AMBIGUOUS REPRESENTATIONS OF SEMILATTICES AND IMPERFECT INFORMATION

OLEH NYKYFORCHYN, OKSANA MYKYTSEY

Abstract. Crisp and lattice-valued ambiguous representations of one continuous semilattice in another one are introduced and operation of taking pseudo-inverse of the above relations is defined. It is shown that continuous semilattices and their ambiguous representations, for which taking pseudo-inverse is involutive, form categories. Self-dualities and contravariant equivalences for these categories are obtained. Possible interpretations and applications to processing of imperfect information are discussed.

Introduction

The goal of this work is to generalize notions of crisp and $L$-fuzzy ambiguous representations introduced in [7] for closed sets in compact Hausdorff spaces. Fuzziness and roughness were combined to express the main idea that a set in one space can be represented with a set in another space, e.g., a 2D photo can represent 3D object. This representation is not necessarily unique, and the object cannot be recovered uniquely, hence we say “ambiguous representation”.

It turned out that most of results of [7] can be extended to wider settings, namely to continuous semilattices, which are standard tool to represent partial information. This is done in the present paper, and an interpretation of the considered objects is proposed.

The paper is organized as follows. First necessary definitions and facts are given on continuous (semi-)lattices. Then we define compatibilities, which are functions with values 0 and 1 that show whether two pieces of information can be valid together. Next ambiguous representations are introduced as crisp and $L$-fuzzy relations between continuous semilattices. Operation of taking pseudo-inverse is defined for these relations, its properties are proved, and classes of pseudo-invertible representations are investigated. It is shown that continuous semilattices and their pseudo-invertible crisp and $L$-fuzzy ambiguous representations form categories, and self-dualities and contravariant equivalences are constructed for these categories. Finally, we discuss possible meaning of the developed theory. Reader can start with the last section to get the general idea what is in the previous parts of the paper.

1. Preliminaries

We adopt the following definitions and notation, which are consistent with [1] [3]. Proofs of the facts below can also be found there. From now on, semilattice means meet semilattice, if otherwise is not specified. If a poset contains a bottom
(a top) element, then it is denoted by 0 (resp. 1). A top (a bottom) element in a semilattice is also called a unit (resp. a zero).

For a partial order \( \leq \) on a set \( X \), the relation \( \hat{\leq} \), defined as \( x \hat{\leq} y \iff y \leq x \), for \( x, y \in X \), is a partial order called opposite to \( \leq \), and \( (X, \hat{\leq})^{op} \) denotes the poset \( (X, \hat{\leq}) \). If the original order \( \leq \) is a partial order, we write simply \( X^{op} \) for the reversed poset. We also apply \( \hat{} \) to all notation to denote passing to the opposite order, i.e., write \( X = X^{op}, \sup = \inf, 0 = 1 \) etc. For a morphism \( f : (X, \leq) \to (Y, \leq) \) in a category \( \text{Poset} \) of posets and isotone (order preserving) mappings, let \( f^{op} \) be the same mapping, but regarded as \( (X, \hat{\leq}) \to (Y, \hat{\leq}) \). It is obvious that \( f^{op} \) is isotone as well, thus a functor \( (\_)^{op} : \text{Poset} \to \text{Poset} \) is obtained.

For a subset \( A \) of a poset \( (X, \leq) \), we denote

\[
A^\uparrow = \{ x \in X \mid a \leq x \text{ for some } a \in A \}, A^\downarrow = \{ x \in X \mid x \leq a \text{ for some } a \in A \}.
\]

If \( A = A^\uparrow (A = A^\downarrow) \), then a set \( A \) is called upper (resp. lower).

A topological meet (or join) semilattice is a semilattice \( L \) carrying a topology such that the mapping \( \land : L \times L \to L \) (resp. \( \lor : L \times L \to L \)) is continuous. A lattice \( L \) with a topology such that both \( \land : L \times L \to L \) and \( \lor : L \times L \to L \) are continuous is called a topological lattice.

A poset \( (X, \leq) \) is called complete if each non-empty subset \( A \subset X \) has a least upper bound.

A set \( A \) in a poset \( (X, \leq) \) is directed (filtered) if, for all \( x, y \in A \), there is \( z \in A \) such that \( x \leq z, y \leq z \) (resp. \( z \leq x, z \leq y \)). A poset is called directed complete (dcpo for short) if it has lowest upper bounds for all its directed subsets.

The Scott topology \( \sigma(X) \) on \( (X, \leq) \) consists of all those \( U \subseteq X \) that satisfy \( x \in U \iff U \cap D \neq \emptyset \) for every \( \leq \)-directed \( D \subseteq X \) with a least upper bound \( x \). Note that \( \subseteq \) above implies \( U = U^\uparrow \).

In a dcpo \( X \), a set is Scott closed iff it is lower and closed under suprema of directed subsets.

A mapping \( f \) between dcpo’s \( X \) and \( Y \) is Scott continuous, i.e., continuous w.r.t. \( \sigma(X) \) and \( \sigma(Y) \), if and only if it preserves suprema of directed sets.

Let \( L \) be a poset. We say that \( x \) is way below \( y \) and write \( x \ll y \) iff, for all directed subsets \( D \subseteq L \) such that sup \( D \) exists, the relation \( y \leq \sup D \) implies the existence of \( d \in D \) such that \( x \leq d \). “Way-below” relation is transitive and antisymmetric. An element satisfying \( x \ll x \) is said to be compact or isolated from below, and in this case the set \( \{ x \}^\uparrow \) is Scott open.

A poset \( L \) is called continuous if, for each element \( y \in L \), the set \( y_\downarrow = \{ x \in L \mid x \ll y \} \) is directed and its least upper bound is \( y \). A domain is a continuous dcpo. If a domain is a semilattice, it is called a continuous semilattice.

A complete lattice \( L \) is called completely distributive if, for each collection of sets \( (M_t)_{t \in T} \) in \( L \), the equality \( \inf \{ \sup M_t \mid t \in T \} = \sup \{ \inf \{ \alpha_t \mid t \in T \} \mid (\alpha_t)_{t \in T} \in \prod_{t \in T} M_t \} \) holds. This property implies distributivity, but the converse fails. Then both \( L \) and \( L^{op} \) are continuous, and the join of Scott topologies on \( L \) and \( L^{op} \) provides the unique compact Hausdorff topology on \( L \) with a basis consisting of small sublattices (Lawson topology). In the sequel completely distributive lattices will be regarded with Lawson topologies.
For a subset $R \subset S_1 \times S_2 \times \cdots \times S_n$, an index $k \in \{1, 2, \ldots, n\}$, and elements $\alpha_1 \in S_1, \ldots, \alpha_{k-1} \in S_{k-1}, \alpha_{k+1} \in S_{k+1}, \ldots, \alpha_n \in S_n$, the set
\[
\varprojlim_{\text{all factors except } \alpha_k} (R \cap (\{\alpha_1\} \times \cdots \times \{\alpha_{k-1}\} \times S_k \times \{\alpha_{k+1}\} \times \cdots \times \{\alpha_n\}))
\]
\[
= \{\alpha \in S_k \mid (\alpha_1, \ldots, \alpha_{k-1}, \alpha, \alpha_{k+1}, \ldots, \alpha_n) \in R\} \subset S_k
\]
is called a cut of $R$. We denote it $\alpha_1 \ldots \alpha_{k-1} R \alpha_{k+1} \ldots \alpha_n$.

The following obvious property is quite useful.

1.1. Lemma. Let $S_1, S_2, \ldots, S_n$ be dcpos, $R \subset S_1 \times S_2 \times \cdots \times S_n$. Then $R$ is Scott closed if and only if all its cuts are Scott closed.

Proof. Necessity is obvious. To prove sufficiency, observe that all cuts of $R$ being Scott closed (hence lower sets) implies that $R$ is a lower set as well. Without loss of generality we can consider only the case $n = 2$. Let a subset $D \subset R \subset S_1 \times S_2$ be directed. Then the set $D' = D \downarrow \subset R$ is directed as well and lower in $S_1 \times S_2$, hence is the product $D_1 \times D_2$ of directed lower sets $D_1 \subset S_1$ and $D_2 \subset S_2$. For any $x \in D_1$ the set $\{x\} \times D_2$ is contained in $R$, therefore $D_2$ is contained in the Scott closed cut $xR$. This implies that the least upper bound $b = \sup D_2$, which exists because $S_2$ is a dcpo, is an element of this cut, hence $(x, b) \in R$ for all $x \in D_1$. Thus $D_1$ is contained in the Scott closed cut $Rb$, therefore $a = \sup D_1$ in the dcpo $S_1$ also belongs to this cut. We obtain that $(a, b) = \sup D' = \sup D$ belongs to $R$ for any directed subset $D \subset R$, i.e., $R$ is Scott closed.

Similarly, for a subset $R \subset S_1 \times S_2 \times \cdots \times S_n$, an index $k \in \{1, 2, \ldots, n\}$, and subsets $A_1 \subset S_1, \ldots, A_{k-1} \subset S_{k-1}, A_{k+1} \subset S_{k+1}, \ldots, A_n \subset S_n$, we denote
\[
A_1 \ldots A_{k-1} R A_{k+1} \ldots A_n = \{\alpha \in S_k \mid \text{there are } \alpha_1 \in S_1, \ldots, \alpha_{k-1} \in S_{k-1}, \\
\alpha_{k+1} \in S_{k+1}, \ldots, \alpha_n \in S_n \text{ such that } (\alpha_1, \ldots, \alpha_{k-1}, \alpha, \alpha_{k+1}, \ldots, \alpha_n) \in R\}.
\]

2. Compatibilities for continuous semilattices

Let $\text{Sem}_0$ be the category of all continuous (meet) semilattices with zeros and all Scott continuous zero-preserving semilattice morphisms. We denote by $[S \to S']_0$ the set of all arrows from $S$ to $S'$ in $\text{Sem}_0$.

We use the results of [6] and denote by $S^\wedge$ the set of all (probably empty) Scott open filters in $S$ except $S$ itself. We order $S^\wedge$ by inclusion, then $S^\wedge$ is a continuous semilattice with the bottom element $\emptyset$. Then $S^\wedge$ can be regarded as $[S \to \{0, 1\}]_0$, i.e., its elements can be identified with the bottom-preserving meet-preserving Scott continuous maps $S \to \{0, 1\}$ (the preimages of $\{1\}$ under such maps are precisely the non-trivial Scott open filters in $S$). For an arrow $f : S_1 \to S_2$ in $\text{Sem}_0$ the formula $f^\wedge(F) = f^{-1}(F)$, $F \in S_2^\wedge$, determines the mapping $f^\wedge : S_1^\wedge \to S_2^\wedge$, which is an arrow in $\text{Sem}_0$ as well, hence the contravariant functor $(-)^\wedge$ in $\text{Sem}_0$ is obtained. The assignment $s \mapsto \{F \in S^\wedge \mid s \in F\}$ is an isomorphism $u_S : S \to S^{\wedge\wedge}$ which is a component of a natural transformation $u : 1_{\text{Sem}_0} \to (-)^{\wedge\wedge}$, hence the functor $(-)^{\wedge\wedge}$ is involutive, i.e., is a self-duality. In fact it is a restriction of the Lawson duality [11].

We slightly change the terminology introduced in [6]:

2.1. Definition. Let $S, S'$ be continuous semilattices with bottom elements respectively $0, 0'$. A mapping $P : S \times S' \to \{0, 1\}$ is called a compatibility if:
(1) $P$ is distributive w.r.t. $\land$ in the both variables, and $P(0, y) = P(x, 0') = 0$ for all $x \in S$, $y \in S'$;
(2) $P$ is Scott continuous.

If, additionally, the following holds:

(3) $P$ separates elements of $S$ and of $S'$, i.e.:
(3a) for each $x_1, x_2 \in S$, if $P(x_1, y) = P(x_2, y)$ for all $y \in S'$, then $x_1 = x_2$;
(3b) for each $y_1, y_2 \in S'$, if $P(x, y_1) = P(x, y_2)$ for all $x \in S$, then $y_1 = y_2$;
then we call $P$ a separating compatibility.

The definition of (separating) compatibility is symmetric in the sense that the mapping $P' : S' \times S \to \{0, 1\}$, $P'(y, x) = P(x, y)$ is a (separating) compatibility as well, which we call the reverse compatibility. For compatibilities we use also infix notation $xPy \equiv P(x, y)$.

We can consider a compatibility $P : S \times S' \to \{0, 1\}$ as a characteristic mapping of a binary relation $P \subseteq S \times S'$, hence it is natural to denote $xP = \{y \in S' \mid xPy = 1\}$, $Py = \{x \in S \mid xPy = 1\}$ for all $x \in S$, $y \in S'$.

The following statement from [6] is of crucial importance:

2.2. Proposition. Let $S, S'$ be continuous meet semilattices with bottom elements $0, 0'$ resp. If $P : S \times S' \to \{0, 1\}$ is a separating compatibility, then the mapping $i$ that takes each $x \in S$ to $xP$ is an isomorphism $S \to S^\land$. Conversely, each isomorphism $i : S \to S^\land$ is determined by the above formula for a unique separating compatibility $P : S \times S' \to \{0, 1\}$.

Similarly, for a fixed separating compatibility $P : S \times S' \to \{0, 1\}$ and subsets $A \subseteq S$, $B \subseteq S'$, the sets

$$A^\perp = \{y \in S' \mid xPy = 0 \text{ for all } x \in A\}, \quad B^\perp = \{x \in S \mid xPy = 0 \text{ for all } y \in B\}$$

will be called the transversals of $A$ and $B$ respectively.

It is easy to see that $A^\perp$ and $B^\perp$ are Scott closed, and $A^\perp \perp = (A^\perp)^\perp$ is the Scott closure of $A$, i.e., the least Scott closed (hence lower) subset in $S$ that contains $A$, similarly for $B^\perp$.

Obviously the transversal operation $(-)^\perp$ is antitone, i.e., $A \subseteq B$ implies $A^\perp \supset B^\perp$, and for a filtered family $\{A_\alpha \mid \alpha \in \mathcal{A}\}$ of closed lower sets the equality

$$\bigcap_{\alpha \in \mathcal{A}} A_\alpha^\perp = \text{Cl}(\bigcup_{\alpha \in \mathcal{A}} A_\alpha^\perp)$$

is valid. This implies

$$\bigcap_{\alpha \in \mathcal{A}} A_\alpha = (\text{Cl}(\bigcup_{\alpha \in \mathcal{A}} A_\alpha^\perp))^\perp = (\bigcup_{\alpha \in \mathcal{A}} A_\alpha^\perp)^\perp.$$  

3. Category of ambiguous representations

3.1. Definition. Let $S_1, S_2$ be continuous semilattices with zeros. An ambiguous representation of $S_1$ in $S_2$ is a binary relation $R \subseteq S_1 \times S_2$ such that

(a) if $(x, y) \in R$, $x \leq x'$ in $S_1$, and $y' \leq y$ in $S_2$, then $(x', y') \in R$ as well;
(b) for all $x \in S_1$ the set $xR = \{y \in S_2 \mid (x, y) \in R\}$ is non-empty and closed under directed sups in $S_2$.

Observe that (a) implies $(x, 0_2) \in R$ for all $x \in S$. It also implies that $xR$ in (b) is a lower set, hence due to (b) is Scott closed.
Thus we can rearrange the requirements as follows, obtaining an equivalent definition:

3.2. Definition. For continuous semilattices \( S_1, S_2 \) with zeros, a binary relation \( R \subset S_1 \times S_2 \) is an ambiguous representation of \( S_1 \) in \( S_2 \) if

(a’) for all \( x \in S_1 \) the set \( xR = \{ y \in S_2 \mid (x, y) \in R \} \) is non-empty and Scott closed (i.e., a directed complete lower set).

(b’) for all \( y \in S_2 \) the set \( Ry = \{ x \in S_1 \mid (x, y) \in R \} \) is an upper set.

We call such ambiguous representations crisp to distinguish them from \( L \)-fuzzy ambiguous representations that will be defined in the next section.

Let separating compatibilities \( P_1 : S_1 \times \hat{S}_1 \to \{0, 1\} \), \( P_2 = S_2 \times \hat{S}_2 \to \{0, 1\} \) be fixed.

For an ambiguous representation \( R \subset S_1 \times S_2 \) define the relation \( R^- \subset \hat{S}_2 \times \hat{S}_1 \) with the formula

\[
R^- = \{ (\hat{y}, \hat{x}) \in \hat{S}_2 \times \hat{S}_1 \mid \text{if } xP_1 \hat{x} = 1 \text{ for some } x \in S_1, \text{then there is } y \in xR, \ yP_2 \hat{y} = 1 \},
\]

or, equivalently

\[
R^- = \{ (\hat{y}, \hat{x}) \in \hat{S}_2 \times \hat{S}_1 \mid \text{if } x \in S_1 \text{ is such that } yP_2 \hat{y} = 0 \text{ for all } y \in xR, \text{then } xP_1 \hat{x} = 0 \}.
\]

Obviously \( R^- \) is an ambiguous representation as well, hence we can calculate \( R^- = (R^-)^- \subset S_1 \times S_2 \) using the reverse (in fact the same) separating compatibilities again.

3.3. Proposition. For each ambiguous representation \( R \subset S_1 \times S_2 \) the inclusion \( R^- \subset R \) holds. The equality \( R = R^- \) is equivalent to the condition

(c) if \( (x, y) \in R \) and \( y' \ll y \) in \( S_2 \), then there is \( x' \ll x \) in \( S \) such that \( (x', y') \in R \).

Proof. Observe the validity of the formula

\[
\hat{y}R^- = \{ x \in S_1 \mid \hat{y} \in (xR)^- \}^-.
\]

Thus

\[
xR^- = \{ \hat{y} \in \hat{S}_2 \mid \hat{x} \in (\hat{y}R^-)^- \}^- = \{ \hat{y} \in \hat{S}_2 \mid \hat{x} \in \{ x \in S \mid \hat{y} \in (xR)^- \}^- \}^-.
\]

Taking into account

\[
\hat{x} \in \{ x \in S \mid \hat{y} \in (xR)^- \}^- \iff \hat{y} \in (\hat{x}R)^-,
\]

we obtain

\[
\hat{x}R^- \subset \{ \hat{y} \in \hat{S}_2 \mid \hat{y} \in (\hat{x}R)^- \}^- = (\hat{x}R)^- = \hat{x}R
\]

for all \( \hat{x} \in S \), which is the required inclusion.

The set \( \{ x \in S \mid \hat{y} \in (xR)^+ \} \) is lower, therefore its double transversal is the closure, thus

\[
\hat{x}R^- = \{ \hat{y} \in \hat{S}_2 \mid \hat{x} \in \text{Cl}\{ x \in S \mid \hat{y} \in (xR)^+ \} \}^- = \{ \hat{y} \in \hat{S}_2 \mid \hat{y} \in (xR)^+ \text{ for all } x \ll \hat{x} \}^- = \text{Cl}\{ (xR)^+ \mid x \ll \hat{x} \}^-.
\]

The family \( \{(xR)^+ \mid x \ll \hat{x} \} \) of closed lower sets is filtered, hence the transversal of its intersection equals

\[
\text{Cl}\{ \bigcup \{(xR)^+ \mid x \ll \hat{x} \} \} = \text{Cl}\{ \bigcup \{xR \mid x \ll \hat{x} \} \},
\]
and the equality $R^\preceq = R$ is equivalent to
\[ xR = \text{Cl}(\bigcup \{ xR \mid x \preceq \bar{x} \} ), \]
which in fact is the condition (c).
\[ \square \]

The equality $R^\preceq = R$ implies $(R^\sim)^\preceq = R^\sim$, hence, if (c) holds for $R$, then it holds for $R^\sim$ as well. Therefore on such ambiguous representations the operation $(\cdot)^\sim$ is involutive, and we call each of $R$ and $R^\sim$ the pseudo-inverse to the other one. The ambiguous representations satisfying (c) are called pseudo-invertible.

One of the reasons to consider this subclass is that, if we compose ambiguous representations as relations, i.e., for $R \subset S_1 \times S_2$, $Q \subset S_2 \times S_3$:
\[ RQ = \{(x, z) \in S_1 \times S_3 \mid \text{there is } y \in S_2 \text{ such that } (x, y) \in R, (y, z) \in Q \}, \]
then the resulting relation can fail to satisfy closedness in the condition (b) of the definition of ambiguous representation, hence ambiguous representations do not form a category.

To improve things, redefine the composition as
\[ R;Q = \{(x, z) \in S_1 \times S_3 \mid z \in \text{Cl}(xRQ) \} \]
\[ = \{(x, z) \in S_1 \times S_3 \mid \text{for all } z' \preceq z \text{ there is } y \in S_2 \text{ such that } (x, y) \in R, (y, z') \in Q \}. \]
Now closedness is at hand, but the composition “;” is not associative.

3.4. Lemma. For all ambiguous representations $R \subset S_1 \times S_2$, $Q \subset S_2 \times S_3$ the inclusion $Q^\sim;R^\sim \subset (R;Q)^\sim$ holds.

Proof. Since $\hat{z}Q^\sim;R^\sim = \text{Cl}(zQ^\sim R^\sim)$ for all $\hat{z} \in \hat{S}_3$, and $\hat{z}(R;Q)^\sim$ is closed in $S_1$, it is sufficient to prove $Q^\sim R^\sim \subset (R;Q)^\sim$.

If $(\hat{z}, \hat{x}) \in Q^\sim R^\sim$, then choose $\hat{y} \in \hat{S}_2$ such that $(\hat{z}, \hat{y}) \in Q^\sim$ and $(\hat{y}, \hat{x}) \in R^\sim$, and combine

if $xP_1\hat{x} = 1$ for some $x \in S_1$, then there is $y \in xR$, $yP_2\hat{y} = 1$,
if $yP_2\hat{y} = 1$ for some $y \in S_2$, then there is $z \in yQ$, $zP_3\hat{z} = 1$

to obtain

if $xP_1\hat{x} = 1$ for some $x \in S_1$, then there is $z \in xRQ$, $zP_3\hat{z} = 1$.

Moreover the latter $z$ belongs to $xR;Q$, hence $(\hat{z}, \hat{x}) \in (R;Q)^\sim$.
\[ \square \]

3.5. Corollary. Let ambiguous representations $R \subset S_1 \times S_2$, $Q \subset S_2 \times S_3$ be pseudo-invertible. Then $Q^\sim;R^\sim \subset (R;Q)^\sim$, and the composition $R;Q$ is pseudo-invertible as well.

Proof. By the above and taking into account that $(\cdot)^\sim$ is isotone:
\[ R;Q = R^\sim;Q^\preceq \subset (Q^\sim;R^\sim)^\sim \subset (R;Q)^\preceq, \]
and the reverse inclusion is known, hence $R;Q = (R;Q)^\preceq = (Q^\sim;R^\sim)^\sim$, i.e., $R;Q$ is pseudo-invertible. Apply $(\cdot)^\sim$ to this again and obtain $(R;Q)^\sim = (Q^\sim;R^\sim)^\preceq = Q^\sim;R^\sim$.
\[ \square \]

3.6. Proposition. Composition “;” of the pseudo-invertible ambiguous representations is associative.
Proof: Recall that, for ambiguous representations \( R \subset S_1 \times S_2, \ Q \subset S_2 \times S_3 \), the composition is calculated as

\[
R;Q = \{(x, z) \in S_1 \times S_3 \mid \text{for all } z' \ll z \text{ there is } y \in S_2 \text{ such that } (x, y) \in R, (y, z') \in Q\}.
\]

It is also important that, for elements \( a \ll c \) in a continuous semilattice, there is an element \( b \) such that \( a \ll b \ll c \).

Now, let \( (x, t) \in R;Q:T \). For any \( t' \ll t \) choose \( t'' \) such that \( t' \ll t'' \ll t \), then there is \( y \in S_2 \) such that \( (x, y) \in R, (y, t'') \in Q:T \). The latter implies that there is \( z \in S_3 \) such that \( (y, z) \in Q, (z, t') \in T \).

Similarly, let \( (x, t) \in (R;Q):T \), then for all \( t' \ll t \) choose \( t'' \ll t \), and there is \( z' \in S_3 \) such that \( (x, z') \in R;Q, (z', t'') \in T \). Pseudo-invertibility of \( T \) implies the existence of \( z \ll z' \) such that \( (z, t') \in T \) as well. There is also \( y \in S_2, (x, y) \in R, (y, z) \in Q \).

On the other hand, if, for \( x \in S_1, \ t \in S_4 \), elements \( y \in S_2, z \in S_3 \) exist for all \( t' \ll t \) such that \( (x, y) \in R, (y, z) \in Q, (z, t') \in T \), then \( (x, t') \in RQT \), hence \( (x, t') \in (R;Q:T) \) and \( (x, t') \in (R;Q):T \), which in turn implies both \( (x, t) \in R;Q:T \) and \( (x, t) \in (R;Q):T \). Thus \( R;Q:T = (R;Q):T \). □

It is easy to verify that, for a continuous semilattice \( S \) with zero, the relation \( E_S = \{(x, y) \in S \times S \mid y \leq x \} \) is a pseudo-invertible ambiguous representation that is a neutral element for composition. Thus:

3.7. Proposition. All continuous semilattices with bottom elements and all pseudo-invertible ambiguous representation form a category \( \text{SemPR} \), which contain \( \text{Sem}_0 \) as a subcategory.

An obvious embedding \( \text{Sem}_0 \to \text{SemPR} \) is of the form: \( IS = S \) for an object \( S \), and \( If = \{(x, y) \in S_1 \times S_2 \mid y \leq f(x)\} \) for an arrow \( f : S_1 \to S_2 \).

We denote an arrow \( R \) from \( S_1 \) to \( S_2 \) in \( \text{SemPR} \) with \( R : S_1 \Rightarrow S_2 \) and use for the composition of \( R \) and \( Q \) the synonymic notations \( R;Q \) (in direct order) and \( Q \circ R \) (in reverse order) both in \( \text{Sem}_0 \) and \( \text{SemPR} \).

3.8. Proposition. The correspondence \((-)^{\land}\) is an involutive contravariant functor (a self-duality) in \( \text{SemPR} \), which is an extension of the functor \((-)^{\lor}\) in \( \text{Sem}_0 \).

4. Category of \( L \)-fuzzy ambiguous representations

Now we extend the notion of ambiguous representation to lattice-valued relations in the spirit of [5] and [6].

4.1. Definition. Let \( S_1, S_2 \) be continuous semilattices with zeros \( 0_1 \) and \( 0_2 \) resp., \( L \) a completely distributive lattice with a bottom element \( 0 \) and a top element \( 1 \). An \( L \)-fuzzy ambiguous representation (or an \( L \)-ambiguous representation for short) of \( S_1 \) in \( S_2 \) is a ternary relation \( R \subset S_1 \times S_2 \times L \) such that

(a) if \( (x, y, \alpha) \in R, x \leq x' \in S_1, y' \leq y \in S_2 \), and \( \alpha' \leq \alpha \) in \( L \), then \( (x', y', \alpha') \in R \) as well;

(b) for all \( x \in S_1 \) the set \( xR = \{(y, \alpha) \in S_2 \times L \mid (x, y, \alpha) \in R\} \) is Scott closed in \( S_2 \times L \) and contains all the elements of the forms \((0_2, \alpha)\) and \((y, 0)\);

(c) for all \( x \in S_1, y \in S_2, \alpha, \beta \in L \), if \((x, y, \alpha) \in R, (x, y, \beta) \in R\), then \((x, y, \alpha \lor \beta) \in R\).

The following definition is equivalent.
4.2. **Definition.** For continuous semilattices $S_1, S_2$ with zeros and a completely distributive lattice $L$, a ternary relation $R \subset S_1 \times S_2 \times L$ is an $L$-ambiguous representation of $S_1$ in $S_2$ if

(a') for all $y \in S_2$, $\alpha \in L$ the set $Ry\alpha = \{ x \in S_1 \mid (x, y, \alpha) \in R \}$ is an upper set in $S_1$;

(b') for all $x \in S_1$, $\alpha \in L$ the set $xR\alpha = \{ y \in S_2 \mid (x, y, \alpha) \in R \}$ is non-empty and Scott closed in $S_2$;

(c') for all $x \in S_1$, $y \in S_2$ the set $xyR = \{ \alpha \in L \mid (x, y, \alpha) \in R \}$ is non-empty, directed, and Scott closed in $L$.

Obviously, due to complete distributivity of $L$, (c') is equivalent to any of the following properties:

(c'') for all $x \in S_1$, $y \in S_2$ the set $xyR = \{ \alpha \in L \mid (x, y, \alpha) \in R \}$ is a non-empty directed lower set such that, if $\beta \in xyR$ for all $\beta \ll \alpha$, then $\alpha \in xyR$; or

(c''') for all $x \in S_1$, $y \in S_2$ the set $xyR$ is a lower set with a greatest element (i.e., a set of the form $\{ \alpha \}$).

Observe also that (a')+(b') mean that, for all $\alpha \in L$, the cut $R\alpha = \{ (x, y) \in S_1 \times S_2 \mid (x, y, \alpha) \in R \}$ is a (crisp) ambiguous representation of $S_1$ in $S_2$ as defined in the previous section. We will call it the $\alpha$-cut of $R$ and denote $R_\alpha$.

We assume again that separating compatibilities $P_1 : S_1 \times \hat{S}_1 \to \{0, 1\}$, $P_2 = S_2 \times \hat{S}_2 \to \{0, 1\}$ are fixed.

For an ambiguous representation $R \subset S_1 \times S_2 \times L$ define the relation $R^- \subset \hat{S}_2 \times \hat{S}_1 \times L$ through its $\alpha$-cuts as follows:

$$(R^-)_\alpha = \bigcap_{\beta \ll \alpha} (R_\beta)^-, $$

or, equivalently, with the formulae

$$R^- = \{(\hat{y}, \hat{x}, \alpha) \in \hat{S}_2 \times \hat{S}_1 \mid \text{if } \beta \ll \alpha \text{ and } xP_1 \hat{x} = 1 \text{ for some } x \in S_1, $$

then there is $(y, \beta) \in xR$, $yP_2 \hat{y} = 1\},$$

or

$$R^- = \{(\hat{y}, \hat{x}) \in \hat{S}_2 \times \hat{S}_1 \mid \text{if } \beta \ll \alpha \text{ and } x \in S_1 \text{ is such that } yP_2 \hat{y} = 0 $$

for all $(y, \beta) \in xR, \text{ then } xP_1 \hat{x} = 0\}\}.$$

A shorter formula uses transversals:

$$\hat{y}(R^-)_\alpha = \bigcap_{\beta \ll \alpha} \{ x \in S_1 \mid \hat{y} \in (xR_\beta)\} \perp.$$

4.3. **Proposition.** The relation $R^-$ is an $L$-ambiguous representation as well.

**Proof.** For the intersection of crisp ambiguous representations is a crisp ambiguous representation as well, (a')+(b') for $R^-$ are immediate. To verify c'', assume that $\beta \in \hat{y}\hat{x}R^-$ for all $\beta \ll \alpha$, i.e., $(\hat{y}, \hat{x}) \in \bigcap_{\beta \ll \alpha} \bigcap_{\gamma \ll \beta} (R_\gamma)^-$. In a completely distributive lattice $L$ we have $\gamma \ll \alpha$ if and only if there is $\beta$ such that $\gamma \ll \beta \ll \alpha$, hence $(\hat{y}, \hat{x}) \in \bigcap_{\gamma \ll \alpha} (R^-)\},$ which implies $\alpha \in \hat{y}\hat{x}R^-.$

Obviously $\hat{y}\hat{x}R^-$ is a lower set that contains 0. Show that it is directed. If $\alpha, \beta \in \hat{y}\hat{x}R^-$, then for all $\gamma \ll \alpha \lor \beta$ there are $\alpha' \ll \alpha, \beta' \ll \beta$ such that $\gamma \leq \alpha' \lor \beta'$. 
Therefore

\[ \tilde{x} \in \hat{y}(R_\alpha)^\sim \cap \hat{y}(R_\beta)^\sim \]
\[ = \{ x \in S_1 \mid \hat{y} \in (xR_\alpha)^\perp \} \cap \{ x \in S_1 \mid \hat{y} \in (xR_\beta)^\perp \} \]
\[ = \{ x \in S_1 \mid \hat{y} \in (xR_\alpha)^\perp \text{ or } \hat{y} \in (xR_\beta)^\perp \} \]
\[ \subseteq \{ x \in S_1 \mid \hat{y} \in (xR_{\alpha \lor \beta})^\perp \} = \hat{y}(R_{\alpha \lor \beta})^\sim \subseteq \hat{y}(R_\gamma)^\sim. \]

Thus \( \alpha \lor \beta \in \hat{y}\tilde{x}R^\sim \), and the latter set is directed in \( L \). \( \square \)

Hence \( R^\sim = (R^\sim)^\sim \subseteq S_1 \times S_2 \times L \) is an \( L \)-ambiguous representation as well.

4.4. **Proposition.** For each ambiguous representation \( R \subseteq S_1 \times S_2 \) the inclusion \( R^\sim \subseteq R \) holds. The equality \( R = R^\sim \) is equivalent to the condition

(d) if \( (x, y, \alpha) \in R, \ y' \ll y \text{ in } S_2, \) and \( \alpha' \ll \alpha \text{ in } L \), then there is \( x' \ll x \text{ in } S \) such that \( (x', y', \alpha') \in R \).

**Proof.** Recall that

\[ \hat{y}(R^\sim)_\beta = \bigcap_{\gamma \ll \beta} \{ x \in S_1 \mid \hat{y} \in (xR_\gamma)^\perp \} = \bigcup_{\gamma \ll \beta} \{ x \in S_1 \mid \hat{y} \in (xR_\gamma)^\perp \}^\perp. \]

Hence

\[ x(R^\sim)_\alpha = \bigcap_{\beta \ll \alpha} \{ \hat{y} \in \hat{S}_2 \mid x \in (\hat{y}(R^\sim)_\beta)^\perp \}^\perp \]
\[ = \bigcap_{\beta \ll \alpha} \{ \hat{y} \in \hat{S}_2 \mid x \in \left( \bigcup_{\gamma \ll \beta} \{ x' \in S_1 \mid \hat{y} \in (x'R_\gamma)^\perp \} \right)^\perp \}^\perp \]
\[ = \bigcap_{\beta \ll \alpha} \{ \hat{y} \in \hat{S}_2 \mid x \in Cl\left( \bigcup_{\gamma \ll \beta} \{ x' \in S_1 \mid \hat{y} \in (x'R_\gamma)^\perp \} \right) \}^\perp \]
\[ = \bigcup_{\beta \ll \alpha} \{ \hat{y} \in \hat{S}_2 \mid \text{for all } x' \ll x \text{ there is } \gamma \ll \beta \text{ such that } \hat{y} \in (x'R_\gamma)^\perp \} \]
\[ = \bigcap_{\beta \ll \alpha} \{ \hat{y} \in \hat{S}_2 \mid \text{for all } x' \ll x \text{ } \hat{y} \in (x'R_\beta)^\perp \} \]
\[ = \bigcap_{\beta \ll \alpha} (xR_\beta)^\perp \subseteq \bigcap_{\beta \ll \alpha} (xR_\beta)^\perp = \bigcap_{\beta \ll \alpha} (xR_\beta) = xR_\alpha, \]

therefore \( R^\sim \subseteq R \). Clarify why the “\(*\)” sign with an asterisk is valid. Obviously, if \( \gamma \ll \beta \) and \( \hat{y} \in (x'R_\gamma)^\perp \), then \( \hat{y} \in (x'R_\beta)^\perp \), and \( (-)^\perp \) is antitone, hence “\( \supseteq \)” is immediate. On the other hand,

there is \( \gamma \ll \beta \) such that for all \( x' \ll x \) \( \hat{y} \in (x'R_\gamma)^\perp \)
\[ \implies \text{ for all } x' \ll x \text{ there is } \gamma \ll \beta \text{ such that } \hat{y} \in (x'R_\gamma)^\perp, \]

\[ \therefore \text{ there is } \gamma \ll \beta \text{ such that for all } x' \ll x \text{ } \hat{y} \in (x'R_\gamma)^\perp, \]
hence
\[ \bigcap_{\beta \leq \alpha} \left\{ \hat{y} \in \hat{S}_2 \mid \text{for all } x' \ll x \text{ there is } \gamma \ll \beta \text{ such that } \hat{y} \in (x'R_\gamma)^{\perp} \right\} \]
\[ \subset \bigcap_{\beta \leq \alpha} \left\{ \hat{y} \in \hat{S}_2 \mid \text{there is } \gamma \ll \beta \text{ such that for all } x' \ll x \hat{y} \in (x'R_\gamma)^{\perp} \right\} \]
\[ = \bigcap_{\gamma \ll \beta \ll \alpha} \left\{ \hat{y} \in \hat{S}_2 \mid \text{for all } x' \ll x \hat{y} \in (x'R_\gamma)^{\perp} \right\} \]
\[ = \bigcap_{\gamma \ll \alpha} \left\{ \hat{y} \in \hat{S}_2 \mid \text{for all } x' \ll x \hat{y} \in (x'R_\gamma)^{\perp} \right\}, \]
therefore “\( \subset \)” (after renaming \( \gamma \) with \( \beta \)) is also obtained.

It is also clear that, for \( \bar{R} = R \) to be valid, it is necessary and sufficient that the only “\( \subset \)” in the above sequence is “\( = \)”, i.e., each \( y \in xR_\alpha \) must be a closure point of all lower sets \( \{x\} \bar{Q}_\beta \) for \( \beta \ll \alpha \), which in fact is (d).

The \( L \)-ambiguous representations \( R \) that satisfy \( R = R^\omega \) are also called pseudo-invertible.

To define composition of \( L \)-ambiguous representations, we need an additional operation \( \ast : L \times L \to L \) that makes \( L = (L, \ast) \) a unital quantale, i.e., this operation is infinitely distributive w.r.t. supremum in both variables (hence Scott continuous) and 1 is a two sided unit for “\( \ast \)”. Note that commutativity is not demanded, hence from now on “\( \ast \)” is a (possibly) noncommutative lower semicontinuous conjunction for an \( L \)-valued fuzzy logic. The operation \( \alpha \ast \beta = \beta \ast \alpha \) satisfies the same requirements, hence \( L = (L, \ast) \) is a unital quantale as well.

Then, for \( L \)-ambiguous representations \( R \subset S_1 \times S_2 \times L \) and \( Q \subset S_2 \times S_3 \times L \), the composition \( R \ast Q \) can be defined in a manner usual for \( L \)-fuzzy relations:

\[ R \ast Q = \{ (x, z, \alpha) \in S_1 \times S_3 \times L \mid \alpha \leq \sup(\beta \ast \gamma) \text{ there is } y \in S_3 \text{ such that } (x, y, \beta) \in R, (y, z, \gamma) \in Q \}. \]

Similarly to the case of crisp ambiguous representations, this composition is associative, but \( R \ast Q \) can fail to be an \( L \)-ambiguous representation, namely (b) is not always valid. Therefore we “improve” the composition as follows: \( R \ast Q \subset S_1 \times S_3 \times L \) is such that \( xRQ \subset \text{Cl}(xR \ast Q) \) for all \( x \in S_1 \). Here is an expanded version of the latter definition: for \( x \in S_1, z \in S_3, \alpha \in L \) we have \( (x, z, \alpha) \in R \ast Q \) if and only if for all \( z' \ll z, \alpha' \ll \alpha \) there are \( n \in \mathbb{N}, y_1, \ldots, y_n \in S_2, \beta_1, \gamma_1, \ldots, \beta_n, \gamma_n \in L \) such that

\[ (x, y_1, \beta_1), \ldots, (x, y_n, \beta_n) \in R, (y_1, z', \gamma_1), \ldots, (y_n, z', \gamma_n) \in Q, \]
\[ \beta_1 \ast \gamma_1 \lor \cdots \lor \beta_n \ast \gamma_n \geq \alpha'. \]

The simplest operation “\( \ast \)” that obviously satisfies the above conditions is the lattice meet “\( \land \)”. In this case for “\( \ast \)” we use the denotation “\( \lor \)”.

For an \( L \)-ambiguous representation \( R \) we regard \( R^\land \) as a \( L \)-ambiguous representation, and use “\( \lor \);” for the compositions of such representations.

4.5. Lemma. For all \( L \)-ambiguous representations \( R \subset S_1 \times S_2 \times L, Q \subset S_2 \times S_3 \times L \) the inclusion \( Q^\land \lor R^\land \subset (R \ast Q)^\land \) holds.
Proof. Let \((\hat{\alpha}, \hat{x}, \alpha) \in Q^* \cap R^\sim\). For each \(\alpha' \ll \alpha\) we can choose \(\alpha''\) such that \(\alpha' \ll \alpha'' \ll \alpha\), then for all \(\hat{x}' \ll \hat{x}\) there are \(n \in \mathbb{N}, \hat{y}_1, \ldots, \hat{y}_n \in S_2, \gamma_1, \beta_1, \ldots, \gamma_n, \beta_n \in L\) such that
\[
(\hat{z}, \hat{y}_1, \gamma_1), \ldots, (\hat{z}, \hat{y}_n, \gamma_n) \in Q^*, (\hat{y}_1, \hat{x}', \beta_1), \ldots, (\hat{y}_n, \hat{x}', \beta_n) \in R^\sim,
\]
\[
\gamma_1 \ast \beta_1 \vee \cdots \vee \gamma_n \ast \beta_n = \beta_1 \ast \gamma_1 \vee \cdots \vee \beta_n \ast \gamma_n \geq \alpha''.
\]

For all \(x \in S_1\) such that \(xP_1 x' = 1\), and all \(\beta'_1 \ll \beta_1, \ldots, \beta'_n \ll \beta_n\) there are \(y_1, \ldots, y_n \in S_2\) such that \((x', y_1, \beta'_1), \ldots, (x', y_n, \beta'_n) \in R, y_1 P_1 y_1 = \cdots = y_n P_2 y_n = 1\). Analogously, for all \(\gamma'_1 \ll \gamma_1, \ldots, \gamma'_n \ll \gamma_n\) there are \(z_1, \ldots, z_n \in S_3\) such that \((y_1, z_1, \gamma'_1), \ldots, (y_n, z_n, \gamma'_n) \in Q, z_1 P_3 z_1 = \cdots = z_n P_3 z_n = 1\). Then the element \(z = z_1 \land \cdots \land z_n\) satisfies \(z P_3 z = 1\) and \((y_1, z, \gamma'_1), \ldots, (y_n, z, \gamma'_n) \in Q\) as well.

Obviously \((x, z, \beta'_1 \ast \gamma'_1 \vee \cdots \vee \beta'_n \ast \gamma'_n) \in R \ast Q\). Due to Scott continuity (i.e., lower semicontinuity) of \(\ast\) and \(\lor\), we can choose the above \(\beta'_1, \ldots, \beta'_n, \gamma'_1, \ldots, \gamma'_n\) so that \(\beta'_1 \ast \gamma'_1 \lor \cdots \lor \beta'_n \ast \gamma'_n \geq \alpha'\). Hence for all \(\alpha' \ll \alpha, \hat{x}' \ll \hat{x}, x \in S_1, x P_1 \hat{x}'\) there is \(z \in S_3\) such that \(z P_3 z = 1, (x, z, \alpha') \in R \ast Q\), i.e., \((\hat{z}, \hat{x}, \alpha) \in (R \ast Q)^\sim\).

\(\square\)

**Mutatis mutandis** we obtain an analogue of a statement for crisp ambiguous representations:

4.6. **Corollary.** Let \(L\)-ambiguous representations \(R \subset S_1 \times S_2 \times L, Q \subset S_2 \times S_3 \times L\) be pseudo-invertible. Then \(Q^* \cap R^\sim = (R^* Q)^\sim\), and the composition \(R \ast Q\) is pseudo-invertible as well.

4.7. **Proposition.** Composition \(\ast\) of the pseudo-invertible \(L\)-ambiguous representations is associative.

*Proof.* is similar to the one for crisp representations and reduces to the observation that, for \(L\)-ambiguous representations \(R \subset S_1 \times S_2 \times L, Q \subset S_2 \times S_3 \times L, S \subset S_3 \times S_4 \times L\), both statements \((x, t, \alpha) \in (R^* Q)^\ast S\) and \((x, t, \alpha) \in R^* (Q^\ast S)\) are equivalent to the existence, for all \(\alpha' \ll \alpha\) and \(t' \ll t\), of \(n \in \mathbb{N}, y_1, \ldots, y_n \in S_2, z_1, \ldots, z_n \in S_3, \beta_1, \gamma_1, \delta_1, \ldots, \beta_n, \gamma_n, \delta_n \in L\) such that
\[
(x, y_1, \beta_1), \ldots, (x, y_n, \beta_n) \in R, (y_1, z_1, \gamma_1), \ldots, (y_n, z_n, \gamma_n) \in Q,
\]
\[
(z_1, t', \delta_1), \ldots, (z_n, t', \delta_n) \in S, \beta_1 \ast \gamma_1 \ast \delta_1 \lor \cdots \lor \beta_n \ast \gamma_n \ast \delta_n \geq \alpha'.
\]

Hence we obtain a category:

4.8. **Proposition.** All continuous semilattices with bottom elements and all pseudo-invertible \(L\)-ambiguous representations form a category \(\text{Sem} \mathcal{PR}_L\), which contains \(\text{Sem} \mathcal{PR}\) as a subcategory.

The embedding \(I^L_1 : \text{Sem} \mathcal{PR} \rightarrow \text{Sem} \mathcal{PR}_L^*\) preserves the objects and turns each crisp ambiguous representation \(R \subset S_1 \times S_2\) into an \(L\)-ambiguous one as follows:
\[
I^L_1 R = \{(x, y, \alpha) \subset S_1 \times S_2 \times L \mid (x, y) \in R \text{ or } \alpha = 0\}.
\]

Clearly there is also the embedding \(I^L_1 : \text{Sem} \mathcal{PR} \rightarrow \text{Sem} \mathcal{PR}_L\) into the category built upon the “swapped” operation \(\hat{\circ}\).

We denote an arrow \(R\) from \(S_1\) to \(S_2\) in \(\text{Sem} \mathcal{PR}_L\) with \(R : S_1 \Rightarrow^* S_2\). The composition of \(R\) and \(Q\) is denoted by \(R^* Q\) (in direct order) or \(Q \circ R\) (in reverse order) in \(\text{Sem} \mathcal{PR}_L\), and by \(R^* Q\) or \(Q \circ R\) respectively in \(\text{Sem} \mathcal{PR}_L^*\).
4.9. Proposition. The self-duality \((-)^{-} \colon \text{Sem}\mathcal{PR} \to \text{Sem}\mathcal{PR}\) extends to contravariant functors \((-)^{-} \colon \text{Sem}\mathcal{PR}^r \to \text{Sem}\mathcal{PR}^r\) and \((-)^{-} \colon \text{Sem}\mathcal{PR}^l \to \text{Sem}\mathcal{PR}^l\). Both pairwise compositions of these functors are isomorphic to the identity functors.

Hence \((-)^{-}\) is a “contravariant equivalence” between \text{Sem}\mathcal{PR}^r and \text{Sem}\mathcal{PR}^l.

5. Examples and interpretation

Although the above arguments are formally correct, motivation for introduction of so complicated objects and constructions is rather obscure. Here we present one of the possible interpretations to advocate the proposed theory.

Consider a system which can be in different states, and these states can change, e.g., a game, position in which changes after moves of players. Assume that any party involved (e.g., a player) at a moment of time can only imperfect information about the state of the system (“imperfect” means that this information only reduces uncertainty but not necessarily eliminates it). To each such observation we assign a continuous meet semilattice \(S\) with zero, and its elements are regarded as possible pieces of information (or statements) about the state of the system (cf. \cite{5} for a detailed explanation why continuous semilattices are an appropriate tool for this purpose, and \cite{1,2} for more information on continuous posets). If \(x \leq y\) in \(S\), then the information \(x\) is more specific (restrictive) than \(y\). Respectively \(0 \in S\) means “no information”. The meet of \(x\) and \(y\) is the most specific piece of information including both \(x\) and \(y\) (as particular cases). It is not necessarily equivalent to “\(x\) or \(y\)” in the usual logical sense.

5.1. Example. Let \(S\) be the set of all non-empty segments \([a, b] \subset [0, 1]\) ordered by reverse inclusion. We regard \([a, b]\) as the statement “only points of \([a, b]\) have been selected”. Then \([0, \frac{1}{2}] \land \left[\frac{1}{2}, 1\right] = [0, 1]\), which is wider than “\([0, \frac{1}{2}]\) or \([\frac{1}{2}, 1]\)”.

The simplest non-trivial such semilattice is \([0, 1]\), which has many natural interpretations, e.g., \(0 = “\text{maybe possible}”, 1 = “\text{surely impossible}”\) or \(0 = “\text{game outcome is unknown}”, 1 = “\text{player wins}”\).

Another important case is when \(S\) is the hyperspace \(\exp X\) of all non-empty closed sets of a compactum \(X\). Points of \(X_i\) are possible states of the system, and \(A \subset X_i\) represents the fact that one of the states \(x \in A\) is achieved. Then \(\exp X\) is ordered by reverse inclusion, hence \(X \in \exp X\) is the least element that means “anything can happen”. The meet of \(A\) and \(B\) is their union, therefore can be interpreted as “\(A\) or \(B\)”. The ambiguous representations considered in the two previous sections were first introduced and their properties proved for this particular case in \cite{7}.

A crisp ambiguous representation \(R \subset S \times S'\), i.e., an arrow \(R : S \Rightarrow S'\) in \text{Sem}\mathcal{PR}\, consists of all pairs \((x, x')\) such that, given an information \(x\) in the observation \(S\), one can assure that \(x'\) will be valid in the observation \(S'\). It is easy to understand why \(y \geq x\), \(y' \leq x'\), and \(xRx'\) imply \(yRy'\), and why \(xR0\) always holds. If we can observe \(x'\) but not \(x\), then the “visible” information \(x'\) represents the “hidden” information \(x\), which is not necessarily unique, therefore the term “ambiguous representation” has been chosen. In particular, an ambiguous representation models a move in the game with imperfect information: one imperfect knowledge on the complete state is replaced with another one.

In particular, an ambiguous representation \(R : S \Rightarrow \{0, 1\}\) may mean that all statements \(x \in S\) such that \(xR1\) are impossible, and the remaining ones are
probably (but not necessarily) possible, or that any piece of information such that 

\[ xR1 \text{ guarantees that the player can win } \] 

(depending on the chosen interpretation of \( \{0, 1\} \)).

Recall that \( \text{Sem}_0 \) is a subcategory of \( \text{Sem}^\text{PR} \), with the morphisms being meet-preserving zero-preserving Scott continuous mappings. An ambiguous representation \( R : S \to S' \) in \( \text{Sem}^\text{PR} \) belongs to \( \text{Sem}_0 \) if and only if \( x_1Ry_1, x_2Ry_2, y \leq y_1, \) and \( y \leq y_2 \) imply existence of \( x \) such that \( x \leq x_1, x \leq x_2, \) and \( xRy \). In other words, \( R \) is consistent with the interpretation of “\( \land \)” as “or” both in \( S \) and \( S' \): if, given \( x_i \), one may obtain \( y_i, i = 1, 2 \), then “\( y_1 \) or \( y_2 \)” can be obtained from “\( x_1 \) or \( x_2 \)”.

In particular, an arrow \( R : S \to \{0, 1\} \) in \( \text{Sem}_0 \) declares some elements of \( S \) impossible in such a way that if \( x_1 \) and \( x_2 \) are impossible, then there is a statement \( x \) that includes \( x_1 \) and \( x_2 \) and is impossible as well.

5.2. Example. Let \( S \) be the previously defined semilattice of all segments \([a, b] \subset [0, 1]\), \( R, R' \subset S \times \{0, 1\} \) be the ambiguous representations defined as follows:

\[ [a, b]R1 \iff [a, b] \not\in \frac{1}{2}, \quad [a, b]R'1 \iff [a, b] \subset [\frac{1}{3}, \frac{2}{3}], \]

i.e., \( R \) requires that the point \( \frac{1}{2} \) must be selected, and \( R' \) demands that among the selected points must be a point \( \leq \frac{1}{3} \) or \( \geq \frac{2}{3} \). It is easy to see that \( R' \) but not \( R \) is an arrow in \( \text{Sem}_0 \).

Cartesian product \( S \times S' \times \ldots \) represents “joint knowledge” about states of the system observed at different moments or by different parties. An arrow \( P : S \times S' \to \{0, 1\} \) carries an information on simultaneous realization of statements \( x \in S, y \in S' : (x, y)P1, \) then it is impossible. If we additionally require the mapping \((x, y) \mapsto (x, y)P1, \) which we denote with the same letter \( P, \) to be meet-preserving in each argument, then the definition of compatibility is obtained. Meet-preservation means that if \( x_1 \) and \( x_2 \) are incompatible (cannot be valid together) with \( y, \) then “\( x_1 \) or \( x_2 \)” is incompatible with \( y \) as well, similarly for the second argument. A compatibility \( P : S \times S' \to \{0, 1\} \) is separating if for all \( x_1 \neq x_2 \) in \( S \) there is \( y \in S' \) such that exactly one of \( x_i \) is incompatible with \( y \) w.r.t. \( P, \) similarly for \( y_1 \neq y_2 \) in \( S' \) and \( x \in S \). Then elements of \( S' \) can be regarded as “negative statements” about state of the game observed at \( S \) : given \( y \in S' \) and a separating compatibility \( P, \) we declare impossible all \( x \in S \) such that \( (x, y)P1, \) for each \( A \subset S' \) its transversal \( A^\perp = \{ x \in S \mid xPy = 0 \text{ for all } y \in A \} \) consists of all statements in \( S \) that are compatible with all “negative statements” from \( A \). Hence elements of \( S' \) prevent or prohibit elements of \( S, \) and vice versa.

5.3. Example. Let \( L \) be a completely distributive lattice, then so is \( \hat{L} = L^{\text{op}}. \) The mapping \( P : L \times L^{\text{op}} \to \{0, 1\} \) defined as

\[ P(x, y) = \begin{cases} 0, & y \not\leq x, \\ 1, & y \leq x, \end{cases} \]

is a separating compatibility. In particular, this implies that \( L^\perp \cong L^{\text{op}} \) for a completely distributive lattice \( L. \)

We can regard the value of \( P(x, y) \) as imposibility of distribution of total benefit between two players, whose gains are \( x \in L \) and \( y \in L^{\text{op}}. \) For simplicity let \( L = \{0, 1\}, \) then the players want to obtain \( x \) and \( 1 - y \) respectively. If \( x + (1 - y) > 1 \iff x > y, \) then this is impossible.
For continuous semilattices $S_1$, $S_2$ with zeros consider separating compatibilities
$P_1 : S_1 \times \hat{S}_1 \to \{0, 1\}$, $P_2 : S_2 \times \hat{S}_2 \to \{0, 1\}$. If $R : S_1 \Rightarrow S_2$ is an ambiguous
representation, then $R^\sim : \hat{S}_2 \Rightarrow \hat{S}_1$ is defined as follows:
\[
R^\sim = \{(\hat{y}, \hat{x}) \in \hat{S}_2 \times \hat{S}_1 \mid \text{if } xP_1\hat{x} = 1 \text{ for some } x \in S_1, \text{then there is } y \in xR, \ yP_2\hat{y} = 1 \}.
\]

Recall that each “negative statement” \( \hat{x} \in \hat{S}_1 \) is completely determined with
the set of all $x \in S_1$ it prohibits, i.e., with \( \{x \in S_1 \mid xP_1\hat{x} = 1\} \). Then \( \hat{x} \) can be
considered as attainable from \( \hat{y} \in \hat{S}_2 \) if and only if it prohibits only those $x \in S_2$ that
have possible consequences $y \in xR$ incompatible with \( \hat{y} \) (hence, if \( \hat{y} \) is valid, then so must be \( \hat{x} \)). Passing from $R : S_1 \Rightarrow S_2$ to $R^\sim : \hat{S}_2 \Rightarrow \hat{S}_1$ is analogous to
passing from $A \Rightarrow B$ to $\neg B \Rightarrow \neg A$ in logic.

For a completely distributive $\mathfrak{L}$ lattice $L$, a pseudo-invertible $L$-fuzzy ambiguous
representation $R$ of $S$ in $S'$ is in fact a pseudo-invertible crisp ambiguous representation
$R : S \Rightarrow S' \times L$ with the additional requirement that $xR(y, \alpha_1)$ and $xR(y, \alpha_2)$
imply $xR(y, \alpha_1 \land \alpha_2)$. If $xR(y, \alpha)$, then the element $\alpha$ of $L$ describes a restriction
on state of nature under which $y$ is attainable from $x$. By definition there is
the most restrictive such $\alpha$. Then $R^\sim$ has the same meaning as above, but depends
on the parameter $\alpha$.

**Concluding remarks and future work**

What we proposed is just a sketch of application of crisp and $L$-fuzzy ambiguous
representations of continuous semilattices. It is easy to note that properties of
\( \text{Sem}\mathcal{PR} \) are similar to ones of dialogue category, with \( \{0, 1\} \) being a tensorial pole,
and the pair $\text{Sem}\mathcal{PR}_L^\sim, \text{Sem}\mathcal{PR}^\sim_L$ looks like a dialogue chirality $[4]$. Than taking
pseudo-inverse could be tensorial negation. Unfortunately, it is not the case, e.g.,
$\{0, 1\}$ is not exponentiable in $\text{Sem}\mathcal{PR}$, similarly verification fails for $\text{Sem}\mathcal{PR}_L^\sim$ and
$\text{Sem}\mathcal{PR}^\sim_L$. Nevertheless, the similarity is not incidental, and we plan to continue
this research to model games in normal and extended form, winning strategies etc.
We are also going to show why completely distributive lattices arise in games with
imperfect information.

Authors also express deepest gratitude to Prof. Michael Zarichnyi for valuable
ideas.
