ARESTOV’S THEOREMS ON BERNSTEIN’S INEQUALITY

Tamás Erdélyi

April 26, 2019

Abstract. We give a simple, elementary, and at least partially new proof of Arestov’s famous extension of Bernstein’s inequality in $L^p$ to all $p \geq 0$. Our crucial observation is that Boyd’s approach to prove Mahler’s inequality for algebraic polynomials $P_n \in \mathcal{P}_n^c$ can be extended to all trigonometric polynomials $T_n \in \mathcal{T}_n^c$.

1. Introduction and Notation

Let $\mathcal{T}_n^c$ be the collection of all trigonometric polynomials $T_n$ of the form

$$T_n(z) = \sum_{j=-n}^{n} a_j z^j, \quad a_j \in \mathbb{C}, \quad z \in \mathbb{C} \setminus \{0\}.$$ 

Let $\mathcal{P}_n^c$ be the collection of all algebraic polynomials $P_n$ of the form

$$P_n(z) = \sum_{j=0}^{n} a_j z^j, \quad a_j \in \mathbb{C}, \quad z \in \mathbb{C}.$$ 

Let $D$ denote the open unit disk, and let $\partial D$ denote the unit circle of the complex plane. We define the Mahler measure (geometric mean of $Q$ on $\partial D$)

$$\|Q\|_0 = M_0(Q) := \exp \left( \frac{1}{2\pi} \int_0^{2\pi} \log |Q(e^{it})| \, dt \right)$$ 

for bounded measurable functions $Q$ on $\partial D$. It is well known, see [HL-52], for instance, that

$$\|Q\|_0 = M_0(Q) = \lim_{p \to 0+} M_p(Q),$$

where

$$\|Q\|_p = M_p(Q) := \left( \frac{1}{2\pi} \int_0^{2\pi} |Q(e^{it})|^p \, dt \right)^{1/p}, \quad p > 0.$$ 

Key words and phrases. Bernstein’s inequality in $L^p$ for all $p \geq 0$, Arestov’s theorem.

Typeset by AMSTeX
It is also well known that for a function $Q$ continuous on $\partial D$ we have
\[ \|Q\|_{\infty} = M_{\infty}(Q) := \max_{t \in [0,2\pi]} |Q(e^{it})| = \lim_{p \to \infty} M_{p}(Q). \]

It is a simple consequence of the Jensen formula that
\[ M_0(Q) = |c| \prod_{k=1}^{n} \max\{1,|z_k|\} \]
for every polynomial of the form
\[ Q(z) = c \prod_{k=1}^{n} (z - z_k), \quad c, z_k \in \mathbb{C}. \]

Bernstein’s inequality
\[ \|T'_n\|_{\infty} \leq n\|T_n\|_{\infty}, \quad T_n \in T_n^c, \]
plays a crucial role in proving inverse theorems of approximation as well as many other results in approximation theory. See [BE-95], for instance. As far as the history of Bernstein’s inequality is concerned we refer to Nevai’s lovely papers [N-14] and [N-19] and the references in them. We do not repeat the full story here. In 1981 Arestov [A-81] proved that
\[ \|T_n\|_p \leq n\|T_n\|_p, \quad T_n \in T_n, \]
for all $p \geq 0$, extending the result known only for $p \geq 1$ for a long time. Simpler proof of Bernstein’s inequality in $L_p$ for all $p \geq 0$ have been given by Golitschek and Lorentz in [GL-89] which is presented in the book [DL-93] by DeVore and Lorentz. A very elegant and even more simplified proof was published recently in [QZ-19] by Queffélec and Zarouf. A central part of their proof is to prove (1.1) for $p = 0$ first. Mahler [M-61] showed (1.1) for $p = 0$ but only for polynomials $P_n \in P_n^c$, and he gave a rather involved proof. Mahler’s inequality was also posed as a problem by Vaaler in the Problems section of the American Mathematical Monthly and solved by Boyd [VB-91] using an elementary theorem of Bernstein. We note that Glazyrina [G-05] proved a sharp Markov-type inequality for algebraic polynomials in $L_0$ on finite subintervals of the real line.

In this note we give a simple, elementary, and at least partially new proof of Arestov’s famous extension of Bernstein’s inequality in $L_p$ to all $p \geq 0$. Our crucial observation is that Boyd’s approach to prove Mahler’s inequality for algebraic polynomials $P_n \in P_n^c$ can be extended to all trigonometric polynomials $T_n \in T_n^c$.

**Theorem 1.1.** We have
\[ \|T'_n\|_0 \leq n\|T_n\|_0, \quad T_n \in T_n^c. \]

Equivalently
\[ \int_{\partial D} \log |T'_n(z)/n| |dz| \leq \int_{\partial D} \log |T_n(z)| |dz|, \quad T_n \in T_n^c. \]
Theorem 1.2. With the notation \( \log^+ |a| := \max\{\log |a|, 0\} \) we have

\[
\int_{\partial D} \log^+ |T'_n(z)/n| |dz| \leq \int_{\partial D} \log^+ |T_n(z)| |dz|, \quad T_n \in \mathcal{T}^c_n.
\]

Theorem 1.3. We have

\[
\|T'_n\|_p \leq n\|T_n\|_p, \quad T_n \in \mathcal{T}^c_n,
\]

for every \( p > 0 \).

2. Lemmas

To prove the Theorem 1.1 we need two lemmas.

Lemma 2.1. Associated with \( S_n \in \mathcal{T}^c_n \) let \( P_{2n} \in \mathcal{P}^c_{2n} \) be defined by \( P_{2n}(z) = z^n S_n(z) \). If \( P_{2n} \) has each of its \( 2n \) zeros in \( D \), then \( S'_n \) has each of its zeros in \( D \) as well. The same is true if \( D \) is replaced by the closed unit disk \( \overline{D} \).

Proof. We prove the lemma for \( D \), the case of the closed unit disk \( \overline{D} \) follows from this by a straightforward limiting argument. Suppose \( a \notin D \), that is, \( a \in \mathbb{C} \) and \( |a| \geq 1 \). Suppose also that \( S_n \in \mathcal{T}^c_n \) and \( P_{2n}(z) := z^n S_n(z) \) has each of its \( 2n \) zeros in \( D \), that is

\[
P_{2n}(z) = c \prod_{j=1}^{2n} (z - z_j), \quad 0 \neq c \in \mathbb{C}, \quad z_j \in D.
\]

We have

\[
\frac{a S'_n(a)}{S_n(a)} = \sum_{j=1}^{2n} \frac{a}{a - z_j} - \frac{an}{a} = \sum_{j=1}^{2n} \frac{1}{1 - z_j/a} - n.
\]

Observe that \( |z_j/a| < 1 \) for each \( j = 1, 2, \ldots, 2n \), and hence

\[
\operatorname{Re} \left( \frac{1}{1 - z_j/a} \right) > \frac{1}{2}, \quad j = 1, 2, \ldots, 2n.
\]

Combining (2.1) and (2.2) we obtain

\[
\operatorname{Re} \left( \frac{a S'_n(a)}{S_n(a)} \right) > \frac{2n}{2} - n = 0.
\]

We conclude that \( S'_n(a) \neq 0 \). \( \Box \)

3
Lemma 2.2. Associated with $V_n \in T^n_c$ let $R_{2n} \in P_{2n}^c$ be defined by $R_{2n}(z) = z^n V_n(z)$ and suppose that $R_{2n}$ has each of its $2n$ zeros in the closed unit disk $\overline{D}$. If $T_n \in T_n$ and

\begin{equation}
|T_n(z)| \leq |V_n(z)|, \quad z \in \partial D,
\end{equation}

then

\begin{equation}
|T'_n(z)| \leq |V'_n(z)|, \quad z \in \partial D.
\end{equation}

Proof. Without loss of generality we may assume that $R_{2n}$ has each of its $2n$ zeros in $D$, the case when $R_{2n}$ has each of its $2n$ zeros in the closed unit disk $\overline{D}$ follows from this by a straightforward limiting argument. Let $Q_{2n} \in P_{2n}^c$ be defined by $Q_{2n}(z) := z^n T_n(z)$. Let $\alpha \in \mathbb{C}$, $|\alpha| < 1$, and

\begin{equation}
S_n(z) := (V_n - \alpha T_n)(z) = z^{-n} (R_{2n} - \alpha Q_{2n})(z).
\end{equation}

It follows from (2.3) that

\begin{equation}
|Q_{2n}(z)| \leq |R_{2n}(z)|, \quad z \in \partial D,
\end{equation}

and hence $|\alpha| < 1$ and the fact that $R_{2n} \in P_{2n}^c$ does not vanish on $\partial D$ imply that

\begin{equation}
|\alpha Q_{2n}(z)| < |R_{2n}(z)|, \quad z \in \partial D.
\end{equation}

Therefore Rouche’s Theorem implies that the polynomial $P_{2n} := R_{2n} - \alpha Q_{2n} \in P_{2n}^c$ and $R_{2n}$ has the same number of zeros in $D$, that is, $R_{2n} - \alpha Q_{2n}$ has each of its $2n$ zeros in $D$. By Lemma 2.1 and (2.4) we can deduce that $S'_n = V'_n - \alpha T'_n$ has each of its zeros in $D$. In particular,

\begin{equation}
S'_n(z) = V'_n(z) - \alpha T'_n(z) \neq 0, \quad z \in \partial D,
\end{equation}

for all $\alpha \in \mathbb{C}$, $|\alpha| < 1$. We conclude that

\begin{equation}
|T'_n(z)| \leq |V'_n(z)|, \quad z \in \partial D.
\end{equation}

$\Box$

3. Proof of Theorems 1.1, 1.2, and 1.3

Proof of Theorem 1.1. Associated with $T_n \in T_n^c$ let $P_{2n} \in P_{2n}^c$ be defined by $P_{2n}(z) = z^n T_n(z)$. Without loss of generality we may assume that $P_{2n}$ has exactly $2n$ complex zeros, the case when $P_{2n}$ has less than $2n$ complex zeros follows from this by a straightforward limiting argument.

Case 1. Suppose $P_{2n}$ has all its $2n$ zeros in the closed unit disk $\overline{D}$. It follows from Lemma 2.1 that $T'_n$ has all its zeros in the closed unit disk $\overline{D}$. Let

\begin{equation}
T_n(z) = \sum_{j=-n}^{n} a_j z^j, \quad a_j \in \mathbb{C}, \quad z \in \mathbb{C} \setminus \{0\}.
\end{equation}
Using Jensen’s formula and the multiplicative property of the Mahler measure we can easily deduce that
\[ \| T_n' \|_0 = n \| T_n \|_0 = n |a_n|. \]

Case 2. Suppose that some of the zeros of \( P_{2n} \) are outside the closed unit disk \( \overline{D} \). Let \( z_1, z_2, \ldots, z_m \) be the zeros of \( T_n \) outside the closed unit disk \( \overline{D} \) and let \( z_{m+1}, z_{m+2}, \ldots, z_{2n} \) be the zeros of \( T_n \) in the closed unit disk \( \overline{D} \). We have
\[
T_n(z) = a_n z^{-n} \prod_{j=1}^{m} (z - z_j) \prod_{j=m+1}^{2n} (z - z_j).
\]
We define
\[
V_n(z) := a_n z^{-n} \prod_{j=1}^{m} (1 - \overline{z}_j z) \prod_{j=m+1}^{2n} (z - z_j).
\]
Observe that (2.3) holds, \( V_n \in \mathcal{T}^c_n \), and \( R_{2n} \in \mathcal{P}^c_{2n} \) defined by \( R_{2n}(z) := z^n V_n(z) \) has each of its \( 2n \) zeros in the closed unit disk \( \overline{D} \). Using Lemma 2.2, the (in)equality of the theorem in Case 1, and Jensen’s formula, we obtain
\[
\| T_n' \|_0 \leq \| V_n' \|_0 = n \| V_n \|_0 = n |a_n| \prod_{j=1}^{m} |z_j| = n \| T_n \|_0.
\]
Indeed, the integration by parts formula gives
\[ \int_0^{\infty} \log^+(u/a)p^2a^{p-1} \, da = \int_0^{u} \log^+(u/a)p^2a^{p-1} \, da = \int_0^{u} pa^{p-1} \, da = u^p. \]

For the sake of brevity we will use the notation \( d\mu(a) = p^2a^{p-1} \, da \). Using (3.2), Fubini’s theorem, Theorem 1.2, and Fubini’s theorem again, we obtain
\[
\int_{\partial D} |T'_n(z)/n|^p \, |dz| = \int_{\partial D} \left( \int_0^{\infty} \log^+ |T'_n(z)/(na)| \, |d\mu(a)| \right) \, |dz|
= \int_0^{\infty} \left( \int_{\partial D} \log^+ |T'_n(z)/(na)| \, |dz| \right) \, d\mu(a)
\leq \int_0^{\infty} \left( \int_{\partial D} \log^+ |T_n(z)/a| \, |dz| \right) \, d\mu(a)
= \int_{\partial D} \left( \int_0^{\infty} \log^+ |T_n(z)/a| \, |d\mu(a)| \right) \, |dz|
= \int_{\partial D} |T_n(z)|^p \, |dz|. \]

\[\square\]

4. ACKNOWLEDGEMENT

The author thanks Herve Queffélec and Paul Nevai for checking the details of the proof in this paper and for their suggestions to make the paper more readable.
