ON THE ANDRÉ MOTIVE OF GENERALIZED KUMMER TYPE VARIETIES

ANDREY SOLDATENKOV

Abstract. We study André motives of projective hyperkähler manifolds that are deformation equivalent to the generalized Kummer varieties. We prove that the motives of such manifolds are abelian, i.e. they are contained in the subcategory generated by the motives of abelian varieties. As a consequence, we prove that all Hodge classes in arbitrary degree on such manifolds are absolute.

1. Introduction

1.1. Absolute Hodge classes. Let $X$ be a non-singular projective variety over $\mathbb{C}$. Denote by $X^\text{an}$ the corresponding complex manifold. Recall that the de Rham cohomology $H^*_\text{dR}(X)$ is the hypercohomology of the algebraic de Rham complex $\Omega^*_X/\mathbb{C}$. For every $k$, the $\mathbb{C}$-vector space $H^k_{\text{dR}}(X)$ is endowed with a decreasing Hodge filtration $F^\bullet$. On the other hand, the singular cohomology $H^k(X^\text{an}, \mathbb{C})$ is endowed with the $\mathbb{Q}$-structure given by the subspace $H^k(X^\text{an}, \mathbb{Q})$. Comparison results between the algebraic and the analytic cohomology of coherent sheaves and the quasi-isomorphism $\Omega^*_X^\text{an} \simeq \mathbb{C}$ induce natural isomorphisms of cohomology groups $H^k_{\text{dR}}(X) \simeq H^k(X^\text{an}, \mathbb{C})$.

A cohomology class $\alpha \in F^pH^k_{\text{dR}}(X)$ is called a Hodge class, if its image in $H^k(X^\text{an}, \mathbb{C})$ under the isomorphism described above is contained in the subspace $(2\pi i)^pH^k(X^\text{an}, \mathbb{Q})$. The Hodge conjecture predicts that the property of $\alpha$ being Hodge should be stable under automorphisms of the field of complex numbers. More precisely, let $\sigma \in \text{Aut}(\mathbb{C}/\mathbb{Q})$ be an automorphism and $X_\sigma$ be the variety obtained by base change via $\sigma$. We have a chain of isomorphisms of $\mathbb{Q}$-vector spaces:

\begin{equation}
H^k_{\text{dR}}(X) \simeq H^k_{\text{dR}}(X) \otimes_{\mathbb{C},\sigma} \mathbb{C} \simeq H^k_{\text{dR}}(X_\sigma) \simeq H^k(X_\sigma^\text{an}, \mathbb{C}).
\end{equation}

Recall that an element $\alpha \in F^pH^k_{\text{dR}}(X)$ is called absolute Hodge, if its image under the isomorphisms (1.1) lies in $(2\pi i)^pH^k(X_\sigma^\text{an}, \mathbb{Q})$ for any $\sigma \in \text{Aut}(\mathbb{C}/\mathbb{Q})$. If $\alpha$ is an algebraic class, i.e. it is contained in the $\mathbb{Q}$-subspace spanned by the classes of algebraic subvarieties, then it is absolute Hodge. According to the Hodge conjecture, every Hodge class should be algebraic, therefore absolute Hodge.

According to Deligne [DMOS], any Hodge class on an abelian variety is absolute. In the present paper we prove analogous statement for certain types of projective hyperkähler manifolds. Our proof relies on the generalized Kuga-Satake correspondence from [KSV].

1.2. André motives. It is convenient to state the main result of the paper in the language of motives. We will use the category of motives constructed by André in [A1] as a refinement of Deligne’s motives [DMOS]. André introduced the notion of motivated cohomology class (or a motivated cycle) and used the motivated classes to construct a semi-simple Tannakian category $(\text{Mot}_A)$ of André motives. We will briefly recall the construction in section 2.

For a variety $X$ we will denote by $\text{Mot}(X)(n) \in (\text{Mot}_A)$ its André motive with a Tate twist by $n$, see section 2. Consider the minimal full Tannakian subcategory $(\text{Mot}_A^b) \subset (\text{Mot}_A)$ containing $\text{Mot}(A)(n)$ for...
all abelian varieties $A$ and $n \in \mathbb{Z}$. We will say that the motive of $X$ is abelian, if it is isomorphic to an object of $(\text{Mot}_{\text{ab}}^b)$. General properties of motivated cycles imply, that on any variety whose motive is abelian all Hodge classes are absolute.

1.3. Main result. In this paper we study varieties of the following type. Let $S$ be a complex projective surface. We will denote by $S^{[n]}$ the Hilbert scheme of length $n$ subschemes of $S$. For a complex abelian surface $A$ consider the Albanese morphism $a: A^{[n+1]} \to A$. The fibre $K^nA = a^{-1}(0)$ is called generalized Kummer variety.

**Definition 1.1.** Let $X$ be a non-singular projective variety. Assume that there exist a smooth projective morphism $\pi: X \to S$, where $S$ is a quasi-projective connected variety, and two points $s_0, s_1 \in S$, such that $X_{s_0} \simeq X$ and $X_{s_1} \simeq K^nA$ for some abelian surface $A$. Then we will say that $X$ is a projective deformation of $K^nA$.

**Theorem 1.2.** Let $X$ be a projective deformation of a generalized Kummer variety. Then the André motive of $X$ is abelian.

The proof will be given in section 4.

**Remark 1.3.** This theorem extends the results of [Sc] and [A2]. In [Sc] the varieties of $K3^{[n]}$-type were considered. Our arguments are based on the Kuga-Satake construction from [KSV] that can be applied to arbitrary hyperkähler manifolds. This can be used to obtain an alternative proof of the main theorem of [Sc]. In [A2] it was shown, that degree two cohomology of any projective hyperkähler manifold is abelian as an object of the category of André motives.

Theorem 1.2 is in line with the general expectation, that the motives of projective hyperkähler manifolds should be of abelian type, see e.g. [FV] for a general discussion.

**Corollary 1.4.** Let $X$ be a projective deformation of a generalized Kummer variety. Then all Hodge classes on $X$ are motivated, in particular they are absolute Hodge.

Theorem 1.2 can be used to prove the Mumford-Tate conjecture (see [Mo, section 2.3]) for some special classes of generalized Kummer type manifolds. Namely, let us say that a projective hyperkähler manifold $X$ (see section 3) is of CM type, if the Mumford-Tate group of $H^2(X, \mathbb{Q})$ is abelian. In this case the Mumford-Tate groups of $H^k(X, \mathbb{Q})$ are abelian for all $k$. This follows from the fact that the Hodge structures on all cohomology groups of $X$ are induced by the natural Lie algebra action, as we recall in section 3.

Assuming that $X$ is a projective deformation of $K^nA$ and that $X$ is of CM type, one can use [Mo, Theorem 3.3.2] to deduce from Theorem 1.2 that the Mumford-Tate conjecture holds for $X$ in arbitrary degrees (see also [Mo, Corollary 4.3.15]). Let us also mention that the Mumford-Tate conjecture in arbitrary degree for $K3^{[n]}$-type varieties has recently been proven in [Fl].

2. Motivated cohomology classes and André motives

We will briefly recall some results of [A1]. Let $(\text{Var}/\mathbb{C})$ be the category of non-singular complex projective varieties and their morphisms. For $X \in (\text{Var}/\mathbb{C})$ we will denote $H^k(X) = H^k(X^{an}, \mathbb{C})$. 

2.1. Motivated classes. Assume that $X \in (\text{Var}/\mathbb{C})$ and let $\mathcal{L}$ be an ample line bundle on $X$. Denote by $h \in H^2(X)$ the first Chern class of $\mathcal{L}$. The Lefschetz operator $L_h \in \text{End}(H^\bullet(X))$ is defined by the cup product with $h$, and it induces isomorphisms $L^k_h : H^{n-k}(X) \isomto H^{n+k}(X)$ for every $k = 0, \ldots, n$, where $n = \dim_{\mathbb{C}}(X)$. The subspace of primitive elements $H^k_{pr}(X) \subset H^k(X)$, $k = 0, \ldots, n$, is by definition the kernel of $L^{n-k+1}_h$.

We will denote by $*_{h} \in \text{End}(H^\bullet(X))$ the Lefschetz involution associated to $h$. Recall that for $x \in H^k_{pr}(X)$ and $i = 0, \ldots, n - k$ we have $*_{h}(L^i_h x) = L^{i-k}_h x$. This uniquely determines $*_{h}$, since $H^\bullet(X)$ is spanned by the elements of the form $L^i_h x$ with $x$ primitive.

For $X, Y \in (\text{Var}/\mathbb{C})$ and two ample line bundles $\mathcal{L}_1 \in \text{Pic}(X)$, $\mathcal{L}_2 \in \text{Pic}(Y)$, let $p_{X}$, $p_{Y}$ denote the two projections from $X \times Y$, and let $h = c_1(p^*_X \mathcal{L}_1 \otimes p^*_Y \mathcal{L}_2) \in H^2(X \times Y)$. For two classes of algebraic cycles $\alpha, \beta \in H^*_c(X \times Y)$, consider the class

$$(2.1) \quad p_{X\ast}(\alpha \cup *_{h}\beta).$$

Let $H^\bullet_M(X)$ be the $\mathbb{Q}$-subspace of $H^\bullet(X)$ spanned by the classes $2.1$ for all $Y$, $\mathcal{L}_1$, $\mathcal{L}_2$, $\alpha$, $\beta$ as above. Elements of $H^\bullet_M(X)$ will be called motivated cohomology classes (or motivated cycles, in the terminology of [A1]). Let us list a few properties of motivated classes.

1. $H^\bullet_M(X)$ is a graded $\mathbb{Q}$-subalgebra of $H^\bullet(X)$;
2. For $f : X \to Y$, we have $f^\ast H^\bullet_M(Y) \subset H^\bullet_M(X)$, hence a functor $H^\bullet_M : (\text{Var}/\mathbb{C})^{\text{op}} \to (\text{GrAlg}/\mathbb{Q})$;
3. For $f$ as above, we have $f_* H^\bullet_M(X) \subset H^\bullet_{\text{dim}(Y)}(Y)$;
4. All classes in $H^\bullet_M(X)$ are absolute Hodge;
5. The following deformation principle holds:

**Theorem 2.1 ([A1, Theorem 0.5]).** Let $\varphi : \mathcal{X} \to S$ be a smooth projective morphism. Assume that the base $S$ is a connected quasi-projective variety. Let $\nu \in \Gamma(S, R^{2p}\varphi_*\mathbb{C})$. Assume that for some $s \in S$ the element $\nu_s \in H^{2p}(\mathcal{X}_s)$ is a motivated cohomology class. Then $\nu_t$ is a motivated class on $\mathcal{X}_t$ for any $t \in S$.

2.2. André motives. The construction of André motives is similar to that of Chow motives. We start by defining the spaces of motivated correspondences: for $X, Y \in (\text{Var}/\mathbb{C})$ with $X$ connected, let $\text{Cor}^M_{\text{pr}}(X, Y) = H^{\text{pr}+\text{dim}(X)}_{\text{pr}}(X \times Y)$. The properties of motivated classes listed above imply that we can define the composition of motivated correspondences in the usual way.

Define a $\mathbb{Q}$-linear category $(\text{Mot}_A)$ whose objects are triples $(X, p, n)$, where $X \in (\text{Var}/\mathbb{C})$, $p \in \text{Cor}^M_0(X, X)$, $p \circ p = p$, and $n \in \mathbb{Z}$. The space of morphisms from $(X, p, n)$ to $(Y, q, m)$ is by definition $q \circ \text{Cor}^M_{m-n}(X, Y) \circ p \subset \text{Cor}^M_{m-n}(X, Y)$. The tensor product on $(\text{Mot}_A)$ is defined using the Cartesian product of varieties. It is shown in [A1], that $(\text{Mot}_A)$ is a semi-simple graded neutral Tannakian category.

For $X \in (\text{Var}/\mathbb{C})$ define $\text{Mot}(X)(n) = (X, [\Delta_X], n) \in (\text{Mot}_A)$.

The subcategory of abelian motives $(\text{Mot}^A_{\text{ab}})$ is the minimal full Tannakian subcategory of $(\text{Mot}_A)$ containing $\text{Mot}(A)(n)$ for all abelian varieties $A$ and $n \in \mathbb{Z}$. It is shown in [A1] that for any $X \in (\text{Var}/\mathbb{C})$, if $\text{Mot}(X) \in (\text{Mot}^A_{\text{ab}})$, then all Hodge classes on $X$ are motivated, in particular absolute Hodge.

3. Hyperkähler manifolds and the Kuga-Satake embedding

We will recall the results of [KSV] and extend them to the relative setting.

3.1. Hyperkähler manifolds. Let $X$ be a non-singular projective simple hyperkähler manifold. This means that $X$ is simply-connected and $H^0(X, \Omega^2_X)$ is spanned by a symplectic form (see e.g. [Hu] and [Be]). Let $2n = \dim_{\mathbb{C}}(X)$. 

Let \( V_\mathbb{Z} = H^2(X, \mathbb{Z}) \) and \( V = V_\mathbb{Z} \otimes \mathbb{Q} \). Let \( q \in S^2V^* \) denote the Beauville-Bogomolov-Fujiki (BBF) form. Recall that this form has the following property: there exists a constant \( c_X \in \mathbb{Q} \), such that for all \( h \in H^2(X, \mathbb{Q}) \) the equality \( q(h)^n = c_X h^{2n} \) holds. We can assume that \( q \) is integral and primitive on \( V_\mathbb{Z} \) and \( q(h) > 0 \) for a Kähler class \( h \). The signature of \( q \) is \((3,b_2(X) - 3)\). Recall also that \( V \) carries a Hodge structure of K3 type.

There exists a natural action of the orthogonal Lie algebra on the total cohomology of \( X \). Let us briefly recall how to define this action. An element \( h \in V \) has Lefschetz property, if the cup product with \( h^k \) induces an isomorphism \( H^{2n-k}(X, \mathbb{Q}) \cong H^{2n+k}(X, \mathbb{Q}) \) for all \( k = 0, \ldots, 2n \). In this case one can consider the corresponding Lefschetz \( sl_2 \)-triple. Let \( \mathfrak{g}_{tot} \subset \text{End}(H^*(X, \mathbb{Q})) \) be the Lie subalgebra generated by all such \( sl_2 \)-triples.

Let \( \tilde{V} = \langle e_0 \rangle \oplus V \oplus \langle e_4 \rangle \) be the graded \( \mathbb{Q} \)-vector space with \( e_i \) of degree \( i \), and \( V \) in degree 2. Let \( \tilde{q} \in S^2\tilde{V}^* \) be the quadratic form, such that: \( \tilde{q}|_V = q \), \( e_0 \) and \( e_4 \) are isotropic and orthogonal to \( V \) and span a hyperbolic plane. It was shown in [Ve1] and [LL] that there exists an isomorphism of graded Lie algebras \( \mathfrak{g}_{tot} \cong \mathfrak{so} (\tilde{V}, \tilde{q}) \).

One can show that the Hodge structures on the cohomology groups of \( X \) are induced by the action of \( \mathfrak{g}_{tot} \). More precisely, let \( W \) be the Weil operator that induces the Hodge structure on \( V \), i.e. it acts on \( V^{p,q} \) as multiplication by \( i(p-q) \). Then \( W \in \mathfrak{so}(V,q) \subset \mathfrak{so}(\tilde{V}, \tilde{q}) \) and \( W \) induces the Hodge structures on \( H^k(X, \mathbb{Q}) \) for all \( k \) (see [Ve1]).

3.2. The Kuga-Satake construction. To a K3 type Hodge structure \( V \) we can associate a Hodge structure of abelian type, which is called the Kuga-Satake Hodge structure. Let us briefly recall the construction. Let \( H = \text{Cl}(V,q) \) be the Clifford algebra. There exists a natural embedding \( V \rightarrow H \). Define \( H^{0,-1} \) to be the right ideal \( V^{2,0} \cdot H_C \) (see [SS, Lemma 3.3]), and \( H^{-1,0} = \overline{H^{0,-1}} \). This defines a rational Hodge structure on \( H \).

Note that \( H \) is canonically an \( \mathfrak{so}(V,q) \)-module, and the Hodge structure on it is induced by the action of the Weil operator \( W \). Since the hyperkähler manifold \( X \) is projective, one can show that \( H \) is polarizable. Moreover, the polarization can be chosen \( \text{Spin}(V,q) \)-invariant (see e.g. [KSV] or [VG]).

Let \( d = \frac{1}{4} m \dim \mathbb{Q}(H) \). The following theorem was proven in [KSV].

**Theorem 3.1.** There exists a structure of graded \( \mathfrak{so}(\tilde{V}, \tilde{q}) \)-module on \( \Lambda^*H^* \) that extends the \( \mathfrak{so}(V,q) \)-module structure. For some \( m > 0 \) there exists an embedding of \( \mathfrak{so}(\tilde{V}, \tilde{q}) \)-modules

\[
H^{*+2n}(X, \mathbb{Q}) \hookrightarrow \Lambda^{*+2d}(\Lambda^{*+m}).
\]

This induces embeddings of Hodge structures

\[
\nu_i : H^{*+2n}(X, \mathbb{Q}(n)) \hookrightarrow \Lambda^{*+2d}(\Lambda^{*+m})(d),
\]

where \( i = -2n, \ldots, 2n \).

3.3. The Kuga-Satake construction in families. Let us consider a smooth projective morphism \( \varphi : X \rightarrow S \) whose fibres are hyperkähler manifolds. Let us fix a base point \( s_0 \in S \) and denote by \( X \) the fibre \( X_{s_0} \). We would like to apply Theorem 3.1 to the family \( \varphi \) and obtain the embedding of the corresponding variations of Hodge structures. In order to do so, we need to construct a family of Kuga-Satake abelian varieties, such that the embeddings \( \nu_i \) from Theorem 3.1 are \( \pi_1(S, s_0) \)-equivariant. We will explain below, that it is possible to do this after we pass to a finite étale covering of \( S \). The base \( S \) can be arbitrary complex-analytic space.
Denote by $\text{Aut}^p(X) \subset \text{GL}(H^*(X, \mathbb{Q}))$ the subgroup of algebra automorphisms that fix the Pontryagin classes of $X$. We will denote by $\text{Aut}^p(X)_\mathbb{Z}$ the arithmetic subgroup of $\text{Aut}^p(X)_\mathbb{Q}$ defined by the the integral cohomology lattice.

Recall that $\mathfrak{s}(V,q)$ acts on $H^*(X, \mathbb{Q})$ by derivations, and this action induces a homomorphism of algebraic groups

$$\alpha: \text{Spin}(V,q) \to \text{Aut}^p(X),$$

see section 3.1 in [So] and references therein. Denote by $\text{Aut}^+(X)$ the image of $\alpha$. Let $\text{MC}(X) = \text{Diff}(X)/\text{Diff}^0(X)$ be the mapping class group of $X$. Here $\text{Diff}(X)$ is the group of diffeomorphisms of $X$, and $\text{Diff}^0(X)$ is the subgroup of diffeomorphisms isotopic to the identity. The mapping class group acts on the cohomology of $X$ fixing Pontryagin classes, hence a group homomorphism

$$\beta: \text{MC}(X) \to \text{Aut}^p(X)_\mathbb{Z}.$$

**Lemma 3.2.** There exists a subgroup of finite index $\text{MC}' \subset \text{MC}(X)$ and a group homomorphism $\beta': \text{MC}' \to \text{Spin}(V,q)_\mathbb{Q}$, such that $\alpha \circ \beta' = \beta$ and the image of $\beta'$ is contained in an arithmetic subgroup of $\text{Spin}(V,q)_\mathbb{Q}$.

**Proof.** Recall that the action of $\text{Aut}^p(X)$ on $V$ preserves the form $q$, thus we have a homomorphism $\text{Aut}^p(X) \to O(V,q)$, see [Ve2, Theorem 3.5(i)]. Let $\Gamma \subset \text{Aut}^p(X)_\mathbb{Z}$ be a torsion-free arithmetic subgroup. Since the induced homomorphism $\Gamma \to O(V,q)_\mathbb{Q}$ has finite kernel by [Ve2, Theorem 3.5(iv)], it is actually injective. Analogously, let $\Gamma' \subset \text{Spin}(V,q)_\mathbb{Q}$ be another torsion-free arithmetic subgroup. Then the action of $\text{Spin}(V,q)$ on $V$ induces an injection $\Gamma' \hookrightarrow O(V,q)_\mathbb{Q}$.

The construction of $\text{MC}'$ is summarized in the following commutative diagram:

$$\begin{array}{ccc}
\text{MC}' & \hookrightarrow & \text{MC}'' \\
\downarrow & & \downarrow \\
\Gamma \cap \Gamma' & \hookrightarrow & \Gamma, \quad \text{Aut}^p(X)_\mathbb{Z} \\
\downarrow & & \downarrow \\
\Gamma' & \hookrightarrow & O(V,q)_\mathbb{Q}
\end{array}$$

Here $\Gamma \cap \Gamma'$ is of finite index in $\Gamma$, because both $\Gamma$ and $\Gamma'$ are arithmetic subgroups of $O(V,q)_\mathbb{Q}$. By the definition of $\Gamma$, it has finite index in $\text{Aut}^p(X)_\mathbb{Z}$. We then let $\text{MC}' = \beta^{-1}(\Gamma \cap \Gamma')$, and define $\beta'$ to be the composition of the two maps in the left column of the diagram and the embedding $\Gamma' \subset \text{Spin}(V,q)_\mathbb{Q}$. □

**Corollary 3.3.** Let $\varphi: \mathcal{X} \to S$ be a smooth family of hyperkähler manifolds with $S$ connected, $s_0 \in S$ a base point, $X$ the fibre of $\varphi$ over $s_0$. Let $V = H^2(X, \mathbb{Q})$ with the BBF form $q$ and $2n = \dim_{\mathbb{C}}(X)$. Then the following statements hold:

1. There exists a finite étale covering $S' \to S$, such that the action of $\pi_1(S', s_0')$ on $H^*(X, \mathbb{Q})$ factors through a homomorphism $\rho: \pi_1(S', s_0') \to \text{Spin}(V,q)_\mathbb{Q}$;
2. There exists a smooth family of compact complex tori $\psi: \mathcal{A} \to S'$ and an embedding of the variations of Hodge structures

$$\tilde{\nu}_i: R^{i+2n} \varphi'_*(\mathcal{Q}(n)) \hookrightarrow R^{i+2d} \varphi_*\mathcal{Q}(d),$$

where $i = -2n, \ldots, 2n$, $2d = \dim_{\mathbb{C}}(A_{\varphi'})$ and $\varphi': \mathcal{X}' = \mathcal{X} \times_S S' \to S'$;
3. In the case when $\varphi$ is projective, $\psi$ is also projective. In this case the fibres of $\psi$ are abelian varieties.
Proof. (1) The monodromy action on the cohomology is induced by a homomorphism \( \rho: \pi_1(S, s_0) \to \mathrm{MC}(X) \). Using the subgroup \( \mathrm{MC}' \subset \mathrm{MC}(X) \) from Lemma 3.2, we get a finite index subgroup \( \rho^{-1}(\mathrm{MC}') \subset \pi_1(S, s_0) \) and the corresponding covering \( S' \). It satisfies the required properties by the definition of \( \mathrm{MC}' \).

(2) Denote by \( \tilde{S} \) the universal covering of \( S \). Let \( \mathcal{H} \) be the variation of the Kuga-Satake Hodge structures over \( \tilde{S} \), constructed fiberwise as in section 3.2. By Lemma 3.2, the image of \( \pi_1(S', s'_0) \) under \( \rho \) is contained in an arithmetic subgroup of \( \text{Spin}(V, q) \). This implies, that the action of the fundamental group of \( S' \) preserves some lattice \( \Lambda \subset \mathcal{H} \). Taking the quotient of \( \mathcal{H}/\Lambda \) by the action of \( \pi_1(S', s'_0) \), we get a family of complex tori \( \psi: A \to S' \). The embeddings of Hodge structures \( \nu_i \) from Theorem 3.1 are monodromy-equivariant. This implies that they induce the embeddings \( \tilde{\nu}_i \) of the corresponding variations of Hodge structures over \( S' \).

(3) This follows from the fact, that when the K3 type Hodge structure \( (V, q) \) is polarized, the corresponding Kuga-Satake Hodge structure admits \( \text{Spin}(V, q) \)-invariant polarizations, see e.g. [KSV].

4. Proof of Theorem 1.2

Consider a smooth projective family of hyperkähler manifolds \( \varphi: \mathcal{X} \to S \) with a connected quasi-projective base \( S \). We assume that there exist two points \( s_0, s_1 \in S \), such that \( \mathcal{X}_{s_0} \simeq X \) and \( \mathcal{X}_{s_1} \simeq K^nA \) for some abelian surface \( A \). We denote \( V = H^2(X, \mathbb{Q}) \) with the BBF form \( q \) (see section 3).

Using part (1) of Corollary 3.3, we may assume that \( \pi_1(S, s_0) \) acts on \( H^*(X, \mathbb{Q}) \) via a homomorphism \( \rho: \pi_1(S, s_0) \to \text{Spin}(V, q) \). Let \( \psi: A \to S \) be the family of Kuga-Satake abelian varieties from part (2) of Corollary 3.3. Consider the product \( \mathcal{Y} = \mathcal{X} \times_S A \) and denote \( \xi: \mathcal{Y} \to S \).

The embeddings \( \tilde{\nu}_i \) can be viewed as global sections of the local system \( R^{2n+2d}\xi_* \mathbb{Q}(n+d) \). We need to prove that the corresponding cohomology class \( \tilde{\nu}_{i,s_0} \in H^{2n+2d}((\mathcal{X}_{s_0} \times A_{s_0}, \mathbb{Q}(n+d)) \) is motivated. By the deformation principle 2.1, it is enough to prove that \( \tilde{\nu}_{i,s_1} \) is motivated. But the fibre \( \mathcal{Y}_{s_1} \simeq \mathcal{X}_{s_1} \times A_{s_1} \simeq K^nA \times A_{s_1} \) by our assumptions. It is shown in [Xu, Theorem 1.1] (see also [DM1] and [DM2]) that the motive of \( K^nA \) is abelian (in [Xu], [DM1] and [DM2] a stronger statement about the Chow motives is proven). This implies that the motive of the fibre \( \mathcal{Y}_{s_1} \) is abelian, and all Hodge classes on \( \mathcal{Y}_{s_1} \) are motivated. The claim now follows from the deformation principle.

Acknowledgements

I am grateful to Salvatore Floccari for his interest in this work and useful comments.
