \text{res}, \sigma \to 0} \mathcal{H}_\beta, \]

where $\mathcal{H}_\beta$ is defined in (1.8) and $\| \cdot \| - \text{res}$ is short for norm resolvent convergence.

Obviously, by standard results (see, e.g., [Kar] Thm. 2.16), the one-parameter unitary group $e^{-it\mathcal{K}_{\beta,\sigma}}$ generated by $\mathcal{K}_{\beta,\sigma}$ strongly converges to $e^{i\beta\sigma t}$, when $\sigma \to 0$. Whether the same strong convergence holds true when $\beta$ depends on time, and therefore the propagator becomes a two-parameter unitary group, is not a consequence of some general result of operator theory: there are indeed adaptations of the aforementioned results to time-dependent operators [Sl, Yo], but they typically work only for bounded operators or in presence of a common core independent of time (which is not the case for $\mathcal{H}_{\beta(t)}$). In the Theorem below we fill this gap for time-dependent point interactions. We believe this result might be of interest on its own.

**Theorem 1.6** (Time-dependent point interaction dynamics).

Let $\beta(t) \in C^1(\mathbb{R})$ and $H_{\beta(t)}$ and $\mathcal{K}_{\beta(t),\sigma}$ be defined as in (1.8) and (1.26), respectively, with $\beta(t)$ in place of $\beta$. Let also $\mathcal{U}_{\text{eff}}(t,s)$ and $\mathcal{U}_\sigma(t,s)$, $t,s \in \mathbb{R}$, be the two-parameter unitary groups generated by $H_{\beta(t)}$ and $\mathcal{K}_{\beta,\sigma}$, then

\[ \mathcal{U}_\sigma(t,s) \xrightarrow{s \to 0} \mathcal{U}_{\text{eff}}(t,s). \]  

**Remark 1.7** (Many-center point interactions).

The result in **Theorem 1.6** is proven for a single time-dependent point interaction at the origin, but we expect that it is possible to extended it to point interactions with finitely many centers. The proof can indeed be adapted to take into account also the off-diagonal terms appearing in the time-evolution generated by a Schrödinger operator with many point interactions.

2. Approximation of the Effective Dynamics

The main goal of this Section is the proof of **Theorem 1.6**. We thus focus on the limiting dynamics described in § 1.2, as anticipated, the existence of such a dynamics was originally proven in [SY], although later other alternative approaches have been developed to deal with the same problem (see, e.g., [Po]). The key idea is to show that the ansatz (1.10) preserves the domain of the quadratic form associated to $\mathcal{H}_{\beta(t)}$, which is independent of $t$. Next, one has to prove that the evolved state still satisfies the boundary condition in (1.8) and therefore belongs to $\mathcal{D}(\mathcal{H}_{\beta(t)})$. This second step is easy to obtain if $\beta(t)$ is regular enough: by direct inspection of the Volterra integral equation (1.12), one can indeed prove that, if $\beta \in C^2_{\text{loc}}(\mathbb{R})$, then $q \in C^2_{\text{loc}}(\mathbb{R})$ as well [SY] Thm. 1], and it is also easy to verify that the boundary condition is satisfied. In the general case, the argument is more involved but still the existence of the dynamics, as a two-parameter unitary group, can be proven for any $\beta \in L^2_{\text{loc}}(\mathbb{R})$ [SY] Thm. 2].

An important intermediate step towards **Theorem 1.6** is the approximation of the time-dependent dynamics generated by $\mathcal{H}_{\beta(t)}$ in terms of a product of time-independent ones, in the spirit of [Yo] Thm. 1, p. 432). The idea is to split the interval $[s,t]$ into smaller intervals and replace in each of them the propagator of $\mathcal{H}_{\beta(t)}$ with the one associated to $\mathcal{H}_{\beta_s}$, $\beta_s$ begin the step function approximation of $\beta(t)$. The proof is then divided into three parts:

- first, we show that the dynamics generated by $\mathcal{H}_{\beta_s}$ strongly converges to $\mathcal{U}_{\text{eff}}$ (Lemma 2.1);
Let Lemma 2.1.
The idea is to prove the result for a dense subset of initial states
Proof.

All the results are then collected at the end of the Section to complete the proof of Theorem 1.6.
Let us then fix the interval \([s, t]\), with \(s, t \in \mathbb{R}\), \(s < t\), and divide it into \(n \in \mathbb{N}\) smaller intervals
\[
I_j := [t_j, t_{j+1}) , \quad t_j := s + \frac{j(t - s)}{n} ,
\]
with \(j = 0, \ldots, n - 1\). Next, we define \(\beta_s(t) \in L^\infty(\mathbb{R})\) as the step function
\[
\beta_s(t) := \beta(t_j) , \quad \text{for } t \in I_j .
\]

Thanks to [SY] Thm. 2 already mentioned above, the dynamics \(\mathcal{V}_n(t, s)\) generated by \(\mathcal{H}_{\beta_s}\) exists as a two-parameter unitary group and, if the initial state \(\psi_s\) at time \(s\) belongs to \(H^2(\mathbb{R}^3 \setminus \{0\})\), it can be represented as in (1.10), i.e.,
\[
(\mathcal{V}_n(t, s)\psi_s)(\mathbf{x}) = (U_0(t - s)\psi_s)(\mathbf{x}) + i \int_s^t d\tau U_0(t - \tau; \mathbf{x})q_n(\tau) , \quad (2.3)
\]
where the charge \(q_n\) now solves the Volterra equation
\[
q_n(t) + 4\sqrt{\pi i} \int_s^t d\tau \frac{1}{\sqrt{t - \tau}} (U_0(\tau - s)\psi_s)(0) = 4\sqrt{\pi i} \int_s^t d\tau \frac{1}{\sqrt{t - \tau}} (U_0(\tau - s)\psi_s)(0) . \quad (2.4)
\]
Note that \(\mathcal{V}_n(t, s)\) can be equivalently represented as
\[
\mathcal{V}_n(t, s) = e^{-i\mathcal{H}_{\beta_n}(t-t_{n-1})} e^{-i\mathcal{H}_{\beta_{n-1}}(t_{n-1}-t_{n-2})} \cdots e^{-i\mathcal{H}_0(t_1-s)} . \quad (2.5)
\]

**Lemma 2.1.**
Let \(\beta(t) \in C^1(\mathbb{R})\), then, for any \(s, t \in \mathbb{R}\),
\[
\mathcal{V}_n(t, s) \xrightarrow{n \to +\infty} \mathcal{U}_{\text{eff}}(t, s) . \quad (2.6)
\]

**Proof.** The idea is to prove the result for a dense subset of initial states \(\psi_s\) and then extend it to the rest of the Hilbert space by density. Let us thus assume that \(\psi_s \in C^0_c(\mathbb{R}^3 \setminus \{0\})\), in which case the representation (2.3) holds true with \(q_n \in L^\infty_{\text{loc}}(\mathbb{R})\) solving (2.4), as proven in [SY].

By bootstrap it is however easy to see that, if \(q_n \in L^\infty_{\text{loc}}(\mathbb{R})\), then also \(q_n \in W^{1,1}_{\text{loc}}(\mathbb{R})\): thanks to the properties of the Abel 1/2-operator, one has
\[
\frac{d}{dt} \int_s^t d\tau \frac{1}{\sqrt{t - \tau}} (U_0(\tau - s)\psi_s)(0) = \int_s^t d\tau \frac{1}{\sqrt{t - \tau}} \frac{d}{d\tau} (U_0(\tau - s)\psi_s)(0) ,
\]
and
\[
\left| \frac{d}{d\tau} (U_0(\tau - s)\psi_s)(0) \right| = \frac{1}{(2\pi)^{3/2}} \left| \int_{\mathbb{R}^3} dk k^2 e^{-ik^2(\tau-s)} \hat{\psi}_s(k) \right| \leq C \int_{\mathbb{R}^3} dk k^2 \left| \hat{\psi}_s(k) \right| \leq C ,
\]
so that the forcing term on the r.h.s. of (2.4) is in \(W^{1,1}_{\text{loc}}(\mathbb{R})\), as the second term on the l.h.s. of the same equation does. Clearly, this implies that the charge \(q_n\) itself enjoys the same regularity. In fact, the same result can be easily obtained from the general theory of Volterra integral equations [Mi].

Using (1.10) and (2.3), we thus get
\[
\|(\mathcal{U}_{\text{eff}}(t, s) - \mathcal{V}_n(t, s))\psi_s\|_2 \leq C \sup_{\tau \in [s, t]} |q(\tau) - q_n(\tau)| , \quad (2.7)
\]
and therefore the strong convergence of the propagators follows from the uniform convergence of the charges, for \(\psi_s \in C^0_c(\mathbb{R}^3 \setminus \{0\})\). Since we are on a finite interval, the latter one is equivalent
to pointwise convergence of $q_n$ to $q$, as $n \to +\infty$, and this is what we are going to prove: taking the difference between the equations (1.12) and (2.4) and setting $\chi_n := q - q_n$ for short, we obtain

$$
\chi_n(t) = 4\sqrt{\pi} \int_s^t ds \frac{\beta_s(\tau)q_n(\tau) - \beta(\tau)q(\tau)}{\sqrt{t - \tau}}.
$$

It follows that $\chi_n \in C_{loc}(\mathbb{R})$ (recall that both $q$ and $q_n$ belong to $W^{1,1}_{loc}(\mathbb{R})$) is a solution of the Volterra equation

$$
\chi_n(t) + 4\sqrt{\pi} \int_s^t ds \frac{\beta_s(\tau)\chi_n(\tau)}{\sqrt{t - \tau}} = F_n(t).
$$

Furthermore,

$$
F_n(t) \xrightarrow{n \to +\infty} 0,
$$

pointwise, since

$$
|F_n(t)| \leq C \sup_{\tau \in [s,t]} |q_n(\tau)| \int_s^t ds \frac{\beta_s(\tau) - \beta(\tau)}{\sqrt{t - \tau}} \xrightarrow{n \to +\infty} 0,
$$

because

$$
\beta_s \xrightarrow{L^p_{n \to +\infty}} \beta, \quad \text{for any } 1 \leq p < +\infty,
$$

and $q_n$ is uniformly bounded. Hence, it just remains to observe that the l.h.s. of (2.8) is invertible for $t$ small enough, since

$$
\left| \int_s^t ds \frac{\beta(\tau)\chi_n(\tau)}{\sqrt{t - \tau}} \right| \leq C \sup_{\tau \in [s,t]} |\chi_n(\tau)| \sqrt{t - s} \xrightarrow{s \to t} 0,
$$

which implies that the l.h.s. of (2.8) can be rewritten as $(I + J)q$, with $J : C_{loc}(\mathbb{R}) \to C_{loc}(\mathbb{R})$ and such that $\|J\|_{C \to C} < 1$, if $t - s$ is small enough. Hence, we get $\chi_n = (I + J)^{-1}F_n$, with $F_n \to 0$ and $(I + J)^{-1}$ bounded from $C_{loc}(\mathbb{R})$ to $C_{loc}(\mathbb{R})$. We conclude that $\chi_n \to 0$ in $C_{loc}(\mathbb{R})$, if $t - s$ is small enough.

The argument above guarantees that $\chi_n \to 0$ in an interval $[s,t_1]$, where $t_1$ is independent of $n$ and determined only by the condition that the r.h.s. of (2.11) is strictly smaller than $\|\chi_n\|_{\infty}$. As such, $t_1$ depends only on $s$ and $\|\beta\|_{\infty}$. Hence it is not difficult to see that, picking $n$ large enough and exploiting the convergence to 0 of $\chi_n$ in $[s,t_1]$, it is possible to reproduce the argument in the interval $[s,2t_1]$. A bootstrap then gives pointwise convergence to 0 of $\chi_n$ in any finite interval $[s,t]$. In the last bootstrap, it is crucial that the considered interval is relatively compact.

By pointwise and thus uniform convergence of $q_n$ to $q$ and (2.7), we conclude that, if $\psi_n \in C_0^\infty(\mathbb{R}^3 \setminus \{0\})$, then

$$
\| (\mathcal{U}_{eff}(t,s) - \mathcal{V}_n(t,s) ) \psi_n \| \xrightarrow{n \to +\infty} 0.
$$

Strong convergence is then consequence of density of $C_0^\infty$ in $L^2(\mathbb{R}^3)$. \hfill $\Box$

We recall that for any $\beta \in \mathbb{R}$, the family of operators $\mathcal{K}_{\beta,s}$ defined in (1.26) and given by

$$
\mathcal{K}_{\beta,s} = -\Delta + \mathcal{W}_s(\cdot), \quad \text{where } -\Delta + \mathcal{W} \text{ is assumed to have a zero-energy resonance, } \mathcal{W}_s(\cdot) = \nu(\cdot)\sigma^2 \mathcal{W}(\cdot), \quad \text{and } \nu(\cdot) = 1 + \sigma + o(\cdot),
$$

converges in norm resolvent sense to $\mathcal{K}_{\beta}$ as $\sigma \to 0$ [AGH-KH Thm. 1.2.5]. A by-product of this result is the strong convergence of the corresponding unitary operators obtained by the piecewise approximations of $\beta(t)$.

Before stating such a result, we have however to formulate a technical lemma concerning the approximation of functions evolved with $e^{-it\mathcal{K}_{\beta,t}}$: it is indeed obvious from the charge equation (1.12) or its approximation (2.4) that if the initial datum $\psi$ at $t = 0$ is a smooth function vanishing at the origin, then it immediately develops a singular part proportional to the charge $q(t)$ solving such equations. In other words, even though $q(0) = 0$, at later times this is not typically the case. However, for small times, such a singular part is $L^2$-small and therefore one can approximate the evolution of $\psi$ with an $H^2$-function vanishing at 0 with a small error.
Lemma 2.2.
Let \( \chi \in H^2(\mathbb{R}^3) \), such that \( \chi(0) = 0 \) and \( \|\chi\|_2 = 1 \). Let also \( \beta \in \mathbb{R} \) and \( t \geq 0 \). Then, there exists \( t_0 > 0 \) and a family of functions \( \chi_m \in H^2(\mathbb{R}^3) \), \( m \in \mathbb{N} \), vanishing at 0, such that \( \|\chi_m\|_2 \leq \|\chi\|_2 \) and, if \( t < t_0 \),
\[
\left\| e^{-i\beta t} \chi - \chi_m \right\|_2 \leq C \left( m^{-3/5} + m^{-1/5}t^{1/2} \right) . \tag{2.12}
\]

Proof. The first simple observation is that, by direct inspection of the charge equation (1.12), for any initial datum vanishing at the origin, we get
\[
\left( 1 - C\sqrt{t} \right) \sup_{\tau \in [0,t]} |q(\tau)| \leq C' \sqrt{t}, \tag{2.13}
\]
where we have simply bounded
\[
|U_0(\tau)| \leq \|U_0(\tau)\|_{L^\infty(\mathbb{R}^3)} \leq C \|\chi\|_{H^2(\mathbb{R}^3)} \leq C,
\]
on the r.h.s. of (1.12). Hence, we can find \( t_0 > 0 \) such that the prefactor on the l.h.s. of (2.13) is, e.g., larger than 1/2, which allows to deduce that, for any \( t \leq t_0 \),
\[
\sup_{\tau \in [0,t]} |q(\tau)| \leq C \sqrt{t}. \tag{2.14}
\]

Set now for \( m \in \mathbb{N}_0 \)
\[
\chi_m(x) := e^{-\frac{1}{m^2}} \left( e^{-i\beta t} \chi \right) (x). \tag{2.15}
\]
We claim that such a sequence satisfies (2.12). By the characterization of the operator domain, we know that \( \chi \in \mathcal{D}(\mathcal{H}_\beta) \) and the same holds true at time \( t \), i.e.,
\[
\left( e^{-i\beta t} \chi \right)(x) = \phi(x) + \frac{q(t)e^{-x}}{4\pi x}, \tag{2.16}
\]
where \( q(t) \) is a solution of (1.12), \( \phi \in H^2(\mathbb{R}^3) \) and we have used a slightly different domain decomposition than the one given in (1.8): starting from the domain given there, one simply recovers the expression above adding and subtracting \( \frac{q(t)e^{-x}}{4\pi x} \) and observing that \( e^{-x} \in L^2(\mathbb{R}^3) \). Hence,
\[
\left\| e^{-i\beta t} \chi - \chi_m \right\|_2^2 = \int_{\mathbb{R}^3} dx \left( 1 - e^{-\frac{1}{m^2}} \right)^2 \left| \phi(x) + \frac{q(t)e^{-x}}{4\pi x} \right|^2 \\
+ \int_{\mathbb{R}^3} dx \left( 1 - e^{-\frac{1}{m^2}} \right)^2 \left| \phi(x) + \frac{q(t)e^{-x}}{4\pi x} \right|^2 \tag{2.17}
\]
where \( R > 0 \) is a parameter to be chosen later.

Next, we estimate
\[
\int_{\mathbb{R}^3} dx \left( 1 - e^{-\frac{1}{m^2}} \right)^2 \left| \phi(x) + \frac{q(t)e^{-x}}{4\pi x} \right|^2 \leq C m^{-3} \int_{\mathbb{R}^3} \frac{dx}{m^2 R} \left[ |\phi(x)|^2 + \frac{m^2 |q(t)|^2}{x^2} \right] \\
\leq C \left( R^3 + R t \right), \tag{2.18}
\]
by (2.13) and the fact that \( \phi \in H^2(\mathbb{R}^3) \) and thus \( \phi \in L^\infty(\mathbb{R}^3) \). On the other hand,
\[
\int_{\mathbb{R}^3} dx \left( 1 - e^{-\frac{1}{m^2}} \right)^2 \left| \phi(x) + \frac{q(t)e^{-x}}{4\pi x} \right|^2 \leq \frac{C}{m^2} \int_{\mathbb{R}^3} \frac{dx}{x^2} \left[ |\phi(x)|^2 + \frac{|q(t)|^2}{x^2} \right] \\
\leq C m^{-2} \left( R^{-2} + R^{-1} t \right). \tag{2.19}
\]

Altogether the above estimates yield
\[
\left\| e^{-i\beta t} \chi - \chi_m \right\|_2^2 \leq C \left( R^3 + R t + m^{-2} R^{-2} + m^{-2} R^{-1} t \right) \leq C \left( m^{-6/5} + m^{-2/5} t \right) \tag{2.20}
\]
after an optimization over \( R \). \( \square \)
Before discussing the convergence of $\mathcal{V}_{n,\sigma}$ to $\mathcal{V}_n$, we need one more technical result: we are going to show that a strong estimate over a dense set of the difference between the unitary evolutions generated by $\mathcal{H}_\beta$ and $\mathcal{X}_{\beta,\sigma}$ is sufficient to control the difference between the unitaries $\mathcal{V}_n(t,s)$ and $\mathcal{V}_{n,\sigma}(t,s)$ in weak sense.

**Lemma 2.3.**

Let $t_0 = s, t_1, \ldots, t_n = t$ be a partition of the bounded interval $[s,t]$ as in (2.1). Let $\phi, \psi \in H^2(\mathbb{R}^3)$, with $\|\phi\|_2 \leq 1$, $\|\psi\|_2 \leq 1$ and $\phi(0) = \psi(0) = 0$. Assume that for any such $\psi$ and $\tau$ of order $1/n$ there exists $\delta$ finite such that

$$\left\| \left( e^{-i\mathcal{H}_\beta \tau} - e^{-i\mathcal{X}_{\beta,\sigma} \tau} \right) \psi \right\|_2 \leq \delta, \quad (2.21)$$

then,

$$|\langle \phi | (\mathcal{V}_n(t,s) - \mathcal{V}_{n,\sigma}(t,s)) \psi \rangle | \leq \delta n + O(n^{-1}). \quad (2.22)$$

**Remark 2.4** (Dependence of the dense set).

The wave functions $\phi$ and $\psi$ in the above Lemma are chosen to vary in a dense set in $L^2(\mathbb{R}^3)$ and the a priori estimate (2.21) might fail outside such a set, i.e., we allow for $\delta$ to diverge as $\psi$ leaves the dense domain. This is however harmless in the rest of the proof (see in particular the proof of Theorem 1.6) since the convergence of unitary operators can always be tested on a dense subset.

**Proof.** The result is proved by recursion on the quantity

$$|\langle \phi | (\mathcal{V}_n(t,s) - \mathcal{V}_{n,\sigma}(t,s)) \psi \rangle |,$$

with $t \in [t_j, t_{j+1}]$ and $j = 0, 1, \ldots, n - 1$. For $j = 0$, we have $t \in [s, t_1]$, and therefore

$$|\langle \phi | (\mathcal{V}_n(t,s) - \mathcal{V}_{n,\sigma}(t,s)) \psi \rangle | \leq \left\| \left( e^{-i\mathcal{H}_\beta (t-s)} - e^{-i\mathcal{X}_{\beta,\sigma} (t-s)} \right) \psi \right\|_2 \leq \delta.$$ 

Let us now consider $t \in [t_j, t_{j+1}]:$

$$|\langle \phi | (\mathcal{V}_n(t,s) - \mathcal{V}_{n,\sigma}(t,s)) \psi \rangle | \leq \left\| \left( e^{-i\mathcal{H}_\beta (t-t_j)} - e^{-i\mathcal{X}_{\beta,\sigma} (t-t_j)} \right) \mathcal{V}_{n,\sigma}(t_j, s) \psi \right\|_2 + \left\| e^{i\mathcal{H}_\beta (t-t_j)} \mathcal{V}_{n,\sigma}(t_j, s) \psi \right\|_2 \leq \delta + \left\| e^{i\mathcal{H}_\beta (t-t_j)} \mathcal{V}_{n,\sigma}(t_j, s) \psi \right\|_2.$$ 

Now, we can apply Lemma 2.2 setting $\chi = e^{2i\mathcal{H}_\beta (t-t_j)} \phi$, and we get a sequence of functions $\chi_m \in H^2(\mathbb{R}^3)$ vanishing at 0 such that $\|\chi_m\|_2 \leq \|\phi\|_2 \leq 1$ and

$$e^{-i\mathcal{X}_{\beta,\sigma} (t-t_j)} \chi - \chi_m = e^{2i\mathcal{H}_\beta (t-t_j)} \phi - \chi_m = O(m^{-3/5} + m^{-1/5} n^{-1/2}),$$

for any $m \in \mathbb{N}_0$, since $t - t_j = O(n^{-1})$. In particular, if we take, e.g., $m > n^{15/2}$, we deduce that

$$e^{2i\mathcal{H}_\beta (t-t_j)} \phi - \chi_m = O(n^{-2}). \quad (2.24)$$

Hence, using the above approximation in the second term of (2.23), we get

$$\left\| e^{i\mathcal{H}_\beta (t-t_j)} \phi \left( \mathcal{V}_n(t_j, s) - \mathcal{V}_{n,\sigma}(t_j, s) \right) \psi \right\| \leq \| \chi_m \left( \mathcal{V}_n(t_j, s) - \mathcal{V}_{n,\sigma}(t_j, s) \right) \psi \| + O(n^{-2}) \quad (2.25)$$

so that

$$|\langle \phi | (\mathcal{V}_n(t,s) - \mathcal{V}_{n,\sigma}(t,s)) \psi \rangle | \leq | \langle \chi_m | (\mathcal{V}_n(t_j, s) - \mathcal{V}_{n,\sigma}(t_j, s)) \psi \rangle | + \delta + O(n^{-2}).$$

Now, $| \langle \chi_m | (\mathcal{V}_n(t_j, s) - \mathcal{V}_{n,\sigma}(t_j, s)) \psi \rangle |$ belongs to the $j$-th step of the recursion, and therefore

$$|\langle \phi | (\mathcal{V}_n(t,s) - \mathcal{V}_{n,\sigma}(t,s)) \psi \rangle | \leq (j+1)\delta + O(n^{-2}).$$

Since the last iteration in the recursion is given by $j = n - 1$, the desired bound is proved. \qed

The technical results proven in Lemmas 2.2 and 2.3 are used to prove the convergence of $\mathcal{V}_{n,\sigma}(t,s)$ to $\mathcal{V}_n(t,s)$, which in turn is going to play a key role in the proof of Theorem 1.6.
Lemma 2.5.
For any finite \( t, s \in \mathbb{R} \) and for any \( \psi, \phi \in H^2(\mathbb{R}^3) \), with \( \psi(0) = \phi(0) = 0 \) and \( \| \phi \|_2 = \| \psi \|_2 = 1 \), as \( \sigma \to 0 \), with \( \sigma n \leq 1 \),
\[
|\langle \phi, (V_{n,\sigma}(t,s) - V_n(t,s)) \psi \rangle| = O(n^5 \sigma^2) + n^{-1} o_\sigma(1) + o_n(1).
\]

Proof. The idea is to use Lemma 2.3 and thus focus on estimating the quantity
\[
\| [e^{-i\xi_\beta t} - e^{-i\xi_{\sigma,\beta} t}] \psi \|_2
\]
(2.27)
for any \( \psi \in H^2(\mathbb{R}^3) \) such that \( \psi(0) = 0, \beta \in \mathbb{R} \) and
\[
t \sim \frac{1}{n}.
\]

Note that, by the assumptions on \( \psi \), we also have
\[
\psi \in \mathcal{D}(\mathcal{H}_\beta) \cap \mathcal{D}(\mathcal{K}_{\sigma,\beta}),
\]
(2.29)
which is going to be important later.

The starting point is the representation formula \([\mathcal{P}_3, \text{Thm. 8.3, Ch. 1}]\) for a unitary group \( e^{-itA} \) generated by a self-adjoint operator \( A \): for any \( \psi \in L^2(\mathbb{R}^3) \), one has uniformly with respect to \( t \) on bounded intervals the following convergence in norm:
\[
e^{-itA} \psi = \lim_{k \to +\infty} \left( 1 + \frac{itA}{k} \right)^{-k} \psi = \lim_{k \to +\infty} \left( \frac{k}{it} \right)^k \left( A - \frac{ik}{t} \right)^{-k} \psi.
\]
(2.30)
Since the vector \( \psi \) we are considering satisfies (2.29), it is possible to write a more explicit bound on the error:
\[
e^{-it\xi_\beta} - \left( \frac{k}{it} \right)^k \left( \mathcal{H}_\beta - \frac{ik}{t} \right)^{-k} \psi = -i \int_0^t \left( e^{-it\xi_\beta} - \left( 1 + \frac{it}{k} \mathcal{H}_\beta \right)^{-k} \right) \mathcal{H}_\beta \psi \, d\tau
\]
(2.31)
where \( o_k(1) \in L^2(\mathbb{R}^3) \) converges to zero as \( k \to \infty \) uniformly with respect to \( t \) and \( \beta \) on bounded intervals. An analogous uniform estimate holds for \( \mathcal{K}_{\sigma,\beta} \), therefore we deduce that
\[
\| [e^{-i\xi_\beta t} - e^{-i\xi_{\sigma,\beta} t}] \psi \|_2 = \left( \frac{k}{|t|} \right)^k \sup_{\chi \in L^2(\mathbb{R}^3), \| \chi \|_2 \leq 1} \| \chi \left( \mathcal{H}_\beta - \frac{ik}{t} \right)^{-k} - \left( \mathcal{K}_{\sigma,\beta} - \frac{ik}{t} \right)^{-k} \psi \|_2 + |t| o_k(1).
\]
(2.32)
Now we claim that, given two self-adjoint operators \( A \) and \( B \), \( z \in \rho(A) \cap \rho(B) \) and \( k \in \mathbb{N} \), if there exists some \( \delta_z < +\infty \) such that, for any \( \phi, \psi \in L^2(\mathbb{R}^3) \), such that \( \| \psi \|_2 \leq 1, \| \phi \|_2 \leq 1 \),
\[
\| \phi \left( (A-z)^{-k} - (B-z)^{-k} \right) \psi \|_2 \leq \delta_z \| \phi \|_2 \| \psi \|_2,
\]
(2.33)
then
\[
\| \phi \left( (A-z)^{-k} - (B-z)^{-k} \right) \psi \|_2 \leq \frac{k \delta_z}{|\Im(z)|^{k-1}}.
\]
(2.34)
The result can be proven by induction writing
\[
(A-z)^{-k} - (B-z)^{-k} = ((A-z)^{-1} - (B-z)^{-1}) (A-z)^{-k+1}
\]
\[+ (B-z)^{-1} ((A-z)^{-k+1} - (B-z)^{-k+1}),
\]
and using the inequalities
\[
\| (A-z)^{-1} \| \leq \frac{1}{|\Im(z)|}, \quad \| (B-z)^{-1} \| \leq \frac{1}{|\Im(z)|}.
\]
in the consequent estimate
\[
\left| \left\langle \phi \left[ (A - z)^{-k} - (B - z)^{-k} \right] \psi \right\rangle \right|_2 \leq \left| \left\langle \phi \left[ (A - z)^{-k+1} - (B - z)^{-k+1} \right] \psi \right\rangle \right|_2
\]
\[
+ \left| \left\langle (B - z^*)^{-1} \phi \left[ (A - z)^{-k+1} - (B - z)^{-k+1} \right] \psi \right\rangle \right|_2
\]
\[
\leq \frac{\delta}{|\text{Im}(z)|^{k-1}} + \left| \left\langle (B - z^*)^{-1} \phi \left[ (A - z)^{-k+1} - (B - z)^{-k+1} \right] \psi \right\rangle \right|_2,
\]
which leads to (2.34) by the induction hypothesis.

Therefore, using (2.34) in (2.32), we get (keeping in mind that \( \psi \) has norm one)
\[
\left\| e^{-iH_{\beta}t} - e^{-iK_{\beta,t}} \psi \right\|_2 \leq k^2 \delta_{n,k,\sigma} + |t|o(1),
\]
where \( \delta_{n,k,\sigma} \) is that, for any normalized \( \phi, \psi \in L^2(\mathbb{R}^3) \),
\[
\left| \left\langle \phi \left( (H_{\beta} - \frac{ik}{t})^{-1} - (K_{\beta,\sigma} - \frac{ik}{t})^{-1} \right) \psi \right\rangle \right|_2 \leq \delta_{n,k,\sigma}.
\]

Notice that we already know that such a \( \delta_{n,k,\sigma} \) does exist thanks to the norm resolvent convergence of \( K_{\beta,\sigma} \) to \( H_{\beta} \) stated in [AGH-KH] Thm. 1.2.5 and, more precisely, \( \delta_{n,k,\sigma} \to 0 \), as \( \sigma \to 0 \), for fixed \( n, k \in \mathbb{N} \). However, we are going to estimate the dependence of \( \delta_{n,k,\sigma} \) on the parameters \( n, k, \) and \( \sigma \), showing that
\[
\delta_{n,k,\sigma} = O \left( \sigma^3 \sqrt{n}k + n^{-3/2}k^{-3/2}o(1) \right).
\]

In fact, the result is proven by simply tracking down in [AGH-KH] Proof of Thm. 1.2.5 the dependence of the remainders on the spectral parameter. With the same notation as in [AGH-KH], we have (recall the definition (1.27) of \( \nu(\sigma) \))
\[
(H_{\beta} + \lambda_n)^{-1} - (-\Delta + \lambda_n)^{-1} = -\frac{1}{\beta + \sqrt{\sigma n}} \langle G_{\lambda_n} \rangle \langle G_{\lambda_n} \rangle,
\]
\[
(K_{\beta,\sigma} + \lambda_n)^{-1} - (-\Delta + \lambda_n)^{-1} = -\nu(\sigma) A_{\sigma,n} (1 + B_{\sigma,n})^{-1} C_{\sigma,n},
\]
where the operators \( A_{\sigma,n}, B_{\sigma,n} \) and \( C_{\sigma,n} \) are defined in (2.42) below, we have set for short
\[
\lambda_n := -\frac{ik}{t},
\]
\[
G_{\lambda}(x) := (-\Delta + \lambda)^{-1}(x) \text{ is the Green function of the Laplacian, } v = \sqrt{|W|}, u = \text{sgn}(W)\sqrt{|W|}
\]
and \( \phi_0 \) is the \( L^2 \) solution of the zero-energy equation
\[
u(-\Delta)^{-1}v\phi_0 = -\phi_0
\]
which is known to exist and being non-trivial thanks to the resonance condition, which also ensures that \( \langle v | \phi_0 \rangle \neq 0 \). Note that, since \( \lambda_n \) is purely imaginary ad its modulus diverges as \( n, k \to +\infty \), the Green function \( G_{\lambda_n} \) belongs to \( L^2(\mathbb{R}^3) \) uniformly in \( n \) and \( k \). The operators \( A_{\sigma,n}, B_{\sigma,n} \) and \( C_{\sigma,n} \) are integral operators whose kernels are given by (see also [AGH-KH] Defs. (1.2.12) – (1.2.14))
\[
A_{\sigma,n}(x, x') := G_{\lambda_n}(x - \sigma x')v(x'),
\]
\[
B_{\sigma,n}(x, x') := \nu(\sigma)u(x)G_{\lambda_n}(x - x')v(x'),
\]
\[
C_{\sigma,n}(x, x') := u(x)G_{\lambda_n}(\bar{x} - x').
\]
At fixed \( n \) and \( k \) it is not difficult to see [AGH-KH] Lemma 1.2.2 that
\[
A_{\sigma,n} \to A_n := |G_{\lambda_n} \rangle \langle v |,
\]
\[
B_{\sigma,n} \to B := u(-\Delta)^{-1}v,
\]
\[
C_{\sigma,n} \to C_n := |u \rangle \langle G_{\lambda_n} |,
\]
where \( u \) and \( v \) are meant as the multiplication operators by \( u \) and \( v \), respectively. The convergences above can be proven in Hilbert-Schmidt norm. Note that the operator \( B \) is independent of \( n \) and \( k \).

In order to estimate the difference between the resolvent we use (2.38) and (2.39) to write
\[
\left\langle \phi \left| (\mathcal{H}_\beta + \lambda_n)^{-1} - (\mathcal{H}_\beta + \lambda_n^*)^{-1} \right| \psi \right\rangle_2 = -\sigma \nu(\sigma) \left\langle \phi \left| (A_{\sigma,n} - A) (1 + B_{\sigma,n})^{-1} C_{\sigma,n} \psi \right\rangle_2 \right.
\]
\[
- \sigma \nu(\sigma) \left\langle \psi \left| A_n (1 + B_{\sigma,n})^{-1} (C_{\sigma,n} - C_n) \psi \right\rangle_2 \right.
\]
\[
- \left\langle \phi \left| \sigma \nu(\sigma) A_n (1 + B_{\sigma,n})^{-1} C_n - \frac{1}{\beta + \sqrt{\lambda_n}} |G_{\lambda_n}| \right| \psi \right\rangle_2 \right] .
\] (3)

Note that the quantity \( \beta + \sqrt{\lambda_n} \) is invertible because
\[
\text{Im} \left( \beta + \sqrt{\lambda_n} \right) = \frac{1}{\pi} k \text{Im} \left( \sqrt{i} \right) \neq 0,
\]
for any \( k, n \). Terms (1) and (2) above are the easiest to bound and can in fact bounded in the very same way: since however the bound requires an estimate of the norm of \( B_{\sigma,n} \), which is also involved in term (3), we start from this last one. By (2.45) and (2.46),
\[
\left\langle \phi \left| A_n (1 + B_{\sigma,n})^{-1} C_n - \frac{1}{\beta + \sqrt{\lambda_n}} |G_{\lambda_n}| \right| \psi \right\rangle_2 \right.
\]
\[
= \left\langle \phi \left| G_{\lambda_n} \right| \psi \right\rangle_2 \left\langle v \left| (1 + B_{\sigma,n})^{-1} \right| u \right\rangle_2 - \frac{1}{\beta + \sqrt{\lambda_n}} \right.
\]
\[
\quad \leq \frac{C}{\sqrt{|\lambda_n|}} \| \phi \|_2 \| \psi \|_2 \left\langle v \left| (1 + B_{\sigma,n})^{-1} \right| u \right\rangle_2 - \frac{1}{\beta + \sqrt{\lambda_n}} \right],
\] (2.48)
where however we have to require that
\[ \sigma \sqrt{|\lambda_n|} = C \sigma \sqrt{kn} \ll 1. \] (2.52)
to ensure that all the remainders tend to 0. Note that the above convergence in particular implies that
\[ \nu(\sigma) \left\| (1 + B_{\sigma,n})^{-1} \right\| \leq \frac{C}{\sqrt{|\lambda_n|}} \leq \frac{C}{\sqrt{kn}}. \] (2.53)

The final estimate of (3) is thus
\[ \|(3)\| = O \left( \sigma^2 |\lambda_n|^{1/2} \right) + o(\sigma). \] (2.54)

Let us now consider the terms (1) and (2) and, since the argument is the same, let us focus on (1). A direct inspection of [AGH-KH, Lemma 1.2.2] reveals that the Hilbert-Schmidt convergence of \( A_{\sigma,n} \) to \( A_n \) is in fact uniform in \( n \) and \( k \). More precisely, the dependence on \( \lambda_n \) can be easily scaled out: by setting \( y = \sqrt{|\lambda_n|} x \) and \( y' = \sqrt{|\lambda_n|} x' \), one has
\[
|\lambda_n|^{-3/4} [(A_{\sigma,n} - A)\psi] (|\lambda_n|^{-1/2} y) = |\lambda_n|^{-1} \int_{\mathbb{R}^3} dy' \left[ G_i(y) - G_i(y - \sigma y') \right] v(|\lambda_n|^{-1/2} y') \tilde{\psi}(y') =: |\lambda_n|^{-1} \left( D_{\sigma,n} \tilde{\psi} \right)(y),
\] (2.55)
where we have set
\[ \tilde{\psi}(y) = |\lambda_n|^{-3/4} \psi(|\lambda_n|^{-1/2} y), \]
so that the \( L^2 \) norms of the function is preserved. Exploiting then the smoothness and boundedness of \( v \), one can apply the argument of [AGH-KH, Proof of Lemma 1.2.2] to show that
\[ \lim_{\sigma \to 0} \|D_{\sigma,n}\| = 0, \quad \text{uniformly in } n \in \mathbb{N}. \] (2.56)
Moreover, by the very same scaling argument, one can also easily show that
\[ \|A_{\sigma,n}\| \leq \frac{C}{|\lambda_n|}, \quad \|C_{\sigma,n}\| \leq \frac{C}{|\lambda_n|}. \] (2.57)

Therefore, using (2.53) and the above estimates, we obtain
\[ \|(1)\| = k^{-5/2} n^{-5/2} o_{\sigma}(1), \] (2.58)
which combined with (2.54) yields (2.37).

Hence, (2.28) becomes
\[ \left\| e^{-i\mathcal{K}_{\beta,t} t} - e^{-i\mathcal{K}_{\sigma,t} t} \right\|_2 \leq C \left( k^{5/2} n^{3/2} \sigma^3 + k^{-1/2} n^{-3/2} o_{\sigma}(1) \right) + |t| o_k(1). \]

If we finally choose \( k = n \) for simplicity, we deduce
\[ \left\| e^{-i\mathcal{K}_{\beta,t} n} - e^{-i\mathcal{K}_{\sigma,t} n} \right\|_2 \leq C n^4 \sigma^2 + n^{-2} o_{\sigma}(1) + |t| o_n(1), \]
and plugging this in (2.22), we get for any \( \phi, \psi \in H^2(\mathbb{R}^3) \) vanishing at the origin and normalized,
\[ \left| (\phi \big| (\nabla_n(t, s) - \nabla_{n,\sigma}(t, s)) \psi) \right| \leq C n^5 \sigma^2 + n^{-1} o_{\sigma}(1) + o_n(1). \]

Finally, we address the approximation à la Yoshida for the group generated by the approximant operators \( \mathcal{K}_{\beta,\sigma}(t) \). We thus define the unitary operator \( \nabla_{n,\sigma}(t, s) \) analogously to (2.5), with \( \mathcal{K}_{\beta,\sigma} \) in place of \( \mathcal{K}_{\beta} \), i.e., for any \( s, t \in \mathbb{R} \),
\[ \nabla_{n,\sigma}(t, s) := e^{-i\mathcal{K}_{\beta,-1,\sigma}(t-t_{n-1})} e^{-i\mathcal{K}_{\beta,-2,\sigma}(t_{n-1}-t_{n-2})} \cdots e^{-i\mathcal{K}_{\beta,0,\sigma}(t_1-s)}, \] (2.59)
where the slicing of the interval \([s, t]\) is given by (2.1) and we recall the definition (1.26) of the operator \( \mathcal{K}_{\beta,\sigma}(t) \). Before addressing the main question, it is useful to state one more technical Lemma.
Lemma 2.6.
Let $\beta, \beta' \in \mathbb{R}$ finite and $0 < \tau < 1$. Let also $\psi \in H^2(\mathbb{R}^3)$, with $|\psi(0)| = 0$ and $\|\psi\|_2 \leq 1$. Then,
\[
\left\| \left( e^{-iK_{\beta,\sigma} \tau} - e^{-iK_{\beta',\sigma} \tau} \right) \psi \right\|_2^2 = \tau \sigma (\sqrt{\sigma}) + \tau^{3/2} O(1).
\] (2.60)

Proof. Since at time $\tau = 0$ the l.h.s. of (2.60) vanishes, it is sufficient to estimate its time derivative:
\[
\partial_\tau \left\| \left( e^{-iK_{\beta,\sigma} \tau} - e^{-iK_{\beta',\sigma} \tau} \right) \psi \right\|_2^2 = -2 \text{Re} \left[ \partial_\tau \left( \psi^* e^{iK_{\beta',\sigma} \tau} e^{-iK_{\beta,\sigma} \tau} \psi \right) \right] = \frac{2 (\beta - \beta') \sigma}{\nu(\sigma)} \text{Im} \left( \psi^* e^{iK_{\beta',\sigma} \tau} W_\sigma e^{-iK_{\beta,\sigma} \tau} \psi \right),
\] (2.61)
so that
\[
\left\| \partial_\tau \left( e^{-iK_{\beta,\sigma} \tau} - e^{-iK_{\beta',\sigma} \tau} \right) \psi \right\|_2^2 \leq C |\beta - \beta'| \sigma \left\| W_\sigma e^{-iK_{\beta,\sigma} \tau} \psi \right\|_2.
\] (2.62)

Next, we estimate the norm on the r.h.s. of expression above. We are going to apply Gronwall lemma and therefore we first bound the quantity at time $\tau = 0$: since $\psi \in H^2(\mathbb{R}^3)$ and $\psi$ vanishes at the origin,
\[
\sigma^2 \left\| W_\sigma \psi \right\|_2^2 = \sigma \int_{\mathbb{R}^3} \text{d} x W^2(x) |\psi(\sigma x)|^2 = o(\sigma),
\] (2.63)
thanks to the compactness of the support of $V$. If we now set $\psi_\tau := e^{-iK_{\beta',\sigma} \tau} \psi$ for short, we can estimate
\[
 \left\| \partial_\tau \left( W_\sigma \psi_\tau \right) \right\|_2^2 = 2 \text{Im} \left( K_{\beta',\sigma} \psi_\tau \right) \left( W_\sigma \psi_\tau \right) \leq 2 \left\| K_{\beta',\sigma} \psi_\tau \right\|_2 \left\| W_\sigma \psi_\tau \right\|_2 \leq \left\| W_\sigma \psi_\tau \right\|_2^2 + \left\| K_{\beta',\sigma} \psi \right\|_2^2,
\]
which implies
\[
\sigma^2 \left\| W_\sigma e^{-iK_{\beta',\sigma} \tau} \psi \right\|_2^2 \leq \sigma^2 \left\| W_\sigma \psi_\tau \right\|_2^2 e^{\tau} + \sigma^2 \left\| K_{\beta',\sigma} \psi \right\|_2^2 (e^{\tau} - 1) = o(\sigma) + \tau O(1),
\] (2.64)
since $e^{\tau} - 1 \leq 4\tau$, for $\tau \leq 1$, and
\[
\left\| K_{\beta',\sigma} \psi_\tau \right\|_2^2 \leq 2 \left\| \Delta \psi \right\|_2^2 + 2 \left\| W_\sigma \psi \right\|_2^2 \leq C + o(\sigma^{-1}).
\]
Hence, (2.62) yields
\[
\left\| \partial_\tau \left( e^{-iK_{\beta,\sigma} \tau} - e^{-iK_{\beta',\sigma} \tau} \right) \psi \right\|_2^2 = |\beta - \beta'| (o(\sqrt{\sigma}) + \sqrt{\sigma} O(1)),
\]
which implies the result. \hfill \Box

We are now in position to prove the last estimate on the Yoshida approximation for the dynamics generated by $K_{\beta(\cdot),\sigma}$.

Lemma 2.7.
Let $W$ be resonant in the sense of Definition 1.3. Let also $t, s \in \mathbb{R}$ and $\sigma \leq 1$, and $\psi \in H^2(\mathbb{R}^3)$, with $|\psi(0)| = 0$ and $\|\psi\|_2 = 1$. Then, for all $n \to \infty, \sigma \to 0$ such that $\sigma \sqrt{n}$ is uniformly bounded, and $\frac{\beta}{n} < 1$,
\[
\left\| (V_{\sigma,n}(t, s) - U_{\sigma}(t, s)) \psi \right\|_2 = n^{-1/2} o(\sigma^{1/4}) + O(n^{-1/4} \sigma^{1/2}).
\] (2.65)

Proof. Since at time $t = s$ the l.h.s. of (2.65) vanishes, it is sufficient to estimate its time derivative: for $\tau \in [t_j, t_{j+1}]$, $j = 0, \ldots, n - 1$,
\[
\partial_\tau \left( \left( U_{\sigma}(\tau, s) - V_{\sigma,n}(\tau, s) \right) \psi \right)^2 = -2 \text{Re} \left[ \partial_\tau \left( \psi^* U_{\sigma}(\tau, s) V_{\sigma,n}(\tau, s) \psi \right) \right]
= 2 \text{Im} \left( \psi^* U_{\sigma}(\tau, s) \left( K_{\beta,\sigma} - K_{\beta(\tau),\sigma} \right) V_{\sigma,n}(\tau, s) \psi \right)
= \frac{2 (\beta_j - \beta(\tau)) \sigma}{\nu(\sigma)} \text{Im} \left( \psi^* U_{\sigma}(\tau, s) W_\sigma V_{\sigma,n}(\tau, s) \psi \right).
\] (2.66)
so that (recall (2.22))

$$
\left| \partial_t \left( (\mathcal{U}_\sigma(t, s) - \mathcal{V}_{\sigma,n}(t, s)) \psi \right) \right|^2 \leq C \sup_{\tau \in [s, t]} |\beta_\ast(\tau) - \beta(\tau)| \sigma \| \mathcal{W}_{\sigma} \mathcal{V}_{\sigma,n}(\tau, s) \psi \|_2
$$

$$
\leq \frac{C \sigma}{n} \sup_{\tau \in [s, t]} \| \mathcal{W}_{\sigma} \mathcal{V}_{\sigma,n}(\tau, s) \psi \|_2 \quad (2.67)
$$

by differentiability of $\beta(t)$ and the fact that $t_{j+1} - t_j \propto n^{-1}$.

Now, we estimate the norm on the r.h.s. of expression above. We are going to apply Gronwall lemma and therefore we first bound the quantity at time $\tau = s$, using (2.63); if we set $\psi_\tau := \mathcal{V}_{\sigma,n}(\tau, s) \psi$ for short, we can estimate, for $\tau \in [t_j, t_{j+1}]$, $j = 0, \ldots, n - 1$,

$$
\left| \partial_t \left( \| \mathcal{W}_{\sigma} \psi_\tau \|_2 \right)^2 \right| = 2 \left| \text{Im} \langle \mathcal{K}_{\beta_j, \sigma} \psi_\tau | \mathcal{W}_{\sigma} \psi_\tau \rangle \right| \leq 2 \| \mathcal{K}_{\beta_j, \sigma} \psi_{t_j} \|_2 \| \mathcal{W}_{\sigma} \psi_\tau \|_2 \leq \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2 + \| \mathcal{K}_{\beta_j, \sigma} \psi_{t_j} \|_2^2,
$$

which implies, via the Gronwall lemma,

$$
\sigma^2 \| \mathcal{W}_{\sigma} \mathcal{V}_{\sigma,n}(\tau, s) \psi \|_2^2 \leq \sigma^2 \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2^2 e^{-\tau - t_j} + \sigma^2 \| \mathcal{K}_{\beta_j, \sigma} \psi_{t_j} \|_2^2 (e^{-\tau - t_j} - 1)
$$

$$
\leq \sigma^2 \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2^2 e^{-\tau - t_j} + 4 (\tau - t_j) \sigma^2 \| \mathcal{K}_{\beta_j, \sigma} \psi_{t_j} \|_2^2 \quad (2.68)
$$

since $e^{-\tau - t_j} - 1 \leq 4 (\tau - t_j)$, for $\tau - t_j \leq 1$.

Next, we claim that, for any $j = 0, \ldots, n - 1$,

$$
\sigma \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2 = O(\sqrt{n}) + O(\sigma \sqrt{n}), \quad \text{if } \sigma \sqrt{n} \text{ is uniformly bounded.} \quad (2.69)
$$

We proceed iteratively, using (2.68) $j$ times, to obtain

$$
\sigma \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2 \leq \sigma \| \mathcal{W}_{\sigma} \psi_{t_{j-1}} \|_2 e^{\frac{1}{2}(t_{j-1} - t_{j-1})} + 4 \sigma \sqrt{t_j - t_{j-1}} \| \mathcal{K}_{\beta_{j-1}, \sigma} \psi_{t_{j-1}} \|_2
$$

$$
\leq \sigma \left( 1 + O(n^{-1}) \right) \| \mathcal{W}_{\sigma} \psi_{t_{j-1}} \|_2 + \frac{C \sigma}{\sqrt{n}} \left[ 1 + \frac{\sigma}{n} \sum_{i=0}^{j-2} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 \right]. \quad (2.70)
$$

since

$$
\| \mathcal{K}_{\beta_{j-1}, \sigma} \psi_{t_{j-1}} \|_2 \leq \| \mathcal{K}_{\beta_{j-2}, \sigma} \psi_{t_{j-2}} \|_2 + \sigma \| \beta_{j-1} - \beta_{j-2} \| \| \mathcal{W}_{\sigma} \psi_{t_{j-2}} \|_2
$$

$$
\leq \| \mathcal{K}_{\beta_{j-2}, \sigma} \psi_{t_{j-2}} \|_2 + \sigma \sum_{i=0}^{j-2} |\beta_{i+1} - \beta_i| \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 \leq C \left[ 1 + \frac{\sigma}{n} \sum_{i=0}^{j-2} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 \right]. \quad (2.71)
$$

Hence, we deduce that for all $\tau \in [t_j, t_{j+1}]$,

$$
\sigma \| \mathcal{W}_{\sigma} \psi_\tau \|_2 \leq \left( 1 + \frac{C}{n} \right) \sigma \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2 + \frac{C' \sigma}{n^{3/2}} \sum_{i=0}^{j-1} \sigma \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 + \frac{C'' \sigma}{\sqrt{n}}
$$

$$
\leq \left( 1 + \frac{C}{n} \right) \sigma \| \mathcal{W}_{\sigma} \psi_{t_j} \|_2 + \frac{C' \sigma^2}{\sqrt{n}} \sup_{i=0, \ldots, j-1} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 + \frac{C'' \sigma}{\sqrt{n}}. \quad (2.72)
$$

Therefore, we also get

$$
\sigma \sup_{i \in \{0, \ldots, j\}} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 \leq \left( 1 + \frac{C}{n} \right) \sigma \sup_{i \in \{0, \ldots, j-1\}} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2
$$

$$
+ \frac{C' \sigma^2}{\sqrt{n}} \sup_{i \in \{0, \ldots, j-1\}} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2 + \frac{C'' \sigma}{\sqrt{n}}. \quad (2.72)
$$

i.e., if we set $a_j := \sigma \sup_{i \in \{0, \ldots, j\}} \| \mathcal{W}_{\sigma} \psi_{t_i} \|_2$, we obtain the recursive relation

$$
a_j \leq \left( 1 + \frac{C}{n} + \frac{C' \sigma}{\sqrt{n}} \right) a_{j-1} + \frac{C'' \sigma}{\sqrt{n}},
$$
which implies
\[ a_j \leq \left( 1 + \frac{C}{n} + \frac{C' \sigma}{\sqrt{n}} \right)^j a_0 + \sum_{i=0}^{j} \left( 1 + \frac{C}{n} + \frac{C' \sigma}{\sqrt{n}} \right)^i \frac{C'' \sigma^i}{\sqrt{n}} \leq e^{K(\sqrt{n})} \left( a_0 + C'' \sigma \sqrt{n} \right), \]
where
\[ K(x) = 2C' x^2 + 2C' \sqrt{(C')^2 x^4 + 4Cx^2}. \]

Therefore, \( (2.69) \) holds under the assumption that \( \sigma \rightarrow 0 \) and \( n \rightarrow \infty \).

Using \( (2.69) \) in \( (2.71) \), we also have, for any \( j = 0, \ldots, n-1 \), and provided that \( \sigma \sqrt{n} \) is uniformly bounded,
\[
\|K_{\beta, \sigma} \psi(t)\|_2 = \mathcal{O}(1).
\] (2.73)

Hence going back to \( (2.68) \), we obtain
\[
\sigma \|W_\sigma V_{\sigma, n}(t, s) \psi\|_2 = o(\sqrt{\sigma}) + \mathcal{O}(\sigma \sqrt{n}),
\] (2.74)
and the result then follows. \( \square \)

We now complete the proof of the main result in this Section.

**Proof of Theorem 1.6** The idea is to prove the result in three steps: we first replace \( \mathcal{U}_{\text{eff}}(t, s) \) with its Yoshida approximants; the resulting dynamics is then generated by a time-independent point interaction and, as such, can be approximated by \( V_{n, \sigma}(t, s) \), i.e., the dynamics generated by \( K_{\beta, \sigma} \) in the corresponding interval; finally, we undo the step function approximation of \( \beta(t) \) and obtain \( \mathcal{U}_\sigma(t, s) \).

To prove strong convergence of unitary operators, it is sufficient to prove weak convergence on a dense subset. This can be easily proved as follows. Let \( V_n \xrightarrow{w} \rightarrow V \) on a dense subset \( \mathcal{D} \subset \mathcal{H} \). In addition, given \( \psi \in \mathcal{H} \), let us denote by \( (\psi_m)_{m \in \mathbb{N}} \) its approximation in \( \mathcal{D} \). Then
\[
\frac{1}{2} \|(V - V_n) \psi\|^2 \leq \|(V - V_n) \psi_m\|^2 + \|(V - V_n)(\psi - \psi_m)\|^2
\]
\[
\leq \langle \psi_m | (2 - V^* V_n - V_n^* V) \psi_m \rangle_2 + 4 \|\psi - \psi_m\|^2
\]
\[
\leq 2 \text{Re} \langle V \psi_m | (V - V_n) \psi_m \rangle_2 + 4 \|\psi - \psi_m\|^2
\]
that converges to zero as \( n \rightarrow \infty \), since \( m \) can be chosen arbitrarily large. Hence, it is sufficient to prove the convergence for all \( \psi, \phi \in H^2(\mathbb{R}^3) \) such that \( \psi(0) = \phi(0) = 0 \).

Now, for \( \psi, \phi \in H^2(\mathbb{R}^3) \) such that \( \psi(0) = \phi(0) = 0 \), and for all \( t, s \in \mathbb{R} \) with \( s < t \):
\[
|\langle \phi | (\mathcal{U}_{\text{eff}}(t, s) - \mathcal{U}_\sigma(t, s)) \psi \rangle| \leq \|\phi \| (|\mathcal{U}_{\text{eff}}(t, s) - V_{n}(t, s)| \psi \| | + \|\phi \| (|V_{n}(t, s) - \mathcal{U}_\sigma(t, s)| \psi \| | + \|\phi \| (|V_{n, \sigma}(t, s) - \mathcal{U}_\sigma(t, s)| \psi \| | + \|\phi \| (|V_{n, \sigma}(t, s) - \mathcal{U}_\sigma(t, s)| \psi \| |.
\] (2.75)

and, using the results proven in Lemmas 2.1, 2.5 and 2.7 respectively, we get
\[
|\langle \phi | (\mathcal{U}_{\text{eff}}(t, s) - \mathcal{U}_\sigma(t, s)) \psi \rangle| \leq o_n(1) + \mathcal{O}(n^5 \sigma^2) + n^{-1} o_\sigma(1) + n^{-1/2} o(\sigma^{1/4}) + \mathcal{O}(n^{-1/4} \sigma^{1/2}),
\] (2.76)

provided that \( \sigma n \ll 1, \sigma \sqrt{n} \) is uniformly bounded, and \( n \) is big enough such that \( \frac{t-s}{n} < 1 \). If we now pick
\[
n = n_\sigma = \sigma^{-1/3} \xrightarrow{\sigma \to 0} +\infty,
\] (2.77)
the above conditions are satisfied, and
\[
|\langle \phi | (\mathcal{U}_{\text{eff}}(t, s) - \mathcal{U}_\sigma(t, s)) \psi \rangle| = \mathcal{O}(\sigma^{1/2}) + o_\sigma(1) \xrightarrow{\sigma \to 0} 0.
\] \( \square \)
3. Convergence of Fluctuations

In this Sect. we prove the quasi-classical convergence, in strong topology, of the unitary operator of microscopic coherent quantum fluctuations, perturbing the quasi-classical solution. The key idea is to use coherent states that, in the quasi-classical limit, are “singular enough” to produce an effective point interaction. The strong convergence of fluctuations is sufficient to prove the strong convergence of evolved particle observables given in Theorem 1.1. Let us start with some preliminary definitions and remarks.

The operator of fluctuations for coherent states is defined as follows. Let $W_\varepsilon(B)$ be the Weyl operator appearing in the definition of $\Xi_\varepsilon$ (recall (1.17)). Then, the operator of microscopic fluctuations $Z_\varepsilon(t, s)$ is defined by

$$Z_\varepsilon(t, s) := W_\varepsilon^\dagger \left( \frac{\alpha_\varepsilon(t)}{i\varepsilon} \right) e^{-iH_\varepsilon(t-s)} W_\varepsilon \left( \frac{\alpha_\varepsilon(s)}{i\varepsilon} \right),$$

where $\alpha_\varepsilon(t)$ satisfies (1.24), i.e., $\alpha_\varepsilon(t) = e^{-i(t-s)\alpha_\varepsilon(s)}$. Its strong limit for $\varepsilon \to 0$, of which we prove the existence, is the operator of quasi-classical fluctuations $Z(t, s)$, defined by

$$Z(t, s) := \mathcal{U}_{\text{eff}}(t, s) \circ e^{-i\varepsilon \Gamma(1)(t-s)},$$

where $d\Gamma(1)$ stands for the number operator defined in terms of the unscaled creation and annihilation operators $a^1, a$ (recall (1.11)). Therefore, $Z$ is a factorized unitary operator on the full space $\mathcal{H}$, and its factorization is due to the chosen scaling in $H_\varepsilon$, that guarantees no quasi-classical back-reaction on the field.

The relation between the fluctuation operators $Z_\varepsilon(t, s)$, $Z(t, s)$ and the full Heisenberg evolution of a particle observable $B$ can be derived as follows. Let $B$ be a bounded particle operator, acting on $L^2(\mathbb{R}^3)$, and let $B_\varepsilon(t, s)$ and $B(t, s)$ be the associated microscopic and quasi-classical Heisenberg evolved operators as defined in (1.14) and (1.15), respectively, then, for any $t, s \in \mathbb{R}$ and any $\psi \in L^2(\mathbb{R}^3)$,

$$\| (B(t, s) - B_\varepsilon(t, s)) \psi \|^2_{L^2(\mathbb{R}^3)} = \| (B(t, s) - B_\varepsilon(t, s)) \psi \otimes \Xi_{\varepsilon, s} \|^2_{\mathcal{H}}$$

$$= \left( \psi \otimes \Xi_{\varepsilon, s} \right) (|B(t, s)|^2 + |B_\varepsilon(t, s)|^2 - B^*(t, s)B_\varepsilon(t, s) - B_\varepsilon^*(t, s)B(t, s) ) \psi \otimes \Xi_{\varepsilon, s} \right)_{\mathcal{H}}.$$

If we now plug in the definition of $Z$ and $Z_\varepsilon$ and use (1.17), we can write

$$\| (B(t, s) - B_\varepsilon(t, s)) \psi \|^2_{L^2(\mathbb{R}^3)} = \left( \psi \otimes \Xi_{\varepsilon, s} \right) \left( W_\varepsilon^\dagger (B(t, s) - B_\varepsilon(t, s))^2 W_\varepsilon \right) \psi \otimes \Xi_{\varepsilon, s} \right)_{\mathcal{H}}$$

$$= \left( \psi \otimes \Xi_{\varepsilon, s} \right) \left( Z_\varepsilon^\dagger \left[ Z_\varepsilon^\dagger B^2 \otimes 1Z_\varepsilon + Z_\varepsilon^\dagger B^2 \otimes 1Z_\varepsilon - Z_\varepsilon^\dagger B \otimes 1Z_\varepsilon + Z_\varepsilon^\dagger B \otimes 1Z_\varepsilon \right] \right) \psi \otimes \Xi_{\varepsilon, s} \right)_{\mathcal{H}},$$

where we used the following property of Weyl operators (recall (1.24))

$$e^{-i\varepsilon \Gamma(1)(t-s)} W_\varepsilon \left( \frac{\alpha_\varepsilon(s)}{i\varepsilon} \right) = W_\varepsilon ( \frac{e^{-i(t-s)\alpha_\varepsilon(s)}}{i\varepsilon} ) e^{-i\Gamma(1)(t-s)} = W_\varepsilon \left( \frac{\alpha_\varepsilon(t)}{i\varepsilon} \right) e^{-i\varepsilon \Gamma(1)(t-s)},$$

which, combined with (1.17), i.e., $\varepsilon^{-1}d\Gamma(1) = d\Gamma(1)$, implies, for any particle operator $A$,

$$W_\varepsilon^\dagger \left( \frac{\alpha_\varepsilon(t)}{i\varepsilon} \right) \left( \mathcal{U}_{\text{eff}}^\dagger \otimes 1 \right) A \otimes 1 \left( \mathcal{U}_{\text{eff}} \otimes 1 \right) W_\varepsilon \left( \frac{\alpha_\varepsilon(s)}{i\varepsilon} \right) = Z_\varepsilon A \otimes 1Z_\varepsilon,$$

and we omit the dependence on $t$ and $s$ of $Z(t, s)$ and $Z_\varepsilon(t, s)$ for convenience. If we now exploit the identity

$$Z_\varepsilon^\dagger = Z^\dagger B^2 \otimes 1Z_\varepsilon + Z^\dagger B^2 \otimes 1Z_\varepsilon - Z^\dagger B \otimes 1Z_\varepsilon + Z^\dagger B \otimes 1Z_\varepsilon,$$

$$= (Z^\dagger - Z^\dagger)B^2 \otimes 1Z_\varepsilon + Z^\dagger B^2 \otimes 1(Z - Z_\varepsilon) - Z^\dagger B \otimes 1Z(Z^\dagger - Z^\dagger)B \otimes 1Z_\varepsilon + h.c.$$

in the expression above, we deduce that

$$\| (B(t, s) - B_\varepsilon(t, s)) \psi \|^2_{L^2(\mathbb{R}^3)} \leq C \| B \|_B \| \psi \|^2 \| \Xi_{\varepsilon, s} \| (Z - Z_\varepsilon) \psi \| \Xi_{\varepsilon, s} \|_{\mathcal{H}}.$$

The estimate (3.4) makes apparent the link between the Heisenberg evolution of the observable $B$ and the fluctuation operators $Z_\varepsilon$, $Z$. More precisely, the convergence stated in Theorem 1.1 is equivalent to show strong convergence of the fluctuation operator $Z_\varepsilon$ to $Z$, which we are going to prove in next Proposition 3.1. Note that a similar quasi-classical limit of coherent state fluctuations
has been studied (with less singular coherent states that do not carry any \( \varepsilon \)-dependence on the classical solution \( \alpha \)) for the renormalized Nelson model in \([GNV]\).

Finally, for later purposes, let us remark that the form factor \( \lambda_x(k) = \frac{e^{ikx}}{k} \) has the following important property, as first remarked in \([LT]\):

\[
\lambda_x = \lambda_{>,x} + \lambda_{<,x} ; \quad \lambda_{<,x} \in L^\infty(\mathbb{R}; \mathfrak{S}) ; \quad \lambda_{>,x} = [-i\nabla, \xi_x], \quad \xi_x \in L^\infty(\mathbb{R}; \mathfrak{S}) .
\]

3.1. **Strong convergence.** In order to prove strong convergence of \( Z_\sigma \), we make use of an intermediate auxiliary operator

\[
Z_\sigma(t, s) = \mathcal{U}_\sigma(t, s) \otimes e^{-i\Phi(t) - s} ,
\]

with \( \sigma = \sigma_\varepsilon \) properly chosen, i.e., such that

\[
\varepsilon^{1/6} \ll \sigma \ll 1 ,
\]

and where \( \mathcal{U}_\sigma \) is the two-parameter group defined in \([72]\) and generated by \( \mathcal{K}_{\beta(t), \sigma} \). The precise result is given in the following

**Proposition 3.1 (Convergence of fluctuations).**

For any \( \Phi \in \mathcal{H} \),

\[
\lim_{\varepsilon \to 0} \left\| (Z(t, s) - Z_\varepsilon(t, s)) \Phi \right\|_{\mathcal{H}} = 0 .
\]

Before proving the above result, let us give some preparatory lemmas. The first one is a well-known result about Weyl operators (for an explicit proof, see, e.g., \([Fa1]\)). For the last property, it is useful to remark that \( \alpha_\varepsilon(k, t) \) is by construction a rapidly decaying function in Schwartz class and therefore its scalar product by any polynomial, as, e.g., \( \sqrt{k^2 + 1} \), is always bounded.

**Lemma 3.2.**

The Weyl operators \( W_\varepsilon \left( \frac{\alpha(t)}{i\varepsilon} \right) \) are strongly differentiable with respect to \( t \in \mathbb{R} \) on \( \mathcal{D}(d\Gamma_\varepsilon(1)^{1/2}) \), with derivative given by

\[
i\partial_t W_\varepsilon \left( \frac{\alpha(t)}{i\varepsilon} \right) = \frac{i}{\varepsilon} \left( \alpha^\dagger_\varepsilon(\alpha_\varepsilon) - a_\varepsilon(\alpha_\varepsilon) - i \text{Im} \langle \alpha_\varepsilon | \alpha_\varepsilon \rangle \right) W_\varepsilon \left( \frac{\alpha(t)}{i\varepsilon} \right) = \frac{i}{\varepsilon} W_\varepsilon \left( \frac{\alpha(t)}{i\varepsilon} \right) \left( \alpha^\dagger_\varepsilon(\alpha_\varepsilon) - a_\varepsilon(\alpha_\varepsilon) + i \text{Im} \langle \alpha_\varepsilon | \alpha_\varepsilon \rangle \right) .
\]

In addition, \( W_\varepsilon(\cdot) \) maps \( \mathcal{D}[H_0] \) and \( \mathcal{D}(d\Gamma_\varepsilon(\omega)^{1/2}) \), with \( \omega(k) := \sqrt{k^2 + 1} \), into themselves.

Another useful result is the weak differentiability of \( Z_\varepsilon \) in a suitable dense domain.

**Lemma 3.3.**

The operator \( Z_\varepsilon(t, s) \) is weakly differentiable, with respect to both \( t \in \mathbb{R} \) and \( s \in \mathbb{R} \), on \( \mathcal{D}[H_0] \). The weak derivatives have the following form:

\[
i\partial_t Z_\varepsilon(t, s) = L_\varepsilon(t)Z_\varepsilon(t, s) , \quad i\partial_s Z_\varepsilon(t, s) = -Z_\varepsilon(t, s)L_\varepsilon(s) ,
\]

where \( (L_\varepsilon(t))_{t \in \mathbb{R}} \) is the family of operators

\[
L_\varepsilon(t) = \left( -\Delta + W_{\sigma(t)}(x) \right) \otimes 1 + 2\text{Re} \langle \lambda_x | \alpha_\varepsilon(t) \rangle \nabla + a_\varepsilon(\lambda_x) + a_\varepsilon^\dagger(\lambda_x) + \frac{1}{\varepsilon} d\Gamma_\varepsilon(1) .
\]

**Proof.** Using \([Lemma 3.2]\) and the definition of \( Z_\varepsilon(t, s) \), it is easy to see that it is possible to differentiate with respect to both \( t \) and \( s \) the quantity

\[
(\Theta | Z_\varepsilon(t, s) \Phi )_{\mathcal{H}} ,
\]

for any \( \Theta, \Phi \in \mathcal{D}[H_0] \subset \mathcal{D}(d\Gamma_\varepsilon(1)^{1/2}) \). Indeed, \( e^{-iH_\varepsilon(t) - s} \) is weakly differentiable on \( \mathcal{D}[H_\varepsilon] = \mathcal{D}[H_0] \), and \( W_\varepsilon(\cdot) \) is strongly differentiable on \( \mathcal{D}(d\Gamma_\varepsilon(1)^{1/2}) \), and maps \( \mathcal{D}[H_0] \) into itself. The explicit form of the derivative is given using again \([Lemma 3.2]\) the action as translations of Weyl operators when acting on creation and annihilation operators, and the equation for the time derivative of \( \alpha_\varepsilon \), i.e., \( i\partial_t \alpha_\varepsilon(t) = \alpha_\varepsilon(t) \).
The two final preparatory results are essentially Gronwall-type estimates for the time-evolved expectation of the Laplace operator.

**Lemma 3.4.**
For any \( t \in \mathbb{R} \), there exists a finite constant \( C_t > 0 \) such that for every \( \Phi \in \mathcal{D}[H_+] = \mathcal{D}[H_0] \),
\[
\langle \Phi | e^{itH_+} (\Delta) e^{-itH_+} | \Phi \rangle_{\mathcal{H}} \leq C_t \left( \langle \Phi | H_+ + H_1 | \Phi \rangle_{\mathcal{H}} + \| \Phi \|^2_{\mathcal{H}} \right),
\]
(3.11)
where \( H_+ := -\Delta + d\Gamma(1) \geq 0 \).

Before proving the above result, let us point out the more regular behavior as \( \varepsilon \to 0 \) of the operator \( H_+ \) compared with \( H_0 \), since the former has no prefactor \( \varepsilon^{-1} \) in front of the field energy.

**Proof.** Since \( -\Delta \leq H_+ \), adding and subtracting \( H_1 \), it is possible to write for any \( \Phi \in \mathcal{D}[H_0] \)
\[
\langle \Phi | e^{itH_+} (\Delta) e^{-itH_+} | \Phi \rangle_{\mathcal{H}} \leq \langle \Phi | e^{itH_+} H_+ e^{-itH_+} | \Phi \rangle_{\mathcal{H}} = \langle \Phi | e^{itH_+} (H_+ + H_1) e^{-itH_+} | \Phi \rangle_{\mathcal{H}} - \langle \Phi | e^{itH_+} H_1 e^{-itH_+} | \Phi \rangle_{\mathcal{H}} \cdot
\]
(3.12)

Let us control the two terms of the last sum separately. The form associated to \( H_1 \) is a small perturbation of the one associated to \( H_+ \), as it has been proved in other papers dealing with the polaron Hamiltonian (see, e.g., [FT]). Indeed, there exist \( a \in (0,1) \) and \( b > 0 \), such that
\[
\langle \Phi | e^{itH_+} H_1 e^{-itH_+} | \Phi \rangle_{\mathcal{H}} | \leq a \langle \Phi | e^{itH_+} H_+ e^{-itH_+} | \Phi \rangle_{\mathcal{H}} + b \| \Phi \|^2_{\mathcal{H}}.
\]
(3.13)

It remains to bound the first term of the sum. We will use a Gronwall and density argument. Without loss of generality, we can assume that \( t > 0 \). Let \( -M, M \geq 0 \), be a lower bound for \( H_+ \), and suppose that \( \Phi \in \mathcal{D}((H_+ + M)^{3/2}) \), the latter being a dense domain. Since \( e^{-itH_+} \) is weakly differentiable on \( \mathcal{D}[H_0] \cap \mathcal{D}((H_+ + M)^{3/2}) \), and maps \( \mathcal{D}((H_+ + M)^{3/2}) \) into itself for any \( t \in \mathbb{R} \), it is possible to write
\[
\langle \Phi | e^{itH_+} (H_+ + H_1) e^{-itH_+} | \Phi \rangle_{\mathcal{H}} \leq \langle \Phi | H_+ + H_1 | \Phi \rangle_{\mathcal{H}} + \int_0^t ds \| \Phi | e^{isH_+} (H_+ + H_1, H_0 + H_1) e^{-isH_+} | \Phi \rangle_{\mathcal{H}}.
\]

Now, the commutator, as a quadratic form, yields
\[
[H_+ + H_1, H_0 + H_1] = [H_+, H_1] + [H_1, H_0] = (\varepsilon - 1)(a^{\dagger}_1(\lambda_\chi) - a_\varepsilon(\lambda_\chi)).
\]

It is well-known [CF] Prop. A.2 that \( a^{\dagger}_1(\lambda_\chi) - a_\varepsilon(\lambda_\chi) \) is small in the sense of quadratic forms w.r.t. \( H_+ \), with \( a' \in (0,1/4) \) and \( b' > 0 \), so that, for any \( \Theta \in \mathcal{D}[H_+] \),
\[
\left| \left\langle \Theta \left| a^{\dagger}_1(\lambda_\chi) - a(\lambda_\chi) \right\rangle \right| \leq 2 \left\langle \Theta \left| a^{\dagger}_1(\lambda_\chi) \right\rangle \right| \leq 2a' \left\langle \Theta | H_+ | \Theta \right\rangle_{\mathcal{H}} + 2b' \| \Theta \|^2_{\mathcal{H}}.
\]
(3.14)

By KLMN theorem, the above bound yields an estimate below for \( H_+ + H_1 \): for any \( \Theta \in \mathcal{D}[H_+] \),
\[
\left( \Theta | H_+ + H_1 | \Theta \right)_{\mathcal{H}} \geq (1 - a') \left( \Theta | H_+ | \Theta \right)_{\mathcal{H}} - b' \| \Theta \|^2_{\mathcal{H}}
\]
(3.15)
or, equivalently,
\[
a' \left( \Theta | H_+ | \Theta \right)_{\mathcal{H}} + \left( \Theta | H_1 | \Theta \right)_{\mathcal{H}} + b' \| \Theta \|^2_{\mathcal{H}} \geq 0.
\]
(3.16)

Now, we use (3.16) in (3.14) to obtain (remembering that \( 3a' < 1 \))
\[
\left| \left\langle \Theta \left| a^{\dagger}_1(\lambda_\chi) - a(\lambda_\chi) \right\rangle \right| \leq 3a' \left( \Theta | H_+ | \Theta \right)_{\mathcal{H}} + \left( \Theta | H_1 | \Theta \right)_{\mathcal{H}} + 3b' \| \Theta \|^2_{\mathcal{H}}
\]
\[
\leq \left( \Theta | H_+ + H_1 | \Theta \right)_{\mathcal{H}} + 3b' \| \Phi \|^2_{\mathcal{H}}.
\]

Therefore, using the fact that \( |1 - \varepsilon| < 1 \), we get
\[
\langle \Phi | e^{itH_+} (H_+ + H_1) e^{-itH_+} | \Phi \rangle_{\mathcal{H}} \leq \int_0^t ds \left( \langle \Phi | e^{isH_+} (H_+ + H_1) e^{-isH_+} | \Phi \rangle_{\mathcal{H}} + \langle \Phi | H_+ + H_1 | \Phi \rangle_{\mathcal{H}} + 3b't \| \Phi \|^2_{\mathcal{H}}.\]
If we now set
\[ P(t) := \langle \Phi \, \epsilon^{itH_+ + H_I} e^{-itH_+} \, \Phi \rangle_\mathcal{H}, \quad B(t) := 3b't \| \Phi \|_\mathcal{H}^2, \]
we can rewrite the previous inequality as (recall that \( t \geq 0 \))
\[ P(t) \leq P(0) + \int_0^t d\tau \, P(\tau) + B(t). \quad (3.17) \]

Gronwall lemma then yields
\[ P(t) \leq P(0) + B(t) + \int_0^t d\tau \, (P(0) + B(\tau)) e^{-\tau} \leq e^t \langle \Phi \, |H_+ + H_I| \, \Phi \rangle_\mathcal{H} + 3b't e^t \| \Phi \|_\mathcal{H}^2. \]

Therefore inserting this bound in (3.12), we get for the expectation of \( H_+ \) (considering now also the analogous case \( t < 0 \)):
\[ (1 - a) \langle \Phi \, e^{itH_+} H e^{-itH_+} \, \Phi \rangle_\mathcal{H} \leq e^{|t|} \langle \Phi \, |H_+ + H_I| \, \Phi \rangle_\mathcal{H} + \left( 3b'|t| e^{|t|} + b \right) \| \Phi \|_\mathcal{H}^2. \quad (3.18) \]

This concludes the proof for \( \Phi \in \mathcal{D}(H_{\epsilon} + M)^{3/2} \), since \( a < 1 \). The proof is then extended to any \( \Phi \in \mathcal{D}[H_0] \) by a density argument. \( \square \)

**Lemma 3.5.**

*Let \( \mathcal{W} \in C_0^\infty(\mathbb{R}^3) \). Then, for any \( t, s \in \mathbb{R} \), there exists a constant \( C_{t,s} > 0 \) depending only on \( \| \nabla \mathcal{W} \|_\infty \) and \( \| \Delta \mathcal{W} \|_\infty \), such that, for every \( \Phi \in \mathcal{D}[H_0] \),
\[ \langle \Phi \, Z_\sigma^\dagger (t,s)(-\Delta \otimes 1) Z_\sigma (t,s) \rangle_\mathcal{H} \leq C_{t,s} \sigma^{-6} \left( \| (\nabla \otimes 1) \Phi \|_\mathcal{H}^2 + \| \Phi \|_\mathcal{H}^2 \right). \quad (3.19) \]

**Proof.** First of all, let us notice that \( Z_\sigma (t,s) = U_\sigma^\dagger (t,s)\Delta U_\sigma (t,s) \otimes 1 \). Omitting the multiplication by the identity when it is obvious from the context, we can write
\[ \langle \Phi \, Z_\sigma^\dagger (t,s)(-\Delta \otimes 1) Z_\sigma (t,s) \rangle_\mathcal{H} = \langle U_\sigma (t,s) \Phi \, |-\Delta| U_\sigma (t,s) \Phi \rangle_\mathcal{H} =: R(t,s). \]

Suppose now that \( \Phi \in \mathcal{D}(H_0) \). Without loss of generality, we can also assume that \( t \geq s \geq 0 \). Hence, we get the integral inequality
\[ R(t,s) \leq R(s,s) + \int_s^t d\tau \left| \langle U_\sigma (t,s) \Phi \, (-\nabla_\sigma (t,s) \Phi) \rangle_\mathcal{H} \right|, \]
where we have written \( \mathcal{W}_{\sigma,\tau}(x) \) to stress the dependence on \( t \in \mathbb{R} \) of \( \beta(t) \) in the definitions of \( \nu(\sigma) \) and \( \mathcal{W}_\sigma \) given by (1.27) and (1.23), respectively. The commutator has the following explicit form:
\[ [-\Delta, \mathcal{W}_{\sigma,\tau}] = (\nabla \mathcal{W}_{\sigma,\tau})(x) \cdot \nabla. \]

Therefore, keeping in mind that \( \| \beta(t) \| \leq C \) for all \( t \in \mathbb{R} \), we obtain
\[ R(t,s) \leq R(s,s) + (t - s)\sigma^{-4} \| \nabla \mathcal{W} \|_\infty \| \Phi \|_\mathcal{H}^2 + 2\sigma^{-3} \| \Delta \mathcal{W} \|_\infty \| \Phi \|_\mathcal{H} \int_s^t d\tau \| \nabla U_\sigma (\tau,s) \Phi \|_\mathcal{H} \]
\[ \quad \leq R(s,s) + \left( (t - s)\sigma^{-4} \| \nabla \mathcal{W} \|_\infty + \sigma^{-6} \| \nabla \mathcal{W} \|_\infty^2 \right) \| \Phi \|_\mathcal{H}^2 + \int_s^t d\tau \, R(t,s). \]

The result for \( \Phi \in \mathcal{D}(H_0) \) then follows by Gronwall lemma, and it is extended by density to \( \Phi \in \mathcal{D}[H_0] \). \( \square \)

We can now conclude the proof of Proposition 3.1. **Proof of Proposition 3.1.** Since the operators \( Z_\epsilon \) and \( Z \) are bounded, in order to prove strong convergence it suffices to show that \( Z_\epsilon \) weakly converges to \( Z \). Therefore, we want to prove that for all \( \Phi, \Theta \in \mathcal{H} \),
\[ \lim_{\epsilon \to 0} \langle \Theta \, (Z(t,s) - Z_\epsilon (t,s)) \Phi \rangle_\mathcal{H} = 0; \]
however, by triangular inequality, we can show separately the convergences of \( Z_\epsilon \) to \( Z_\sigma \) and of \( Z_\sigma \) to \( Z \). By Theorem 1.6 we already know that \( U_\sigma \) converges strongly to \( U_{\text{eff}} \) on \( L^2(\mathbb{R}^3) \), which implies that \( Z_\sigma \) converges to \( Z \), provided that \( \sigma \to 0 \), as \( \epsilon \to 0 \), which we are going to assume. Therefore, it suffices to prove convergence of \( Z_\epsilon \) to \( Z_\sigma \).
We restrict to the dense set
\[ \mathcal{D} := \mathcal{D}(H_0) \cap (\mathcal{D}(d\Gamma(\omega)^{1/2}) \subset \mathcal{D}[H_0], \]
and prove weak convergence to zero on \( \mathcal{D} \) for the quadratic form associated to \( Z^1_\varepsilon(t, s)Z_\varepsilon(t, s) - 1 \), whenever \( \sigma = O(\varepsilon^\gamma) \), with suitable \( \gamma > 0 \). Note that, since \( \omega(k) = \sqrt{k^2 + 1} \geq 1 \), \( d\Gamma(1) \leq d\Gamma(\omega) \) and consequently \( \mathcal{D}(d\Gamma(\omega)^{1/2}) \subset \mathcal{D}(d\Gamma(1)^{1/2}) \). By the polarization identity
\[ \langle \Theta \big| (Z_\sigma - Z_\varepsilon) \Phi \rangle_{\mathcal{H}} = \left\langle Z^1_\sigma \Theta \big| (Z^1_\sigma Z_\varepsilon - 1) \Phi \right\rangle_{\mathcal{H}} \]
we obtain the following bound
\[ \left\langle \Theta \big| (Z^1_\sigma Z_\varepsilon - 1) \Phi \right\rangle_{\mathcal{H}} \xrightarrow{\varepsilon \to 0} 0, \quad \forall \Phi \in \mathcal{H}, \]
then, by the same polarization identity, it follows that \( Z_\sigma(t, s) - Z_\varepsilon(t, s) \) converges weakly to zero.

Furthermore, by the uniform boundedness in \( \varepsilon \) of both \( Z_\sigma \) and \( Z_\varepsilon \), it is sufficient to prove the convergence of the quadratic form on the dense set \( \mathcal{D} \), which we are going to do now. The operator \( Z^1_\varepsilon \) is strongly differentiable on \( \mathcal{D}(H_0) \) and maps \( \mathcal{D}[H_0] \) into itself, while \( Z_\varepsilon \) is weakly differentiable on \( \mathcal{D}[H_0] \). Without loss of generality, we can suppose that \( t \geq s \geq 0 \). Therefore, it is possible to write
\[ \left| \left\langle \Phi \big| (Z^1_\sigma Z_\varepsilon - 1) \Phi \right\rangle_{\mathcal{H}} \right| \leq \int_s^t d\tau \left| \partial_\tau \left\langle \Phi \big| (Z^1_\sigma(\tau, s)Z_\varepsilon(\tau, s) - 1) \Phi \right\rangle_{\mathcal{H}} \right| \]
\[ = \int_s^t d\tau \left| \left\langle \Phi \big| Z^1_\sigma(\tau, s) (L_\varepsilon(\tau) - L_\sigma(\tau)) Z_\varepsilon(\tau, s) \Phi \right\rangle_{\mathcal{H}} \right|. \]
Now, since by hypothesis \( 2\text{Re} \langle \lambda_\varepsilon | \alpha_\varepsilon(t) \rangle_{\mathcal{D}} = \mathcal{W}_{\sigma, \varepsilon}(x) \), and \( \frac{1}{2}d\Gamma_\varepsilon(1) = d\Gamma(1) \) by (1.7), we have that
\[ L_\varepsilon(t) - L_\sigma(t) = a_\varepsilon(\lambda_\varepsilon) + a_\varepsilon^t(\lambda_\varepsilon) = \sqrt{\varepsilon}(a(\lambda_\varepsilon) + a^t(\lambda_\varepsilon)). \]
Therefore, we obtain the following bound
\[ \left| \left\langle \Phi \big| (Z^1_\sigma Z_\varepsilon - 1) \Phi \right\rangle_{\mathcal{H}} \right| \leq \sqrt{\varepsilon} \int_s^t d\tau \left| \left\langle (a(\lambda_\varepsilon) + a^t(\lambda_\varepsilon)) Z_\sigma(\tau, s) \Phi \big| Z_\varepsilon(\tau, s) \Phi \right\rangle_{\mathcal{H}} \right|. \]
Let us define
\[ S := \int_s^t d\tau \left| \left\langle (a(\lambda_\varepsilon) Z_\sigma(\tau, s) \Phi \big| Z_\varepsilon(\tau, s) \Phi \right\rangle_{\mathcal{H}} \right|, \]
\[ T := \int_s^t d\tau \left| \left\langle a^t(\lambda_\varepsilon) Z_\sigma(\tau, s) \Phi \big| Z_\varepsilon(\tau, s) \Phi \right\rangle_{\mathcal{H}} \right|. \]
The term \( S \) is easy to bound, exploiting the fact that \( d\Gamma(\omega)^k \) commutes with \( d\Gamma(1) \) and therefore with \( Z_\sigma \) for any positive \( k \):
\[ S \leq \int_s^t d\tau \left| (a(\lambda_\varepsilon) Z_\sigma(\tau, s) \Phi \big| \Phi \right\rangle_{\mathcal{H}} \left| \Phi \right\rangle_{\mathcal{H}} \leq (t - s) \sup_{\tau \in (s, t)} \left| (a(\lambda_\varepsilon) Z_\sigma(\tau, s) \Phi \big| \Phi \right\rangle_{\mathcal{H}} \left| \Phi \right\rangle_{\mathcal{H}} \]
\[ \leq (t - s) \left| \lambda_\varepsilon^{-1/2} \omega \right|_{L^\infty(\mathbb{R}^3; \delta)} \left| d\Gamma(\omega)^{1/2} \Phi \right|_{\mathcal{H}} \left| \Phi \right\rangle_{\mathcal{H}} \leq C \left| d\Gamma(\omega)^{1/2} \Phi \right|_{\mathcal{H}} \left| \Phi \right\rangle_{\mathcal{H}}, \]
which is uniformly bounded on (3.20).
The $T$ term requires some additional care: recalling (3.5), we observe that one can split $T$ into a regular and a singular part, i.e., $T \leq T_{\text{reg}} + T_{\text{sing}}$, where
\[
T_{\text{reg}} := \int_s^t d\tau \left| \left\langle a^\dagger(\lambda_{<,s}) Z_\sigma(\tau,s) \Phi \middle| Z_\varepsilon(\tau,s) \Phi \right\rangle \right|_\mathcal{H},
\]
\[
T_{\text{sing}} := \int_s^t d\tau \left| \left\langle a^\dagger(\lambda_{>,s}) Z_\sigma(\tau,s) \Phi \middle| Z_\varepsilon(\tau,s) \Phi \right\rangle \right|_\mathcal{H}.
\]

The regular part can be treated analogously to $S$:
\[
T_{\text{reg}} \leq (t-s) \|\lambda_{<,s}\|_{L^\infty(\mathbb{R}^3;\mathcal{H})} \left\| (d\Gamma(1) + 1)^{1/2} \Phi \right\|_\mathcal{H} \left\| \Phi \right\|_\mathcal{H},
\]
which is uniformly bounded w.r.t. $\varepsilon$.

It remains to estimate the singular part. Let us split again such term in two parts: $T_{\text{sing}} = \tilde{T}_1 + \tilde{T}_2$, where
\[
\tilde{T}_1 := \int_s^t d\tau \left| \left\langle a^\dagger(\xi_\tau) \cdot \nabla Z_\sigma(\tau,s) \Phi \middle| Z_\varepsilon(\tau,s) \Phi \right\rangle \right|_\mathcal{H},
\]
\[
\tilde{T}_2 := \int_s^t d\tau \left| \left\langle \nabla \cdot a^\dagger(\xi_\tau) Z_\sigma(\tau,s) \Phi \middle| Z_\varepsilon(\tau,s) \Phi \right\rangle \right|_\mathcal{H}.
\]

The first one is bounded as follows.
\[
\tilde{T}_1 \leq (t-s) \sup_{\tau \in (s,t)} \left| a^\dagger(\xi_\tau) \cdot \nabla Z_\sigma(\tau,s) \Phi \right|_\mathcal{H} \left\| \Phi \right\|_\mathcal{H} \leq C \sup_{\tau \in (s,t)} \sum_{j=1}^3 \left| a^\dagger((\xi_\tau)_j) \partial_j Z_\sigma(\tau,s) \Phi \right|_\mathcal{H}
\]
\[
\leq C \|\xi_\tau\|_{L^\infty(\mathbb{R}^3;\mathcal{H})} \left\| \nabla Z_\sigma(\tau,s) d\Gamma(1)^{1/2} \Phi \right\|_\mathcal{H} \left\| \Phi \right\|_\mathcal{H} \leq C \left| \left\langle Z_\sigma(\tau,s) \Theta \right\rangle \right| \left| \left\langle -\Delta \right\rangle \right| \left\| \Phi \right\|_\mathcal{H} \left| \left\langle Z_\sigma(\tau,s) \Theta \right\rangle \right|^{1/2},
\]
with $\Theta := d\Gamma(1)^{1/2} \Phi$. Therefore, by Lemma 3.3 it follows that there exists a constant $C_{t,s} > 0$, depending on $\Phi$, such that
\[
\tilde{T}_1 \leq C_{t,s} \sigma^{-3}.
\]

The second term is bounded using Lemma 3.4
\[
\tilde{T}_2 \leq \sum_{j=1}^3 \left| a^\dagger((\xi_\tau)_j) \partial_j Z_\sigma(\tau,s) \Phi \right|_\mathcal{H} \left\| \partial_j Z_\varepsilon(\tau,s) \Phi \right\|_\mathcal{H}
\]
\[
\leq C \|\xi_\tau\|_{L^\infty(\mathbb{R}^3;\mathcal{H})} \left\| (d\Gamma(1) + 1)^{1/2} \Phi \right\|_\mathcal{H} \left\| (-\Delta)^{1/2} Z_\varepsilon(\tau,s) \Phi \right\|_\mathcal{H}.
\]

Now, setting $W_t := W_\varepsilon(\frac{\alpha(t)}{4\varepsilon})$ and using the fact that $\Delta$ commutes with $W_t$ for any $t \in \mathbb{R}$, we get by Lemma 3.3
\[
\left\| (-\Delta)^{1/2} Z_\varepsilon(\tau,s) \Phi \right\|_\mathcal{H}^2 \leq C_t \left( \left\| W_\varepsilon \Phi \right\|_{H^1 + H^1} \right) \left\| \Phi \right\|_\mathcal{H}^2.
\]

However, by the translation properties of Weyl operators, one has
\[
W_s^\dagger(H_+ + H_I) W_s = -\Delta + d\Gamma_\varepsilon(1) + H_I + \|\alpha_\varepsilon(s)\|^2 + a(\alpha_\varepsilon(s)) + a^\dagger(\alpha_\varepsilon(s)) + 2\text{Re} \left\langle \alpha_\varepsilon(s) \right\rangle \left\langle \lambda_\varepsilon \right\rangle_{\mathcal{H}},
\]
so that
\[
\left\| (-\Delta)^{1/2} Z_\varepsilon(\tau,s) \Phi \right\|_\mathcal{H}^2 \leq C_t \left[ \left\langle \Phi \right\rangle \left| -\Delta + d\Gamma_\varepsilon(1) + H_I + a(\alpha_\varepsilon(s)) + a^\dagger(\alpha_\varepsilon(s)) \right\rangle \right]_\mathcal{H}
\]
\[
+ \left( 2\text{Re} \left\langle \alpha_\varepsilon(s) \right\rangle \left\langle \lambda_\varepsilon \right\rangle_{\mathcal{H}} + \|\alpha_\varepsilon(s)\|^2_{\mathcal{H}} + 1 \right) \left\| \Phi \right\|_\mathcal{H}^2.
\]

Now, since
\[
\|\langle \alpha_\varepsilon(s) | \lambda_\varepsilon \rangle_{\mathcal{H}} \|_{\infty} \leq C \|\alpha_\varepsilon(s)\|_{\mathcal{H}} = O(\varepsilon^{-1/8}), \quad \|\alpha_\varepsilon(s)\|_{\mathcal{H}}^2 = O(\varepsilon^{-1/4}),
\]
it follows that
\[
\tilde{T}_2 \leq C \varepsilon^{-1/4}.
\]
Hence, putting together (3.23) with (3.24), (3.25) and (3.27), we finally get, for any $\Phi \in \mathcal{D}$,

$$\left| \left\langle \Phi \left( \mathcal{Z}^e_\varepsilon \mathcal{Z}_e - 1 \right) \Phi \right\rangle \right| \lesssim \mathcal{O}(\varepsilon^{1/2} \sigma^{-3}) + \mathcal{O}(\varepsilon^{1/4}) = o(1),$$

as long as $\sigma \gg \varepsilon^{1/6}$. \hfill \Box
