On the Divisibility of Character Values of the Symmetric Group

Jyotirmoy Ganguly, Amritanshu Prasad, and Steven Spallone

Abstract. Fix a partition \( \mu = (\mu_1, \ldots, \mu_m) \) of an integer \( k \) and positive integer \( d \). For each \( n > k \), let \( \chi^\lambda_\mu \) denote the value of the irreducible character of \( S_n \) at a permutation with cycle type \( (\mu_1, \ldots, \mu_m, 1^{n-k}) \). We show that the proportion of partitions \( \lambda \) of \( n \) such that \( \chi^\lambda_\mu \) is divisible by \( d \) approaches 1 as \( n \) approaches infinity.

Let \( k \) be a positive integer, and \( \mu = (\mu_1, \ldots, \mu_m) \) a partition of \( k \). For a partition \( \lambda \) of an integer \( n \geq k \), let \( \chi^\lambda_\mu \) denote the value of the irreducible character of \( S_n \) corresponding to \( \lambda \) at an element with cycle type \( (\mu_1, \ldots, \mu_m, 1^{n-k}) \). The purpose of this article is to prove:

Main Theorem. For any positive integers \( k \) and \( d \), and any partition \( \mu \) of \( k \),

\[
\lim_{n \to \infty} \frac{\#\{\lambda \vdash n \mid \chi^\lambda_\mu \text{ is divisible by } d\}}{p(n)} = 1.
\]

Here \( p(n) \) denotes the number of partitions of \( n \).

In particular, for any integer \( d \), the probability that an irreducible character of \( S_n \) has degree divisible by \( d \) converges to 1 as \( n \to \infty \).

Recall the theorem of Lassalle [4, Theorem 6], which implies that there exists an integer \( A^\lambda_\mu \) such that

\[
\chi^\lambda_\mu = \frac{f_\lambda}{(n)_k} A^\lambda_\mu.
\]

Here \( (n)_k = n(n-1) \cdots (n-k+1) \), and \( f_\lambda \) is the degree of the irreducible character of \( S_n \) corresponding to \( \lambda \). Therefore, in order to prove the

main theorem, we focus on the divisibility properties of $f_\lambda$. For each prime number $q$, let $v_q(m)$ denote the $q$-adic valuation of an integer $m$, in other words, $q^{v_q(m)}$ is the largest power of $q$ that divides $m$. Also write $\log n = \log_q n$. The main theorem will follow from the following result:

**Theorem A.** For every prime number $q$ and non-negative integer $m$,

$$\lim_{n \to \infty} \frac{\#\{\lambda \vdash n \mid v_q(f_\lambda) \leq m + (q - 1)\log n\}}{p(n)} = 0.$$

In the rest of this article, we first prove Theorem A, and then show that it implies the main theorem.

1. **Proof of Theorem A**

The proof of Theorem A is based on the theory of $q$-core towers. This construction originated in the seminal paper [5] of Macdonald, and was developed further by Olsson in [6]. We now recall the relevant aspects.

Let $[q]$ denote the set $\{0, \ldots, q - 1\}$, and consider the disjoint union

$$T_q = \coprod_{i=0}^{\infty} [q]^i.$$

The set $T_q$ can be regarded as a rooted $q$-ary tree with root $\emptyset$. The children of a vertex $(a_1, \ldots, a_i) \in [q]^i$ are the vertices $(a_1, \ldots, a_i, a_{i+1})$, where $a_{i+1} \in [q]$. A partition $\lambda$ is said to be a $q$-core if no cell in its Young diagram has hook length divisible by $q$. Denote the set of all $q$-core partitions by $C_q$. The $q$-core tower construction associates to each partition $\lambda$ of $n$ a function $T_\lambda^q : T_q \to C_q$ known as the $q$-core tower of $\lambda$. For a partition $\lambda$, define:

$$w_i(\lambda) = \sum_{x \in [q]^i} |T_\lambda^q(x)|.$$

Then the $q$-core tower satisfies the following constraint:

$$(2) \quad \sum_{i=0}^{\infty} w_i(\lambda)q^i = n.$$

In particular, $T_\lambda^q(x) = \emptyset$ for all $i > \log_q n$. This function $\lambda \mapsto T_\lambda^q$ is a bijection from the set of partitions of $n$ onto the set of $q$-core towers satisfying the condition $(2)$.

Let $n$ be a positive integer with $q$-ary expansion:

$$(*) \quad n = a_0 + a_1q + \cdots + a_rq^r,$$

with $a_i \in [q]$ for $i = 1, \ldots, r$, and $a_r > 0$. 

Define $a(n) = \sum_{i=0}^{r} a_i$.

Recall the following Theorem:

**Theorem 1 ([5 Equation (3.3)])**. For a partition $\lambda$, let $w(\lambda) = \sum_{i=0}^{r} w_i(\lambda)$. For any partition $\lambda$ of $n$ and any prime $q$, 

$$v_q(f_\lambda) = \frac{w(\lambda) - a(n)}{q - 1}.$$

Theorem 1 can be used to find constraints on partitions with small values of $v_q(f_\lambda)$. Suppose that $v_q(f_\lambda) \leq b$. By Theorem 1, this is equivalent to 

$$w(\lambda) \leq a(n) + b(q - 1).$$

The expansion (2) implies that $r \leq \log n < r + 1$, so that $a(n) \leq (q - 1)(r + 1) \leq (q - 1)(\log n + 1)$. So if $v_q(f_\lambda) \leq b$, then 

$$w(\lambda) \leq (q - 1)(\log n + 1 + b).$$

Thus an upper bound for the number $p_b(n)$ of partitions $\lambda$ of $n$ such that $v_q(f_\lambda) \leq b$ can be obtained by counting the number of $q$-core towers with $(q - 1)(\log n + 1 + b)$ or fewer cells. The total number of vertices in the first $r + 1$ rows of $T_q$, i.e., in $\bigcup_{i=0}^{r} [q]^i$, is:

$$1 + q + \cdots + q^{r+1} = \frac{q^{r+1} - 1}{q - 1} < qn,$$

since $q^r \leq n$. Let $c_q(n)$ denote the number of $q$-core partitions of $n$. Set 

$$N_b = (q - 1)(\log n + b + 1).$$

Let $\tilde{c}_q(n)$ denote $\max\{c_q(i) \mid 1 \leq i \leq n\}$. There are $(w^{N_b} + N_b - 1)$ ways to distribute $w$ cells into $N$ nodes. Thus

$$p_b(n) \leq \tilde{c}_q(N_b)^{N_b} \left( qn + N_b \right) \left( qn + N_b \right)^{N_b}$$

It is known that, for every integer $q$, there exists a polynomial $f_q(n)$ such that $\tilde{c}_q(n) \leq f_q(n)$ for all $n \geq 0$. Indeed, for $q = 2$, it is well-known that $c_2(n) \leq 1$, and for $q = 3$, using a formula of Granville and Ono [2 Section 3, p. 340], $c_3(n) \leq 3n + 1$. For $q \geq 4$, the existence of $f_q(n)$ follows from Anderson [1 Corollary 7].

We get:

$$p_b(n) \leq f_q(N_b)^{N_b} (qn + N_b)^{N_b},$$

whence

$$\log p_b(n) \leq N_b[\log f_q(N_b) + \log(qn + N_b)].$$
Taking \( b = m + (q - 1) \log n \) gives \( N_b = (q - 1)(q \log n + m + 1) \). Thus \( \log p_b(n) = o(n^\epsilon) \) for every \( \epsilon > 0 \). On the other hand, the Hardy-Ramanujan asymptote \(^3\) for \( p(n) \) implies that \( \log p(n) \) grows faster than \( n^{2-\epsilon} \) for any \( \epsilon > 0 \). Thus Theorem A follows.

2. Proof of the Main Theorem

The identity (1) implies that

\[
\nu_q(\chi_\mu^\lambda) \geq \nu_q(f_\lambda) - \nu_q((n)_k).
\]

Using Legendre’s formula on the valuation of a factorial, that \( \nu_q(n!) = \frac{n-a(n)}{q-1} \), we have:

\[
\nu_q((n)_k) = \nu_q\left(\frac{n!}{(n-k)!}\right) = \frac{k + a(n-k) - a(n)}{q-1} \leq k + (q - 1) \log n.
\]

Hence if \( \nu_q(f_\lambda) \geq m + (q - 1) \log n \), then \( \nu_q(\chi_\mu^\lambda) \geq (m - k) \). Thus taking \( m = k + b \) in Theorem A tells us that

\[
\lim_{n \to \infty} \frac{\#\{\lambda \vdash n \mid \nu_p(\chi_\mu^\lambda) \leq b\}}{p(n)} = 0.
\]

From this the main theorem follows.
