ALMOST SURE RATES OF MIXING FOR PARTIALLY HYPERBOLIC ATTRACTORS

JOSÉ F. ALVES, WAEH BAHSOUN, AND MARKS RUIZIBOEV

Abstract. We introduce random towers to study almost sure rates of correlation decay for random partially hyperbolic attractors. Using this framework, we obtain general results on almost sure exponential, stretched exponential and polynomial correlation decay rates. We then apply our results to random perturbations of systems, including Axiom A attractors, derived from Anosov partially hyperbolic systems and solenoidal attractors with random intermittency.

1. Introduction

One of the most fundamental questions in ergodic theory of chaotic dynamical systems is that of the rate of correlation decay with respect to a physical measure. For deterministic chaotic systems there are two popular techniques to obtain such rates. The first one is based on functional analytic techniques that require strong hyperbolic properties of the underlying system (see the recent breakthrough [18] and references therein). The other method, which is based on Markov extensions [45] and coupling techniques [46, 24], has been applied to obtain correlation decay rates [5, 21, 22, 30] and probabilistic limit theorems [29, 39, 40] for different classes of deterministic chaotic systems that admit a 'weak' form of hyperbolicity.

Recently, there has been a significant interest in obtaining probabilistic limit theorem for random dynamical systems [1, 12, 13, 25, 26, 27, 31] and related time dependent systems [32, 33, 36]. As in the case of deterministic dynamical systems, some knowledge on the correlation decay rate of the underlying system is required to obtain probabilistic limit laws for random dynamical systems. However, despite the pioneering work of [16], which was followed by [37], and the recent progress made in [15] on almost sure correlation decay rates for random endomorphisms, there are no general tools on the almost sure correlation decay rates for random dynamical systems where the constituent maps are partially hyperbolic diffeomorphisms.

The purpose of this work is to provide, for the first time, a general tool that can be used to obtain almost sure correlation decay rates for random attractors [23] that exhibit a ‘weak’ form of hyperbolicity. Indeed, we introduce random hyperbolic towers and show that such towers can be used to study pathwise statistics on random partially hyperbolic attractors. We obtain general results on the almost sure rate of correlation decay and apply these results to random perturbations of classical systems, including Axiom A attractors and derived from Anosov partially hyperbolic attractors, and to solenoidal attractors with random intermittency. To the best of our knowledge, even in the particular classical case of Axiom A attractors there are no such general statements in the literature and existing work [25, 42], albeit using different methods, only cover the specific case of Anosov diffeomorphisms.

1.1. Random dynamical systems. Let $M$ be a smooth compact Riemannian manifold of finite dimension. Denote by $\text{Diff}^1(M)$ the set of $C^1$ diffeomorphisms whose derivative is Hölder endowed with the $C^1$ topology. Given $\mathcal{F} \subset \text{Diff}^1(M)$, consider $\theta$ a Borel probability measure with compact support $\mathcal{B} \subset \mathcal{F}$. Let $\Omega = \mathcal{B}^\mathbb{Z}$ and $P = \theta^\mathbb{Z}$. Then the left shift map $\sigma : \Omega \to \Omega$ preserves $P$. Given $\omega \in \Omega$, consider the random dynamical system

$$f_\omega^0 = \text{Id}, \quad f_\omega^n = f_{\sigma^{n-1}\omega} \circ \cdots \circ f_\omega \quad \text{and} \quad f_\omega^{-n} = (f_\omega^n)^{-1}, \text{ for } n \geq 0.$$
We call a family of Borel probability measures \( \{ \mu_\omega \} \) on \( M \) equivariant if
\[
(f_\omega)_* \mu_\omega = \mu_{\sigma \omega}
\]
for \( P \) almost all \( \omega \in \Omega \). The family \( \{ \mu_\omega \} \) is called physical if for \( P \)-almost all \( \omega \in \Omega \), the set of points \( x \in M \) such that
\[
\frac{1}{n} \sum_{i=0}^{n-1} \delta_{f_\omega^i(x)} \xrightarrow{\text{weakly}} \mu_\omega
\]
has positive Lebesgue measure. This set is called the basin of \( \mu_\omega \) and denoted \( B(\mu_\omega) \).

In this paper we study the existence of equivariant families of physical measures \( \{ \mu_\omega \} \) and their statistical properties. In particular, we consider random correlations
\[
C_n(\varphi, \psi; \mu_\omega) = \int (\varphi \circ f_\omega^n) \psi d\mu_\omega - \int \varphi d\mu_{\sigma \omega^n} \int \psi d\mu_{\sigma \omega^n},
\]
for observables \( \varphi, \psi : M \to \mathbb{R} \). Let \( \mathcal{F}_1 \) and \( \mathcal{F}_2 \) be spaces of observables on \( M \) and let \( \{ \rho_n \}_{n \in \mathbb{N}} \) be a sequence of positive numbers such that \( \lim_{n \to \infty} \rho_n = 0 \). We say that the random dynamical system admits “quenched” decay of correlations at rate \( \rho_n \) if for \( P \)-almost all \( \omega \in \Omega \) and any \( \varphi \in \mathcal{F}_1, \psi \in \mathcal{F}_2 \), there are constants \( C_\omega, C_{\varphi, \psi} \) such that
\[
|C_n(\varphi, \psi; \mu_\omega)| \leq C_\omega C_{\varphi, \psi} \rho_n.
\]

1.2. Hyperbolic product structures. Let \( \text{Leb} \) denote the Riemannian volume on Borel subsets of \( M \). Given a submanifold \( \gamma \subset M \) we use \( \text{Leb}_\gamma \) to denote the volume induced by the restriction of the Riemannian metric on \( \gamma \). We say that an embedded disk \( \gamma \subset M \) is a stable manifold at fibre \( \omega \) if \( \text{dist}(f_\omega^n(x), f_\omega^n(y)) \to 0 \) as \( n \to \infty \) for every \( x, y \in \gamma \). Similarly, an embedded disk \( \gamma \subset M \) is called an unstable manifold at \( \omega \) if \( \text{dist}(f_{\sigma^{-n}\omega}(x), f_{\sigma^{-n}\omega}(y)) \to 0 \) as \( n \to \infty \) for every \( x, y \in \gamma \).

Notice that if \( \gamma \) is a stable manifold at \( \omega \) then \( f_\omega(\gamma) \) is a stable manifold at \( \sigma(\omega) \). Let \( \text{Emb}^1(D^n, M) \) be the space of \( C^1 \) embeddings from \( D^n \) into \( M \). We say that \( \Gamma^u_\omega = \{ \gamma^u_\omega \} \) is a continuous family of \( C^1 \) unstable manifolds at \( \omega \) if there is a compact set \( K^u \), a unit disk \( D^u \) of some \( \mathbb{R}^d \), and a map \( \Phi^u : K^u \times D^u \to M \) such that
- \( \gamma^u = \Phi^u(\{x\} \times D^u) \) is an unstable manifold;
- \( \Phi^u \) maps \( K^u \times D^u \) homeomorphically onto its image;
- \( x \mapsto \Phi^u(\{x\} \times D^u) \) is a continuous map from \( K^u \) to \( \text{Emb}^1(D^n, M) \).

Continuous families of \( C^1 \) stable manifolds are defined similarly. We say that \( \Lambda_\omega \subset M \) has a product structure if there exist a continuous family of unstable manifolds \( \Gamma^u_\omega = \{ \gamma^u_\omega \} \) and a continuous family of stable manifolds \( \Gamma^s_\omega = \{ \gamma^s_\omega \} \) such that
- \( \Lambda_\omega = (\bigcup \gamma^u_\omega) \cap (\bigcup \gamma^s_\omega) \);
- \( \dim \gamma^u_\omega + \dim \gamma^s_\omega = \dim M \);
- each \( \gamma^s_\omega \) meets each \( \gamma^u_\omega \) in exactly one point;
- stable and unstable manifolds meet transversally with angles bounded away from 0 by a constant independent of \( \omega \).
Let $\Lambda_\omega \subset M$ be a set with a product structure, whose defining families are $\Gamma^s_\omega$ and $\Gamma^u_\omega$. A subset $\Lambda_0,\omega \subset \Lambda_\omega$ is called an $s$-subset if $\Lambda_0,\omega$ also has a product structure, and its defining families, $\Gamma^s_0,\omega$ and $\Gamma^u_0,\omega$, can be chosen with $\Gamma^s_0,\omega \subset \Gamma^s_\omega$ and $\Gamma^u_0,\omega \subset \Gamma^u_\omega$; $u$-subsets are defined similarly. Given $x \in \Lambda_\omega$, let $\gamma^s(x)$ denote the element of $\Gamma^s_\omega$ containing $x$, for $* = s, u$. For each $n \geq 1$ we let $(f^\omega_n)^u$ denote the restriction of the map $f^\omega_n$ to unstable manifolds $\gamma^u_\omega$ and $\det D^uf^\omega_n$ denote the Jacobian of $D^uf^\omega_n$.

The random dynamical system admits a hyperbolic product structure on $\{\Lambda_\omega\}_{\omega \in \Omega}$ if for almost every $\omega \in \Omega$ the set $\Lambda_\omega$ has a product structure and properties (P0)-(P4) below hold:

(P0) **Detectable:** $\text{Leb}_{\gamma^s_\omega}(\Lambda_\omega \cap \gamma^s_\omega) > 0$ for some $\gamma^s_\omega \in \Gamma^u_\omega$.

(P1) **Markov:** there is a partition $\mathcal{P}_\omega = \{\Lambda_i,\omega\}$ of $\Lambda_\omega$ such that

1. $\text{Leb}_{\gamma^s_\omega}(\Lambda_\omega \setminus \bigcup \Lambda_i,\omega) \cap \gamma^s_\omega = 0$ on each $\gamma^s_\omega \in \Gamma^u_\omega$;

2. For each $\Lambda_i,\omega$ there is $R_i,\omega \in \mathbb{N}$ with $x \to R_i,\omega$ measurable such that $f^{R_i,\omega}(\Lambda_i,\omega)$ is a $u$-subset and for all $x \in \Lambda_i,\omega$:

$$f^{R_i,\omega}(\gamma^s(x)) \subset \gamma^s \cap f^{R_i,\omega}(x) \quad \text{and} \quad f^{R_i,\omega}(\gamma^u(x)) \supset \gamma^u \cap f^{R_i,\omega}(x).$$

This allows us to introduce the random return time $R_\omega: \Lambda_\omega \to \mathbb{N}$ by $R_\omega|_{\Lambda_i,\omega} = R_i,\omega$, and the random induced map $f_\omega^R: \Lambda_\omega \to \Lambda_{\sigma R_\omega}$ by $f_\omega^{R_\omega}|_{\Lambda_i,\omega} = f^{R_i,\omega}$. For $x \in \Lambda_\omega$, we define a sequence $(\tau_{\omega,i})$, of return times

$$\tau_{\omega,1}(x) = R_\omega(x), \quad \tau_{\omega,i+1}(x) = \tau_{\omega,i}(x) + R_{\sigma \tau_{\omega,i}} \circ f^{\tau_{\omega,i}}(x). \quad (3)$$

We also define a separation time $s(x, y)$ for $x, y \in \Lambda_\omega$ as the smallest $n \geq 0$ such that $(f_\omega^R)^n(x)$ and $(f_\omega^R)^n(y)$ lie in distinct elements of $\mathcal{P}_{\sigma R_\omega}$. In the properties below we consider constants $C > 0$ and $0 < \beta < 1$ independent of $\omega \in \Omega$ and we assume for almost all $\omega \in \Omega$ the following are satisfied:

(P2) **Contraction on stable leaves:** for all $\gamma^s \in \Gamma^s_\omega$, all $x, y \in \gamma^s$ and all $n \in \mathbb{N}$ we have

$$\text{dist}(f^\omega_n(y), f^\omega_n(x)) \leq \beta^n.$$

(P3) **Expansion and distortion on unstable leaves:** for all $\Lambda_i,\omega \in \mathcal{P}_\omega$ and all $x, y \in \Lambda_i,\omega$ with $y \in \gamma^u_\omega(x)$ we have

1. $\|D^u(f_\omega^R)^{-1}(x)\| \leq \beta$;

2. $\log \frac{\det D^u(f_\omega^R)^{-1}(x)}{\det D^u(f_\omega^R)^{-1}(y)} \leq C \beta^s(f^\omega_n(x), f^\omega_n(y)).$

(P4) **Regularity of the foliations:** given $\gamma_\omega, \gamma'_\omega \in \Gamma^u_\omega$, define $\Theta_\omega: \gamma_\omega \cap \Lambda_\omega \to \gamma'_\omega \cap \Lambda_\omega$ as $\Theta_\omega(x) = \gamma'_\omega(x) \cap \gamma'_\omega$; we assume

1. $\Theta_\omega$ is absolutely continuous and

$$\frac{d([\Theta_\omega] \circ \text{Leb}_{\gamma'_{\omega}})(x)}{d \text{Leb}_{\gamma_{\omega}}}(x) = \prod_{t=0}^{\infty} \frac{\det D^u f_{\sigma \omega}(f^t_\omega(x))}{\det D^u f_{\sigma \omega}(f^t_\omega(\Theta_\omega^{-1}(x)))}.$$

2. Denoting $\rho_\omega$ the density in the previous item, we have for all $x, y \in \gamma_\omega \cap \Lambda_\omega$

$$\log \frac{\rho_\omega(x)}{\rho_\omega(y)} \leq C \beta^s(x, y).$$
1.3. **Tower extensions.** We now introduce our main tool to study statistical properties of systems satisfying conditions (P₀)–(P₄). We define a random tower for almost every $\omega$ as

$$\Delta_\omega = \{(x, \ell) \mid x \in \Lambda_{\sigma^{-\ell}\omega}, 0 \leq \ell \leq R_{\sigma^{-\ell}\omega}(x) - 1\}$$

and the random tower map $F_\omega: \Delta_\omega \to \Delta_{\sigma\omega}$ by

$$F_\omega(x, \ell) = \begin{cases} (x, \ell + 1), & \text{if } \ell + 1 < R_{\sigma^{-\ell}\omega}(x), \\ (f_{\sigma^{-\ell}\omega}^{\ell+1}x, 0), & \text{if } \ell + 1 = R_{\sigma^{-\ell}\omega}(x). \end{cases}$$

Let $\Delta_{\omega,\ell} = \{(x, \ell) \in \Delta_\omega\}$ be the $\ell$th level of the tower, which is a copy of $\{x \in \Lambda_\omega \mid R_{\sigma^{-\ell}\omega}(x) > \ell\}$. The partition $P_{\omega}$ of $\Lambda_\omega = \Delta_{\omega,0}$ naturally lifts to a partition $Q_\omega = \{\Delta_{\omega,\ell,i}\}$ of $\Delta_\omega$ for almost every $\omega \in \Omega$. Define a sequence of partitions $(Q^n_\omega)$ as follows:

$$Q^0_\omega = Q_\omega \text{ and } Q^n_\omega = \bigvee_{i=0}^{n-1} F_\omega^{-i}Q^{i+1}_\omega \text{ for } n \geq 1. \quad (6)$$

We shall denote by $Q_n(z)$ the element of $Q^n_\omega$ containing the point $z \in \Delta_\omega$. For almost every $\omega \in \Omega$ and $(x, \ell) \in \Delta_\omega$ we define tower projections $\pi_\omega: \Delta_\omega \to M$ as $\pi_\omega(x, \ell) = f_{\sigma^{-\ell}\omega}^\ell(x)$.

Then $\pi_\omega$ is a semi-conjugacy, i.e. $\pi_\omega F_\omega = f_\omega \circ \pi_\omega$. Let

$$\delta_{\sigma^{k}\omega,k} = \sup_{A \in Q_{2k}^\omega} \text{diam}(\pi_{\sigma^{k}\omega}(F_{\omega}^k(A))). \quad (7)$$

By definition for any $k \geq 1$ and $Q \in Q_{2k}^\omega$ we have

$$\text{diam}(\pi_{\sigma^{k}\omega}F_{\omega}^k(Q)) \leq \delta_{\sigma^{k}\omega,k}. \quad (7)$$

Remark 1.1. In two of our applications (Axiom A and DA attractors) the systems admit a stronger expansion than the one stated in (P₃)(1), namely for all $\omega$ and for all $\Lambda_{i,\omega} \in P_{\omega}$ and all $x \in \Lambda_{i,\omega}$ we have

$$\|D^n(f_{\omega}^{R_{\omega}^{-j}})^{-1}(x)\| \leq \beta^{j}, \text{ for all } 0 \leq j \leq R_{\omega}.$$ 

Therefore, in situations like this, it is straightforward to verify that $\delta_{\sigma^{k}\omega,k}$ decays exponentially fast in $k$, with constants not depending on $\omega$. However, this is not the case of the solenoid with intermittency presented in Subsection 1.5.3.

1.4. **Statements of results.** In this work measurability for the function $\omega \mapsto \Lambda_\omega$ is understood in the sense of [23, Section 3]. We say a hyperbolic product structure admits uniformly summable tails if there exists $C > 0$ so that for almost every $\omega \in \Omega$ we have $\gamma_{\omega} \in G_{\omega}$ for which

$$\sum_{n \geq 0} \text{Leb}_{\gamma_{\omega}} \{R_{\sigma^{-n}\omega} > n\} \leq C.$$

The uniform summability condition above is needed to prove the existence of an equivariant family of measures.

**Theorem 1.2.** Every random dynamical system with a measurable hyperbolic product structure and uniformly summable tails admits a family of equivariant physical measures.
To obtain quenched correlation decay rates for the equivarant physical measures we need more information on the tail of return times. We say a hyperbolic product structure \( \{\Lambda_{\omega}\}_{\omega \in \Omega} \) is aperiodic if there are \( N_0 \in \mathbb{N} \) and \( \{t_i \in \mathbb{Z}_+ \mid i = 1, 2, \ldots, N_0\} \) such that for almost every \( \omega \in \Omega \) there exists \( \gamma \in \Gamma_{\omega}^{\prime} \) such that \( \gcd\{t_i\} = 1 \) and \( \text{Leb}_{\gamma}\{x \in \Lambda_{\omega} \mid R_{\omega}(x) = t_i > 0\} \)

Let \( \eta \in (0, 1] \) and \( C^{\eta}(M) \) be the set of Hölder continuous functions of exponent \( \eta \) on \( M \).

**Theorem 1.3.** Consider a random dynamical system with a measurable aperiodic hyperbolic product structure and uniformly summable tails.

1. If there are \( C, c > 0 \) such that for almost every \( \omega \) and some \( \gamma_{\omega} \in \Gamma_{\omega}^{u} \) we have
   \[
   \text{Leb}_{\gamma_{\omega}}\{R_{\omega} > n\} \leq Ce^{-cn},
   \]
   then there are \( C', c' > 0 \) such that for any \( \varphi, \psi \in C^{\eta}(M) \) there is \( C_{\varphi, \psi} > 0 \) so that for almost every \( \omega \)
   \[
   |C_n(\varphi, \psi, \mu_{\omega})| \leq C_{\varphi, \psi} \max\{e^{-c'n}, \delta_{\sigma(n/\gamma_{\omega}, [n/4])}\}.
   \]
2. If there are \( a \in (0, 1], C, c > 0 \) and \( n_1 : \Omega \to \mathbb{N} \) with \( P\{n_1 > n\} \leq Ce^{-cn} \) such that for almost every \( \omega \) and some \( \gamma_{\omega} \in \Gamma_{\omega}^{u} \) for all \( n \geq n_1(\omega) \) we have
   \[
   \text{Leb}_{\gamma_{\omega}}\{R_{\omega} > n\} \leq Ce^{-cn},
   \]
   then there exist \( C', c' > 0 \) and \( 0 < a' \leq 1 \) such that for any \( \varphi, \psi \in C^{\eta}(M) \) there is a constant \( C_{\varphi, \psi} > 0 \) and \( C_{\omega} : \Omega \to \mathbb{R} \) such that \( P\{C_{\omega} > n\} \leq C'e^{-c'n^{a'}} \) and for almost every \( \omega \)
   \[
   |C_n(\varphi, \psi, \mu_{\omega})| \leq C_{\varphi, \psi} \max\{C_{\omega}e^{-c'n}, \delta_{\sigma(n/\gamma_{\omega}, [n/4])}\}.
   \]
   Moreover, if \( a = 1 \) then \( a' = 1 \).

**Theorem 1.4.** Consider a random dynamical system with a measurable aperiodic hyperbolic product structure and uniformly summable tails. Assume, there exist \( C, c, a > 0, b \geq 0 \) and \( d \in (0, 1] \) such that for almost every \( \omega \) and some \( \gamma_{\omega} \in \Gamma_{\omega}^{u} \)

1. \( \int \text{Leb}_{\gamma_{\omega}}\{R_{\omega} = n\}dP(\omega) \leq C(\log n)^b n^{-2-a}; \)
2. there exists \( n_1 : \Omega \to \mathbb{N} \) with \( P\{n_1 > n\} \leq Ce^{-cn^d} \) such that for all \( n \geq n_1(\omega) \)
   \[
   \text{Leb}_{\gamma_{\omega}}\{R_{\omega} > n\} \leq C(\log n)^b n^{-1-a}.
   \]

Then there are \( C', c' > 0 \) and \( d' \in (0, 1] \) such that for every \( \varepsilon > 0 \) and every \( \varphi, \psi \in C^{\eta}(M) \) there is \( C_{\varphi, \psi} \) (independent of \( \varepsilon \)) and a random variable \( C_{\omega} : \Omega \to \mathbb{R} \) with \( P\{C_{\omega} > n\} \leq C'e^{-c'n^{d'}} \) such that for almost every \( \omega \)
   \[
   |C_n(\varphi, \psi, \mu_{\omega})| \leq C_{\varphi, \psi} \max\{C_{\omega}n^{-a+\varepsilon}, \delta_{\sigma(n/\gamma_{\omega}, [n/4])}\}.
   \]

1.4.1. Partially hyperbolic attractors. In this subsection we introduce random perturbations of partially hyperbolic attractors with uniformly contracting direction and mostly expanding central-unstable direction. Theorem [15] below, which extends the results of [6] to the random setting, is our main tool to verify that random perturbations of Axiom A and derived from Anosov attractors admit a random hyperbolic product structure with exponential tails. To build such structures, we need to assume that the constituent maps
of the random dynamical system belong in some small neighbourhood of a deterministic transitive dynamical system, in particular to assure the existence of recurrence times.

Let \( f \in \text{Diff}^1(M) \) and \( U \subset M \) be an open set for which \( f(U) \subset U \), which we refer to as a trapping region. We are going to consider a partially hyperbolic situation for which the corresponding attractor \( K = \cap_{n \geq 0} f^n(U) \) has a dominated decomposition with a uniform contracting direction as in [3]. Let us now introduce these concepts in the random setting. We consider \( \mathcal{F} \) a small neighbourhood of \( f \) in the \( C^1 \) topology and \( \theta \) a compactly supported Borel probability measure whose support \( \mathcal{B} \) is contained in \( \mathcal{F} \) and \( f \in \mathcal{B} \). For \( \mathcal{F} \) sufficiently small, we still have \( f_\omega(U) \subset U \) for every \( \omega \in \Omega = \mathbb{B}^\mathbb{Z} \) and \( f_\omega \in \mathcal{F} \). Defining the random attractor

\[
K_\omega = \bigcap_{n \geq 0} f_{\sigma^{-n}_\omega}(U) \quad (8)
\]

and using the \( C^1 \) persistence of dominated splittings (see e.g. [19, Section B.1]), for each \( \omega \in \Omega \) there exists a continuous splitting of \( T_K M = E^s_\omega \oplus E^u_\omega \), which is \( Df_\omega \)-equivariant:

\[
Df_\omega(x)E^s_\omega(x) = E^s_{\sigma_\omega}(f_\omega(x)) \quad \text{and} \quad Df_\omega(x)E^u_\omega(x) = E^u_{\sigma_\omega}(f_\omega(x)).
\]

Moreover, this is still partially hyperbolic: there exists \( 0 < \lambda < 1 \) such that (for some choice of Riemannian metric on \( M \), which is independent of \( \omega \)) for each \( \omega \in \Omega \) and \( x \in K_\omega \) we have

\[
\|Df_\omega \mid E^s_\omega(x)\| \cdot \|Df_\omega^{-1} \mid E^u_{\sigma_\omega}(f_\omega(x))\| < \lambda \quad \text{and} \quad \|Df_\omega \mid E^u_\omega(x)\| < \lambda. \quad (9)
\]

To emphasise uniform contraction we will write \( E^s \) instead of \( E^s_\omega \) and say that \( K_\omega \) is a partially hyperbolic attractor of the type \( E^s \oplus E^u \). We say that \( f_\omega \) has non-uniform expansion in the centre-unstable direction \( E^u \) on some set \( H_\omega \subset U \) if there exists \( c > 0 \) such that for every \( \omega \in \Omega \) and \( x \in H_\omega \)

\[
\limsup_{n \to +\infty} \frac{1}{n} \sum_{j=1}^n \log \|Df_{\sigma^{-j}_\omega}^{-1} \mid E^u_{\sigma^j_\omega}(f_\omega^j(x))\| < -c. \quad (10)
\]

For the specific case of \( f \), this implies that there is a local unstable manifold \( D \subset K \) such that points in \( D \) have non-uniform expansion in the centre-unstable direction; see [9, Theorem A]. We say that \( \{f_\omega\}_{\omega \in \Omega} \) is \( C^1 \)-close to \( f \mid D \) on domains \( \{D_\omega\}_{\omega \in \Omega} \) of \( cu \)-nonuniform expansion, if

1. each \( f_\omega \) is close to \( f \) in the \( C^1 \) topology;
2. each \( f_\omega \) has a partially hyperbolic set \( K_\omega \) of the type \( E^s \oplus E^u \) with a local unstable manifold \( D_\omega \subset K_\omega \) close to \( D \) in the \( C^1 \) topology;
3. each \( f_\omega \) is non-uniformly expanding on random orbits along the \( E^u_\omega \) direction for \( \text{Leb}_{D_\omega} \) almost every \( x \in D_\omega \).

If (10) holds at \( x \in D_\omega \), then the expansion time function

\[
E_\omega(x) = \min \left\{ N \geq 1 : \frac{1}{n} \sum_{i=1}^n \log \|Df_{\sigma^{-i}_\omega}^{-1} \mid E^u_{\sigma^i_\omega}(f_\omega^i(x))\| < -c, \quad \forall n \geq N \right\} \quad (11)
\]

is well defined and finite. The set \( \{E_\omega > n\} \) plays an important role in the statement of our next result.
Theorem 1.5. Let $f \in \text{Diff}^{1+}(M)$ have a transitive partially hyperbolic set $K \subset M$ and a local unstable manifold $D \subset K$. If $\{f_\omega\}_{\omega \in \Omega}$ is a random perturbation $C^1$-close to $f|_D$ on domains $\{D_\omega\}_{\omega \in \Omega}$ of cu-nonuniform expansion, then there exists $\Lambda_\omega \subset K_\omega$ with a hyperbolic product structure. Moreover, if there exist $C, c > 0$ and $0 < \tau \leq 1$ such that $\text{Leb}_{D_\omega}\{E_\omega > n\} = Ce^{-cn\tau}$ for all $\omega \in \Omega$, then there exist $\Lambda', c' > 0$ such that $\text{Leb}_{D_\omega}\{R_\omega > n\} = C'e^{-c'n\tau}$ for all $\omega \in \Omega$.

1.5. Applications. In this subsection we provide examples of random dynamical systems where our general results above apply.

1.5.1. Axiom A attractors. As an application of Theorem 1.3 and Theorem 1.5 we consider the classical case of topologically mixing uniformly hyperbolic Axiom A attractors. Observe that this is a particular case of partially hyperbolic attractors, as considered in Section 1.3.1. In this case, the random attractors are defined as in [8]. As in the general partially hyperbolic setting, we consider $\mathcal{N}$ a small neighbourhood of $f$ in the $C^1$ topology and $\theta$ a compactly supported Borel probability measure whose support contains $f$ and is contained in $\mathcal{N}$. The proof of the next result is given in Subsection 3.5.

Theorem 1.6. Let $f \in \text{Diff}^{1+}(M)$ have a topologically mixing uniformly hyperbolic attractor $K \subset M$. If $\{f_\omega\}_{\omega \in \Omega}$ is a small random perturbation of $f$, then it admits a unique family of equivariant physical measures $\{\mu_\omega\}_{\omega \in \Omega}$ supported on the random attractors. Moreover, there is $c > 0$ such that for any $\varphi, \psi \in C^0(M)$ there is a constant $C_{\varphi, \psi} > 0$ for which $|\mathcal{C}_n(\varphi, \psi, \mu_\omega)| \leq C_{\varphi, \psi} e^{-cn}$.

1.5.2. Derived from Anosov. Here we present random perturbations of partially hyperbolic diffeomorphisms whose centre-unstable direction is non-uniformly expanding. The deterministic case was introduced in [3] Appendix A] as a perturbation (not necessarily small) of an Anosov diffeomorphism. We sketch below the main steps of its construction.

Consider a linear Anosov diffeomorphism $f_0$ on the $d$-dimensional torus $M = \mathbb{T}^d$, for some $d \geq 3$, having a hyperbolic splitting $TM = E^u \oplus E^s$ with $\dim(E^u) \geq 2$. Let $V \subset M$ be a small compact domain, such that for the canonical projection $\pi : \mathbb{R}^d \to M$ there exist unit open cubes $K^0, K^1 \subset \mathbb{R}^d$ with $V \subset \pi(K^0)$ and $f_0(V) \subset \pi(K^1)$. Let $f$ be a diffeomorphism on $M$ such that:

1. $f$ has invariant cone fields $C^{cu}$ and $C^s$ with small width containing the unstable bundle $E^u$ and the stable bundle $E^s$ of $f_0$, respectively, with $Df$ contracting uniformly vectors in $C^s$;
2. $f$ is $cu$-volume expanding in $M$: there is $\sigma_1 > 0$ such that $|\det(Df|T_xD^{cu})| > \sigma_1$ for any $x \in M$ and any disk $D^{cu}$ through $x$ whose tangent space is contained in $C^{cu}$;
3. $f$ is $cu$-expanding $M \setminus V$: there is $\sigma_2 < 1$ such that $\|(Df|T_xD^{cu})^{-1}\| < \sigma_2$ for any $x \in M \setminus V$ and any disk $D^{cu}$ whose tangent space is contained in $C^{cu}$;
4. $f$ is not too $cu$-contracting on $V$: there is a small $\delta_0 > 0$ such that $\|(Df|T_xD^{cu})^{-1}\| < 1 + \delta_0$ for any $x \in V$ and any disk $D^{cu}$ whose tangent space is contained in $C^{cu}$.

For example, if $f_1 : \mathbb{T}^d \to \mathbb{T}^d$ is a diffeomorphism satisfying items (1), (2) and (4) above and coinciding with $f_0$ outside $V$, then any $f$ in a $C^1$ neighbourhood of $f_1$ satisfies all the
conditions (1)-(4). It is not difficult to see that examples of this type can be produced in such a way that the following property holds:

(5) \( f \) preserves the unstable foliation of \( f_0 \).

The above construction yields a family in \( \text{Diff}^{1+}(M) \) such for any centre-unstable disk \( D \) we have \( \text{Leb}_D\{\mathcal{E} > n\} \) with exponential decay; see [3, Appendix A]. The existence of physical measures for these maps follows from the results in [3]. Stably ergodic examples of this type with a unique physical measure are given in [43] under a volume hyperbolicity condition. This in particular assures the next property:

(6) \( f \) is transitive in \( M \).

Let \( \mathcal{F} \) be a family of maps in \( \text{Diff}^{1+}(M) \) satisfying properties (1)-(6) above.

**Theorem 1.7.** Let \( f \in \mathcal{F} \) and \( \{f_\omega\}_{\omega \in \Omega} \) be a small random perturbation of \( f \) in \( \mathcal{F} \). Then there is some \( N \in \mathbb{N} \) such that \( \{f^N_\omega\}_{\omega \in \Omega} \) admits a unique family of equivariant physical measures \( \{\mu_\omega\}_{\omega \in \Omega} \). Moreover, there exists \( c > 0 \) such that for any \( \varphi, \psi \in C^0(M) \) we have a constant \( C_{\varphi,\psi} > 0 \) for which \( |C_n(\varphi, \psi, \mu_\omega)| \leq C_{\varphi, \psi} e^{-cn} \).

To obtain Theorem 1.7 we are going to apply Theorem 1.6 with \( K = M \). Firstly, observe that property (5) above and [2, Lemma 7.4] guarantee that for any unstable disk \( D \) for \( f \) there exist \( C, c > 0 \) and \( 0 < \tau \leq 1 \) such that \( \text{Leb}_D\{\mathcal{E}_\omega > n\} = Ce^{-cn} \) for all \( \omega \in \Omega \). Moreover, taking \( D_\omega = D \) we trivially have that \( \{f_\omega\}_{\omega \in \Omega} \) is a random perturbation \( C^1 \)-close to \( f|_D \) on domains \( \{D_\omega\}_{\omega \in \Omega} \) of \( c \)-nonuniform expansion. Hence, by Theorem 1.6 there exists \( \Lambda_\omega \subset K_\omega \) with a hyperbolic product structure and there exist \( C', c' > 0 \) such that \( \text{Leb}_{D_\omega}\{R_\omega > n\} = C'e^{-c'n^\tau} \) for all \( \omega \in \Omega \). Finally, using Theorem 1.2 and Theorem 1.3 we get the conclusion. Note that as we cannot a priori assure that the hyperbolic product structure is aperiodic, we have to take some power \( N \).

1.5.3. **Solenoid with intermittency.** Here we present an application of Theorem 1.4 to a variation of the classical solenoid attractor on the solid torus. The idea is to replace the uniformly expanding base map by a map with a neutral fixed point. The deterministic case has been treated in [8]. Here we consider a randomised version of this example.

Let \( 0 < \alpha_0 < \alpha_1 < 1 \) be fixed real numbers and let \( \theta \) be the normalised Lebesgue measure on \([\alpha_0, \alpha_1]\). For each \( \alpha \in [\alpha_0, \alpha_1] \), consider the circle map \( T_\alpha : S^1 \to S^1 \) defined by

\[
T_\alpha(x) = \begin{cases} 
(1 + (2x)\alpha), & \text{if } x \in (0, 1/2); \\
2\alpha(1-x)^{1+\alpha}, & \text{if } x \in (1/2, 1).
\end{cases}
\]

Let \( M = S^1 \times \mathbb{D}^2 \) denote the solid torus in \( \mathbb{R}^3 \), where \( \mathbb{D}^2 \) is the unit disk in \( \mathbb{R}^2 \), and consider a skew product \( g_\alpha : M \to M \),

\[
g_\alpha(x, y, z) = \left( T_\alpha(x), \frac{1}{10}y + \frac{1}{2}\cos x, \frac{1}{10}z + \frac{1}{2}\sin x \right). \tag{12}
\]

As in the case of classical solenoid (see for example [35]) it is easily checked that \( g_\alpha \) is a diffeomorphism onto its image for every \( \alpha \in [\alpha_0, \alpha_1] \).
Now let $\Omega = [\alpha_0, \alpha_1]^2$, $P = \theta^2$ and $\omega_k$ denote the $k$th component of $\omega \in \Omega$. Note that the composition defined as $g^n_\omega = g_{\omega_{n-1}} \circ \cdots \circ g_{\omega_0}$ defines a random dynamical system on $M$ as in Section 1. The proof of the next result is provided in Section 1.

**Theorem 1.8.** The random system $\{g_\omega\}_{\omega \in \Omega}$ admits a family $\{\mu_\omega\}_{\omega \in \Omega}$ of equivariant physical measures. Moreover, for every $\varepsilon > 0$ and almost every $\omega \in \Omega$ there exists a constant $C_\omega > 0$ such that for any $\varphi, \psi \in C^0(M)$ there is a constant $C_{\varphi, \psi} > 0$ so that

1. if $\eta > 1 - \alpha_0$, then we have $|C_n(\varphi, \psi, \mu_\omega)| \leq C_\omega C_{\varphi, \psi} n^{1-1/\alpha_0 + \varepsilon}$;
2. if $\eta \leq 1 - \alpha_0$, then we have $|C_n(\varphi, \psi, \mu_\omega)| \leq C_\omega C_{\varphi, \psi} n^{\eta/\alpha_0 + \varepsilon}$,

where $C_\omega$ satisfies $P\{C_\omega > n\} \leq C e^{u'n^v}$ for some $u' > 0$ and $v' \in (0, 1)$.

Note that the rate in the above theorem is driven by the fastest mixing map for the set of parameters considered.

### 2. Random hyperbolic towers

Our proofs of Theorems 1.2, 1.3 and 1.4 are based on considering quotients along stable manifolds to obtain a random Young tower for the quotient dynamics. For this purpose we first introduce measures that are suitable to take quotients along stable manifolds.

#### 2.1. Natural measures

Fix $\hat{\gamma}_\omega \in \Gamma^u_\omega$. For any $\gamma_\omega \in \Gamma^u_\omega$ and $x \in \gamma_\omega \cap \Lambda_\omega$ let $\hat{x}_\omega$ be the intersection point $\gamma^u_\omega(x) \cap \hat{\gamma}_\omega$. Define $\hat{\rho}_\omega : \gamma_\omega \cap \Lambda_\omega \to \mathbb{R}$ as

$$
\hat{\rho}_\omega(x) = \prod_{i=0}^{\infty} \frac{\det D^u f_{\sigma^i \omega}(f^i_\omega(x))}{\det D^u f_{\sigma^i \omega}(f^i_\omega(\hat{x}_\omega))}.
$$

Further, let $m_{\gamma_\omega}$ be the measure defined by

$$
dm_{\gamma_\omega}{\text{Leb}_{\gamma_\omega}} = \hat{\rho}_\omega \mathbb{1}_{\gamma_\omega \cap \Lambda_\omega}.
$$

For any $\omega \in \Omega$, $\gamma'_\omega \in \Gamma^u_\omega$ and $x' \in \gamma'_\omega \cap \gamma^u_\omega(x)$ i.e. $x' = \Theta_\omega(x)$, by (P4)(1) we have

$$
\frac{\hat{\rho}_\omega(x')}{\hat{\rho}_\omega(x)} = \frac{d(\Theta_\omega)_* \text{Leb}_{\gamma'_\omega}}{d \text{Leb}_{\gamma'_\omega}}(x'),
$$

which implies

$$
\frac{d(\Theta_\omega)_* m_{\gamma_\omega}}{d \text{Leb}_{\gamma'_\omega}}(x') = \hat{\rho}_\omega(x) \frac{d(\Theta_\omega)_* \text{Leb}_{\gamma'_\omega}}{d \text{Leb}_{\gamma'_\omega}}(x') = \hat{\rho}_\omega(x')
$$

Thus,

$$
[\Theta_\omega]_* m_{\gamma_\omega} = m_{\gamma'_\omega}.
$$

**Lemma 2.1.** Assume that $f^{R_{\sigma_\omega}}(\gamma \cap \Lambda_\omega) \subset \gamma'$ for $\gamma \in \Gamma^u_\omega$ and $\gamma' \in \Gamma^{u_{\sigma_\omega}}_\omega$. Let $J f^{R_{\sigma_\omega}}_\omega$ denote the Jacobian of $f^{R_{\sigma_\omega}}_\omega$ with respect to $m_{\gamma}$ and $m'_{\gamma}$. Then

1. $J f^{R_{\sigma_\omega}}_\omega(x) = J f^{R_{\sigma_\omega}}_\omega(y)$ for any $y \in \gamma^u_\omega(x)$.
(2) There exists a constant $C_1 > 0$ such that for any $x, y \in \Lambda_\omega \cap \gamma$
\[
\left| \frac{J_f R^\omega(x)}{J_f R^\omega(y)} - 1 \right| \leq C_1 \beta s(f^R_\omega(x), f^R_\omega(y)).
\]

Proof. (1) For Leb, almost every $x \in \gamma \cap \Lambda_\omega$ we have
\[
J_f R^\omega(x) = \left| \det D^u f^\omega(x) \right| \cdot \frac{\hat{\rho}_\sigma f^\omega(x)}{\hat{\rho}_\omega(x)}.
\]

Denoting $\varphi_\omega(x) = \log |\det D^u f_\omega(x)|$, we write the right hand side of (14) as
\[
\sum_{i=0}^{R_\omega-1} \varphi_{\sigma^i \omega}(f^i_\omega(x)) - \sum_{i=0}^{\infty} \left( \varphi_{\sigma^i \omega}(f^i_\omega(x)) - \varphi_{\sigma^i \omega}(f^i_\omega(\hat{x})) \right)
\]
\[
+ \sum_{i=0}^{R_\omega-1} \left( \varphi_{\sigma^i R^\omega_\omega}(f^i_\omega R^\omega_\omega(x)) - \varphi_{\sigma^i R^\omega_\omega}(f^i_\omega R^\omega_\omega(f^R_\omega(x))) \right)
\]
\[
= \sum_{i=0}^{R_\omega-1} \varphi_{\sigma^i \omega}(f^i_\omega(x)) + \sum_{i=0}^{\infty} \left( \varphi_{\sigma^i R^\omega_\omega}(f^i_\omega R^\omega_\omega(x)) - \varphi_{\sigma^i R^\omega_\omega}(f^i_\omega R^\omega_\omega(f^R_\omega(x))) \right).
\]
Thus we have shown that $J_f R^\omega(x)$ can be expressed just in terms of $\hat{x}$ and $f^R_\omega(x)$, which is enough for proving the first part of the lemma.

(2) It follows from (14) that
\[
\log J_f R^\omega(x) = \log \left| \det D^u f^\omega(x) \right| + \log \frac{\hat{\rho}_\sigma f^\omega(x)}{\hat{\rho}_\omega(x)} + \log \frac{\hat{\rho}_\omega(y)}{\hat{\rho}_\omega(x)}.
\]
Observing that $s(x, y) > s(f^R_\omega(x), f^R_\omega(y))$ the conclusion follows from (P.3) and (P.4)(2).

Notice that the family $\{m_\gamma\}$ introduced in the previous section defines a measurable system on $\Lambda_\omega$ since $\Gamma^u_\omega$ is a continuous family. Thus, it defines a measure $m_\omega$ on $\Lambda_\omega$. We introduce a measure on $\Delta_\omega$ that we still denote $m_\omega$ by letting $m_\omega|\Delta_\omega, t = m_{\sigma^{-t}\omega}|\{R_{\sigma^{-t}\omega} > \ell\}$. We let $JF_\omega$ denote the Jacobian of $F_\omega$ with respect to the measure $m_\omega$.

Lemma 2.2. There exists $C_3 > 0$ such that for almost every $\omega \in \Omega$, for any $k \in Q_{k-1}$ and $x, y \in Q \in Q_{k-1}$
\[
\left| \frac{F^k_\omega(x)}{F^k_\omega(y)} - 1 \right| \leq C_3 \beta s(F^k_\omega(x), F^k_\omega(y)).
\]

Proof. Recall that by the definition of $\tau_\omega, j$ we have $(F^R_\omega)^j = F^R_\omega^\omega, j$. Also let $P_{\omega, k} = \vee_{j=0}^{n-1} (F^R_\omega)^{-1}_{\sigma^j \omega, j} P_{\sigma^j \omega, \omega}$. By Lemma 2.1 for a.e. $\omega$, for all $i \geq 1$ and all $x, y \in \Delta_\omega, 0, i$ holds
\[
\left| \frac{J F^R_\omega(x)}{J F^R_\omega(y)} - 1 \right| \leq C_1 \beta s(F^R_\omega(x), F^R_\omega(y)).
\]
It follows that there is a constant \( C_F > 0 \), which is independent of \( \omega \) such that for all \( n \geq 1 \) and all \( x, y \) belonging to a same element of \( \mathcal{P}_{\omega,n} \)

\[
\left| \frac{J(F^{R^x}_{\omega})^n(x)}{J(F^{R^y}_{\omega})^n(y)} - 1 \right| \leq C_F \beta^s((F^{R^x}_{\omega})^n(x),(F^{R^y}_{\omega})^n(y)), \tag{16}
\]

By definition if \( x \) and \( y \) belong to a same element of \( \mathcal{P}_{\omega,n} \), then \((F^{R^x}_{\omega})^j(x)\) and \((F^{R^y}_{\omega})^j(y)\) belong to a same element of \( \mathcal{P}_{\sigma^j \omega,\sigma^j \omega} \) for every \( 0 \leq j < n \). Moreover,

\[
s((F^{R^x}_{\omega})^j(x), (F^{R^y}_{\omega})^j(y)) = s((F^{R^x}_{\omega})^n(x), (F^{R^y}_{\omega})^n(y)) + (n - j). \tag{17}
\]

Then by (15) and (17) we have

\[
\log \frac{J(F^{R^x}_{\omega})^n(x)}{J(F^{R^y}_{\omega})^n(y)} = \sum_{j=0}^{n-1} \log \frac{J(F^{R^x}_{\omega})^j((F^{R^x}_{\omega})^j(x))}{J(F^{R^y}_{\omega})^j((F^{R^y}_{\omega})^j(y))} \leq \sum_{j=0}^{n-1} C_1 \beta^s((F^{R^x}_{\omega})^n(x),(F^{R^y}_{\omega})^n(y)) \leq C_F \beta^s((F^{R^x}_{\omega})^n(x),(F^{R^y}_{\omega})^n(y)),
\]

where \( C_F > 0 \) depends only on \( C_1 \) and \( \beta \). This implies that (16) holds.

Since \( JF^k_{\omega}(x) \equiv 1 \) for every \( x \in \Delta_{\omega,\ell} \) with \( \ell > 0 \), it follows that \( JF^k_{\omega}(x) = J(F^{R^x}_{\omega})^n(x') \) and \( JF^k_{\omega}(y) = J(F^{R^y}_{\omega})^n(y') \), where \( n \) is the number of visits of \( x \) and \( y \) to the base prior to time \( k \), and \( x', y' \) are the projections of \( x, y \) to the zeroth level of the tower \( \Delta_{\omega} \) for some \( \omega' \in \Omega \). The point \( x', y' \) belong to a same element of \( \mathcal{P}_{\omega',n} \) and \( s(x, y) = s(x', y') \). Using (16) and (17) we obtain that

\[
\left| \frac{JF^k_{\omega}(x)}{JF^k_{\omega}(y)} - 1 \right| \leq C_F \beta^s((F^x_{\omega})(x),(F^y_{\omega})(y)). \tag{19}
\]

For all \( k \geq 1 \) and all \( x, y \in \Delta_{\omega} \) belonging to a same element of \( \mathcal{Q}^{k}_{\omega} \). \( \square \)

2.2. Equivariant measures. In this subsection we prove Theorem 1.2. For \( x \in \Lambda_{\omega} \), we set \( \tilde{F}^\omega_{\omega}(x) = f_{R_{\omega}}(x) \in \Lambda_{\eta_{R_{\omega}}(x)} \). We refine recursively \( \mathcal{P}_{\omega} \) on \( \Lambda_{\omega} \) with the partitions associated to the images of each element of \( \mathcal{P}_{\omega} \):

\[
\mathcal{P}_{\omega}^{(k)} = \bigvee_{j=0}^{k} \bigvee_{n \in \mathbb{N}} (\tilde{F}^j_{\omega})^{-1} \mathcal{P}_{\sigma^n(\omega)},
\]

where \( L_{\omega}^j = \{ n \in \mathbb{N} : \tilde{F}^j_{\omega}(\Lambda_{\omega}) \cap \Lambda_{\sigma^n(\omega)} \neq \emptyset \} \), and set \( \mathcal{P}_{\omega}^{(k),n} = \mathcal{P}_{\omega}^{(k)} \cap (\tilde{F}^k_{\omega})^{-1}(\Lambda_{\sigma^n(\omega)}) \), for \( n \in \mathbb{N} \). Note that if \( B \in \mathcal{P}_{\omega}^{(k),n} \), then \( \tilde{F}^k_{\omega}(B) = \Lambda_{\sigma^n(\omega)} \). Given \( B \subset \Lambda_{\omega} \) set

\[
(\tilde{F}^{-1})_{\omega}(B) = \bigcup_{n \in \mathbb{N}} \left\{ x \in \Lambda_{\sigma^{-n}(\omega)} : R_{\sigma^{-n}(\omega)}(x) = n \text{ and } \tilde{F}_{\sigma^{-n}(\omega)}(x) \in B \right\}.
\]
and define \([((F^j)^{-1})_\omega(B)]\) by induction. Let \(\lambda_{n-\omega}\) be a probability measure on \(\Lambda_{n-\omega}\) and define

\[
((F^j)^{-1})^*\{\lambda_{n-\omega}\}(B) = \sum_{n \in \mathbb{N}} \lambda_{n-\omega}(([F^j])^{-1}_\omega(B) \cap \Lambda_{n-\omega}).
\]

**Proposition 2.3.** For almost every \(\omega \in \Omega\) there is a probability measure \(\hat{\nu}_{\sigma^{-n}\omega}\) on \(\Lambda_{\sigma^{-n}\omega}\) such that \((F^j)^*\{\hat{\nu}_{\sigma^{-n}\omega}\}\)\(n \in \mathbb{N}\) = \(\hat{\nu}_{\omega}\). Moreover, \(\hat{\nu}_{\omega}\) admits absolutely continuous conditional measures on unstable leaves.

**Proof.** For each \(\omega \in \Omega\), choose \(\gamma^0_\omega \in \Gamma^u_\omega\) and set \(m^0_\omega = m_{\gamma^0_\omega}\). For \(j \geq 1\) define

\[
m^j_\omega = \sum_{k=1}^{j} \sum_{B \in \mathcal{P}(k,\omega)} (\hat{F}^k_{\sigma^{-j}\omega})(m^0_{\sigma^{-j}\omega}|B).
\]

By Lemma 2.1, for any measurable set \(A \subset \Lambda_\omega\)

\[
m^j_\omega(A) \leq \sum_{k=1}^{j} \sum_{B \in \mathcal{P}(k,\omega)} C_1 m^0_\omega(A) m_{\sigma^{-j}\omega}(B)
\]

\[
\leq C_2 m^0_\omega(A),
\]

where we have used the uniform integrability. Let

\[
\hat{\nu}^n_\omega = \frac{1}{n} \sum_{j=0}^{n-1} m^j_\omega.
\]

Then \(\hat{\nu}^n_\omega\) has an accumulation point, in the weak* topology. Let \(\hat{\nu}^n\omega\) be a convergent subsequence. By a diagonal argument we construct along the sequence \(\{\hat{\nu}^n_\omega\}\) for almost every \(\omega \in \Omega\), a convergent subsequence \(\{\hat{\nu}^n_\sigma\omega\}\) for every \(\ell \in \mathbb{Z}\). The limiting measure \(\hat{\nu}_\omega\) satisfies the equivariance property; i.e. \((F^j)^*\{\hat{\nu}_{\sigma^{-n}\omega}\}\)\(n \in \mathbb{N}\) = \(\hat{\nu}_{\omega}\).

We now show that \(\hat{\nu}_\omega\) admits absolutely continuous conditional measures on unstable leaves. Let \(\rho^j_\omega\) be the density of \(m^j_\omega\) with respect to \(m_{\gamma^0_\omega}\) on an unstable leaf \(\gamma_\omega\). Observe that \(\rho^0_\omega \equiv 0\) or by Lemma 2.1

\[
\frac{\rho^j_\omega(y)}{\rho^j_\omega(x)} \leq \exp(C_F \beta^s(x,y)),
\]

for all \(x, y \in \gamma_\omega \cap \Lambda_\omega\). This implies that there exists \(C_0 > 0\) such that

\[
\frac{1}{C_0} \leq \rho^j_\omega(x) \leq C_0
\]

for all \(x \in \gamma_\omega \cap \Lambda_\omega\). Let \((U_k)\) be a sequence, where \(U_k\) is a finite partition of \(\Lambda_\omega\) consisting of \(u\)-subsets with \(U_1 \subset U_2 \subset \cdots\) and \(\bigvee_{i=1}^\infty U_k\) is a partition of \(\Lambda_\omega\) into unstable leaves. Let
\( U_k \in \mathcal{U}_k \) containing \( \gamma_\omega \) and shrinking to \( \gamma_\omega \). Given \( \mathcal{O} \subset \gamma_\omega \) an open set with \( m_{\gamma_\omega}(\partial \mathcal{O}) = 0 \), let \( \mathcal{S}_\mathcal{O} \) be the \( s \)-subset of \( \Lambda_\omega \) corresponding to \( \mathcal{O} \). By (20) we have
\[
\frac{1}{C_0^2} \frac{m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)} \leq \frac{\hat{\nu}(\mathcal{O})}{\hat{\nu}(\Lambda_\omega)} \leq \frac{C_0^2 m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)}.
\]
Consequently,
\[
\frac{1}{C_0^2} \frac{m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)} \leq \frac{\hat{\nu}\left(\mathcal{O} \cap \mathcal{S}_\mathcal{O}\right)}{\hat{\nu}(\mathcal{O})} \leq \frac{C_0^2 m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)},
\]
and so
\[
\frac{1}{C_0^2} \frac{m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)} \leq \frac{\hat{\nu}_\omega\left(\mathcal{O} \cap \mathcal{S}_\mathcal{O}\right)}{\hat{\nu}_\omega(\mathcal{O})} \leq \frac{C_0^2 m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)}.
\]
Notice that \( X_n = \mathbb{E} \hat{\nu}_\omega \left(1_{\mathcal{S}_\mathcal{O}}|\mathcal{F}_k\right) \), where \( \mathcal{F}_k \) is the sigma algebra generated by \( \mathcal{U}_k \), is a martingale. By the Martingale Convergence Theorem
\[
\frac{1}{C_0^2} \frac{m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)} \leq \hat{\nu}_\omega(\mathcal{O}) \leq \frac{C_0^2 m_{\gamma_\omega}(\mathcal{O})}{m_{\gamma_\omega}(\Lambda_\omega)},
\]
for almost every \( \gamma_\omega \).

Notice, by the above construction and the absolute continuity of the holonomy map, that the family of measures \( \hat{\nu}_\omega \) are physical. We introduce a measure on \( \Delta_\omega \) that we denote \( \nu_\omega \) by letting \( \nu_\omega|_{\Delta_{\omega, \ell}} = \hat{\nu}_{\sigma^{-\ell}_\omega}|\{R_{\sigma^{-\ell}_\omega} > \ell\} \).

2.3. Quotient dynamics. Let \( \bar{\Lambda}_\omega = \Lambda_\omega/\sim \), where \( x \sim y \) if and only if \( y \in \gamma^*_\omega(x) \). This quotient space gives rise to a quotient tower \( \bar{\Delta}_\omega \) with levels \( \bar{\Delta}_{\omega, \ell} = \Delta_{\omega, \ell}/\sim \). A partition of \( \bar{\Delta}_\omega \) into \( \bar{\Delta}_{\omega, 0, \ell} \), that we denote by \( \bar{P}_\omega \), and a sequence \( \bar{Q}_n^\omega \) of partitions of \( \bar{\Delta}_\omega \) as in (6) are defined in a natural way.

As \( j^F_\omega \) takes \( \gamma^*\)-leaves to \( \gamma^*\)-leaves and \( R_\omega \) has been defined in such a way that it is constant along the stable manifolds, the return time \( \bar{R} : \bar{\Delta}_{\omega, 0} \to \mathbb{N} \), tower map \( \bar{F}_\omega : \bar{\Delta}_\omega \to \bar{\Delta}_{\sigma, \omega} \) and the separation time \( \bar{s}_\omega : \bar{\Delta}_{\omega, 0} \times \bar{\Delta}_{\omega, 0} \to \mathbb{N} \) naturally induced by the corresponding ones defined for \( \Delta_{\omega, 0} \) and \( \Delta_\omega \) for almost every \( \omega \). We extend the separation time to \( \Delta_\omega \) by taking \( \bar{s}(x, y) = \bar{s}(x', y') \) if \( x \) and \( y \) belong to the same \( \bar{\Delta}_{\omega, \ell} \), where \( x', y' \) are the corresponding elements of \( \bar{\Delta}_{\sigma^{-\ell}_\omega, 0, \ell} \), and \( \bar{s}(x, y) = 0 \) otherwise. Since (13) holds, for a.e. \( \omega \in \Omega \) we define a measure \( \bar{m}_\omega \) on \( \bar{\Delta}_\omega \) whose representative is \( m_\omega \) on each \( \gamma \in \Gamma^\omega_\omega \). We also extend the return time to \( \Delta \) by setting
\[
\bar{R}_\omega(x) = \min\{n > 0 : \bar{F}_\omega^n(x) \in \bar{\Delta}_{\sigma^n \omega 0}\}.
\]
Note that \( \hat{R}_\omega(x) = \bar{R}_\omega(x) \) for all \( x \in \bar{\Delta}_{\omega, 0} \), and
\[
\bar{m}_\omega\{\bar{R}_\omega > n\} = \sum_{\ell > n} \bar{m}_\omega(\bar{\Delta}_{\omega, \ell}) = \sum_{\ell > n} \bar{m}_{\sigma^{-\ell}_\omega}\{\bar{R}_{\sigma^{-\ell}_\omega} > \ell\}.
\]
Obviously, \( \bar{F}_\omega \) satisfies uniform expansion and Markov property. Let \( J\bar{F}_\omega \) denote the Jacobian of \( \bar{F}_\omega \) with respect to this measure \( \bar{m}_\omega \). The following lemma shows bounded distortion
Lemma 2.4. For all \( k \geq 1 \) and all \( x, y \in \tilde{\Delta}_\omega \) which belongs to a same element of \( \tilde{Q}_{k-1}^{\omega} \)

\[
\left| \frac{JF_{\omega}^k(x)}{JF_{\omega}^k(y)} - 1 \right| \leq C_{F,\beta}(\hat{F}_\omega^k(x),\hat{F}_\omega^k(y)).
\]

Proof. The first item of Lemma 2.1 implies that the Jacobian \( JF_\omega \) is well defined with respect to \( \tilde{m}_\omega \) for almost every \( \omega \). Lemma 2.2 implies the desired estimates. \( \square \)

For \( \omega \in \Omega \) we introduce some function spaces. First of all we consider

\[
F_\beta^+ = \{ \varphi_\omega : \tilde{\Delta}_\omega \to \mathbb{R} \mid \exists C_\varphi > 0, \forall I_\omega \in \tilde{Q}_\omega, \text{ either } \varphi_\omega|I_\omega = 0 \]

or \( \varphi_\omega|I_\omega > 0 \) and \( |\log \frac{\varphi_\omega(x)}{\varphi_\omega(y)}| \leq C_{\varphi} \beta^{\delta(x,y)}, \forall x, y \in I_\omega \}.
\]

Let \( \kappa_\omega : \Omega \to \mathbb{R}_+ \) be a random variable with \( \inf_\Omega \kappa_\omega > 0 \) and

\[
P\{ \omega \mid \kappa_\omega > n \} \leq \theta^n.
\]

Define the space of random bounded functions as

\[
L_{\infty}^{\kappa_\omega} = \{ \varphi_\omega : \tilde{\Delta}_\omega \to \mathbb{R} \mid \exists C_\varphi > 0, \sup_{x \in \tilde{\Delta}_\omega} |\varphi_\omega(x)| \leq C_{\varphi} \kappa_\omega \}
\]

and a space of random Lipschitz functions

\[
F_\beta^{n,\omega} = \{ \varphi_\omega \in L_{\infty}^{\kappa_\omega} \mid \exists C_\varphi > 0, |\varphi_\omega(x) - \varphi_\omega(y)| \leq C_{\varphi} \kappa_\omega \beta^{\delta(x,y)}, \forall x, y \in \tilde{\Delta}_\omega \}.
\]

Note that in our setting \( \tilde{m}_\omega(\tilde{\Delta}_\omega) \) is uniformly bounded. To obtain mixing rates we need finer information on the tail of the return times. Suppose that there exists a random variable \( n_1 : \Omega \to \mathbb{N} \) and a decreasing sequence \( \{ u_n \}_{n \in \mathbb{N}} \) such that

\[
\begin{align*}
\tilde{m}_\omega \{ \bar{R} > n \} &\leq u_n \text{ for all } n > n_1(\omega), \\
P\{ n_1 > n \} &\leq Ce^{-cn^\theta}.
\end{align*}
\]

We have the following theorem.

Theorem 2.5. Let \( \tilde{F}_\omega : \tilde{\Delta}_\omega \to \tilde{\Delta}_{\sigma_\omega} \) be the quotient tower map.

1. \( \{ \tilde{F}_\omega \} \) admits an equivariant family of measures \( \{ \tilde{\nu}_\omega \} \) such that \( d\tilde{\nu}_\omega / d\tilde{m}_\omega \in F_\beta^+ \cap F_\beta^1 \)

and \( \frac{1}{C_0} \leq d\tilde{\nu}_\omega / d\tilde{m}_\omega \leq C_0 \) for some \( C_0 > 0 \).

2. Let be a probability measure \( \lambda_\omega \) on \( \tilde{\Delta}_\omega \) with \( \varphi = d\lambda / d\tilde{m}_\omega \in F_\beta^{n,\omega} \cap F_\beta^+ \).

(a) If \( u_n \leq Ce^{-cn^\theta} \), for some \( C, c > 0, \theta \in (0, 1] \). Then there is a random variable \( n_0 : \Omega \to \mathbb{N} \) such that

\[
\begin{align*}
\left| (\tilde{F}_\omega^n)_* \lambda_\omega - \tilde{\nu}_{\sigma_\omega} \right| &\leq C' e^{-c'n^\theta} \text{ for all } n > n_0(\omega), \\
P\{ n_0 > n \} &\leq C''n^{-b},
\end{align*}
\]

for some \( C', C'', c' > 0, b > 1 \). If \( n_1(\omega) \) is uniformly bounded, then for all \( n > 0 \)

\[
\left| (\tilde{F}_\omega^n)_* \lambda_\omega - \tilde{\nu}_{\sigma_\omega} \right| \leq C' e^{-c'n^\theta}.
\]
(b) If \( u_n \leq Cn^{-a} \) and \( \int \tilde{m}_\omega (\tilde{R}_\omega > n) dP(\omega) \leq Cn^{-a-1} \) for some \( C > 0, a > 1 \),
Then there is a random variable \( n_0 : \Omega \to \mathbb{N} \) such that
\[
\begin{align*}
| (\tilde{F}_\omega^{n})_\omega \cdot \lambda_\omega - \tilde{\nu}_{\alpha n} \omega | & \leq C' n^{1+\varepsilon-a} \text{ for all } n > n_0(\omega), \quad \varepsilon > 0, \\
P\{n_0 > n\} & \leq C'' \varepsilon^{-a},
\end{align*}
\]
for some \( C', C'', c' > 0, b > 1 \).

Moreover, \( c' \) does not depend on \( \varphi \) and \( C' \) depends only on the Lipschitz constant of \( \varphi \). Furthermore, the analogous estimates hold for \( | (\tilde{F}_\omega^{n-\alpha} \omega )_\omega \cdot \lambda_\omega - \tilde{\nu}_\omega | \) in each of the above cases respectively.

The proof of Theorem 2.5 is given in Subsection 2.3.1 below. Item (1) follows from [15] and Item (2) essentially follows from results in [15, 16, 17, 28] after showing that the constants appearing in the results [15, 28] depend on the observables only through their Lipschitz constants.

2.3.1. Convergence to equilibrium. Now we prove item (2) of Theorem 2.5. Let \( \Delta = \{(\omega, x) | x \in \Delta_\omega \} \). Denote by \( \Delta \otimes \omega \Delta \) the relative product over \( \Omega \), that is \( \Delta \otimes \omega \Delta = \{(\omega, x, x') | x \in \Omega, x, x' \in \Delta_\omega \} \). These are measurable subsets of the appropriate product spaces and naturally carry the measures \( P \times \tilde{m}_\omega \) and \( P \times m_\omega \times \tilde{m}_\omega \) respectively. We can lift the tower map \( \tilde{F} \) to a product action on \( \Delta \otimes \omega \Delta \) with the property \( \tilde{F}_\omega \times \tilde{F}_\omega : \Delta_\omega \times \Delta_\omega \to \Delta_\omega \times \Delta_\omega \) by applying \( \tilde{F} \) in each of the \( x, x' \) coordinates. With respect to this map, we define auxiliary stopping times \( \tau_i^\omega < \tau_{i+1}^\omega < \ldots \) to the base as follows: let \( \ell_0 \) be a fixed large constant. For \( (\omega, x, x') \in \Delta \otimes \omega \Delta \) set
\[
\begin{align*}
\tau_1^\omega (x, x') & = \inf \{ n \geq \ell_0 | \tilde{F}_\omega^n x \in \Delta_{\sigma^n \omega, 0} \}; \\
\tau_2^\omega (x, x') & = \inf \{ n \geq \tau_1^\omega (x, x') + \ell_0 | \tilde{F}_\omega^n x' \in \Delta_{\sigma^n \omega, 0} \}; \\
\tau_3^\omega (x, x') & = \inf \{ n \geq \tau_2^\omega (x, x') + \ell_0 | \tilde{F}_\omega^n x \in \Delta_{\sigma^n \omega, 0} \}; \\
\tau_4^\omega (x, x') & = \inf \{ n \geq \tau_3^\omega (x, x') + \ell_0 | \tilde{F}_\omega^n x' \in \Delta_{\sigma^n \omega, 0} \};
\end{align*}
\]
and so on, with the action alternating between \( x \) and \( x' \). Notice that for odd \( i \)'s the first (resp. for even \( i \)'s the second) coordinate of \( (\tilde{F}_\omega \times \tilde{F}_\omega)^{\tau_i^\omega} (x, x') \) makes a return to \( \Delta_{\sigma^{\tau_i^\omega} \omega, 0} \).

Let \( i \geq 2 \) be the smallest integer such that \( (\tilde{F}_\omega \times \tilde{F}_\omega)^{\tau_i^\omega} (x, x') \in \Delta_{\sigma^{\tau_i^\omega} \omega, 0} \times \Delta_{\sigma^{\tau_i^\omega} \omega, 0} \). Then we define the stopping time \( T_\omega \) by
\[
T_\omega (x, x') = \tau_i^\omega (x, x').
\]

Next define a sequence of partitions \( \xi_1^\omega < \xi_2^\omega < \ldots \) of \( \Delta_\omega \times \Delta_\omega \) so that \( \tau_i^\omega \) is constant on the elements of \( \xi_j^\omega \) for all \( i \leq j, i, j \in \mathbb{N} \). Given a partition \( \mathcal{Q} \) of \( \Delta_\omega \) we write \( \tilde{Q}(x) \) to denote the element of \( \mathcal{Q} \) containing \( x \). With this convention, we let
\[
\xi_i^\omega (x, x') = \left( \bigcup_{k=0}^{\tau_i^\omega - 1} \tilde{F}_\omega^{-k} P_{\sigma^k \omega} \right) (x) \times \Delta_\omega.
\]

Letting \( \pi : \Delta_\omega \times \Delta_\omega \to \Delta_\omega \) be the projection to the first coordinate, we define
\[ \xi_2^\omega(x, x') = \pi \xi_1^\omega(x, x') \times \left( \sqrt[k=0]{F_{-k}^{-1} \mathcal{P}_\sigma^k \omega} \right)(x'). \]

Let \( \pi' \) be the projection onto the second coordinate. We define \( \xi_3^\omega \) by refining the partition on the first coordinate, and so on. If \( \xi_2^\omega \) is defined then we define \( \xi_3^\omega \) by refining each element of \( \xi_2^\omega \) in the first coordinate so that \( \tau_{2i+1}^\omega \) is constant on each element of \( \xi_2^\omega \). Similarly \( \xi_3^\omega \) is defined by refining each element of \( \xi_2^\omega \) in the second coordinate so that \( \tau_{2i+1}^\omega \) is constant on each new partition element. Now we define a partition \( \mathcal{P}_\omega \) of \( \Delta^\omega \times \Delta^\omega \) such that \( \tau_{2i+1}^\omega \) is constant on its element. For definiteness suppose that \( i \) is even and choose \( \Gamma \in \xi_i^\omega \) such that \( T_{\omega}|_{\Gamma} > \tau_{i-1}^\omega \). By construction \( \Gamma = A \times B \) such that \( F^{\tau_{i}^\omega}(B) = \Delta_{\sigma^{\tau_i^\omega}0} \) and \( \tilde{F}^{\tau_{i}^\omega} A \) is spread around \( \Delta_{\sigma^{\tau_i^\omega}0} \). We refine \( A \) into countably many pieces and choose those parts which are mapped onto the corresponding base at time \( \tau_{i}^\omega \). Note that \( \{T_{\omega} = \tau_{i}^\omega\} \) may not be measurable with respect to \( \xi_i^\omega \). However, since \( \tau_{i+1}^{\omega} \geq \ell_0 + \tau_i^{\omega} \) and \( \xi_{i+1}^\omega \) is defined by dividing \( A \) into pieces where \( \tau_{i+1}^\omega \) is constant, \( \{T_{\omega} = \tau_{i}^\omega\} \) is measurable with respect to \( \xi_{i+1}^\omega \).

**Lemma 2.6.** Let \( \lambda_\omega \) and \( \lambda'_\omega \) be two probability measures on \( \{\Delta^\omega\} \) with densities \( \varphi, \varphi' \in \mathcal{F}_\beta \cap \mathcal{L}_\infty^\omega \). Let \( \lambda = \lambda_\omega \times \lambda'_\omega \).

1. For each \( \omega \), for each \( i \geq 2 \) and \( \Gamma \in \xi_i^\omega \) such that \( T_{\omega}|_{\Gamma} > \tau_{i-1}^\omega \) we have

\[ \lambda\{T_{\omega} = \tau_{i}^\omega | \Gamma\} \geq C_\lambda V_{\sigma^{\tau_{i-1}^\omega}0}^{\tau_{i-1}^\omega}. \]

2. For each \( \omega \), for each \( i \) and \( \Gamma \in \xi_i^\omega \)

\[ \lambda\{\tau_{i+1}^\omega - \tau_i^\omega > \ell_0 + n | \Gamma\} \leq M_0 MC_\lambda^{-1} \cdot m\{\hat{R}_{\sigma^{\tau_{i-1}^\omega}0} > n\}, \]

where \( 0 < C_\lambda < 1 \), which only depends on the Lipschitz constant of \( \varphi, \varphi' \). We can fix \( C_\lambda = \frac{2D_{\beta}+1}{2D_{\beta}+1} \), independent of \( \lambda \), for all \( i \) sufficiently large, i.e. \( i \geq i_0(\lambda) \), which only depends on the Lipschitz constant of \( \varphi, \varphi' \).

The above lemma shows the constant appearing in the estimates in [15] for the polynomial case and in [28] for the (stretched)-exponential case depend on the observables \( \varphi, \varphi' \) only through their Lipschitz constants and consequently estimates of \( \bar{m}_\omega \times \bar{m}_\omega\{T_{\omega} > n\} \) has the same property.

We now consider \( \bar{F}_{\omega} = (\bar{F}_\omega \times \bar{F}_\omega)^{T_{\omega}} \) which is a mapping from \( \hat{\Delta}^\omega = \hat{\Delta}^\omega \times \hat{\Delta}^\omega \) into \( \hat{\Delta}_{\sigma^{T_{\omega}}} \). Let \( \xi_i^\omega \) be the partition of \( \Delta^\omega \) on which \( T_{\omega} \) is constant. Let \( T_{1,\omega} < T_{2,\omega} \ldots \) be stopping times on \( \Delta^\omega \) defined as

\[ T_{1,\omega} = T_{\omega}, \quad T_{n,\omega} = T_{n-1,\omega} + T_{\sigma^{T_{n-1,\omega}}} \circ \hat{F}^{n-1}. \]

Further as in [15] we obtain estimates for \( \bar{m}_\omega \times \bar{m}_\omega\{T_{i,\omega} > n\} \) of the same type as for \( \bar{m}_\omega \times \bar{m}_\omega\{R_{\omega} > n\} \) for all \( i, n \geq 1 \). In particular, if \( \bar{m}_\omega \times \bar{m}_\omega\{R_{\omega} > n\} \) is uniform with respect to \( \omega \) then \( \bar{m}_\omega \times \bar{m}_\omega\{T_{i,\omega} > n\} \) is uniform. Thus the following lemma completes the proof of Theorem 2.5.
Lemma 2.7. Let $\lambda = \lambda_\omega \times \lambda'_\omega$. There exists $0 < \varepsilon_1 < 1$ independent of $d\lambda/(d\tilde{m}_\omega \times d\hat{m}_\omega)$ and a $C > 0$ such that for almost every $\omega$ and all $n \in \mathbb{N}$

$$ |(\tilde{F}_\omega^n)_*(\lambda_\omega) - (\hat{F}_\omega^n)_*(\lambda'_\omega)| \leq C \sum_{i=0}^{\infty} \varepsilon_1^i \lambda(T_i, \omega) \leq n < T_{i+1, \omega} \}. $$

2.4. Decay of correlations. In this subsection we prove Theorems [1.3] and [1.4] by establishing a relation between decay of future correlations for the original dynamics and that of quotient dynamics. Recall that for $\varphi, \psi : M \to \mathbb{R}$ we have

$$ C_n(\varphi, \psi; \mu_\omega) = \int (\varphi \circ f^n_\omega) \psi d\mu_\omega - \int \varphi d\mu \int \psi d\mu_\omega. $$

Let $\pi : \Delta_\omega \to M$, be the tower projection. Let $\bar{\pi}_\omega : \Delta_\omega \to \bar{\Delta}_\omega$ be the projection to the corresponding quotient tower. Then we have $\mu_\omega = (\pi_\omega)_* \nu_\omega$ and $\nu_\omega = (\bar{\pi}_\omega)_* \nu_\omega$, where $\{\nu_\omega\}$ is the equivariant family of physical measures for hyperbolic tower, $\{\mu_\omega\}$ is the equivariant family of physical measures of the original dynamics, $\{\nu_\omega\}$ is the equivariant family of absolutely continuous measures for the quotient tower. Notice that $\{\nu_\omega\}$ is the same as the measures constructed in Theorem 2.5 since the conditional measures of $\nu_\omega$ are equivalent to $m_\omega$. For $\varphi, \psi \in C^n(M)$ define $\psi_\omega = \psi \circ \pi_\omega$ and $\bar{\psi}_\omega = \varphi \circ \pi_\omega$. Then we have

$$ C_n(\varphi, \psi; \mu_\omega) = \int (\varphi \circ f^n_\omega) \psi d\mu_\omega - \int \varphi d\mu \int \psi d\mu_\omega =$$

$$ \int (\varphi \circ f^n_\omega) \bar{\psi}_\omega d\nu_\omega - \int \varphi \bar{\psi}_\omega d\nu_\omega \nu_\omega = C_n(\bar{\varphi}_\omega, \bar{\psi}_\omega; \nu_\omega). $$

Fix an integer $k = [n/4]$ and define discretizations $\bar{\varphi}_{\omega,k}$ of $\bar{\varphi}_\omega$ on $\Delta_\omega$ as follows

$$ \bar{\varphi}_{\omega,k}|_A = \inf \{ \bar{\varphi}_{\sigma, k} \circ F^k_\omega(x) \mid x \in A \in \mathcal{Q}_{2k}^\omega \}. $$

$\bar{\varphi}_{\omega,k}$ is defined similarly. The main result of this section is the following proposition.

Proposition 2.8. For any $n \in \mathbb{N}$, $\varphi, \psi \in C^n(M)$

$$ |C_n(\varphi, \psi; \mu_\omega)| \leq C_{\varphi, \psi} \max \{ \delta^n_{(n/4)}(\bar{\varphi}_{\sigma, k} \circ F^k_\omega(A)) \}_{k, \sigma} \} \} $$

for some constant $C_{\varphi, \psi} > 0$ and for a.e. $\omega \in \Omega$.

By (22) it is sufficient to estimate $C_n(\bar{\varphi}_\omega, \bar{\psi}_\omega; \nu_\omega)$. We will estimate this in several steps. Obviously, for any $x \in A$

$$ |\bar{\varphi}_{\sigma, k} \circ F^k_\omega(x) - \bar{\varphi}_{\omega, k}(x)| \leq \| \varphi \|_{C^n} \text{diam}(\pi_{\sigma, k}(F^k_\omega(A)))^n. $$

(23)

Recall that

$$ \delta_{\omega, k} = \sup_{A \in \mathcal{Q}_{2k}^\omega} \text{diam}(\pi_{\sigma, k}(F^k_\omega(A))). $$
Notice that \( C_n(\tilde{\varphi}_\omega, \tilde{\psi}_\omega; \nu_\omega) = C_{n-k}(\tilde{\varphi}_{\sigma^n\omega} \circ F^n_{\sigma^{n-k}\omega}, \tilde{\psi}_\omega; \nu_\omega) \). Indeed, by equivariance of \( \nu_\omega \) we have

\[
\int (\tilde{\varphi}_{\sigma^n\omega} \circ F^n_\omega) \psi_\omega d\nu_\omega - \int \tilde{\varphi}_{\sigma^n\omega,k} d\nu_{\sigma^n\omega} \int \tilde{\psi}_\omega d\nu_\omega
\]

\[
= \int (\tilde{\varphi}_{\sigma^n\omega} \circ F_{\sigma^{n-k}\omega}) \circ F^n_{\sigma^{n-k}\omega} \psi_\omega d\nu_\omega - \int \tilde{\varphi}_{\sigma^n\omega,k} \circ F^k_{\sigma^{n-k}\omega} d\nu_{\sigma^{n-k}\omega} \int \tilde{\psi}_\omega.
\]

We have

\[
|C_n(\tilde{\varphi}_\omega, \tilde{\psi}_\omega; \nu_\omega) - C_{n-k}(\tilde{\varphi}_{\sigma^n\omega,k} \tilde{\psi}_\omega; \nu_\omega)|
\leq \left| \int (\tilde{\varphi}_{\sigma^n\omega} \circ F^k_{\sigma^{n-k}\omega} \circ F^n_{\sigma^{n-k}\omega} \tilde{\psi}_\omega d\nu_\omega \right|
\]

\[
+ \left| \int (\tilde{\varphi}_{\sigma^n\omega} \circ F_{\sigma^{n-k}\omega} \circ F^{n-k}_{\sigma^{n-k}\omega} \tilde{\psi}_\omega d\nu_\omega \right|
\leq 2\|\varphi\|_{C_0} \|\psi\|_{\infty} \delta_n^{\sigma_{n-k}\omega}.
\]

Denote by \( \tilde{\psi}_{\omega,k} \) the signed measure whose density with respect to \( \nu_\omega \) is \( \tilde{\psi}_{\omega,k} \). Let \( \tilde{\psi}_{\omega,k} \) denote the density of \( (F^k_{\sigma^{-k}\omega}, \tilde{\psi}_{\sigma^{-k}\omega,\nu_{\sigma^{-k}\omega}}) \). Then we have

\[
|C_{n-k}(\tilde{\varphi}_{\sigma^n\omega,k} \tilde{\psi}_\omega; \nu_\omega) - C_{n-k}(\tilde{\varphi}_{\sigma^n\omega,k} \tilde{\psi}_\omega; \nu_\omega)| \leq 2\|\varphi\|_{\infty} \|\psi\|_{C_0} \delta_n^{\sigma_{n-k}\omega}.
\]

Indeed, the left hand side of \[25\] is

\[
\leq \left| \int \varphi_{\sigma^n\omega,k} F_{\sigma^{n-k}\omega} \tilde{\psi}_\omega - \tilde{\psi}_{\omega,k} d\nu_\omega \right|
\]

\[
+ \left| \int \varphi_{\sigma^n\omega,k} d\nu_\omega \int (\tilde{\psi}_\omega - \tilde{\psi}_{\omega,k}) d\nu_\omega \right| \leq 2\|\varphi\|_{\infty} \left| \int (\tilde{\psi}_\omega - \tilde{\psi}_{\omega,k}) d\nu_\omega \right|
\]

Observing that

\[
\tilde{\psi}_\omega = (F^k_{\sigma^{-k}\omega} \circ \tilde{\psi}_\omega \circ F^k_{\sigma^{-k}\omega}) \nu_{\sigma^{-k}\omega},
\]

and letting \( |\cdot| \) denote the total variation of a signed measure we have

\[
\left| \int (\tilde{\psi}_\omega - \tilde{\psi}_{\omega,k}) d\nu_\omega \right| = |\tilde{\psi}_\omega - \tilde{\psi}_{\omega,k} |
\]

\[
= |F^k_{\sigma^{-k}\omega} \circ \tilde{\psi}_\omega \circ F^k_{\sigma^{-k}\omega} \nu_{\sigma^{-k}\omega} - (F^k_{\sigma^{-k}\omega} \circ \tilde{\psi}_{\sigma^{-k}\omega,\nu_{\sigma^{-k}\omega}}) |
\]

\[
= \left| \int \tilde{\psi}_\omega \circ F^k_{\sigma^{-k}\omega} - \tilde{\psi}_{\sigma^{-k}\omega,\nu_{\sigma^{-k}\omega}} d\nu_{\sigma^{-k}\omega} \right| \leq \|\psi\|_{C_0} \delta_n^{\sigma_{n-k}\omega}.
\]

This shows \[25\]. Next we observe that

\[
C_{n-k}(\tilde{\varphi}_{\sigma^n\omega,k} \tilde{\psi}_\omega; \nu_\omega) = C_n(\tilde{\varphi}_{\sigma^n\omega,k} \tilde{\psi}_{\sigma^{-k}\omega,\nu_{\sigma^{-k}\omega}}).
\]
Indeed,

\[ \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ F_{\sigma^{-k},\omega,k} d\nu_{\omega} = \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ F_{\omega}^{n-k} d(\hat{\psi}_{\omega,k} \nu_{\omega}) \]

\[ = \int \bar{\varphi}_{\sigma^{-k},\omega,k} d((F_{\omega}^{n-k})_{*}(\hat{\psi}_{\omega,k} \nu_{\omega})) = \int \bar{\varphi}_{\sigma^{-k},\omega,k} d((F_{\sigma^{-k},\omega,k})_{*}(\hat{\psi}_{\sigma^{-k},\omega,k} \nu_{\sigma^{-k},\omega})) \]

\[ = \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ F_{\sigma^{-k},\omega,k} \hat{\psi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} = \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ \tilde{F}_{\sigma^{-k},\omega,k} \hat{\psi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega}. \]

Also,

\[ \int \bar{\varphi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} \int \hat{\psi}_{\omega,k} d\nu_{\omega} = \int \bar{\varphi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} \int d(F_{\sigma^{-k},\omega,k})_{*} \hat{\psi}_{\sigma^{-k},\omega,k} \nu_{\sigma^{-k},\omega} = \int \bar{\varphi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} \int \hat{\psi}_{\sigma^{-k},\omega,k} \nu_{\sigma^{-k},\omega}. \]

Finally we show that \( \bar{\varphi}_{\sigma^{-k},\omega,k} \) and \( \hat{\psi}_{\sigma^{-k},\omega,k} \) belong to right functions spaces and thus the results for the quotient tower are applicable.

Suppose that \( \psi \) is not identically zero. Fix \( k \leq n/4 \) and let

\[ \Psi_{\omega,k} = b_{\omega,k}(\hat{\psi}_{\omega,k} + 2\|\hat{\psi}_{\omega,k}\|_{\infty}), \]

where \( (3\|\psi\|_{\infty})^{-1} \leq b_{\omega,k} \leq \|\psi\|^{-1} \) is chosen so that \( \int \Psi_{\omega,k} d\nu_{\omega} = 1. \) Then \( 1 \leq \|\Psi_{\omega,k}\|_{\infty} \leq 3. \)

Let \( \tilde{m}_{\omega} \) denote the reference measure on quotient tower \( \Delta_{\omega} \), and let

\[ \rho_{\omega} = \frac{d\tilde{\nu}_{\omega}}{d \tilde{m}_{\omega}}, \quad d\tilde{\lambda}_{\omega,k} = \Psi_{\omega,k} \rho_{\omega} d\tilde{m}_{\omega}. \]

Recalling that \( \int \Psi_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} = 1 \) we have

\[ \left| \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ F_{\sigma^{-k},\omega,k} \hat{\psi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} - \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ \tilde{F}_{\sigma^{-k},\omega,k} \hat{\psi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} \right| \]

\[ = \frac{1}{b_{\sigma^{-k},\omega,k}} \left| \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ F_{\sigma^{-k},\omega,k} \Psi_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} - \int \bar{\varphi}_{\sigma^{-k},\omega,k} \circ \tilde{F}_{\sigma^{-k},\omega,k} \nu_{\sigma^{-k},\omega} \right| \]

\[ = \frac{1}{b_{\sigma^{-k},\omega,k}} \left| \int \bar{\varphi}_{\sigma^{-k},\omega,k} d(\tilde{F}_{\sigma^{-k},\omega,k})_{*} \hat{\lambda}_{\sigma^{-k},\omega,k} - \int \bar{\varphi}_{\sigma^{-k},\omega,k} d\nu_{\sigma^{-k},\omega} \right| \]

\[ \leq 3\|\hat{\psi}\|_{\infty} \|\psi\|_{\infty} \int \left| \frac{d(\tilde{F}_{\sigma^{-k},\omega,k})_{*} \hat{\lambda}_{\sigma^{-k},\omega,k}}{d\tilde{m}_{\sigma^{-k},\omega}} - \rho_{\sigma^{-k},\omega} \right| d\tilde{m}_{\sigma^{-k},\omega}. \]

Letting \( \hat{\lambda}_{\sigma^{-k},\omega,k} = (\tilde{F}_{\sigma^{-k},\omega,k})_{*} \hat{\lambda}_{\sigma^{-k},\omega,k} \), the above equality implies

\[ C_{n}(\bar{\varphi}_{\sigma^{-k},\omega,k}, \hat{\psi}_{\sigma^{-k},\omega,k}; \tilde{\nu}_{\sigma^{-k},\omega}) \leq 3\|\hat{\psi}\|_{\infty} \|\psi\|_{\infty} \left| (\tilde{F}_{\sigma^{-k},\omega,k})_{*} \hat{\lambda}_{\sigma^{-k},\omega,k} - \tilde{\nu}_{\sigma^{-k},\omega} \right|. \] (27)

Let \( \phi_{\omega,k} \) denote the density of the measure \( \hat{\lambda}_{\omega,k} \) with respect to \( \tilde{m}_{\omega} \). The next lemma shows that \( \phi_{\omega,k} \in F_{\beta}^{+} \), with the constant \( C \) independent of \( \omega \) and \( k \). This is enough for using Theorem 2.5 and concluding the proof of the proposition.
Lemma 2.9. There is $C > 0$, independent of $\omega$ and $k$, and a random variable $K_\omega : \Omega \to \mathbb{R}_+$ such that

$$|\phi_{\omega,k}(\bar{x}) - \phi_{\omega,k}(\bar{y})| \leq C K_\omega \beta^{3(\bar{x}, \bar{y})},$$

for all $\bar{x}, \bar{y} \in \bar{\Delta}_\omega$.

Proof. Since $\bar{F}_{\sigma}^{2k} \nu_{\omega} = \nu_{\sigma^{2k} \omega}$ and $\rho_\omega = d\nu_\omega / dm_\omega$, we write

$$\rho_\omega(\bar{x}) = \sum_{Q \in Q_{2k}^\omega} \frac{\rho_{\sigma^{-2k} \omega}(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x})}{JF_{\sigma^{-2k} \omega}^2(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x})}.$$  \hspace{1cm} (28)

By definition we have

$$\phi_{\omega,k} = \frac{d\lambda_{\omega,k}}{dm} = \frac{d}{dm}(\bar{F}_{\sigma^{-2k} \omega}^2 \lambda_{\sigma^{-2k} \omega,k})$$

and $d\lambda_{\sigma^{-2k} \omega,k} / dm_\omega = \Psi_{\sigma^{-2k} \omega,k} \rho_{\sigma^{-2k} \omega}$. Since $\Psi_{\omega,k}$ is constant on elements of $Q_{2k}^\omega$, letting $\Psi_{\sigma^{-2k} \omega}(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x}) = c_{\omega,Q}$ we have

$$\phi_{\omega,k}(\bar{x}) = \sum_{Q \in Q_{2k}^\omega} c_{\omega,Q} \cdot \frac{\rho_{\sigma^{-2k} \omega}(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x})}{JF_{\sigma^{-2k} \omega}^2(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x})}.$$  \hspace{1cm} (29)

Hence,

$$\phi_{k}(\bar{x}) - \phi_{k}(\bar{y}) = \sum_{Q \in Q_{2k}^\omega} c_{\omega,Q} \cdot \frac{\rho_{\sigma^{-2k} \omega}(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x})}{JF_{\sigma^{-2k} \omega}^2(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{x})} - \frac{\rho_{\sigma^{-2k} \omega}(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{y})}{JF_{\sigma^{-2k} \omega}^2(\bar{F}_{\sigma^{-2k} \omega}^2 Q)^{-1}(\bar{y})}.$$  \hspace{1cm} (30)

Let $\omega' = \sigma^{-2k} \omega$. For $Q \in Q_{2k}^\omega$, let $\bar{x}', \bar{y}' \in Q$ be such $\bar{F}_{\omega'}^{2k}(\bar{x}') = \bar{x}$ and $\bar{F}_{\omega'}^{2k}(\bar{x}') = \bar{x}$. We have

$$\frac{\rho_{\omega'}(\bar{x}')}{JF_{\omega'}^{2k}(\bar{x}')} - \frac{\rho_{\omega'}(\bar{y}')}{JF_{\omega'}^{2k}(\bar{y}')} = \left( \frac{\rho_{\omega'}(\bar{y}')}{JF_{\omega'}^{2k}(\bar{y}')} \right) \left( \frac{\rho_{\omega'}(\bar{x}')}{JF_{\omega'}^{2k}(\bar{x}')} \right) - 1.$$  \hspace{1cm} (31)

It follows from Theorem 1.2 that there is $C_\rho > 0$ independent of $\omega$ such that

$$\left| \frac{\rho_{\omega'}(\bar{x}')}{\rho_{\omega'}(\bar{y}')} - 1 \right| \leq C_\rho \beta^{3(\bar{x}', \bar{y}')}.$$  \hspace{1cm} (32)

On the other hand, by Lemma 2.4 there is $D > 0$ such that independent of $\omega$ such that

$$\frac{JF_{\omega'}^{2k}(\bar{y}')}{JF_{\omega'}^{2k}(\bar{x}')} - 1 \leq D \beta^{3(\bar{F}_{\omega'}^{2k}(\bar{x}'), F_{\omega'}^{2k}(\bar{y}'))}.$$  \hspace{1cm} (33)

Since $s(\bar{x}', \bar{y}') \geq s(\bar{F}_{\omega'}^{2k}(\bar{x}'), F_{\omega'}^{2k}(\bar{y}')) = s(\bar{x}, \bar{y})$, we have

$$\log \left| \frac{\rho(\bar{x}')}{\rho(\bar{y}')} \right| \leq (C_\rho + D) \beta^{3(\bar{x}, \bar{y})}.$$  \hspace{1cm} (34)

Recalling (28) and the fact that $|c_Q| \leq \|\Psi_{\omega,k}\|_\infty \leq 3$, it follows from (29), (30) and (34) that there is some constant $C > 0$ not depending on $\phi_k$ such that

$$\left| \phi_{\omega,k}(\bar{x}) - \phi_{\omega,k}(\bar{y}) \right| \leq C K_\omega \beta^{3(\bar{x}, \bar{y})}.$$  \hspace{1cm} (35)

Actually, we may take $C = 3\|\rho\|_\infty (C_\rho + D) / K_\omega$. \hspace{1cm} \qed
Lemma 2.4 shows that the Lipschitz constant of \( \phi_{\omega,k} \in \mathcal{F}_\beta^+ \) is independent of \( \omega \) and \( k \). Thus, the rate of decay of \( |(P_{\sigma_k}^k)_{\lambda}\omega_{\lambda,\omega,k} - \bar{\nu}_{\sigma^{-1}k}\omega| \) can be estimated as in Theorem 2.5 with uniform constants for all \( 0 \leq k \leq n/4 \). This completes the proofs of Theorems 1.3 and 1.4.

3. Partially hyperbolic attractors

3.1. Preliminary results. Here we present the “random version” of the main results in [3 Section 2], where it was shown that \( f \) satisfies a bounded curvature property over disks having the tangent space at each point contained in a cone field around the centre-unstable direction.

First of all we fix continuous extensions (not necessarily invariant under \( Df \)) of the two subbundles \( E^s \) and \( E^{cu} \) to the trapping region \( U \supset K \). Given \( 0 < a < 1 \), we define the **centre-unstable cone field** \( C^{cu}_a(x) = (C^{cu}_a(x))_{x \in U} by**

\[
C^{cu}_a(x) = \{ v_1 + v_2 \in E^s_x \oplus E^{cu}_x : \|v_1\| \leq a\|v_2\| \}
\]

and the **stable cone field** \( C^s_a(x) = (C^s_a(x))_{x \in U} similarly, reversing the roles of the bundles in [32].** Slightly increasing \( \lambda < 1 \), if necessary, we may fix \( a \) so that dominated decomposition extends to the cone fields for all maps nearby \( f \), i.e.

\[
\|Df_\omega(x)v^s\| \cdot \|Df_\omega^{-1}(f_\omega(x))v^{cu}\| \leq \lambda \|v^s\| \cdot \|v^{cu}\|
\]

for all \( v^s \in C^s_a(x), v^{cu} \in (f_\omega(x))_{x \in U} \) and \( \omega \in \Omega \). Moreover, the domination property implies that for \( f_\omega \) sufficiently close to \( f \) we have

\[
Df_\omega C^{cu}_a(x) \subset C^{cu}_a(f_\omega(x)) \quad \text{and} \quad Df_\omega^{-1} C^s_a(x) \subset C^s_a(f_\omega^{-1}x).
\]

We say that an embedded sub-manifold \( S \subset U \) is **tangent to the centre-unstable cone field** if \( T_x S \subset C^{cu}_a(x) \) for all \( x \in S \). Note that as we assume contraction in the \( E^s \) direction, the local unstable manifolds are necessarily tangent to the centre-unstable cone field.

The curvature of local unstable manifolds and their iterates will be approximated in local coordinates by the notion of Hölder variation of the tangent bundle as follows. Let \( \varepsilon > 0 \) be sufficiently small so that if \( V_x = B(x, \varepsilon) \), then the exponential map \( \exp_x : V_x \to T_x M \) is a diffeomorphism onto its image for all \( x \in M \). We are going to identify \( V_x \) through the local chart \( \exp^{-1}_x \) with the neighborhood \( U_x = \exp_x V_x \) of the origin in \( T_x M \). Identifying \( x \) with the origin in \( T_x M \) and reducing \( \varepsilon \), if necessary, we get that \( E^{cu}_x \) is contained in \( C^{cu}_a(y) \) for all \( y \in U_x \). Then the intersection of \( E^{cu}_x \) with \( C^{cu}_a(y) \) is the zero vector. So if \( x \in S \) then \( T_y S \) is the graph of a linear map \( A_\varepsilon(x) : E^{cu}_x \to E^s_x \) for \( y \in U_x \cap S \). Given \( C > 0 \) and \( \zeta \in (0,1) \), we say that the tangent bundle of \( S \) is \((C,\zeta)\)-Hölder if

\[
\|A_\varepsilon(x)\| \leq C \text{dist}_S(x,y)^\zeta, \quad \text{for all} \quad y \in U_x \cap S \quad \text{and} \quad x \in U,
\]

where \( \text{dist}_S(x,y) \) is the distance measured along \( S \). Up to choosing smaller \( a > 0 \) we may assume that there are \( \lambda < \lambda_1 < 1 \) and \( 0 < \zeta < 1 \) such that for all norm one vectors \( v^s \in C^s_a(x), v^{cu} \in C^{cu}_a(x), x \in U \) it holds

\[
\|Df_\omega(x)v^s\| \cdot \|Df_\omega^{-1}(f_\omega(x))v^{cu}\|^1 + \zeta \leq \lambda_1.
\]
For these values of $\lambda_1$ and $\zeta$, given a $C^1$ submanifold $S \subset U$ tangent to the centre-unstable cone field we define
\[
\kappa(S) = \inf\{C > 0 : TS \text{ is } (C, \zeta)\text{-Hölder}\}.
\] (36)

The proofs of the conclusions in the next proposition may be obtained by mimicking the proofs of the corresponding ones in [3, Proposition 2.2 & Corollary 2.4]. Actually, the proof of Proposition 2.2 in [3] holds in a more general setting of submanifolds tangent to the centre-unstable cone fields, than just local unstable manifolds, but here we do not need it in its full generality. The main ingredients are the cone invariance and dominated decomposition properties that we have already extended for nearby perturbations $f_\omega$ of the diffeomorphism $f$; see also [2, Section 4] in the random setting.

**Proposition 3.1.** There is $C_1 > 0$ such that for every local unstable manifold $\Sigma \subset U$ and every $\omega \in \Omega$

1. there exists $n_1$ such that $\kappa(f^{\omega}_n(\Sigma)) \leq C_1$ for all $n \geq n_1$ with $f^{\omega}_n(\Sigma) \subset U$ for all $1 \leq k \leq n$;
2. if $\kappa(S) \leq C_1$ then $\kappa(f^{\omega}_n(\Sigma)) \leq C_1$ for all $n \geq 1$ such that $f^{\omega}_n(\Sigma) \subset U$ for all $1 \leq k \leq n$;
3. in particular, if $\Sigma$ is as in the previous item, then for every $n \geq 1$ we have

\[
J_n : f^{\omega}_n(\Sigma) \ni x \mapsto \log |\det(Df^{\sigma_n\omega}_{\omega}[T_x f^{\omega}_n(\Sigma)])|
\]

is $(L_1, \zeta)$-Hölder continuous with $L_1 > 0$ depending only on $C_1$ and $f$.

From the condition of non-uniform expansion along the centre-unstable direction we will be able to deduce some uniform expansion at certain times which are precisely defined through the following notion. Given $0 < \alpha < 1$, we say that $n \geq 1$ is a $\alpha$-hyperbolic time for $(\omega, x) \in \Omega \times U$ if

\[
\prod_{j=n-k+1}^{n} \|Df_{\sigma^j_\omega}^{-1}|E^{cu}_{f^{j}_\omega{x}}\| \leq \alpha^k, \quad \text{for all } k = 1, \ldots, n.
\]

The condition of non-uniform expansion for random orbits along the centre-unstable direction is enough to ensure that almost all points have infinitely many $\alpha$-hyperbolic times easily adapting the proof of [3, Corollary 3.2], based on an idea of Pliss [11].

**Proposition 3.2.** There exist $\rho, \alpha > 0$ depending only on $f$ such that for $P \times \text{Leb}$ almost all $(\omega, x) \in \Omega \times U$ and a sufficiently large integer $n \geq 1$, there exist $1 \leq n_1 < \cdots < n_k \leq n$, with $k \geq \rho n$, which are $\alpha$-hyperbolic times for $(\omega, x)$.

Let $n$ be a $\alpha$-hyperbolic time for $(\omega, x) \in \Omega \times U$. This implies that $Df^{-k}_{\sigma^{n-k}_\omega}|E^{cu}_{f^{\omega}_n(x)}$ is a contraction for all $k = 1, \ldots, n$. In addition, if $\alpha > 0$ and $\epsilon > 0$ are taken small enough in the definition of the cone fields and the random perturbations, then taking $\delta_1 > 0$ also small, we have by continuity

\[
\|Df^{-1}_\omega|E^{cu}_{f_\omega(x)}\| \leq \alpha^{-1/4}\|Df^{-1}_\omega|E^{cu}_{f_\omega(y)}\|,
\] (37)

for all $\omega \in \Omega, x \in \overline{f(U)}$ and $y \in U$ with $\text{dist}(x, y) \leq \delta_1$. 
In the sequel, we will refer to a local unstable manifold of size $\delta_1$ simply as *cu-disk* of a certain radius $r > 0$. Using (37), the next result can be obtained by adapting the proof of [3, Lemma 2.7].

**Proposition 3.3.** Given a local unstable manifold $\Sigma \subset U$, a point $x \in \Sigma$ and $n \geq 1$ a $\alpha$-hyperbolic time for $(\omega, x)$, there exists a set $V_{\omega,n}(x) \subset \Sigma$ such that $f_\omega^n$ maps diffeomorphically onto a cu-disk of radius $\delta_1$ around $f_\omega^n(x)$. Moreover,

$$\text{dist}_{f_\omega^{n-k}(\Xi)}(f_\omega^{n-k}(y), f_\omega^{n-k}(z)) \leq \alpha^{k/2} \text{dist}_{f_\omega^1(\Xi)}(f_\omega^n y, f_\omega^n z),$$

for every $k = 1, \ldots, n$ and every $y, z \in V_{\omega,n}(x)$.

These sets $V_{\omega,n}(x)$ will be referred to as *hyperbolic predisks*. Notice that their images $B_{\delta_1}^\omega(f_\omega^n(x))$ are cu-disks of radius $\delta_1$.

**Remark 3.4.** The proof of [3, Lemma 2.7] works under the less restrictive assumption of having $\alpha^{-1/2}$ instead of $\alpha^{-1/4}$ in (37). Also, that proof gives that $n$ is a $\alpha^{1/2}$-hyperbolic time for each $y \in V_{\omega,n}(x)$. Under (37), it is straightforward to check that $n$ is still an $\alpha^{1/4}$-hyperbolic time for any point $z \in U$ such that $\text{dist}(f_\omega(y), f_\omega(z)) \leq \delta_1$, for some $y \in V_{\omega,n}(x)$.

Using the previous lemma and the Hölder continuity given by Proposition 3.1 the following bounded distortion result can be deduced as in [3, Proposition 2.8].

**Proposition 3.5.** There exists $C > 1$ such that given any $C^1$ cu-disk $\Sigma$ with $\kappa(\Sigma) \leq C$, any $x \in \Sigma$ and $n \geq 1$ a $\alpha$-hyperbolic time for $(\omega, x)$, then

$$\log \left| \frac{\det Df_\omega^n|T_y \Sigma}{\det Df_\omega^n|T_z \Sigma} \right| \leq C \text{dist}_{f_\omega^1(\Xi)}(f_\omega^n y, f_\omega^n z)^\eta,$$

for every $y, z \in V_{\omega,n}(x)$.

### 3.2. Partition on a reference leaf.

Here we find a cu-disk $\Sigma_\omega \subset D_\omega$ whose hyperbolic pre-disks contained in it return to a neighborhood of $\Sigma_\omega$ under forward iterations and their images project along stable leaves covering $\Sigma_\omega$ completely. Then we define a partition on $\Sigma_\omega$ whose construction is inspired essentially by [3, 5, 7, 10]. In particular, we improve the product structure construction of [4], which was performed for deterministic diffeomorphisms, to incorporate random perturbations in a partially hyperbolic setting. We then estimate the decay of return times adapting the ideas of [30] to the random partially hyperbolic setting.

Let $D_\omega$ be a local unstable manifold as in Theorem 1.5. Given $\delta_1 > 0$ as in Proposition 3.3 we take $0 < \delta_s < \delta_1/2$ such that points in $x \in K_\omega$ have local stable manifolds $W^s_{\omega,\delta_s}(x)$ of size $\delta_s$. Notice that as we are assuming uniform contraction in the stable direction $E^s$, the these stable manifolds with uniform size exist; see e.g. [11, Chapter 7]. Moreover, they depend continuously on $\omega$ in the $C^1$ topology. Given any cu-disk $\Sigma_\omega \subset D_\omega$, we define the *cylinder* over $\Sigma_\omega$

$$C(\Sigma_\omega) = \bigcup_{x \in \Sigma_\omega} W^s_{\omega,\delta_s}(x)$$
and consider \( \pi_\omega \) the projection from \( C(\Sigma_\omega) \) onto \( \Sigma_\omega \) along the local stable leaves. We say that a \( cu \)-disk \( \gamma \) \( u \)-crosses \( C(\Sigma_\omega) \) if \( \pi_\omega(\gamma \cap C(\Sigma_\omega)) = \Sigma_\omega \).

The next result is purely deterministic, it is a consequence of the transitivity of \( f \) on the partially hyperbolic set \( K \) and it follows from \([10\text{, Lemma 3.1 \\& 3.2}]\).

**Lemma 3.6.** There are \( p \in D \) and \( L \geq 1 \) such that for any \( \delta_0 > 0 \) sufficiently small and each \( cu \)-disk \( \Sigma \) of radius \( \delta_1/9 \) there is \( 0 \leq \ell \leq L \) such that \( f^\ell(\Sigma) \) intersects \( W^s_{\delta_1/4}(p) \) and \( u \)-crosses \( C(B^s_{\delta_1}(p)) \), where \( B^s_{\delta_1}(p) \) is the \( cu \)-disk in \( D \) of radius \( 2\delta_0 \) centred at \( p \).

Now we fix \( p \in D \), \( L \geq 1 \) and \( \delta_0 > 0 \) small enough such that the conclusions of Lemma 3.6 hold, and define

\[
\Sigma^0_\omega = B^s_{\delta_0}(p) \quad \text{and} \quad \Sigma^1_\omega = B^s_{2\delta_0}(p).
\]

For \( i = 0, 1 \) we consider the corresponding cylinders

\[
C_i^\omega = C(\Sigma^i_\omega).
\]

We also choose \( \delta_0 > 0 \) small so that any \( cu \)-disk intersecting \( W^s_{\delta_1/4}(p) \) is at a distance at least \( \delta_1/2 \) from the top and bottom of \( C_0^\omega \).

Since we assume that each \( f_\omega \) has a partially hyperbolic set \( K_\omega \) with a local unstable manifold \( D_\omega \subset K_\omega \) close to \( D \) in the \( C^1 \) topology, choosing \( f_\omega \) sufficiently close to \( f \), for each \( i = 0, 1 \) there is a local unstable disk \( \Sigma^i_\omega \subset D_\omega \) close to \( \Sigma^0_\omega \) such that

\[
C_i^\omega = C(\Sigma^i_\omega)
\]

is close to \( C_0^\omega \) in the Hausdorff distance. Here we use the fact that the local stable manifolds also depend continuously on the dynamics. Denoting \( \pi_\omega \) the projection along the stable leaves of the cylinder \( C_\omega \), we have

\[
\pi_\omega(C_i^\omega) = \Sigma^i_\omega, \quad \text{for } i = 0, 1.
\]

For each \( n \geq 1 \) and \( \omega \in \Omega \), define

\[
H_{\omega,n} = \{ x \in \Sigma^0_\omega : n \text{ is a } \alpha \text{-hyperbolic time for } (\omega, x) \}.
\]

Since \( \Sigma^0_\omega \subset D_\omega \), From Proposition 3.2 and Proposition 3.3 we have for each \( x \in H_{\omega,n} \) a hyperbolic preball \( V_{\omega,n}(x) \subset \Sigma^0_\omega \) which is mapped by \( f^n_\omega \) diffeomorphically onto the disk \( B^s_{\delta_1}(f^n_\omega(x)) \) with uniformly bounded distortion, by Proposition 3.5. For each \( 0 < a \leq 1 \), consider the set \( V_{\omega,n}(x) \subset V_{\omega,n}(x) \) such that

\[
f^n_\omega \text{ maps } V^n_{\omega,n}(x) \text{ diffeomorphically onto } B_{a\delta_1}(f^n_\omega(x)).
\]

Notice that \( V^1_{\omega,n}(x) = V_{\omega,n}(x) \). It follows that for each \( x \in H_{\omega,k} \) and \( y \in H_{\omega,n} \) with \( n \geq k \), we have

\[
\begin{align*}
V_{\omega,n}^{1/9}(y) \cap V_{\omega,k}^{1/9}(x) \neq \emptyset & \implies V_{\omega,n}^{1/9}(y) \subset V_{\omega,k}^{1/3}(x); \\
V_{\omega,n}^{1/3}(y) \cap V_{\omega,k}^{1/3}(x) \neq \emptyset & \implies V_{\omega,n}^{1/3}(y) \subset V_{\omega,k}^{1/3}(x).
\end{align*}
\]

To see this, observe first that by Proposition 3.3 we have

\[
\text{diam } \left( f^k_\omega(V_{\omega,n}^{1/9}(y)) \right) \leq \frac{2\delta_1}{9} \left\lfloor \frac{n-k}{\alpha} \right\rfloor \leq \frac{2\delta_1}{9}.
\]
Then, assuming that $V_{\omega,n}^{1/9}(y)$ intersects $V_{\omega,n}^{1/9}(x)$, we necessarily have $f_{\omega}^{k}(V_{\omega,n}^{1/9}(y))$ intersecting $f_{\omega}^{k}(V_{\omega,n}^{1/9}(x))$, which by definition is the ball of radius $\delta_1/9$ around $f_{\omega}^{k}(x)$. Together with \((42)\), this implies that $f_{\omega}^{k}(V_{\omega,n}^{1/9}(y))$ is contained in the ball of radius $\delta_1/3$ around $f_{\omega}^{k}(x)$, and so the first case of \((41)\) follows. The second case of \((41)\) can be obtained similarly.

Remark 3.7. Since in Lemma 3.6 we have at most a finite number of iterates $N_0$, shrinking $\delta_0$ if necessary, a similar conclusion can be drawn for the random perturbations: for any $\omega$ and any $cu$-disk $\Sigma$ of radius $\delta_1/9$ there is $0 \leq \ell \leq L$ such that $f_{\omega}^{\ell}(\Sigma)$ intersects $W_{s,\delta_1/2}(y)$ for some $y \in \Sigma^0_{\sigma,\omega}$ and $u$-crosses $C_{\sigma,\omega}^{\ell}$. Indeed, since the images $f_{\omega}^{\ell}(V_{\omega,n}^{1/9}(x))$ of hyperbolic predisks $V_{\omega,n}^{1/9}(x)$ with $x \in \Sigma_\omega$ are $cu$-disks of radius $\delta_1/9$, we easily get that for each hyperbolic predisk $V_{\omega,n}^{1/9}(x)$ with $x \in \Sigma_\omega$, there is $0 \leq \ell_\omega \leq L$ for which $f_{\omega}^{\ell_\omega}(V_{\omega,n}^{1/9}(x))$ intersects $W_{\delta_1/2}(y)$, for some $y \in \Sigma^0_{\sigma,\omega}$, and $u$-crosses $C_{\sigma,\omega}^{\ell_\omega}$.

Hence, for each $i = 0, 1$ there are $cu$-disks $\xi_{\omega,x}^{n,\ell_\omega} \subset \xi_{\omega,x}^{n,\ell_\omega} \subset V_{\omega,n}^{1/9}(x)$ such that

$$
\pi_{\sigma,\omega}^{n,\ell_\omega} \left( f_{\omega}^{n+\ell_\omega}(\xi_{\omega,x}^{n,\ell_\omega}) \right) = \sum_{\sigma,\omega}^{n+\ell_\omega} \text{ and } \pi_{\sigma,\omega}^{n,\ell_\omega} \left( f_{\omega}^{n+\ell_\omega}(\xi_{\omega,x}^{n,\ell_\omega}) \right) = \sum_{\sigma,\omega}^{n+\ell_\omega},
$$

with the property that $f_{\omega}^{n+\ell_\omega}(\xi_{\omega,x}^{n,\ell_\omega})$ intersects $W_{\delta_1/2}(y)$, for some $y \in \Sigma^0_{\sigma,\omega}$. As condition \((43)\) may in principle hold for several values of $0 \leq \ell_\omega \leq L$, for definiteness we will assume that $\ell_\omega$ takes the smallest possible value. Observe that the $cu$-disk $\xi_{\omega,x}^{n,\ell_\omega}$ is associated to $x$, by construction, but does not necessarily contain $x$. In the sequel we will often simplify the notation and refer to elements of the type $\xi_{\omega,x}^{n,\ell_\omega}$ or $\xi_{\omega,x}^{n,\ell_\omega}$ as $\xi_\omega$ or $\tilde{\xi}_\omega$, respectively. In such cases we will also consider

$$
\ell_\omega = \ell_\omega \text{ and } V_{\omega,n}^{a}(\xi) = V_{\omega,n}^{a}(x)
$$

with $V_{\omega,n}^{a}(x)$ defined as in \((40)\). Given $x \in H_{\omega,k}$, define for $\xi = \xi_{\omega,x}^{n,\ell_\omega}$ and $n > k$

$$
A_{\omega,n}(\xi) = \left\{ y \in \xi : \text{ dist } f_{\omega}^{n+\ell_\omega}(D_{\omega}) \left( f_{\omega}^{k+\ell_\omega}(y), f_{\omega}^{k+\ell_\omega}(\xi) \right) \leq \delta_0 \alpha^{(n-k)/2} \right\}.
$$

Remark 3.8. Without loss of generality, here we assume that the $cu$-disks $f_{\omega}^{k+\ell_\omega}(\xi)$ and $f_{\omega}^{k+\ell_\omega}(\xi)$ are still disks of radius $2\delta_0$ and $\delta_0$, respectively. It follows from the definition of $A_{\omega,n}(\xi)$ that $f_{\omega}^{k+\ell_\omega}(\xi)$ contains a neighbourhood of the outer component of the boundary of $f_{\omega}^{k+\ell_\omega}(A_{\omega,n}(\xi))$ of size at least

$$
2\delta_0 - \delta_0 (1 + \alpha^{(n-k)/2}) = \delta_0 (1 - \alpha^{(n-k)/2}).
$$

Using the fact that $0 \leq \ell_\omega \leq L$ and taking

$$
K_0 = \max_{0 \leq \ell \leq L} \{ \| Df_{\omega}^{\ell} \| : \omega \in \Omega \},
$$

\((45)\).
we easily get that \( f^k_\omega(\tilde{\xi}) \) contains a neighbourhood of the outer component of the boundary of \( f^{k+\ell}_\omega(A_{\omega,n}(\xi)) \) of size at least

\[
\frac{\delta_0 \left( 1 - \alpha^{(n-k)/2} \right)}{K_0}.
\]

This last remark partly motivates the choice of the constants that we introduce next. We take

\[
\delta_2 = \delta_0 + \frac{\delta_1}{2} K_0
\]

and choose \( N_1 \in \mathbb{N} \) such that

\[
\delta_2 \alpha^{\frac{N_1}{2}} \leq \delta_0 \quad \text{and} \quad \frac{2\delta_1}{9} \alpha^{\frac{N_1}{2}} \leq \delta_0 \left( 1 - \alpha^{N_1/2} \right).
\]

Below we describe the inductive process that leads to a partition \( \mathcal{P}_\omega \) of each local unstable disk \( \Sigma_0^\omega \). The sets \( \xi_{n,\ell}^\omega \subset \Sigma_0^\omega \) as in (43) are the natural candidates to be in \( \mathcal{P}_\omega \).

**First step of induction.** Fixing some large \( N_0 \in \mathbb{N} \), we ignore the dynamics until time \( N_0 \). Since \( H_{\omega,N_0} \) is a compact set, there is a finite set \( E_{\omega,N_0} \subset H_{\omega,N_0} \cap \Sigma_0^\omega \) such that

\[
H_{\omega,N_0} \cap \Sigma_0^\omega \subset \bigcup_{x \in E_{\omega,N_0}} V_{1/3}^{1/9}(x).
\]

Consider \( x_1, \ldots, x_{J_{N_0}} \in E_{\omega,N_0} \) such that

\[
\mathcal{P}_{\omega,N_0} = \left\{ \xi_{x_1,\ell_1}^{\omega,N_0}, \ldots, \xi_{x_{J_{N_0}},\ell_{J_{N_0}}}^{\omega,N_0} \right\}
\]

is a maximal family of pairwise disjoint sets as in (43) contained in \( \Sigma_0^\omega \). The sets in \( \mathcal{P}_{\omega,N_0} \) are precisely the elements of the partition \( \mathcal{P} \) constructed in our first step of the construction. Consider also

\[
\Sigma^c_{\omega,N_0} = \Sigma_0^\omega \setminus \bigcup_{\xi \in \mathcal{P}_{\omega,N_0}} \xi.
\]

For each \( \xi \in \mathcal{P}_{\omega,N_0} \), we define

\[
S_{\omega,N_0}(\xi) = V_{1/3}^{1/9}(\xi),
\]

with \( V_{1/3}^{1/9}(\xi) \) as in (40). We also define

\[
S_{\omega,N_0}(\Sigma_0^\omega) = \bigcup_{\xi \in \mathcal{P}_{\omega,N_0}} S_{\omega,N_0}(\xi).
\]

and for \( \Sigma^c_{\omega} = \Sigma_0^\omega \setminus \Sigma_0^\omega \)

\[
S_{\omega,N_0}(\Sigma^c_{\omega}) = \left\{ x \in \Sigma_0^\omega : \text{dist}_{D_{\omega}}(x, \partial \Sigma_0^\omega) < 2\delta_1 \alpha^{N_0/2} \right\}.
\]

(48)
General step of induction. The next steps of the construction follow the ideas of the first one with minor modifications. Given \( n > N_0 \), assume that \( \mathcal{P}_{\omega,k}, \Sigma_{\omega,k} \) and \( S_{\omega,k} \) have been defined for all \( N_0 \leq k \leq n - 1 \). As before, let \( E_{\omega,n} \subset H_{\omega,n} \cap \Sigma_{\omega,n-1} \) be a finite set of points such that

\[
H_{\omega,n} \cap \Sigma_{\omega,n-1} \subset \bigcup_{x \in E_{\omega,n}} V_{\omega,n}^{1/9}(x).
\]

(49)

Consider \( x_1, \ldots, x_j \in E_n \) such that \( P_{\omega,n} = \{ \xi_{\omega,n}^{x_1,\ell_1}, \ldots, \xi_{\omega,n}^{x_j,\ell_j} \} \) is a maximal family of pairwise disjoint sets as in (43), all contained in \( \Sigma_{\omega,n-1} \) and satisfying for each \( 1 \leq i \leq j \)

\[
\xi_{\omega,n}^{x_i,\ell_i} \cap \left( \bigcup_{k=N_0}^{n-1} \bigcup_{\xi \in \mathcal{P}_{\omega,k}} A_{\omega,n}(\xi) \right) = \emptyset.
\]

(50)

The sets in \( \mathcal{P}_{\omega,n} \) are the elements of the partition \( \mathcal{P}_\omega \) constructed in the step \( n \) of the algorithm. Consider also for each \( n \geq N_0 \)

\[
\Sigma_{\omega,n} = \Sigma_0^{\omega} \setminus \bigcup_{j=N_0}^{n} \bigcup_{\xi \in \mathcal{P}_{\omega,j}} \xi.
\]

(51)

Given \( \xi \in \mathcal{P}_{\omega,k} \) for some \( N_0 \leq k \leq n \), we define for \( n - k < N_1 \)

\[
S_{\omega,n}(\xi) = V_{\omega,k}^{1/3}(\xi).
\]

and for \( n - k \geq N_1 \)

\[
S_{\omega,n}(\xi) = \left\{ y \in \xi : 0 < \text{dist}_{f_{\omega,n}^{k+\ell} D_\omega}(f_{\omega,n}^{k+\ell} \xi, f_{\omega,n}^{k+\ell} \xi(\xi)) \leq \delta_2 \alpha^{n-k/2} \right\};
\]

(52)

recall (45) and (47). Then, we define

\[
S_{\omega,n}(\Sigma_0^{\omega}) = \bigcup_{j=N_0}^{n} \bigcup_{\xi \in \mathcal{P}_{\omega,j}} S_{\omega,n}(\xi)
\]

(53)

and

\[
S_{\omega,n}(\Sigma_{\omega}) = \left\{ x \in \Delta_0 : \text{dist}_{D_\omega}(x, \partial \Sigma_0^{\omega}) < \delta_1 \alpha^{n/2} \right\}.
\]

Finally, set

\[
\mathcal{P}_\omega = \bigcup_{n \geq N_0} \mathcal{P}_{\omega,n}.
\]

By construction, the elements in \( \mathcal{P}_\omega \) are pairwise disjoint and contained in \( \Sigma_0^{\omega} \). However, there is still no evidence that the union of these elements covers a full Leb\(_{D_\omega}\) measure subset of \( \Sigma_0^{\omega} \). This will be obtained in Proposition 3.13.

Now we prove some properties about the sets \( S_{\omega,n}(\xi) \) introduced above. First of all observe that, by definition, for each \( \xi \in \mathcal{P}_{\omega,k} \) with \( k \geq N_0 \) we have

\[
V_{\omega,k}^{1/3}(\xi) \supset S_{\omega,k}(\xi) \supset S_{\omega,k+1}(\xi) \supset \cdots
\]

(54)
Moreover, if \( n - k \geq N_1 \), we even have

\[
V_{\omega,k}^{1/9}(\xi) \supset S_{\omega,n}(\xi).
\]  

(55)

From the construction of these sets and (55), it follows that for all \( k_2 \geq k_1 \geq N_0 \), given \( \xi_1 \in \mathcal{P}_{\omega,k_1} \) and \( \xi_2 \in \mathcal{P}_{\omega,k_2} \), we have

\[
S_{\omega,k_2}(\xi_2) \cap V_{\omega,k}^{1/3}(\xi) \neq \emptyset \implies S_{\omega,k_2}(\xi_2) \cup \xi_2 \subset V_{\omega,k_1}(\xi_1).
\]  

(56)

and for any \( n \geq N_1 \)

\[
S_{\omega,k_2+n}(\xi_2) \cap V_{\omega,k}^{1/9}(\xi) \neq \emptyset \implies S_{\omega,k_2+n}(\xi_2) \cup \xi_2 \subset V_{\omega,k}^{1/3}(\xi).
\]  

(57)

In the proof of the next result we use in an important way property (50), which establishes that an element in \( \mathcal{P}_\omega \) obtained at a certain stage of the construction not only does not intersect an element constructed at a previous stage, but also it does not intersect a larger annulus of the type (51) around it. This fact will be useful to deduce the estimates on the tail of recurrence times in Subsection 3.3. We fix once and for all an integer \( Q_0 \geq N_1 \) such that

\[
\delta_2(1 + K_0^C) \alpha^{Q_0/2} < \delta_0 \quad \text{and} \quad \delta_2 K_0 \alpha^{Q_0/2} < \frac{\delta_0 (1 - \alpha^{1/2})}{K_0}.
\]  

(58)

Lemma 3.9. If \( k_2 > k_1 \geq N_0 \), then for all \( \xi_1 \in \mathcal{P}_{\omega,k_1} \) and all \( \xi_2 \in \mathcal{P}_{\omega,k_2} \) we have

\[
S_{\omega,k_2+Q_0}(\xi_1) \cap S_{\omega,k_2+Q_0}(\xi_2) = \emptyset.
\]

Proof. Assume by contradiction that

\[
\exists x \in S_{\omega,k_2+Q_0}(\xi_1) \cap S_{\omega,k_2+Q_0}(\xi_2).
\]  

(59)

By (53), we have

\[
\text{dist}_{f_{\ell_2+\varepsilon_2}^{k_2+\varepsilon_2}(D_\omega)}(f_{\omega}^{k_2+\varepsilon_2}(x), f_{\omega}^{k_2+\varepsilon_2}(\xi_2)) < \delta_2 \alpha^{Q_0/2},
\]  

(60)

for some \( 0 \leq \ell_2 \leq L \) such that

\[
\pi_{\alpha^{k_2+\varepsilon_2}}(f_{\omega}^{k_2+\varepsilon_2}(\xi_2)) = \Sigma_{\alpha^{k_2+\varepsilon_2}}^1.
\]

Using (55) and (60), we find \( y \in \xi_2 \) such that

\[
\text{dist}_{f_{\omega}^{k_2}(D_\omega)}(f_{\omega}^{k_2}(x), f_{\omega}^{k_2}(y)) < \delta_2 K_0 \alpha^{Q_0/2}.
\]  

(61)

Also, from (55) and (59) it follows in particular that \( S_{\omega,k_2+Q_0}(\xi_2) \) intersects \( V_{\omega,k_1}^{1/9}(\xi_1) \), and so by (57) we have \( S_{\omega,k_2+Q_0}(\xi_2) \cup \xi_2 \subset V_{\omega,k}^{1/3}(\xi_1) \). Then, using (51) and Proposition 3.3 we obtain

\[
\text{dist}_{f_{\omega}^{k_1}(D_\omega)}(f_{\omega}^{k_1}(x), f_{\omega}^{k_1}(y)) \leq \alpha^{(k_2-k_1)/2} \text{dist}_{f_{\omega}^{k_2}(D_\omega)}(f_{\omega}^{k_2}(x), f_{\omega}^{k_2}(y)) < \delta_2 K_0 \alpha^{(Q_0+k_2-k_1)/2}.
\]  

(62)

On the other hand, since \( x \in S_{\omega,k_2+Q_0}(\xi_1) \) we also have by definition

\[
\text{dist}_{f_{\omega}^{k_1+\varepsilon_1}(D_\omega)}(f_{\omega}^{k_1+\varepsilon_1}(x), f_{\omega}^{k_1+\varepsilon_1}(\xi_1)) < \delta_2 \alpha^{(Q_0+k_2-k_1)/2},
\]  

(63)
for some $0 \leq \ell_1 \leq L$ such that
\[
\pi_{\sigma^{k_1+\ell_1} \omega} \left( f^{k_1+\ell_1}_\omega (\bar{\xi}_1) \right) = \Sigma^1_{\sigma^{k_1+\ell_1} \omega}.
\]
Recalling the first part of (58), we easily conclude that $x \in A_{\omega,k_2}(\xi_1)$. Then, Remark 3.8 gives that $f^{k_1}_\omega (\bar{\xi}_1)$ contains a neighbourhood of the outer component of the boundary of $f^{k_1}_\omega (A_{\omega,k_2}(\xi_1))$ of size at least
\[
\frac{\delta_0 (1 - \alpha^{(k_2-k_1)/2})}{K_0} \geq \frac{\delta_0 (1 - \alpha^{1/2})}{K_0}.
\]
Recalling now the second part of (58) and using (62) we deduce that $f^{k_1}_\omega(y) \in f^{k_1}_\omega (\bar{\xi}_1)$. So, using (45) together with (62) we obtain
\[
\text{dist}_{f^{k_1+\ell_1}_\omega(D_\omega)}(f^{k_1+\ell_1}_\omega(x), f^{k_1+\ell_1}_\omega(y)) < \delta_2 K_0^2 \alpha (Q_0+k_2-k_1)/2,
\]
which jointly with (63) and the first part of (58) yields
\[
\text{dist}_{f^{k_1+\ell_1}_\omega(D_\omega)}(f^{k_1+\ell_1}_\omega(y), f^{k_1+\ell_1}_\omega(\xi_1)) < \delta_2 (1 + K_0^2) \alpha^{(Q_0+k_2-k_1)/2} < \delta_0 \alpha^{(k_2-k_1)/2}.
\]
This implies that $y \in A_{\omega,k_2}(\xi_1)$ with $\xi_1 \in P_{\omega,k_2}$. Since $y \in \xi_2$ and $\xi_2 \in P_{\omega,k_2}$ we have a contradiction with (50).

In the next result we prove the key fact that every point having a $\alpha$-hyperbolic time at a given time $n$ will necessarily belong to either an element of the partition or to the set $S_{\omega,n}(\Sigma_0^0) \cup S_{\omega,n}(\Sigma_0^0)$. In Lemma 3.12 we will show that the sum of the measure of all these sets is finite. This will be an important step towards proving that $P_{\omega}$ is indeed a Leb mod 0 partition of $\Sigma_0^0$.

**Lemma 3.10.** For each $n \geq N_0$, we have $H_{\omega,n} \cap \Sigma_{\omega,n}^0 \subset S_{\omega,n}(\Sigma_0^0) \cup S_{\omega,n}(\Sigma_0^0)$.

**Proof.** Consider the finite set $E_{\omega,n} \subset H_{\omega,n} \cap \Sigma_{\omega,n}^0$ as in (19). Given any $z \in H_{\omega,n} \cap \Sigma_{\omega,n}^0 \subset H_{\omega,n} \cap \Sigma_{\omega,n}^0$, there is $y \in E_{\omega,n}$ such that $z \in V_{\omega,n}^{1/9}(y)$. It is enough to show that $V_{\omega,n}^{1/9}(y) \subset S_{\omega,n}(\Sigma_0^0) \cup S_{\omega,n}(\Sigma_0^0)$. Since $z \in \Sigma_{\omega,n}^0$, at least one of the following cases holds:

1. $\xi_{\omega,\ell,\gamma} \cap \xi \neq 0$, for some $\xi \in P_{\omega,n}$.
   
   In this case, we have $S_{\omega,n}(\xi) = V_{\omega,n}^{1/3}(\xi)$ and $V_{\omega,n}^{1/9}(y)$ necessarily intersecting $V_{\omega,n}^{1/9}(\xi)$.
   
   Hence, using (41) we get
   
   $V_{\omega,n}^{1/9}(y) \subset V_{\omega,n}^{1/3}(\xi) = S_{\omega,n}(\xi) \subset S_{\omega,n}(\Sigma_0^0)$.

2. $\xi_{\omega,\ell,\gamma} \cap A_{\omega}(\xi) \neq 0$, for some $N_0 \leq k < n$ and $\xi \in P_{\omega,k}$.

   Observe that by definition we have $A_{\omega,n}(\xi) \subset V_{\omega,n}^{1/9}(\xi)$. Assume first that $n-k < N_1$.

   Then, as in the previous situation, using (41) we get

   $V_{\omega,n}^{1/9}(y) \subset V_{\omega,k}^{1/3}(\xi) = S_{\omega,n}(\xi) \subset S_{\omega,n}(\Sigma_0^0)$.

   Assume now that $n-k \geq N_1$. We claim that

   $f^{k}_\omega(V_{\omega,n}^{1/9}(y)) \subset f^{k}_\omega(\tilde{\xi})$.

   (65)
Recall that by Remark 3.8 the set \( f^{k}(\bar{\xi}) \) contains a neighbourhood of the outer component of the boundary of \( f^{k}(A_{\omega,n}(\xi)) \) of size at least
\[
\delta_0(1 - \alpha^{N_1/2})/K_0.
\]

On the other hand, using Proposition 3.3 we obtain
\[
\dim \left(f^{k} \left(V_{\omega,n}^{1/\alpha}(y)\right)\right) \leq \frac{2\delta_1}{9} \alpha^{\frac{n-k}{2}} + \frac{2\delta_1}{9} \alpha^{\frac{n-k}{2}}.
\]

Recalling the choice of \( N_1 \) in (47) and observing that in the situation we are considering the set \( f^{k} \left(V_{\omega,n}^{1/\alpha}(y)\right) \) intersects \( f^{k}(A_{\omega,n}(\xi)) \), we conclude that (65) holds. Then, using (65) and (66) we also obtain
\[
\dim \left(f^{k+\ell} \left(V_{\omega,n}^{1/\alpha}(y)\right)\right) \leq \frac{2\delta_1}{9} K_0 \alpha^{\frac{n-k}{2}}.
\]

Now, since the set \( f^{k+\ell} \left(V_{\omega,n}^{1/\alpha}(y)\right) \) intersects \( f^{k+\ell}(A_{\omega,n}(\xi)) \), we have for each \( u \in f^{k+\ell} \left(V_{\omega,n}^{1/\alpha}(y)\right) \)
\[
\text{dist}_{D_{\omega}}(u, \Sigma^0) \leq \delta_0 \alpha^{\frac{n-k}{2}} + \frac{2\delta_1}{9} K_0 \alpha^{\frac{n-k}{2}} = \delta_0 \alpha^{\frac{n-k}{2}}.
\]

This shows that \( V_{\omega,n}^{1/\alpha}(y) \subset S_{\omega,n}(\xi) \subset S_{\omega,n}(\Sigma^0_{\omega}) \).

(3) \( \xi^{n,\omega}_{\omega,y} \cap \Sigma^0_{\omega} \neq \emptyset \).

This in particular implies that \( V_{\omega,n}^{1/\alpha}(y) \) intersects \( \partial\Sigma^0_{\omega} \). From Proposition 3.3 we get
\[
\dim \left(V_{\omega,n}^{1/\alpha}(y)\right) \leq \frac{2\delta_1}{9} \alpha^{\frac{n}{2}},
\]
and so \( V_{\omega,n}^{1/\alpha}(y) \subset S_{\omega}(\Sigma^0_{\omega}) \).

Now we give some estimates on the measure of the sets involved in the construction of \( P_{\omega} \). We claim that there exists \( C_0 > 0 \) such that for any \( n \geq N_0 \) and \( \xi \in P_{\omega,n} \) we have
\[
\text{Leb}_{D_{\omega}}(V_{\omega,n}(\xi)) \leq C_0 \text{Leb}_{D_{\omega}}(\xi).
\]

In fact, using Proposition 3.3 we get some constant \( C_1 > 0 \) such that
\[
\frac{\text{Leb}_{D_{\omega}}(V_{\omega,n}(\xi))}{\text{Leb}_{D_{\omega}}(\xi)} \leq C_1 \frac{\text{Leb}_{f^{\ell}_{2}(D_{\omega})}(f_{\omega}^{n}(V_{\omega,n}(\xi)))}{\text{Leb}_{f^{\ell}_{2}(D_{\omega})}(f_{\omega}^{n}(\xi))} \leq C_1 \frac{C_2 \delta_1^2}{\text{Leb}_{f^{\ell}_{2}(D_{\omega})}(f_{\omega}^{n}(\xi))},
\]
where \( C_2 > 0 \) is some uniform constant; recall that \( f_{\omega}^{n}(V_{\omega,n}(\xi)) \) is a cu-disk of radius \( \delta_1 \). On the other hand, using that \( f_{\omega}^{n+\ell}(\xi) \) is a cu-disk of radius \( \delta_0 \) and (15) we have
\[
\text{Leb}_{f^{\ell}_{2}(D_{\omega})}(f_{\omega}^{n}(\xi)) \geq \frac{1}{K_0} \text{Leb}_{f^{n+\ell}_{2}(D_{\omega})}(f_{\omega}^{n+\ell}(\xi)) \geq \frac{c_0 \delta_0^2}{K_0},
\]
where \( c_0 > 0 \) is again some uniform constant. From (69) and (70) we deduce (68).
Lemma 3.11. There exists $C > 0$ such that for all $n \geq k \geq N_0$ and $\xi \in \mathcal{P}_{\omega,k}$ we have

$$\text{Leb}_{D_\omega}(S_{\omega,n}(\xi)) \leq C\alpha^{(n-k)/2} \text{Leb}_{D_\omega}(\xi).$$

Proof. Assuming first that $n - k < N_1$, as $S_n(\xi) \subset V_k(\xi)$, it follows from (68) that

$$\text{Leb}_{D_\omega}(S_{\omega,n}(\xi)) \leq C_0 \text{Leb}_{D_\omega}(\xi).$$

Assume now that $n - k \geq N_1$. Recalling that

$$S_{\omega,n}(\xi) = \left\{ y \in \tilde{\xi} : 0 < \text{dist}_{f_{\omega,k+\ell_\omega}(D_\omega)}(f_{\omega,k+\ell_\omega}(y), f_{\omega,k+\ell_\omega}(\xi)) \leq \delta_2 \alpha^{\frac{n-k}{2}} \right\},$$

then by the choice of $N_1$ in (67) we have $f_{\omega,k+\ell_\omega}(S_{\omega,n}(\xi))$ contained in a $cu$-disk of radius $2\delta_0$; recall Remark 3.8. We also have some uniform constant $C_2 > 0$ such that

$$\text{Leb}_{f_{\omega,k+\ell_\omega}(D_\omega)}(f_{\omega,k+\ell_\omega}(S_{\omega,n}(\xi))) \leq C_2 \alpha^{\frac{n-k}{2}}.$$

Hence, using (45), (70) and Proposition 3.5 we get some constant $C_1 > 0$ such that

$$\frac{\text{Leb}_{D_\omega}(S_{\omega,n}(\xi))}{\text{Leb}_{D_\omega}(\xi)} \leq C_1 K_0 \frac{\text{Leb}_{f_{\omega,k+\ell_\omega}(D_\omega)}(f_{\omega,k+\ell_\omega}(S_{\omega,n}(\xi)))}{\text{Leb}_{f_{\omega,k+\ell_\omega}(D_\omega)}(f_{\omega,k+\ell_\omega}(\xi))} \leq \frac{C_1 C_2 K_0}{c_0 \delta_0^2} \alpha^{\frac{n-k}{2}}.$$  

Finally, choose

$$C \geq \frac{C_1 C_2 K_0}{c_0 \delta_0^2}$$

sufficiently large so that $C_0 \leq C\alpha^{N_1/2}$. Using (72) and (71) we easily derive the desired conclusion. \hfill \Box

Lemma 3.12. \( \sum_{n=N_0}^{\infty} \text{Leb}_{D_\omega}(S_{\omega,n}(\Sigma_0^0) \cup S_{\omega,n}(\Sigma_0^c)) < \infty. \)

Proof. First we consider the terms in $S_{\omega,n}(\Sigma_0^0)$. Recalling (55) and using Lemma 3.11 for each $n \geq N_0$ we may write

$$\text{Leb}_{D_\omega}(S_{\omega,n}(\Sigma_0^0)) = \sum_{k=N_0}^{n} \sum_{\xi \in \mathcal{P}_{\omega,k}} \text{Leb}_{D_\omega}(S_{\omega,n}(\xi))$$

$$\leq \sum_{k=N_0}^{n} \sum_{\xi \in \mathcal{P}_{\omega,k}} C\alpha^{(n-k)/2} \text{Leb}_{D_\omega}(\xi)$$

$$= C \sum_{k=N_0}^{n} \alpha^{(n-k)/2} \text{Leb}_{D_\omega}\left( \bigcup_{\xi \in \mathcal{P}_{\omega,k}} \xi \right).$$

Hence

$$\sum_{n \geq N_0} \text{Leb}_{D_\omega}(S_{\omega,n}(\Sigma_0^0)) = \sum_{n \geq N_0} \sum_{k \geq 0} \alpha^{k/2} \text{Leb}_{D_\omega}\left( \bigcup_{\xi \in \mathcal{P}_{\omega,n}} \xi \right) = \frac{1}{1 - \alpha^{1/2}} \text{Leb}_{D_\omega}(\Sigma_0^0).$$
On the other hand, recalling that
\[
S_{\omega,n}(\Sigma^c_\omega) = \{x \in \Sigma^0_\omega : \text{dist}_{D_\omega}(x, \partial \Sigma^0_\omega) < \delta_1 \alpha^{n/2}\},
\] (73)
we can find \(C > 0\) such that \(\text{Leb}_{D_\omega}(S_{\omega,n}(\Sigma^c_\omega)) \leq C \alpha^{n/2}\). This obviously gives that the sum of these terms for \(n \geq N_0\) is finite. \(\square\)

**Proposition 3.13.** \(P_\omega\) is a \(\text{Leb}_{D_\omega}\) mod 0 partition of \(\Sigma^0_\omega\).

**Proof.** Recalling the definition of the sets \(\Sigma^c_{\omega,n}\) in (51), it is enough to show that the intersection of all these sets has zero \(\text{Leb}_{D_\omega}\) measure. Assume by contradiction that
\[
\text{Leb}_{D_\omega}\left(\bigcap_{n \geq N_0} \Sigma^c_{\omega,n}\right) > 0.
\] (74)
Then, since \(\text{Leb}_{D_\omega}\) almost every point in \(\Sigma^0_\omega\) has infinitely many \(\alpha\)-hyperbolic times, there must be some Borel set \(B \subset \Sigma^0_\omega\) with \(\text{Leb}_{D_\omega}(B) > 0\) such that for every \(x \in B\) we can find infinitely many times \(n_1 < n_2 < \cdots\) (in principle depending on \(\omega, x\)) so that \(x \in H_{\omega,n_k} \cap \Sigma^c_{\omega,n_k}\) for all \(k \in \mathbb{N}\). It follows from Lemma 3.10 that
\[
x \in S_{\omega,n_k}(\Sigma^0_\omega) \cup S_{\omega,n_k}(\Sigma^c_\omega), \quad \text{for all } k \in \mathbb{N}.
\] (75)
On the other hand, using Lemma 3.12 and Borel-Cantelli Lemma we easily deduce that for \(\text{Leb}_{\Sigma^1}\) almost every \(x \in \Sigma^0_\omega\) we cannot have \(x \in S_n(\Sigma^0_\omega) \cup S_n(\Sigma^c_\omega)\) for infinitely many values of \(n\). Clearly, this gives a contradiction with the fact that \(\text{Leb}_{D_\omega}(B) > 0\) and (75) holds for every \(x \in B\). \(\square\)

3.3. **Return times.** In the previous section we have constructed for each \(\omega\) a \(\text{Leb}_{\Sigma^1}\) mod 0 partition
\[
P_\omega = \bigcup_{n \geq N_0} P_{\omega,n}
\]
of the cu-disk \(\Sigma^0_\omega \subset D_\omega\). This partition is formed by elements \(\xi^{n,\ell}_{\omega,x} \in P_{\omega,n}\) of the type described in (43). In particular, each \(\xi^{n,\ell}_{\omega,x}\) satisfies
\[
\xi^{n,\ell}_{\omega,x} \subset V_{1/9}(x) \quad \text{and} \quad \pi_{\sigma^{n+\ell}\omega}(\xi^{n,\ell}_{\omega,x}) = \Sigma^0_{\sigma^{n+\ell}\omega},
\]
for some \(0 \leq \ell_{\omega} \leq L\). Naturally, for each \(y \in \ell_{\omega} \in P_{\omega,n}\) we set the recurrence time
\[
R_\omega(y) = n + \ell_{\omega}.
\] (76)

**Remark 3.14.** Consider \(f \in \text{Diff}^1(M)\) as in Theorem 1.5. For the deterministic case, it has been proved in [5, Section 5] that the construction on the reference leaf \(\Sigma^0_\omega\) performed in Subsection 3.2 gives rise to a set with a hyperbolic product structure contained in \(K\) with integrable return times \(\{R_i\}\) and partition \(P = \{\xi_i\}\). If we assume that \(f\) has a unique physical measure \(\mu\) supported on \(K\), then we necessarily have \(\mu = \pi_* \hat{\mu}\), where \(\pi\) is the natural projection from the tower to \(M\) and \(\hat{\mu}\) is the physical measure for the tower map. Additionally, assuming \(\mu\) mixing, we have \(\hat{\mu}\) mixing as well. This implies \(\text{gcd}\{R_i\} = 1\), which then means that there are \(\xi_1, \ldots, \xi_n \in P\) for which the corresponding return times
Observing that there exists $C > 34$, close to $f$, the fact that we can choose $\Sigma^0$ such that these conditions, the estimates on the tail of return times that we prove next remain valid.

First of all observe that by construction we have $\theta > 0$ such that

$$x \in \bigcap_{i=1}^k S_{\omega,t_i}(\Sigma^0).$$

(77)

From here on we fix $\theta > 0$ as in Proposition 3.2. Using Lemma 3.10 and recalling that $\Sigma = \Sigma_{\omega,n}$, for random perturbations sufficiently close to $f$, it is not difficult to see that for each $1 \leq i \leq n$ we can take a domain $\xi_{\omega,i} \in \mathcal{P}_{\omega}$ with return time $R_i$. Observe that since we take only a finite number of domains under these conditions, the estimates on the tail of return times that we prove next remain valid.

Our goal now is to prove that given $C, c > 0$ and $0 < \tau < 1$ there exist $C', c' > 0$ such that

$$\text{Leb}_{D_x}\{\xi > n\} = C e^{-cn} \implies \text{Leb}_{D_x}\{R_x > n\} = C' e^{-c'n}.$$  

(77)

Combining the two inequalities above, we have

$$\text{Leb}_{D_x}\{\xi > n\} \leq \text{Leb}_{D_x}\{R_x > n\} \leq \text{Leb}_{D_x}\{\xi > n\},$$

implying that for each $i$, $1 \leq i \leq n$, the set $S_{\omega,t_i}(\Sigma^0)$ has at least $\lfloor n/2 \rfloor$ hyperbolic times between $\xi$. Assuming also that $\text{dist}_{\omega,n}(\Sigma_{\omega,n}) > \delta_1 \alpha^{m/4}$, we have $\text{dist}_{D_x}(x, \partial \Sigma^0_x) > \delta_1 \alpha^{t/2}$ for each $1 \leq i \leq k$. This implies that

$$x \notin S_{\omega,t_i}(\Sigma^0_x), \quad \text{for all } 1 \leq i \leq k.$$  

(80)

Together with (78) and (79), this gives $x \in S_{\omega,t_i}(\Sigma^0_x)$ for all $1 \leq i \leq k$.  

Define for any $k, n \in \mathbb{N}$ the set

$$X_{\omega,n}(k) = \left\{ x \in \Sigma^c_{\omega,n} \mid \exists t_1 < \cdots < t_k \leq n : x \in \bigcap_{i=1}^k S_{\omega,t_i}(\Sigma^0_x) \right\}.$$  

By Lemma 3.15 we may write

$$\Sigma^c_{\omega,n} \subset \{\xi > n\} \cup \{x \in \Sigma^0_x \mid \text{dist}_{D_x}(x, \partial \Sigma^0_x) \leq \delta_1 \alpha^{m/4}\} \subset X_{\omega,n}(\lfloor k \rfloor),$$

observing that there exists $C > 0$ such that for all $n \in \mathbb{N}$

$$\text{Leb}_{D_x}\{x \in \Sigma^0_x \mid \text{dist}_{D_x}(x, \partial \Sigma^0_x) \leq \delta_1 \alpha^{m/4}\} \leq C \alpha^{m/4},$$  

(81)
the proof of (77) will be complete once we have proved that \( \text{Leb}_D(X_{\omega,n}(k)) \) decays exponentially fast in \( k \). For this we need several auxiliary lemmas that we prove in the sequel. Consider \( Q_0 \geq N_1 \) as in (58) and take some large integer \( Q_1 \geq Q_0 \), to be specified later in (92). Given \( x \in X_{\omega,n}(k) \), consider:

- the moments \( u_1 < \cdots < u_p \leq n \) for which \( x \) belongs to some \( S_{\omega,u_1+n_i}(\xi_i) \) with \( \xi_i \in \mathcal{P}_{\omega,u_i} \) and \( n_i \geq Q_1 \);
- the moments \( v_1 < \cdots < v_q \leq n \) for which \( x \) belongs to some \( S_{\omega,v_1+m_i}(\xi_i) \) with \( \xi_i \in \mathcal{P}_{\omega,v_i} \) and \( m_i < Q_1 \).

Observe that

\[
\sum_{i=1}^p (n_i + 1) + \sum_{i=1}^q (m_i + 1) \geq k. \tag{82}
\]

We distinguish two possible cases:

1. \( \sum_{i=1}^p n_i \geq \frac{k}{2} \).

   Defining for each \( p \in \mathbb{N} \) and \( n_1, \ldots, n_p \geq Q_1 \) the set

   \[
   Y_{\omega}(n_1, \ldots, n_p) = \left\{ x \in \Sigma_0^\omega \mid \exists u_1 < \cdots < u_p \leq n, \xi_1 \in \mathcal{P}_{\omega,u_1}, \ldots, \xi_p \in \mathcal{P}_{\omega,u_p} : x \in \bigcap_{i=1}^p S_{\omega,u_i+n_i}(\xi_i) \right\}
   \]

   and

   \[
   Y_{\omega,k} = \bigcup_{n_1, \ldots, n_p \geq Q_1} \bigcap \frac{k}{2} \sum_{i=1}^p n_i \geq \frac{k}{2}
   \]

   we have in this case \( x \in Y_{\omega,k} \).

2. \( \sum_{i=1}^p n_i < \frac{k}{2} \).

   Since we assume \( n_1, \ldots, n_p \geq Q_1 \), we must have in this case \( p < k/(2Q_1) \). Using (82) and the fact that \( m_1, \ldots, m_q < Q_1 \), we may write

   \[
   qQ_1 + q \geq \sum_{i=1}^q (m_i + 1) \geq k - \sum_{i=1}^p n_i - p \geq \frac{k}{2} - \frac{k}{2Q_1} = \frac{(Q_1 - 1)k}{2Q_1} \geq \frac{k}{2Q_1},
   \]

   which then implies

   \[
   q \geq \left\lceil \frac{k}{4Q_1^2} \right\rceil.
   \]

Hence, defining for any positive integers \( n, q \) the set

\[
Z_{\omega,n}(q) = \left\{ x \in \Sigma_{\omega,n}^\omega \mid \exists v_1 < \cdots < v_q \leq n, \xi_1 \in \mathcal{P}_{\omega,v_1}, \ldots, \xi_p \in \mathcal{P}_{\omega,v_p} : x \in \bigcap_{i=1}^q S_{\omega,v_i}(\xi_i) \right\}, \tag{83}
\]

we have in this case \( x \in Z_{\omega,n}(\lceil k/(4Q_1^2) \rceil) \).
The overall conclusion is that
\[ X_{\omega,n}(k) \subset Y_k \cup Z_{\omega,n} \left( \left[ \frac{k}{|Q_1^2|} \right] \right). \tag{84} \]

Our goal now is to show that the measure of the sets \( Y_{\omega,k} \) and \( Z_{\omega,n}(k) \) decays exponentially fast in \( k \). We start with a preliminary estimate on the measure of the sets used in the definition of \( Y_{\omega,k} \).

**Lemma 3.16.** There is \( C_0 > 0 \) such that for all \( n_1, \ldots, n_p > Q_0 \) we have
\[ \text{Leb}_{D_{\omega}} \left( Y_{\omega}(n_1, \ldots, n_p) \right) \leq C_0^p \alpha^{(n_1+\cdots+n_p)/2}. \]

**Proof.** Defining for each \( u_1 \geq N_0 \) and \( \xi_1 \in P_{\omega,u_1} \) the set
\[
Y_{\omega,u_1}(n_1, \ldots, n_p) = \left\{ x \mid \exists u_2 < \cdots < u_p \xi_2 \in P_{\omega,u_2}, \ldots, \xi_p \in P_{\omega,u_p} : u_2 > u_1, x \in \bigcap_{i=1}^p S_{\omega,u_2+\cdots+n_1}(\xi_i) \right\},
\]
we may write
\[
Y_{\omega}(n_1, \ldots, n_p) = \bigcup_{u_1 \geq N_0} \bigcup_{\xi_1 \in P_{\omega,u_1}} Y_{\omega,u_1}(n_1, \ldots, n_p).
\]

Noticing that the elements \( \xi_1 \in P_{\omega,u_1} \) with \( u_1 \geq N_0 \) are pairwise disjoint, it is enough to show that there is some constant \( C_0 > 0 \) such that for all \( u_1 \geq N_0 \) and \( \xi_1 \in P_{\omega,u_1} \) we have
\[ \text{Leb}_{D_{\omega}} \left( Y_{\omega,u_1}(n_1, \ldots, n_p) \right) \leq C_0^p \alpha^{(n_1+\cdots+n_p)/2} \text{Leb}_{D_{\omega}}(\xi_1). \tag{85} \]

We shall prove (85) by induction on \( p \). Considering \( C_0 > C \), where \( C > 0 \) is the constant in Lemma 3.11, we immediately get the result for \( p = 1 \). Now suppose that \( p > 1 \). We may write
\[
Y_{\omega,u_1}(n_1, \ldots, n_p) = \bigcup_{u_2 > u_1} \bigcup_{\xi_2 \in P_{\omega,u_2}} Y_{\omega,u_2}(n_2, \ldots, n_p) \tag{86}
\]
By Lemma 3.9, for all \( \xi_2 \in P_{\omega,u_2} \) with \( u_2 > u_1 \) we have
\[ S_{\omega,u_2+Q_0}(\xi_1) \cap S_{\omega,u_2+n_1}(\xi_2) = \emptyset. \tag{87} \]
Assuming with no loss of generality that \( Y_{\omega,u_1}(n_1, \ldots, n_p) \) is nonempty, we have in particular
\[ S_{\omega,u_1+n_1}(\xi_1) \cap S_{\omega,u_2+n_2}(\xi_2) \neq \emptyset. \tag{88} \]
From (87) and (88) we easily deduce that \( u_1 + n_1 < u_2 + Q_0 \), or equivalently \( u_2 - u_1 > n_1 - Q_0 \). Observe that
\[
\text{diam} \left( f_{\omega}^{u_2}(S_{\omega,u_2+n_2}(\xi_2)) \right) \leq 2\delta_0,
\]
and so, by (15)
\[
\text{diam} \left( f_{\omega}^{u_2}(S_{\omega,u_2+n_2}(\xi_2)) \right) \leq 2\delta_0 K_0.
\]
Then, using (51) and Proposition 3.3 we get
\[
\text{diam} \left( f_{\omega}^{u_1}(S_{\omega,u_2+n_2}(\xi_2)) \right) \leq \alpha^{u_2-u_1} \text{diam} \left( f_{\omega}^{u_2}(S_{\omega,u_2+n_2}(\xi_2)) \right) \leq 2\delta_0 K_0^{\alpha^{n_1-Q_0}/2}. \tag{89}
\]
Consider now \( \beta_\omega \) the outer component of the boundary of \( f_{\omega}^{u_1}(S_{\omega,u_1+n_1}(\xi_1)) \) and \( N_\omega \) a neighbourhood of \( \beta_\omega \) of size \( 2\delta_0 K_0^{(n_1-Q_0)/2} \) inside \( f_{\omega}^{u_1}(D_\omega) \). Since \( n_1 \geq Q_0 \geq N_1 \), by
definition of $S_{\omega,u_1+n_1}(\xi_1)$ there is $0 \leq \ell \leq L$ such that $f^\ell(\beta_\omega)$ coincides with the boundary of a ball of radius not exceeding $2\delta p$ centred at $p$. Then, using (45) we deduce that the volume of the submanifold $\beta_\omega$ is uniformly bounded. Hence, there must be some constant $C > 0$ (not depending on $u_1 \geq N_0$ or on $\xi_1 \in \mathcal{P}_{\omega,u_1}$) such that

$$\text{Leb}_{f^\omega}^1(D_\omega)(\mathcal{N}_\omega) \leq C\alpha^{n_1/2}. \quad (90)$$

Now, since $f^u_\omega(S_{\omega,u_2+n_2}(\xi_2))$ intersects $\beta_\omega$, it follows from (89) that $f^u_\omega(S_{\omega,u_2+n_2}(\xi_2))$ is contained in $\mathcal{N}_\omega$. This in particular implies that

$$f^u_\omega(\xi_2) \subset \mathcal{N}_\omega. \quad (91)$$

On the other hand, by the induction hypothesis we have

$$\text{Leb}_{D_\omega}^p \left(Y^\xi_{\omega,u_2}(n_2, \ldots, n_p)\right) \leq C_0^{p-1}\alpha^{(n_2+\cdots+n_p)/2} \text{Leb}_{D_\omega}(\xi_2),$$

Using (54) and the definition of $Y^\xi_{\omega,u_1}(n_1, \ldots, n_p)$, we easily deduce that

$$Y^\xi_{\omega,u_1}(n_1, \ldots, n_p) \subset S_{\omega,u_1+n_1}(\xi_1) \subset V_{u_1}(\xi_1).$$

Considering the constant $C_1 > 0$ given by Proposition 3.5, we get

$$\text{Leb}_{f^\omega_1(D_\omega)} \left(f^u_\omega \left(Y^\xi_{\omega,u_2}(n_2, \ldots, n_p)\right)\right) \leq C_1 C_0^{p-1}\alpha^{(n_2+\cdots+n_p)/2} \text{Leb}_{f^\omega_1(D_\omega)}(f^u_\omega(\xi_2)).$$

Observe that the sets $\xi_2 \in \mathcal{P}_{\omega,u_2}$ with $u_1 < u_2$ are pairwise disjoint. Moreover, by (57) these sets are all contained in $V_{\omega,u_1}(\xi_1)$. Since $f^u_\omega$ is injective on $V_{\omega,u_1}(\xi_1)$, we easily get that the sets $f^u_\omega(\xi_2)$ with $\xi_2 \in \mathcal{P}_{\omega,u_2}$ and $u_1 < u_2$ are also pairwise disjoint. Then, using (89), (90) and (91) we may write

$$\text{Leb}_{f^\omega_1(D_\omega)}(f^u_\omega \left(Y^\xi_{\omega,u_1}(n_1, \ldots, n_p)\right)) \leq \sum_{u_2=u_1+1}^n \sum_{\xi_2 \in \mathcal{P}_{\omega,u_2}} \text{Leb}_{f^\omega_1(D_\omega)}(f^u_\omega \left(Y^\xi_{\omega,u_2}(n_2, \ldots, n_p)\right)) \leq C_1 C_0^{p-1}\alpha^{(n_2+\cdots+n_p)/2} \sum_{u_2=u_1+1}^n \sum_{\xi_2 \in \mathcal{P}_{\omega,u_2}} \text{Leb}_{f^\omega_1(D_\omega)}(f^u_\omega(\xi_2)) \leq C_1 C_0^{p-1}\alpha^{(n_2+\cdots+n_p)/2} \text{Leb}_{f^\omega_1(D_\omega)}(\mathcal{N}_\omega) \leq CC_1 C_0^{p-1}\alpha^{(n_1+\cdots+n_p)/2}.$$

Taking $C_0 \geq CC_1$, we finish the proof. \[\Box\]

Observe that the constant $C_0$ given by Lemma 3.10 in principle depends on the integer $Q_0$ introduced in (55), but not on $Q_1 \geq Q_0$. Since this holds, we may choose $Q_1$ and integer sufficiently large such that

$$\alpha^{1/2} + C_0 \alpha^{Q_1/2} < 1. \quad (92)$$

The next result gives the expected estimate on the measure of the set $Y_k$.

**Proposition 3.17.** There are $C_1 > 0$ and $\lambda_1 < 1$ such that for all $k \geq 1$ we have

$$\text{Leb}_{D_\omega}(Y_{\omega,k}) \leq C_1 \lambda_1^k.$$
Proof. By the definition of $Y_{\omega,k}$ and Lemma 3.16 we just need to show that 
\[ \sum_{n_1, \ldots, n_p \geq Q_1 \atop \sum n_i = n} C_0^p \alpha^{(n_1 + \cdots + n_p)/2} \]
decays exponentially fast with $k$. We use the generating series
\[ \sum_{n \geq 1} \sum_{n_1, \ldots, n_p \geq Q_1 \atop \sum n_i = n} C_0^p \alpha^{(n_1 + \cdots + n_p)/2} z^n \]
\[ = \sum_{p=1}^{\infty} \left( C_0 \sum_{n=Q_1}^{\infty} \alpha^{n/2} z^n \right)^p \]
\[ = \frac{C_0 \alpha^{Q_1/2} z^{Q_1}}{1 - \alpha^{1/2} z - C_0 \alpha^{Q_1/2} z^{Q_1/2}}. \]
Under condition (92), the function above has no pole in a neighborhood of the unit disk in $\mathbb{C}$. Thus, the coefficients of its power series decay exponentially fast: there are constants $C_1 > 0$ and $\lambda_1 < 1$ such that
\[ \sum_{n_1, \ldots, n_p \geq Q_1 \atop \sum n_i = n} C_0^p \alpha^{(n_1 + \cdots + n_p)/2} \leq C_1 \lambda_1^n, \]
and so we are done. □

At this point we introduce some simplification in the notation. Consider
\[ T_\omega = \{ S_{\omega,n}(\xi) \cup \xi \mid \text{for some } \xi \in \mathcal{P}_{\omega,n} \text{ and } n \geq N_0 \}. \]
Given $T = S_{\omega,n}(\xi) \cup \xi \in T_\omega$ with $\xi \in \mathcal{P}_{\omega,n}$, define
\[ \xi_T = \xi \quad \text{and} \quad t(T) = n. \]
We will refer to $\xi_T$ as the core of $T \in T_\omega$. Notice that for any $T_1, T_2 \in T_\omega$ we have
\[ T_1 \neq T_2 \implies \xi_{T_1} \cap \xi_{T_2} = \emptyset, \quad \text{(93)} \]
and from (57) it follows that
\[ T_1 \cap T_2 \neq \emptyset \implies T_2 \subset V_{\omega,t(T_1)}(\xi_{T_1}) \quad \text{(94)} \]
Finally, from Lemma 3.11 we easily deduce the existence of $C > 0$ such that for every $T \in T_\omega$ we have
\[ \text{Leb}_{D_\omega}(T) \leq C \text{Leb}(\xi_T). \quad \text{(95)} \]

Our goal now is to prove that the measure of $Z_{\omega,n}(q)$ decays exponentially fast with $q$. For that we need a couple of auxiliary lemmas that we prove in the sequel. We start by fixing some large integer $Q_2$ to be specified in (106). Given $x \in Z_{\omega,n}(q)$, consider the times $v_1 < \cdots < v_q \leq n$ as in the definition of $Z_{\omega,n}(q)$ in (83). Take the smallest positive integer $u$ such that $Q_2 u \geq n$ and, for each $1 \leq i \leq u$, consider from the interval $((i-1)Q_2, iQ_2]$ the first element in $\{v_1, \ldots, v_q\}$, if there is at least one. Denote the subsequence of those elements by $w_1 < \cdots < w_p$. We necessarily have $p \geq \lfloor q/Q_2 \rfloor$, and so $(p+1)Q_2 \geq q$. 

Keeping only the elements with odd indexes, we get a sequence $t_1 < \ldots < t_\ell$ with $2\ell \geq p$. This implies that
\[ \ell \geq \frac{q - Q_2}{2Q_2}. \] (96)
Moreover, by construction we have
\[ t_{i+1} - t_i \geq Q_2, \quad \text{for each } 1 \leq i \leq \ell. \] (97)
According to the definition of $Z_{\omega,n}(q)$, for each $1 \leq i \leq \ell$ there is some $T_i \in T_{\omega}$ such that $t(T_i) = t_i$. Set
\[ I = \{1 \leq i \leq \ell \mid T_i \subset T_1 \cap \cdots \cap T_{i-1}\}. \]
Now we consider the two possible cases:

1. $\#I \geq \ell/2$.
   Define for any positive integers $n, k \geq 1$ the set
   \[ Z_{\omega,n}^0(k) = \{ x \in \Sigma_{\omega,n}^c \mid \exists T_1 \supset \cdots \supset T_k \text{ with } t(T_1) < \cdots < t(T_k) \leq n \text{ and } x \in T_{\omega,k}\}. \]
   Keeping only elements with indexes in $I$ and recalling (96), we easily see that in this case we have $x \in Z_{\omega,n}^0(\lfloor(q - Q_2)/(4Q_2)\rfloor)$.

2. $\#I < \ell/2$.
   Considering $J = \{1, \ldots, \ell\} \setminus I$, we necessarily have $\#J \geq \ell/2$. We define
   \[ j_0 = \sup J \quad \text{and} \quad i_0 = \inf\{ i < j_0 \mid T_{j_0} \not\subset T_i \}. \]
   Next we define
   \[ j_1 = \sup\{ j \leq i_0 \mid j \in J \} \quad \text{and} \quad i_1 = \inf\{ i < j_1 \mid T_{j_1} \not\subset T_i \}. \]
   Proceeding inductively, the process must necessarily stop at some $i_{m_0}$. By construction, we have
   \[ J \subset \bigcup_{s=0}^{m_0}\{i_s + 1, \ldots, j_s\}, \]
   which then gives
   \[ \sum_{s=0}^{m_0}(j_s - i_s) \geq \#J \geq \frac{\ell}{2}. \]
   On the other hand, it follows from (97) that $|t_{j_s} - t_{i_s}| \geq Q_2(j_s - i_s)$ for all $0 \leq s \leq m_0$.
   Altogether, this yields
   \[ \sum_{s=0}^{m_0} \frac{t(T_{j_s}) - t(T_{i_s})}{Q_2} = \sum_{s=0}^{m_0} \frac{t_{j_s} - t_{i_s}}{Q_2} \geq \frac{\ell}{2} \geq \frac{q - Q_2}{4Q_2}. \]

Motivated by this second case, we consider for each $T \in T_{\omega}$ the set $\mathcal{F}(T)$ of finite sequences $(T_0, \ldots, T_{2m}) \in T_{\omega}^{2m+1}$ with $m \geq 0$ and $T_0 = T$ such that $t(T_{2i-2}) \leq t(T_{2i-1}) \leq t(T_{2i})$ for each $1 \leq i \leq m$.
in T. Inductively, this process must stop in a finite number of steps. We say that the elements $Z$ are mutually fast with $T$. Take $x \in T$. Then we define $Z_0(k) = x$. Actually, given any $Z_0(k)$, we have $Z_0(k+1) = 0$. On the other hand, as $Z_0(k) = 0$, the sets $Z_0(k) = 0$ and $Z_1(k) = 0$ are contained in elements of $T$. Therefore, we have $Z_0(k) = 0 \cup Z_1(k)$. Proceeding inductively, this process must stop in a finite number of steps. We say that the elements $Z_0(k)$ and $Z_1(k)$ are mutually fast with $k$. 

**Lemma 3.18.** There exists $\lambda_2 < 1$ such that for all $k \geq 1$ we have

$$\text{Leb}_{D_\omega}(Z_{\omega,n}(k)) \leq \lambda_2^k \text{Leb}_{D_\omega}(\Sigma_{\omega,n})$$

**Proof.** We define $T_{\omega,1}$ as the class of elements $T \in T_\omega$ with $t(T) \leq n$ not contained in any other element of $T_\omega$. Then, we define $T_{\omega,2}$ as the class of elements $T \notin T_{\omega,1}$ with $t(T) \leq n$ contained in elements of $T_{\omega,1}$ and not contained in any other elements of $T_\omega$. Proceeding inductively, this process must stop in a finite number of steps. We say that the elements in $T_{\omega,i}$ have rank $i$. Then we define

$$C_{\omega,k} = \bigcup_{i=1}^k \bigcup_{T \in T_{\omega,i}} \xi_T,$$

and

$$\tilde{Z}_{\omega,k} = \left( \bigcup_{T \in T_\omega} T \right) \setminus C_{\omega,k}.$$

We claim that $Z_{\omega,n}(k) \subset \tilde{Z}_{\omega,k}$. Actually, given any $x \in Z_{\omega,n}(k)$, we have $T_1, \ldots, T_k \in T_\omega$ with $T_1 \supset \cdots \supset T_k$ and $t(T_1) < \cdots < t(B_k) \leq n$ such that $x \in T_k \cap \Sigma_{\omega,n}$. Clearly, $T_k$ has rank $r \geq k$. Take $T'_1 \supset \cdots \supset T'_k$ with $T'_i \in T_{\omega,i}$ and $T'_r = T_k$. In particular, $x \in T'_i$ for $i = 1, \ldots, k$, and so $x \in \bigcup_{T \in T_{\omega,k}} T$. On the other hand, as $x \in \Sigma_{\omega,n}$ and $C_{\omega,k} \cap \Sigma_{\omega,n} = \emptyset$, we get $x \notin C_{\omega,k}$. This gives $x \in \tilde{Z}_{\omega,k}$. Now we show that for each $k$ we have

$$\text{Leb}_{D_\omega}(\tilde{Z}_{\omega,k+1}) \leq \frac{C}{C+1} \text{Leb}_{D_\omega}(\tilde{Z}_{\omega,k}),$$

where $C > 0$ is the constant given in [95]. To see this, we start by showing that for all $T \in T_{k+1}$ we have

$$\xi_T \subset \tilde{Z}_{\omega,k} \setminus \tilde{Z}_{\omega,k+1}.$$
Take any $T \in \mathcal{T}_{\omega,k+1}$ and let $T' \in \mathcal{T}_\omega$ be an element of rank $k$ containing $T$. As the cores are pairwise disjoint, we have $\xi_T \cap C_{\omega,k} = \emptyset$, and so $\xi_T \subset T' \setminus C_{\omega,k} \subset \tilde{Z}_{\omega,k}$. As, by definition, we have $\xi_T \subset C_{\omega,k+1}$, it follows that $\xi_T \cap \tilde{Z}_{\omega,k+1} = \emptyset$. This gives (100).

Let us now prove (99). Using (95) and the fact that the cores of the elements in $\mathcal{T}$ are pairwise disjoint, we may write

$$\text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k+1} \right) \leq \sum_{T \in \mathcal{T}_{\omega,k+1}} \text{Leb}_{D_\omega} (T) \leq C \sum_{T \in \mathcal{T}_{\omega,k+1}} \text{Leb}_{D_\omega} (\xi_T) \leq C \text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k} \setminus \tilde{Z}_{\omega,k+1} \right).$$

Therefore,

$$(C + 1) \text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k+1} \right) \leq C \text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k} \right) + C \text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k} \setminus \tilde{Z}_{\omega,k+1} \right) = C \text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k} \right).$$

Inductively, this yields

$$\text{Leb}_{D_\omega} \left( \tilde{Z}_{\omega,k} \right) \leq \left( \frac{C}{C + 1} \right)^k \text{Leb}_{D_\omega} (\Sigma_{\omega,n}^0).$$

Since $Z_{\omega,k} \subset \tilde{Z}_{\omega,k}$, the result follows with $\lambda_2 = C/(C + 1)$. \qed

**Lemma 3.19.** There is $C_2 > 0$ such that for all $k \geq 0$ and $T \in \mathcal{T}_\omega$ we have

$$\text{Leb}_{D_\omega} \left( Z_{\omega}(k; T) \right) \leq C_2 \left( C_2 \alpha^{Q_2/2} \right)^k \text{Leb}_{D_\omega} (\xi_T).$$

**Proof.** We prove the result by induction on $k \geq 0$. For $k = 0$, we have by (95)

$$\text{Leb}_{D_\omega} (Z_{\omega}(0; T)) \leq \text{Leb}_{D_\omega} (T) \leq C \text{Leb}_{D_\omega} (\xi_T).$$

So, in this case it is enough to take $C_2 \geq C$. Given any $k \geq 1$, we may write

$$Z_{\omega}(k; T) \subset \bigcup_{m=1}^k \bigcup_{T \cap T \neq \emptyset} \bigcup_{T_1 \cap T_2 \neq \emptyset, T_2 \subset T_1} \bigcup_{T_{T_{m-1} \cap T_1}} Z_{\omega}(k - m, T_2).$$

Our goal now is to estimate the measure of the triple union above.

Take $T_1 \in \mathcal{T}_\omega$ intersecting $T$ and $T_2 \in \mathcal{T}_\omega$ intersecting $T_1$ with $T_2 \not\subset T_1$ and $t(T_2) - t(T_1) \geq m Q_2$. Consider $t_1 = t(T_1)$ and $t_2 = t(T_2)$. Notice that for each $i = 1, 2$, the set $f^i_{\omega} (T_i) = f^i_{\omega} \left( V_{t_i}^{1/3} (\xi_{t_i}) \right)$ is, by definition, a ball of radius $\delta_i/3$. Hence, recalling (54) and using Proposition 3.3, we may write

$$\text{diam} \left( f^i_{\omega} (T_2) \right) \leq \alpha^{t_2 - t_1} \text{diam} \left( f^i_{\omega} (T_2) \right) \leq \frac{2}{3} \delta_1 \alpha^{t_2 - t_1} \leq \frac{2}{3} \delta_1 \alpha^{mQ_2}.$$

(101)
Now, let $\beta_\omega$ be the boundary of the ball $f^{t_1}_\omega(T_1)$ and consider $\mathcal{N}_\omega$ a neighbourhood of $\beta_\omega$ of size $2\delta \alpha^{mQ_2/2}/3$ inside $f^{t_1}_\omega(D_\omega)$. Notice that $\mathcal{N}_\omega$ is necessarily contained in $f^{t_1}_\omega(V(t_1, \xi_1))$. Let $U_\omega$ be the subset of $V_{\omega, t_1}(\xi_1)$ which is sent diffeomorphically onto $\mathcal{N}_\omega$ under $f^{t_1}_\omega$. One can easily see that there exists some constant $\tilde{C} > 0$ (not depending on $t_1 \geq N_0$ nor on $T_1$) such that

$$\text{Leb}_{f^{t_1}_\omega(D_\omega)}(f^{t_1}_\omega(U_\omega)) \leq \tilde{C} \alpha^{mQ_2/2} \text{Leb}_{f^{t_1}_\omega(D_\omega)}(f^{t_1}_\omega(T_1)).$$

(102)

Recalling that $T_1 \subset V_{\omega, t_1}(\xi_1)$, considering $C_1 > 0$ the constant given by Proposition 3.5 and using (3.5), we obtain

$$\text{Leb}_{D_\omega}(U_1) \leq C_1 \tilde{C} \alpha^{mQ_2/2} \text{Leb}_{D_\omega}(T_1) \leq C_1 \tilde{C} \alpha^{mQ_2/2} \text{Leb}_{D_\omega}(\xi_1).$$

(103)

Now, as $T_2 \cap T_1 \neq \emptyset$ with $T_2 \not\subset T_1$, it follows that $f^{t_1}_\omega(T_2)$ intersects $\beta_\omega$. Then, using (101), we easily deduce that $f^{t_1}_\omega(T_2)$ is contained in $\mathcal{N}_\omega = f^{t_1}_\omega(U_\omega)$. This gives in particular $\xi_{T_2} \subset U_\omega$. Since the cores of these possible $T_2$ are pairwise disjoint, from (103) we get

$$\sum_{T_1 \cap T \neq \emptyset} \text{Leb}_{D_\omega}(\xi_{T_1}) \leq C_1 \tilde{C} \alpha^{mQ_2/2} \text{Leb}_{D_\omega}(\xi_1).$$

(104)

On the other hand, since $T_1 \cap T \neq \emptyset$, it follows from (3.4) that $T_1 \subset V_{\omega, t(T)}(\xi_T)$. Moreover, as the cores of these possible $T_1$ are pairwise disjoint, using (108) we may write

$$\sum_{T_1 \cap T \neq \emptyset} \text{Leb}_{D_\omega}(\xi_{T_1}) \leq \text{Leb}_{D_\omega}(V_{\omega, t(T)}(\xi_T)) \leq C_0 \text{Leb}_{D_\omega}(\xi_T).$$

(105)

Finally, using (104), (105) and the inductive hypothesis, we may write

$$\text{Leb}_{D_\omega}(Z_\omega(k, T)) \leq \sum_{m=1}^{k} \sum_{T_1 \cap T \neq \emptyset} \sum_{T_2 \neq T_1} \text{Leb}_{D_\omega}(Z_\omega(k - m, T_2))$$

$$\leq \sum_{m=1}^{k} \sum_{T_1 \cap T \neq \emptyset} \sum_{T_2 \neq T_1} C_2 (C_2 \alpha^{Q_2/2})^{k-m} \text{Leb}_{D_\omega}(\xi_{T_2})$$

$$\leq \sum_{m=1}^{k} \sum_{T_1 \cap T \neq \emptyset} C_2 (C_2 \alpha^{Q_2/2})^{k-m} C_1 \tilde{C} \alpha^{mQ_2/2} \text{Leb}_{D_\omega}(\xi_{T_1})$$

$$\leq C_2 (C_2 \alpha^{Q_2/2})^{k} C_0 C_1 \tilde{C} C \sum_{m=1}^{k} C_2^{-m} \text{Leb}_{D_\omega}(\xi_T).$$

Hence, taking $C_2 > 0$ sufficiently large enough for

$$\frac{C_0 C_1 \tilde{C} C C_2^{-1}}{1 - C_2^{-1}} \leq 1,$$

we finish the proof. $\square$
At this point we are able to specify the choice of $Q_2$. We take $Q_2$ an integer sufficiently large such that
\[ C_2Q_2^{3/2} < 1, \tag{106} \]
with $C_2 > 0$ as in Lemma 3.19. Under this choice, we easily deduce that $\text{Leb}_{D\omega}(Z^t_\omega(k))$ decays exponentially fast in $k$.

3.4. Hyperbolic product structure. Here we obtain a set $\Lambda_\omega$ with a hyperbolic product structure verifying properties (P$_0$)-(P$_5$) as in Subsection 1.2. Consider the center-unstable disk $\Sigma^u_\omega \subset D_\omega$ as in (38) and the $\text{Leb}_{D\omega}$ mod 0 partition $P_\omega$ of $\Sigma^u_\omega$ defined in Section 3.2. We define
\[ \Gamma^u_\omega = \{ W^u_{\omega,\delta}(x) : x \in \Sigma^u_\omega \}. \]
Moreover, we define $\Gamma_\omega^u$ as the set of all local unstable manifolds contained in $C^0_\omega$ which $u$-cross $C^0_\omega$. Clearly, $\Gamma^u_\omega$ is nonempty because $\Sigma^u_\omega \subset \Gamma^u_\omega$. We need to see that the union of the leaves in $\Gamma^u_\omega$ is compact. By the domination property and Ascoli-Arzela Theorem, any limit leaf $\gamma_\infty$ of leaves in $\Gamma^u_\omega$ is still a $cu$-disk $u$-crossing $C_0$. So, by definition of $\Gamma^u_\omega$, we have $\gamma_\infty \in \Gamma^u_\omega$. We define our set $\Lambda_\omega$ with hyperbolic product structure as the intersection of these families of stable and unstable leaves. The cylinders $\{ C(\xi) \}_{\xi \in P_\omega}$ then clearly form a countable collection of $s$-subsets of $\Lambda_\omega$ that can be used as the sets $\Lambda_1\omega,\Lambda_2\omega,\ldots$ in (P$_1$) with the corresponding return times $R_\omega(\xi)$, for each $\xi \in P_\omega$. Since (P$_0$) is obvious, we are left to verify conditions (P$_1$)-(P$_5$).

3.4.1. Markov and contraction on stable leaves. Condition (P$_1$) is essentially an immediate consequence of the construction. We just need to check that $f^R_\omega(\xi)(C(\xi))$ is a $u$-subset, for any $\xi \in P_\omega$. In fact, choosing the integer $N_0$ in the first step of the construction of $P_\omega$ sufficiently large, and using the fact that the local stable manifolds are uniformly contracted by forward iterations under $f_\omega$, we can easily see that the “height” of $f^R_\omega(\xi)(C(\xi))$ is at most $\delta_s/4$, for each $\xi \in P_\omega$. On the other hand, by the choice of $\delta_0$ we have that $f^R_\omega(\xi)(\xi)$ intersects $W^u_{\omega,\delta_s/2}(y)$, for some $y \in \Sigma^u_\omega$, and $u$-crosses $C^4_{\omega,\nu}(\xi)$, recall Remark 3.7. Hence, the local unstable leaves that form $C(\xi)$ necessarily $u$-cross $C_0$, and so (P$_1$) holds. Property (P$_2$) is clearly verified in our case.

3.4.2. Expansion and bounded distortion. The expansion and bounded distortion on unstable leaves, property (P$_3$), follows from Proposition 3.3 and Proposition 3.5. Indeed, by construction, for each $\xi \in P_\omega$ there is a hyperbolic pre-ball $V_{\omega,n}(\xi)(x)$ containing $\xi$ associated to some point $x \in \Sigma^u_\omega$ with $\alpha$-hyperbolic time $n(\xi)$. Therefore, recalling Remark 3.4 and taking $\delta_s < \delta_1$, for any $\gamma \in \Gamma^u_\omega$ we have that $n$ is a $\alpha^{1/4}$-hyperbolic time for every point in $C(\xi) \cap \gamma$. Since $R_\omega(\xi) - L \leq n(\xi) \leq R_\omega(\xi)$, choosing $N_0$ such that $K_0\alpha^{N_0/2} < 1$, by (15) we obtain (P$_3$).

3.4.3. Regularity of the foliations. Property (P$_4$) is standard for uniformly hyperbolic attractors. In the rest of this section we shall adapt classical ideas to our setting. We begin with the statement of a useful lemma on vector bundles whose proof can be found in [34, Theorem 6.1]. We should say that a metric $d$ on a vector bundle $E$ is admissible if there is
a complementary bundle $E'$ over $X$, and an isomorphism $h: E \oplus E' \to X \times B$ to a product bundle, where $B$ is a Banach space, such that $d$ is induced from the product metric on $X \times B$.

**Lemma 3.20.** Let $p: E \to X$ be a vector bundle over a metric space $X$ endowed with an admissible metric. Let $D \subset E$ be the unit ball bundle, and $F: D \to D$ a map covering a Lipschitz homeomorphism $f: X \to X$. Assume that there is $0 \leq \kappa < 1$ such that for each $x \in X$ the restriction $F_x: D_x \to D_x$ satisfies $\text{Lip}(F_x) \leq \kappa$. Then

1. there is a unique section $\sigma: X \to D$ whose image is invariant under $F$;
2. if $\kappa \text{Lip}(f)^n < 1$ for some $0 < \eta \leq 1$, then $\sigma$ is Hölder condition with exponent $\eta$.

**Proposition 3.21.** Assume the random perturbations $f_\omega$ sufficiently close to $f$ in the $C^1$ topology. If $T_{K_\omega} M = E^{cs}_\omega \oplus E^{cu}_\omega$ is a dominated splitting, then the fibre bundles $E^{cs}_\omega$ and $E^{cu}_\omega$ are Hölder continuous on $K_\omega$.

**Proof.** We consider only the centre-unstable bundle as the other one is similar. For each $x \in K_\omega$, let $L_{\omega,x}$ be the space of bounded linear maps from $E^{cu}_\omega$ to $E^{cs}_\omega$ and let $L^1_{\omega,x}$ denote the unit ball around 0 $\in L_{\omega,x}$. Define $G_{\omega,x}: L^1_{\omega,x} \to L^1_{\sigma_\omega,f_\omega(x)}$ the graph transform induced by $Df_\omega(x)$

$$G_{\omega,x}(\phi) = (Df_\omega|E^{cs}_\omega) \phi (Df_\omega^{-1}|E^{cu}_{\sigma_\omega,f_\omega(x)}).$$

Consider $L_\omega$ the vector bundle over $K_\omega$ whose fibre over each $x \in K_\omega$ is $L_{\omega,x}$, and let $L^1_\omega$ be its unit bundle. Then $G_\omega: L^1_\omega \to L^1_{\sigma_\omega}$ is a bundle map covering $f_\omega|K_\omega$ with

$$\text{Lip}(G_{\omega,x}) \leq \|Df_\omega|E^{cs}_\omega\| : \|Df_\omega^{-1}|E^{cu}_{\sigma_\omega,f_\omega(x)}\| \leq \lambda < 1.$$ 

Let $C$ be a Lipschitz constant for $f_\omega|K_\omega$, and choose $0 < \eta \leq 1$ small so that $\lambda C^n < 1$. By Lemma 3.20 there exists a unique section $\mathbf{s}_0: M \to L^1_\omega$ whose image is invariant under $G_\omega$ and it satisfies a Hölder condition with exponent $\eta$. This unique section is necessarily the null section.  

We now show that the holonomy map $\Theta_\omega$ is absolutely continuous and derive a formula for the density $\rho_\omega$. This will be done in few steps following the ideas of [38].

**Corollary 3.22.** There are $C > 0$ and $0 < \beta < 1$ such that for all $y \in \gamma_\omega^n(x)$ and $n \geq 0$

$$\log \left( \prod_{i=n}^{\infty} \frac{\det D^n f_{\sigma_\omega}(f^n_\omega(x))}{\det D^n f_{\sigma_\omega}(f^n_\omega(y))} \right) \leq C \beta^n.$$ 

**Proof.** Since $Df_{\sigma_\omega}$ is Hölder continuous, Proposition 3.21 implies that $\log |\det D^n f_{\sigma_\omega}|$ is Hölder continuous. The corollary then follows from Proposition 3.3 which implies uniform backward contraction on unstable leaves. 

We now introduce some notion. We say that $\phi: M_1 \to M_2$, where $M_1$ and $M_2$ are submanifolds of $M$, is absolutely continuous if it is an injective map for which there exists $J: M_1 \to \mathbb{R}$ such that

$$\text{Leb}_{M_2}(\phi(A)) = \int_A Jd\text{Leb}_{M_1}.$$
J is called the Jacobian of φ. Property (P4) (1) can be restated as follows, replacing \( \Theta_\omega^{-1} \) by \( \phi_\omega \):

**Proposition 3.23.** Given \( \gamma, \gamma' \in \Gamma_\omega^u \), define \( \phi_\omega : \gamma' \to \gamma \) by \( \phi_\omega(x) = \gamma(x) \cap \gamma' \). Then \( \phi_\omega \) is absolutely continuous and the Jacobian of \( \phi_\omega \) is given by

\[
J_\omega(x) = \prod_{i=0}^{\infty} \frac{\det D^u f_{\sigma_i^r}(f_i^r(x))}{\det D^u f_{\sigma_i^r}(f_i^r(\phi_\omega(x)))}.
\]

Obviously, by Corollary 3.22, the infinite product in Proposition 3.23 converges uniformly. We prove Proposition 3.23 in the following three lemmas.

**Lemma 3.24.** Let \( M_1 \) and \( M_2 \) be manifolds, \( M_1 \) with finite volume, and for each \( n \geq 1 \), let \( \phi_n : M_1 \to M_2 \) be an absolutely continuous map with Jacobian \( J_n \). Assume that

1. \( \phi_n \) converges uniformly to an injective continuous map \( \phi : M_1 \to M_2 \);
2. \( J_n \) converges uniformly to an integrable function \( J : M_1 \to \mathbb{R} \).

Then \( \phi \) is absolutely continuous with Jacobian \( J \).

The proof of Lemma 3.24 is given in [38, Theorem 3.3]. For the sake of completeness, we observe that there is a slight difference in our definition of absolute continuity. Unlike [38], we do not assume continuity of the maps \( \phi_n \). However, the proof of [38, Theorem 3.3] uses only the continuity of the limit function \( \phi \), and so it still works in our case.

Consider now \( \gamma, \gamma' \in \Gamma^u \) and \( \phi : \gamma' \to \gamma \) as in Proposition 3.23. The proof of the next lemma is given in [38, Lemma 3.4] for uniformly hyperbolic diffeomorphisms. Nevertheless, one can easily see that it is obtained as a consequence of [38, Lemma 3.8] whose proof uses only the existence of a dominated splitting.

**Lemma 3.25.** For each \( n \geq 1 \), there is an absolutely continuous \( \pi_{\sigma_n^u} : f_n^u(\gamma) \to f_n^u(\gamma') \) with Jacobian \( G_{\sigma_n^u} \) satisfying

1. \( \lim_{n \to \infty} \sup_{x \in \gamma} \{ \text{dist}_{f_n^u}(\gamma)(\pi_{\sigma_n^u}(f_n^u(x)), f_n^u(\phi_\omega(x))) \} = 0 \);
2. \( \lim_{n \to \infty} \sup_{x \in f_n^u(\gamma)} \{|1 - G_{\sigma_n^u}(x)|\} = 0 \).

We consider the following sequence of random return times for points in \( \Lambda_\omega \),

\[
r_1 = R_\omega \quad \text{and} \quad r_{n+1} = r_n + R_{\sigma_n^u} \circ f_n^u, \quad \text{for } n \geq 1.
\]

Notice that the \( r_n \)'s are defined \( \operatorname{Leb}_\gamma \) almost everywhere on each \( \gamma \in \Gamma_\omega^u \) and they are piecewise constant.

**Remark 3.26.** Using the above sequence of random return times, one can construct a sequence of \( \operatorname{Leb}_\gamma \) mod 0 partitions \((Q_{\omega,n})_n\) by \( s \)-subsets of \( \Lambda_\omega \) with \( r_n \) being constant on each element of \( Q_{\omega,n} \), for which (P1)-(P3)-(1) hold with \( r_n \) replacing \( R_\omega \) and the elements of \( Q_{\omega,n} \) replacing the \( s \)-subsets of \( \Lambda_\omega \). Moreover, the constants \( C > 0 \) and \( 0 < \beta < 1 \) in the backward contraction, implied by Proposition 3.3, can be chosen not depending on \( n \).
Lemma 3.27. \( \phi_{\omega,n} \) converges uniformly to \( \phi_\omega \) and \((J_n)_n\) converges uniformly to \( J \).

Proof. It is sufficient to prove the convergence of the sequence restricted to \( A \) as described above. In particular, \( \phi_{\omega,n} \) and \( J_{\omega,n} \) are given by (107) and (108) respectively. We first prove the convergence of \((\phi_{\omega,n})_n\). By Remark 3.26, we may write for each \( x \in \gamma \)

\[
\text{dist}_\gamma(\phi_{\omega,n}(x), \phi_\omega(x)) = \text{dist}_\gamma(f_{\omega,n}^{-1} \circ \pi_{\sigma^n \omega} \circ f_{\omega,n}^{-1}(x), f_{\omega,n}^{-1}\phi_\omega(x)) \\
\leq C \beta_{\omega,n} \text{dist}_\gamma(f_{\omega,n}^{-1}(\pi_{\sigma^n \omega}(x)), f_{\omega,n}^{-1}\phi_\omega(x)).
\]

Since \( r_n \to \infty \) as \( n \to \infty \) and \( \text{dist}_\gamma(f_{\omega,n}^{-1}(\pi_{\sigma^n \omega}(x)), f_{\omega,n}^{-1}\phi_\omega(x)) \) is bounded, by Lemma 3.25 \( \phi_{\omega,n} \) converges uniformly to \( \phi_\omega \).

We now prove that \((J_n)_n\) converges to \( J \) uniformly. By (108), we have

\[
J_n(x) = \frac{|\det D^u f_{\omega,n}(x)|}{|\det D^u f_{\omega,n}(\phi_\omega(x))|} \cdot \frac{|\det D^u f_{\omega,n}(\phi_{\omega,n}(x))|}{|\det D^u f_{\omega,n}(\phi_{\omega,n}(x))|} \cdot G_{\sigma^n \omega}(f_{\omega,n}(x)).
\]

By the chain rule and Corollary 3.22, the first term in the product converges uniformly to \( J(x) \). Moreover, by Lemma 3.25, the third term converges uniformly to 1. Finally, recalling Remark 3.26, by bounded distortion we have

\[
\frac{|\det D^u f_{\omega,n}(\phi_{\omega,n}(x))|}{|\det D^u f_{\omega,n}(\phi_{\omega,n}(x))|} \leq \exp\left(C \text{dist}_\gamma(f_{\omega,n}^{-1}(\phi_\omega(x)), f_{\omega,n}^{-1}(\phi_{\omega,n}(x)))^\eta\right)
\]

\[
= \exp\left(C \text{dist}_\gamma(f_{\omega,n}^{-1}(\phi_\omega(x)), \pi_{\sigma^n \omega}(f_{\omega,n}(x)))^\eta\right).
\]

Similarly we obtain

\[
\frac{|\det D^u f_{\omega,n}(\phi_{\omega,n}(x))|}{|\det D^u f_{\omega,n}(\phi_{\omega,n}(x))|} \geq \exp\left(-C \text{dist}_\gamma(f_{\omega,n}^{-1}(\phi_\omega(x)), \pi_{\sigma^n \omega}(f_{\omega,n}(x)))^\eta\right).
\]

Therefore, by Lemma 3.25, \( G_{\sigma^n \omega} \circ f_{\omega,n} \) converges uniformly to 1.

This completes the proof of Proposition 3.23 and of (P4)(1); i.e., the holonomy map \( \Theta_\omega \) is absolutely continuous and

\[
\rho_\omega(x) = \frac{d[(\Theta_\omega)_* \text{Leb}_{\gamma_\omega}]}{d\text{Leb}_{\gamma_\omega}(x)} = \prod_{i=0}^{\infty} \frac{\det D^u f_{\sigma_i \omega}(f^{i}_{\omega}(x))}{\det D^u f_{\sigma_i \omega}(f^{i}_{\omega}(\Theta_{\omega}^{-1}(x)))}.
\]

We finally prove (P4)(2) in the next result.
Lemma 3.28. For any \( u \in \Gamma_{\omega}^u \) and any \( x, y \in \gamma_{\omega} \) we have \( \log \frac{\rho_{\omega}(x)}{\rho_{\omega}(y)} \leq C \beta^{s(x,y)} \).

Proof. Let \( k = [s(x,y)]/2 \). Then by bounded distortion and Corollary 3.22 we get

\[
\log \frac{\rho_{\omega}(x)}{\rho_{\omega}(y)} = \log \prod_{i=0}^{k-1} \frac{\det D^u f_{\omega}(f_{\omega}^i(x))}{\det D^u f_{\omega}(f_{\omega}^i(y))} = -\log \prod_{i=0}^{k-1} \frac{\det D^u f_{\omega}(f_{\omega}^i(y))}{\det D^u f_{\omega}(f_{\omega}^i(x))} \leq \sum_{i=0}^{k-1} \log \left| \frac{\det D^u f_{\omega}(f_{\omega}^i(x))}{\det D^u f_{\omega}(f_{\omega}^i(y))} \right| \leq 2C \beta^{s(x,y)} - k + 2C \beta^k \leq 4C \beta^{\frac{1}{2} s(x,y)}.
\]

\( \square \)

3.5. Axiom A attractors. Here we prove Theorem 1.6. Let \( f \in \text{Diff}^{1+}(M) \) have a topologically mixing uniformly hyperbolic attractor \( K \subset M \). Classical results give that under this conditions \( f \) has a unique physical measure which is actually mixing; see [20]. Recall that in this case the attractor necessarily contains the local unstable manifolds. Moreover, such manifolds persist under small \( C^1 \) random perturbations and depend continuously on the perturbations; see e.g. [21] Sections 1 & 2. Consequently, we can choose the reference leaf \( \Sigma_{\omega} \) and the cylinder \( C(\Sigma_{\omega}) \) of Subsection 3.2 depending continuously on \( \omega \in \Omega \). Also, the unstable leaves \( u \)-crossing these cylinders depend continuously on \( \omega \in \Omega \), and so the measurability of \( \Omega \ni \omega \mapsto \Lambda_{\omega} \) follows. In this uniformly hyperbolic case, we trivially have that \( \text{Leb}_{D_{\omega}} \{ \mathcal{E}_{\omega} > n \} \) decays exponentially fast in \( n \), uniformly in \( \omega \). For the aperiodicity see Remark 3.11. So, recalling Remark 3.1 and applying Theorem 1.3 and Theorem 1.5 we obtain Theorem 1.6.

4. Solenoid with intermittency

In this section we prove Theorem 1.8. We will show that the random dynamical system \( \{ g_{\omega} \}_{\omega \in \Omega} \) introduced in Subsection 1.5.3 admits a hyperbolic product structure. First notice that for almost every \( \omega \in \Omega \) the random map \( g_{\omega} \) has an attractor in \( M \) which is given by

\[
K_{\omega} = \bigcap_{n \geq 1} g_{\omega}^{n-1}(M).
\]
Note that $K_\omega$ is measurable in $\omega$ by [23] Theorem 3.11. First we show that for every $\omega$ the attractor $K_\omega$ is partially hyperbolic. By a straightforward computation for $p = (x, y, z) \in M$ we obtain

$$Dg_\omega(x, y, z) = \begin{bmatrix} T'_\omega(x) & 0 & 0 \\ -\sin x/2 & 1/10 & 0 \\ \cos x/2 & 0 & 1/10 \end{bmatrix}.$$ 

It is easily checked that $E^s_\omega \{0\} \times \mathbb{R}^2$ is invariant and uniformly contracted. We will construct $E^c_\omega(p)$ as a countable intersection of centre-unstable cones. For $p \in M$ define

$$C^c_\omega(p) = \{(v_1, v_2, v_3) \in T_pM \mid v_1 \in TS^1, (v_2, v_3) \in \mathbb{R}^2 \text{ and } |v_1| \geq \frac{1}{2}(v_2^2 + v_3^2)^{1/2}\}.$$ 

The first step is to show that $Dg_\omega C^c_\omega(p) \subset C^c_\omega(g_\omega(p))$. For $(v_1, v_2, v_3) \in C^c_\omega$ let $(\vec{v}_1, \vec{v}_2, \vec{v}_3) = Dg_\omega(p)(v_1, v_2, v_3)$. Using the fact $A\sin x + B\cos x \leq \sqrt{A^2 + B^2}$ and the definition of $C^c_\omega$ we have

$$\vec{v}_2^2 + \vec{v}_3^2 = (-\frac{1}{2}v_1\sin x + \frac{1}{10}v_2)^2 + (\frac{1}{2}v_1\cos x + \frac{1}{10}v_3)^2 \leq \frac{1}{4}v_1^2 + \frac{1}{100}(v_2^2 + v_3^2) + \frac{1}{10}|v_1|(v_2^2 + v_3^2)^{1/2} \leq v_1^2(\frac{1}{2} + \frac{1}{9})^2 < \vec{v}_1^2,$$

since $T'_\alpha \geq 1$ on $M$.

Define $E^c_\omega(p) = \bigcap_{k=0}^\infty Dg^{k-\kappa_\omega}_\sigma(g^{k-\kappa_\omega}_\sigma(p))C^c_\omega(g^{k-\kappa_\omega}_\sigma(p))$. The second step is to show that $E^c_\omega(p)$ is a line. By the previous argument, the finite intersections

$$C^{(n)} = \bigcap_{k=0}^n Dg^{k-\kappa_\omega}_\sigma(g^{k-\kappa_\omega}_\sigma(p))C^c_\omega(g^{k-\kappa_\omega}_\sigma(p)) = Dg^{n-\kappa_\omega}_\sigma(p)C^c_\omega(p)$$

form a nested sequence. It is sufficient to prove that the angle between any two vectors $C^{(n)}$ converges to zero as $n$ goes to infinity. For any $(v_1^{(1)}, v_2^{(1)}, v_3^{(1)}), (w_1^{(1)}, w_2^{(1)}, w_3^{(1)}) \in C^{(1)}$ we have

$$\left|\frac{v_2^{(1)}}{v_1^{(1)}} - \frac{w_2^{(1)}}{w_1^{(1)}}\right| = \left|\left(-\frac{1}{2}v_1^{(0)}\sin x + \frac{1}{10}v_2^{(0)}\right)/(v_1^{(0)}T'_\omega(x)) - \left(-\frac{1}{2}w_1^{(0)}\sin x + \frac{1}{10}w_2^{(0)}\right)/(w_1^{(0)}T'_\omega(x))\right| \leq \frac{1}{10}\left|\frac{v_2^{(0)}}{v_1^{(0)}} - \frac{w_2^{(0)}}{w_1^{(0)}}\right|.$$ 

Similarly

$$\left|\frac{v_3^{(1)}}{v_1^{(1)}} - \frac{w_3^{(1)}}{w_1^{(1)}}\right| \leq \frac{1}{10}\left|\frac{v_3^{(0)}}{v_1^{(0)}} - \frac{w_3^{(0)}}{w_1^{(0)}}\right|.$$ 

By induction, we obtain

$$\left|\frac{v_i^{(n)}}{v_1^{(n)}} - \frac{w_i^{(n)}}{w_1^{(n)}}\right| \leq C 10^{-n}, \; i = 2, 3 \text{ for any } (v_1^{(n)}, v_2^{(n)}, v_3^{(n)}), (w_1^{(n)}, w_2^{(n)}, w_3^{(n)}) \in C^{(n)}.$$
This leads to a contradiction. Now the global centre-unstable manifold old at $\omega$ is smooth in $\omega$. Now define
\[
W_{\omega,\varepsilon}^u(p) = \{ q \in M \mid d(g_{\sigma^{-n}\omega}q,g_{\sigma^{-n}\omega}p) \leq \varepsilon, \forall n \geq 0 \},
\]
\[
W_{\omega,\varepsilon}^s(p) = \{ q \in M \mid d(g_q^np,g_q^np) \leq \varepsilon, \forall n \geq 0 \}.
\]
The third step is to show that $W_{\omega,\varepsilon}^s(p)$ and $W_{\omega,\varepsilon}^u(p)$ are stable and unstable manifolds, respectively. Obviously, $W_{\omega,\varepsilon}^u(p)$ is a ball of radius $\varepsilon$ in $\{p\} \times \mathbb{R}^2$ centred at $p$. Let $v : \Omega \times M \to TM$ be a continuous vector field such that $v(\omega,p) \in E_{\omega}^u(p)$. Then the initial value problem
\[
dq_{\omega}/dt = v(\omega,q_{\omega}(t)), \quad \text{with } q_{\omega}(0) = p
\]
has a solution which is continuous in $\omega$. The part of the curve $q_{\omega}(t) \cap B(p,\varepsilon)$ is contained in $W_{\omega,\varepsilon}^u(p)$, where $B(p,\varepsilon)$ is a ball centred at $p$ of radius $\varepsilon$. Since $\|Dg_q^{-1}\|_{E^u} \leq 1$ the distance along $q_{\omega}(t)$ does not grow under backward iterates of $g_{\omega}$. Now suppose there are two solution through $p$ for \(109\) $q_{\omega}(t)$ and $\tilde{q}_{\omega}(t)$. Fix $t_0 > 0$ small enough so that $q_{\omega}(t_0) \in W_{\omega,\varepsilon}^u(p)$ and $q_1 = W^s(q_0) \cap \tilde{q}_{\omega}(\cdot) \cap B(p,\varepsilon) \in W_{\omega,\varepsilon}^s(p)$. Notice that $d(g_{\omega}^{-n}(p),g_{\omega}^{-n}(q_1)) \leq \varepsilon$, $i = 0, 1$ and any $n \in \mathbb{N}$; however, there exists an $n \in \mathbb{N}$ such that $d(g_{\omega}^{-n}(q_0),g_{\omega}^{-n}(q_1)) > 2\varepsilon$. This leads to a contradiction. Now the global centre-unstable manifold at $p$ is defined as
\[
W_{\omega}^u(p) = \bigcup_{k=0}^{\infty} g_{\sigma^{-k}\omega}^k W_{\sigma^{-k}\omega,\varepsilon}^u(g_{\sigma^{-k}\omega}^k(p)).
\]

Let $\Lambda_{\omega} = K_{\omega} \cap ((0,1) \times \mathbb{D}^2)$. For every $(x,y,z) \in \Lambda_{\omega}$ set $\gamma^s(x,y,z) = \{(x,y,z) \mid (y,z) \in \mathbb{D}^2\}$ and let $\gamma^u(x,y,z)$ be the connected component of $\Lambda_{\omega}$ that contains $(x,y,z)$. Thus, $\Lambda_{\omega}$ admits a hyperbolic product structure and it is measurable in $\omega$ by definition.

We now show the random systems satisfies (P0)-(P4) for a suitable partition of $\Lambda_{\omega}$. For each $\omega$ we define a random sequence of pre-images of $\frac{1}{2}$ as follows. Let $x_0^\pm(\omega) = \frac{1}{2}$, and
\[
x_{n}^\pm(\omega) = (T_\omega^\pm)^{-1} x_{n-1}(\sigma\omega) \text{ for } n \geq 2,
\]
where $T_\omega^+ = T_\omega(\frac{1}{2},1)$ and $T_\omega^- = T_\omega(0,\frac{1}{2})$. Set $I_n(\omega)^- = (x_n^-(\omega),x_{n-1}^-(\omega))$ and $I_n(\omega)^+ = (x_n^+(\omega),x_{n-1}^+(\omega))$. We define $s$-subsets as $\Lambda_{n,\omega}^\pm = \{ \{x\} \times \gamma^s(\omega) \mid x \in I_n^\pm(\omega) \}$. Obviously, $\Lambda_{n,\omega}^\pm$ is a mod 0 partition of $\Lambda_{\omega}$ and $g_{\omega}^{n+1}(\Lambda_{n,\omega}^\pm)$ is a u-subset, since $T_\omega^n(I_n(\omega)^-) = (\frac{1}{2},1)$, $T_\omega^n(I_n(\omega)^+) = (0,\frac{1}{2})$ and consequently $T_\omega^{n+1}(I_n(\omega)^\pm) = (0,1)$. Properties (P0)-(P2) are then automatically satisfied. Uniform expansion in (P3) is obvious from the construction. Bounded distortion in (P3) is the same as in \[14\] \[15\], since $D^u g_{\omega}^{R_\omega} = (T_\omega^{R_\omega})'$. In this situation (P4) is obvious, since the projection along stable leaves is just the orthogonal projection to the $x$-axis. Aperiodicity is easy and can be verified in the same way as in \[15\]. Further the tail assumptions, including the uniform tail assumption, of Theorem \[1.3\] are verified in the same way as in \[15\] and we obtain
\[
\begin{aligned}
\text{Leb}_{\omega} \{ R_\omega > n \} & \leq Cn^{-1/\alpha} \log n, \quad \text{whenever } n \geq n_1(\omega), \\
P\{ n_1 > n \} & \leq Ce^{-\alpha n},
\end{aligned}
\]
moreover, \( \int \text{Leb}_\omega \{ R_\omega = n \} dP(\omega) \leq C (\log n)^{\frac{1}{\alpha_0} + 1} n^{-\frac{1}{\alpha_0} - 1} \). Therefore, by Theorem 14 we have

\[
|C_n(\varphi, \psi, \mu_\omega)| \leq C_{\varphi, \psi, \mu} \max \left\{ C_{\omega} n^{1+\varepsilon-1/\alpha_0}, \delta^{\eta}_{\sigma(\mu_\omega, \mu_n)} \right\}
\]

and \( P\{ C_\omega > n \} \leq C e^{b' n^{\theta'}} \) for some \( b', \theta' \in (0, 1] \). We now obtain an estimate on \( \delta^{\eta}_{\sigma(\mu_\omega, \mu_n)} \). Notice that

\[
\delta^{\eta}_{\sigma^{k}\omega, \omega} = \sup_{A \in \mathcal{Q}_k'} \text{diam}(\pi_{\sigma^{k}\omega}(F_k^\omega(A))) \leq \max \left\{ 10^{-k}, \sup_{A \in \mathcal{Q}_k'} \text{diam}(\pi_{\sigma^{k}\omega}(F_k^\omega(\bar{A}))) \right\},
\]

and \( \bar{B} = \tilde{F}_k^\omega(\bar{A}) \in \tilde{Q}_k^{\sigma^{k}\omega} \). We consider two cases. First, if \( \tilde{R}_{\sigma^{k}\omega}|\bar{B} > k \), then \( \pi_{\sigma^{k}\omega}\bar{B} \subset \{ R_{\sigma^{k}\omega} > k \} \). Thus, \( \text{diam}(\pi_{\sigma^{k}\omega}\bar{B}) \leq C k^{-1/\alpha_0} \log k \) for \( k > n_1(\sigma^{k}\omega) \). Second if \( \tilde{R}_{\sigma^{k}\omega}|\bar{B} \leq k \), then there exists \( N \) such that \( S_N \leq k \leq S_{N-1} \) and \( m \leq N \) such that \( S_m - S_{m-1} \geq \frac{k}{N} \). Let \( U = f_{\omega_{N-1}}(\bar{B}) \). Observe that \( U \subset \tilde{Q} \in \tilde{Q}_\omega', \), where \( \omega' = \sigma^{k+S_{m-1}} \), and \( \tilde{R}_{\omega'}|\tilde{Q} \geq \frac{k}{N} \).

By (P3) we have \( |\bar{B}| \leq D \theta^{N-1}|\bar{Q}| \). Thus, if there exists \( c > 0 \) such that \( N \sim k^c \) then \( |\bar{B}| \leq D \theta^k \). On the other hand, if there exists \( c < 1 \) such that \( N \leq k^c \), then using we obtain \( |\bar{B}| \leq D \theta^{N-1} N^{1/\alpha_0} k^{-1/\alpha_0} \log k \leq C k^{-1/\alpha_0} \log k \), for any \( k^{1-c} > n_1(\omega') \). Finally, define

\[
n_2(\omega) = \min \left\{ n \mid \forall k > n, n_1(\sigma^j \omega) < k^{1-c}, k \leq j < 2k \right\},
\]

and notice that

\[
P(n_2 > n) \leq \sum_{k \geq n} \sum_{j=k+1}^{2k-1} P(n_1(\sigma^j \omega) \geq k^{1-c}) \leq C e^{-\tau' n^{\theta'}},
\]

for some \( \tau' > 0 \). Now define \( \bar{C}_\omega = \max \{ C_\omega, n_2(\omega)^{1/\alpha_0} \} \). Then the theorem holds with \( \bar{C}_\omega \).
