Abstract

We introduce the novel multivariate decomposition finite element method (MDFEM) for solving elliptic PDEs with lognormal diffusion coefficients, that is, when the diffusion coefficient $a$ has the form $a = \exp(Z)$ where $Z$ is a Gaussian random field defined as $Z(y) = \sum_{j \geq 1} y_j \phi_j$ with $y_j \sim N(0, 1)$ and a sequence of functions $\{\phi_j\}_{j \geq 1}$. We estimate the expected value of some linear functional of the solution as an infinite-dimensional integral over the parameter space. The proposed algorithm combines the multivariate decomposition method (MDM), to compute infinite-dimensional integrals, with the finite element method (FEM), to solve different instances of the PDE. This allows us to apply higher-order multivariate quadrature methods for integration over the Euclidean space with respect to the Gaussian distribution, and, hence, considerably improves upon existing results which only use first order quadrature rules.

We develop multivariate quadrature methods for integration over the finite-dimensional Euclidean space with respect to the Gaussian distribution. By linear transformations of interlaced polynomial lattice rules from a unit cube to a multivariate box of the Euclidean space we achieve higher-order convergence rates for functions belonging to a class of anchored Gaussian Sobolev spaces. These quadrature rules are then used in the MDFEM algorithm.

Under appropriate conditions, applying higher-order cubature rules we achieve higher-order convergence rates in term of error vs cost, i.e., the computational cost to achieve an accuracy of $O(\epsilon)$ is $O(\epsilon^{-(1+d/\tau)\rho^*/(1-p^*)-d/\tau})$, where $d$ is the physical dimension, $\tau$ is the convergence rate of the finite element method and $p^*$ represents the sparsity of $\{\phi_j\}_{j \geq 1}$. For example, let $d = 1$, $\tau = 2$ and $p^* = \frac{1}{6}$ the cost of attaining the error of $O(\epsilon)$ is $O(\epsilon^{-4/5})$.

Keywords: elliptic PDE, stochastic diffusion coefficient, lognormal case, infinite-dimensional integration, multivariate decomposition method, finite element method, higher order quadrature rule, complexity bounds.

1 Introduction

In this paper we are concerned with the application of higher-order quasi-Monte Carlo (QMC) rules and multivariate decomposition methods (MDM) to elliptic PDEs with random diffusion.
coefficients. We focus on the lognormal diffusion coefficient, the logarithm of which is a Gaussian random field. The goal is to compute the expected value of some functional of the solution. This method was motivated by the need for new techniques for elliptic PDEs with smooth lognormal diffusion coefficients where the classical approaches fail.

A theoretical analysis of (higher-order) QMC rules and the MDM applied to this type of model problem but with uniform diffusion was recently introduced in [27]. By using suitable higher-order QMC rules and FE approximations the MDM takes less computational cost to achieve a comparable approximation than the standard QMCFEM, see, e.g., [11]. For lognormal diffusions we cope with a more challenging problem where the expectation or corresponding integration is taken with respect to the Gaussian distribution over an unbounded domain of the Euclidean space, where existing higher-order QMC algorithms are not directly applied. To solve this problem we propose to use a truncation method recently developed in [7], see also [26]. Exploiting the fast decay of the Gaussian distribution toward infinity the Euclidean domain is truncated, the resulting integral is transformed to the unit cube using a linear transformation, and finally, suitable higher-order QMC rules are applied. The proposed algorithm allows us to achieve arbitrarily higher-order convergence for sufficiently smooth integrands.

Let \( D \subset \mathbb{R}^d \) be a bounded polygon domain in \( \mathbb{R}^d \), with typically \( d = 1, 2 \) or 3, with boundary \( \partial D \). We consider the following elliptic Dirichlet problem

\[
-\nabla \cdot (a(x, y) \nabla u(x, y)) = f(x), \quad \text{for } x \text{ in } D, \quad (1)
\]

\[
u(x, y) = 0, \quad \text{for } x \text{ on } \partial D.
\]

Here, the gradient operator \( \nabla \) is taken with respect to \( x \) and \( a : D \times \Omega \rightarrow \mathbb{R} \) with some \( \Omega \subset \mathbb{R} \).

We consider the case when \( y = \{y_j\}_{j \geq 1} \) is a sequence of parameters distributed on \( \mathbb{R}^N \) according to the product Gaussian measure \( \mu = \bigotimes_{j \geq 1} \mathcal{N}(0, 1) \), and the diffusion coefficient takes the form

\[
a(x, y) := \exp(Z(x, y)), \quad (2)
\]

with

\[
Z(x, y) := \sum_{j \geq 1} y_j \phi_j(x), \quad y_j \in \Omega = \mathbb{R}, \quad y_j \sim \mathcal{N}(0, 1), \quad (3)
\]

where \( \{\phi_j\}_{j \geq 1} \) is a suitable system of real-valued, bounded, and measurable functions.

Let \( G \) be a linear and bounded functional of the solution \( u \). We are interested in computing the expected value of \( G(u) \) with respect to the probability distribution \( \mu \), i.e.,

\[
\mathbb{E}[G(u)] := I(G(u)) := \int_{\mathbb{R}^n} G(u(\cdot, y)) \, d\mu(y), \quad (4)
\]

where

\[
d\mu(y) := \prod_{j \geq 1} \rho(y_j) \, dy_j, \quad \rho(y) := \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2}}.
\]

The weak (or variational) formulation of problem (1) is to find for a given \( y \in \Omega^N \) the solution \( u(\cdot, y) \in V := H^1_0(D) \) such that

\[
\mathcal{B}(y; u, v) := \int_D a(x, y) \nabla u(x, y) \cdot \nabla v(x) \, dx = \int_D f(x)v(x) \, dx, \quad \forall v \in V. \quad (5)
\]
Under some assumptions on the system \( \{ \phi_j \}_{j \geq 1} \) we will show the existence, the uniqueness and an a priori estimation of the solution of the weak formulation. The following assumptions are standard, see, e.g., [1, 2, 16, 19]: assume that there exists a positive sequence \( \{ b_j \}_{j \geq 1} \) with \( 0 < b_j \leq 1 \) for all \( j \) such that the positive constant \( \kappa \), given below, satisfies

\[
\kappa := \left\| \sum_{j \geq 1} \frac{\phi_j}{b_j} \right\|_{L^\infty(D)} < \infty,
\]

and

\[
\{ b_j \}_{j \geq 1} \in \ell^{p^*}(\mathbb{N}) \text{ for some } p^* \in (0, \infty).
\]

Let us define for some space \( X \) and \( p \in (0, \infty) \)

\[
\| v \|_{L^p,\rho}(\mathbb{R}^n; X) := \left( \int_{\mathbb{R}^n} \| v \|_{X}^p \rho(y) \, dy \right)^{1/p}
\]

The following result is implied from [1, Theorem 2.1 and Remark 2.2].

**Proposition 1.** Under conditions (6) and (7) it holds that \( \| a \|_{L^p,\rho}(\mathbb{R}^n; L^\infty(D)) < \infty \) for all \( p \in [1, \infty) \).

For \( \mu \)-a.s. \( y \in \mathbb{R}^N \) we define two random variables

\[
a_{\min}(y) := \essinf_{x \in D} a(x, y), \quad a_{\max}(y) := \sup_{x \in D} |a(x, y)|.
\]

Under the assumption of Proposition 1 the bilinear form \( \mathcal{B}(y; \cdot, \cdot) \) is continuous and coercive for \( \mu \)-a.s. \( y \) with constants \( a_{\min}(y) \) and \( a_{\max}(y) \), respectively. Indeed, using Proposition 1 and by the definition of the parameter \( a \) we have for \( \mu \)-a.s. \( y \in \mathbb{R}^N \)

\[
a_{\min}(y) \geq \exp \left( - \left\| Z(\cdot, y) \right\|_{L^\infty(D)} \right) \frac{1}{\| a(\cdot, y) \|_{L^\infty(D)}} > 0,
\]

and

\[
a_{\max}(y) \leq \exp \left( \left\| Z(\cdot, y) \right\|_{L^\infty(D)} \right) = \| a(\cdot, y) \|_{L^\infty(D)} < \infty.
\]

Applying Proposition 1 leads to

\[
\left\| \frac{1}{a_{\min}} \right\|_{L^p,\rho}(\mathbb{R}^n) \leq \| a \|_{L^p,\rho}(\mathbb{R}^n; L^\infty(D)) < \infty.
\]

For any \( u(\cdot, y) \) and \( v \) belonging to \( V \) using Hölder’s inequality we have

\[
|\mathcal{B}(y; u, v)| = \left| \int_D a(x, y) \nabla u(x, y) \cdot \nabla v(x) \, dx \right| \leq a_{\max}(y) \| u(\cdot, y) \|_V \| v \|_V.
\]

Taking \( v = u(\cdot, y) \) in (5) yields

\[
\mathcal{B}(y; u, u) = \int_D a(x, y) \nabla u(x, y) \cdot \nabla u(x, y) \, dx \geq a_{\min}(y) \| u(\cdot, y) \|_V^2.
\]
The Lax–Milgram lemma implies that there is a unique solution $u$ of the weak form (5), moreover,

$$
\|u(\cdot, \mathbf{y})\|_V \leq \frac{\|f\|_{V^* \cdot}}{a_{\text{min}}(\mathbf{y})}.
$$

Taking the $L_{p,\rho}(\mathbb{R}^n)$ norm of both sides of (11) and applying (10) we have

$$
\|u\|_{L_{p,\rho}(\mathbb{R}^n, V)} \leq \frac{1}{a_{\text{min}}} \left( \frac{1}{L_{p,\rho}(\mathbb{R}^n)} \right) \|f\|_{V^*} < \infty,
$$

for any $f \in V^*$ and $p \in [1, \infty)$.

To compute (4) we cope with three computational challenges: first, the infinite number of variables of the integrand; second, the integration domain is unbounded whereas most existing quasi-Monte Carlo methods integrate only over unit cubes; and, third, the integrand involves solutions of PDEs.

Let us discuss how to solve these problems in more detail. First, to approximate an infinite-dimensional integral we will exploit the multivariate decomposition method, which is developed based on the earlier changing dimension method, see, e.g., [21, 24, 30]. The goal is to decompose the infinite-dimensional problem into multiple finite-dimensional ones. By assessing the relative contribution of specific sets of variables, for a given desired error, the MDM will decide which ones to include in a so-called active set to approximate the infinite MDM sum. We argue, see Proposition 8, that provided certain conditions on $\{\phi_j\}_{j \geq 1}$ are satisfied, sets in the active set have relatively low cardinalities, such that only relatively low-dimensional problems remain which can be solved at small cost. This is the reason why the MDM algorithm improves the complexity of computation.

Next, to compute integrals over the Euclidean space, we exploit the fast decay of the Gaussian distribution to truncate the unbounded domain into boxes. We then use a linear transformation to map the truncated integral into the unit cube. Finally, we apply existing higher-order quasi-Monte Carlo rules, see, e.g., [7, 27]. This is in contrast to existing methods which use the inverse of the Gaussian cumulative distribution function to map the integral into the unit cube and then apply particular QMC rules, see, e.g., [23, 28]. Using such nonlinear mappings might make the transformed integrand singular in the sense that their mixed derivatives might not exist or are unbounded. As a remedy, special function spaces and QMC rules were developed, however, only achieved first order convergence rates which are independent of the dimension of the integrand. The proposed QMC method in this paper by using the linear mapping avoids damaging the smoothness of the integrand. As a result, it allows to achieve arbitrarily higher-order convergence rates for sufficiently smooth integrands. Here, the constant might depend exponentially of the dimension, see Theorem 1, however, since the active set of the MDM algorithm consists of functions of few variables this exponential growth will be controlled, see Proposition 8.

Last, for each variable $\mathbf{y}$ sampled by the QMC method the original stochastic PDE becomes a deterministic one. To solve such problem we use the finite element method (FEM). The combination of the multivariate decomposition method with the finite element method is called the multivariate decomposition finite element method or MDFEM in short.

The structure of this paper is as follows. Section 2 presents main steps of the MDFEM algorithm. Section 3 introduces higher-order QMC rules for multivariate integrals over the Euclidean space with respect to the Gaussian distributions. A novel anchored Gaussian Sobolev function space is introduced and QMC rules are developed for that specific space. Section 4 recalls the definition of interlaced polynomial lattice rules, studies and analyzes their error. Section 5 discusses the parametric regularity of the solution of the PDE. Section 6 previews the finite element method. Under some conditions on the system $\{\phi_j\}_{j \geq 1}$ a novel result on the spatial Hölder
smoothness of the solution of the PDE is derived. Section 7 presents the main contribution of this paper where the cost model, the construction and the complexity of the MDFEM algorithm are presented. A comparison of the MDFEM and the standard QMCFEM is also given which shows the out-performance of the MDFEM.

We will use some notations. We write \( \mathbb{N} := \{1, 2, \ldots\} \) and \( \mathbb{N}_0 := \{0, 1, 2, \ldots\} \). For any \( s \in \mathbb{N} \) we denote by \( \{1 : s\} \) the set of indices \( \{1, 2, \ldots, s\} \). For any \( m \in \mathbb{N}_0 \) let \( C^m(D) \) denote the Hölder space of all functions that are \( m \) times continuously differentiable on \( D \) with norm

\[
\|v\|_{C^m(D)} := \sum_{0 \leq |\tau| \leq m} \sup_{x \in D} |\partial^\tau v(x)|,
\]

for \( \tau \in \mathbb{N}_0^d \) with \( |\tau| := \sum_{j=1}^d \tau_j \). For any real \( r > 0 \) such that \( r \notin \mathbb{N} \) we set \( r = [r] + \{r\} \) and define the following norm

\[
\|v\|_{C^r(D)} := \|v\|_{C^{[r]}(D)} + \max_{|\tau| = [r]} \sup_{x \in D ; \, x \neq x'} \frac{|\partial^\tau v(x) - \partial^\tau v(x')|}{\|x - x'\|^{[r]}},
\]

where \( \|\cdot\| \) is the Euclidean norm. Both the cardinality of a set and the \( \ell^1 \) norm of a vector are denoted by \( |\cdot| \) but it should be clear from the context whichever is meant.

## 2 Application of the MDM to PDEs: MDFEM

In this section we introduce the main steps of MDFEM algorithm. Let us first recall some definitions and notations from [27]. For any \( u \subset \mathbb{N} \), with \( |u| < \infty \), we denote by \( y_u \) the vector \( y \in \mathbb{R}^N \) such that \( (y)_j = y_j \) for \( j \in u \) and 0 otherwise, and by \( u(\cdot, y_u) \) the \( u \)-projected solution of \eqref{eq:u} with \( y = y_u \), that is, the solution of the problem:

\[
-\nabla \cdot (a(x, y_u)\nabla u(x, y_u)) = f(x) \quad \text{for } x \in D, \quad u(x, y_u) = 0 \quad \text{for } x \in \partial D,
\]

where \( a(\cdot, y_u) := \exp \left( \sum_{j \in u} y_j \phi_j \right) \). The weak formulation of the \( u \)-projected problem involves finding \( u(\cdot, y_u) \in V \) such that the following equation holds

\[
\mathcal{B}(y_u; u, v) := \int_D a(x, y_u)\nabla u(x, y_u) \cdot \nabla v(x) \, dx = \int_D f(x)v(x) \, dx, \quad \forall v \in V.
\]

An exact analytical solution of this problem is typically not available so a numerical approximation will be computed using the FEM. Let us define a finite dimensional subspace \( V^h \subset V \), where the \( h > 0 \) is to be specified below, and such that \( V^h \subset V^{h'} \subset V \) for \( h' < h \). The finite element approximation of the weak formulation of the \( u \)-projected problem denoted by \( u^h(\cdot, y_u) \) involves finding \( u^h(\cdot, y_u) \in V^h \) for a given \( y_u \) such that the following equation holds

\[
\mathcal{B}(y_u; u^h, v) := \int_D a(x, y_u)\nabla u^h(x, y_u) \cdot \nabla v(x) \, dx = \int_D f(x)v(x) \, dx, \quad \forall v \in V^h.
\]

The MDFEM algorithm relies on the multivariate decomposition, see, e.g., [25], of the solution

\[
u(\cdot, y) = \sum_{|u| < \infty} u_u(\cdot, y_u),
\]
where the sum is over all finite subsets \( u \subseteq \mathbb{N} \), and we take the anchored decomposition with anchor at 0 to obtain the components

\[
u_u(\cdot, y_u) := \sum_{v \subseteq u} (-1)^{|u| - |v|} u(\cdot, y_v),
\]

(12)

with \( u_0(\cdot, y_0) = u(\cdot, 0) \).

For any multi-index \( \omega_u \in \mathbb{N}^{[u]} \) let us denote \( \partial^{\omega_u} \partial y : = \partial^{[u]} / \prod_{j \in u} \partial y_j \) with \( |\omega_u| := \sum_{j \in u} \omega_j \) and by \( (\partial^{\omega_u} F) (y) \) the value of such partial derivative of the function \( F \) at \( y \). For any \( u \subseteq \mathbb{N} \) the function \( u_u \) satisfies the following properties. The proof of this result is provided in the appendix.

**Lemma 1.** For any \( u \subseteq \mathbb{N} \) the function \( u_u \) depends only on the variables listed in \( u \) and satisfies

\[
u_u(\cdot, y_u) = 0 \text{ when any component of } y_u \text{ equals } 0.
\]

(13)

Moreover, if the solution \( u \) has derivatives of arbitrarily high order with respect to the variable \( y \), see Proposition 4 below, then

\[
(\partial^{\omega_u} u_u)(\cdot, y_u) = (\partial^{\omega_u} u(\cdot, u))(\cdot, y_u) \text{ for any } \omega_u \in \mathbb{N}^{[u]} \text{ and any } y_u \in \mathbb{R}_u,
\]

(14)

and

\[
(\partial^{\omega_u} u_u)(\cdot, 0_u) = 0 \text{ for any } \omega_u \in \mathbb{N}^{[u]} \text{ such that } w \subseteq u.
\]

(15)

Since the functional \( G \) is linear we write

\[
G(u(\cdot, y)) = \sum_{|u| < \infty} G(u_u(\cdot, y_u)) = \sum_{|u| < \infty} \sum_{v \subseteq u} (-1)^{|u| - |v|} G(u(\cdot, y_v)).
\]

(16)

We remark that also because \( G \) is a linear operator the function \( G(u_u(\cdot, u)) \) has the same properties (13), (14) and (15) as \( u_u(\cdot, u) \).

Under the conditions (6) and (7) the decomposition (16) is well-defined. This is deduced using similar arguments as in [27, Remark 5]. Therefore, we can interchange integral and sum to obtain

\[
I(G(u)) = \int_{\mathbb{R}^u} \sum_{|u| < \infty} G(u_u(\cdot, y_u)) \, d\mu(y) = \sum_{|u| < \infty} \int_{\mathbb{R}^u} G(u_u(\cdot, y_u)) \, d\mu(y)
\]

\[
= \sum_{|u| < \infty} \int_{\mathbb{R}^{[u]}} G(u_u(\cdot, y_u)) \, d\mu_u(y_u) =: \sum_{|u| < \infty} I_u(G(u_u)),
\]

(17)

where \( d\mu_u(y_u) := \prod_{j \in u} \rho(y_j) \, dy_j \).

The MDFEM algorithm to approximate (17) takes the form

\[
Q(G(u)) = \sum_{u \in \mathcal{M}} Q_{u,u}(G(u_u^{h^u})) := \sum_{u \in \mathcal{M}} \sum_{i=0}^{n_u - 1} w_u^{(i)} G(u_u^{h^u}(\cdot, y_u^{(i)}))
\]

(18)

where \( Q_{u,u} \) are cubature rules with \( \{(y_u^{(i)}, w_u^{(i)})\}_{i=0}^{n_u - 1} \) being their cubature nodes and respective weights, and

\[
G(u_u^{h^u}(\cdot, y_u)) := \sum_{v \subseteq u} (-1)^{|u| - |v|} G(u (\cdot, y_v)).
\]

(19)
We remind that $u^{h_u}$ is the FE approximation with mesh width $h_u$ of the solution $u$ and emphasize here that to approximate $u(\cdot, y_v)$ for all $v \subseteq u$ we use the same $h_u$.

The computational cost of the MDFEM algorithm is given as

$$\text{cost}(Q) := \sum_{u \in U} n_u \times \text{cost of evaluating } G(u^{h_u}).$$

There are three sources of error in the approximation (18): the error comes from truncating the infinite sum, the QMC error and the FEM error. They are gathered into two terms as follows

$$|I(G(u)) - Q(G(u))| \leq \left| \sum_{u \in U} I_u(G(u_u)) \right| + \left| \sum_{u \in U} (I_u(G(u_u)) - I_u(G(u^{h_u}_u))) + (I_u - Q_{u,n}u) (G(u^{h_u}_u)) \right|. \quad (21)$$

A sufficient condition to achieve an approximation error of $\epsilon > 0$ is that both of these terms are less than $\epsilon/2$. This forces us to construct the active set $\mathcal{U}$ such that the first term is bounded by $\epsilon/2$. For all $u \in \mathcal{U}$ the FE space $V^{h_u}$ and the cubature rule $Q_{u,n}u$ are chosen such that the second term is bounded by $\epsilon/2$ with optimal computational cost (20).

3 Higher-order quasi-Monte Carlo rules for finite dimensional integration with respect to the Gaussian distribution

In this section we consider quasi-Monte Carlo rules for approximating integrals over $\mathbb{R}^s$ with respect to the Gaussian distribution. Particularly, we are interested in computing $s$-dimensional integrals of the form

$$I_s(F) := \int_{\mathbb{R}^s} F(y)\rho(y) \, dy,$$

where with an abuse of notation we omit the subscript referring to the dimension of $\rho$ and write

$$\rho(y) := \prod_{j=1}^s \rho(y_j) \, dy_j, \quad \rho(y) = \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2}}.$$

We first truncate the Euclidean domain into a multidimensional box, then use a linear mapping to transform the truncated integral into one over the unit cube, which is finally approximated using suitable cubature rules. More precisely, the truncated and transformed integrals respectively have the following forms

$$I_s^T(F) := \int_{[-T,T]^s} F(y)\rho(y) \, dy = (2T)^s \int_{[0,1]^s} F(T(y))\rho(T(y)) \, dy,$$

for some $T > 0$ and the mapping $T : [0,1]^s \rightarrow [-T,T]^s$ is defined as

$$T(y) = (2Ty_1 - T, \ldots, 2Ty_s - T).$$
The final integral is approximated using an $n$-point QMC rule of the form
\[
Q_{s,n}(F) := \frac{(2T)^s}{n} \sum_{i=0}^{n-1} F(T(y^{(i)})) \rho(T(y^{(i)})),
\]
where $\{y^{(i)}\}_{i=0}^{n-1}$ are well chosen cubature points.

In the present for simplifying the notation we will drop the index in the derivative and write $F^{(\tau)} := \partial_\tau^\tau F$ for any $\tau \in \mathbb{N}_0^n$, the value of such derivative at $y$ is denoted by $F^{(\tau)}(y)$. The function $F$ is general and depends on $s$ variables, however, in further applications $F$ will be of the form $F(u_a) = G(u_a(\cdot, y_u))$ for some $u$ such that $|u| = s$. As discussed in the previous section the function $F(u) = G(u(\cdot, y_u))$ have the same properties (13), (14) and (15) as $u_a(\cdot, y_u)$. Currently only the properties (13) and (15) are needed, the property (14) will be used in further parts. As a result, we now only consider the integrand $F$ such that $F(y) = 0$ if any component of $y$ is equal to 0, and $F^{(\nuw)}(0) = 0$ for any $\nuw \in \{1 : \alpha\}^{[n]}$ such that $\nuw$ being a proper subset of $\{1 : s\}$. Here, $\alpha \in \mathbb{N}$ is the smoothness parameter.

### 3.1 Reproducing kernel Hilbert space

We begin with introducing the one dimensional function space. The space $H_{\alpha,0,\rho}(\mathbb{R})$ consists of integrable functions over $\mathbb{R}$ with respect to the Gaussian distribution having absolutely continuous derivatives up to order $\alpha - 1$ and square integrable derivative of order $\alpha$ over $\mathbb{R}$ with respect to the Gaussian distribution. The inner product is defined as
\[
\langle F, G \rangle_{H_{\alpha,0,\rho}(\mathbb{R})} := \sum_{\tau=1}^{\alpha-1} F^{(\tau)}(0) G^{(\tau)}(0) + \int_{\mathbb{R}} F^{(\alpha)}(y) G^{(\alpha)}(y) \rho(y) \, dy.
\]
This space is called the anchored Gaussian Sobolev space with anchor at 0. The associated norm is given by $\| \cdot \|_{H_{\alpha,0,\rho}(\mathbb{R})} := \sqrt{\langle \cdot, \cdot \rangle_{H_{\alpha,0,\rho}(\mathbb{R})}}$ which is actually a norm due to the fact that $F(0) = 0$.

There exists yet another Gaussian Sobolev space whose norm as well involves derivatives, see, e.g., [7, 17, 18]. However, instead of anchoring the values of the function and its derivatives up to order $\alpha - 1$ at 0 as in (23) that space takes their averages over $\mathbb{R}$ against the Gaussian distribution. We refer to such space as the unanchored Gaussian Sobolev space. Since functions in there can be represented using Hermite polynomials the unanchored Gaussian Sobolev space is also called the Hermite function space. For more details on this space we refer to [7, 17, 18].

In this paper it suffices to consider the anchored Gaussian Sobolev space $H_{\alpha,0,\rho}(\mathbb{R})$. This is also a reproducing kernel Hilbert space, the reader will find that this property is particularly useful for the error analysis of the MDFEM algorithm. The kernel is given by
\[
K_{\alpha,0,\rho}(x,y) = \sum_{\tau=1}^{\alpha-1} \frac{x^\tau y^{\tau}}{\tau!} + \mathbf{1}_{\{|xy| > 0\}}(xy) \int_0^{+\infty} \frac{(|x| - t)_+^{\alpha-1} (|y| - t)_+^{\alpha-1}}{(\alpha - 1)!} \frac{1}{\rho(t)} \, dt,
\]
where $\mathbf{1}_X(\cdot)$ is the indicator function on the set $X$, $(|x| - t)_+ := \max(|x| - t, 0)$ and $(|x| - t)_+^\alpha := \mathbf{1}_{|x| > t}$, and the empty sum is defined as 0. Such formulas for $H_{\alpha,0,\rho}(\mathbb{R})$ with $\alpha = 1$ was given in [28, Section 3.3]. A slightly different kernel for another anchored Sobolev space over the Euclidean space of higher order smoothness, although, without the specific Gaussian distribution was given in [29, Section 11.5.1]. For completeness we provide the full derivation of this kernel in the appendix.
According to the setting of the MDM, see [27], we need to show that the square root of $K_{\alpha,0,\rho}$ is measurable. Indeed, we have for any $y > 0$

$$K_{\alpha,0,\rho}(y,y) = \sum_{r=1}^{\alpha-1} \frac{|y|^{2r}}{(r!)^2} + \int_0^y (y-t)^{2(\alpha-1)} \frac{dt}{(\alpha-1)!} \leq \sum_{r=1}^{\alpha-1} \frac{|y|^{2r}}{(r!)^2} + \frac{1}{\rho(y)} \int_0^y (y-t)^{2(\alpha-1)} \frac{dt}{(\alpha-1)!}$$

The same bound holds for any $y < 0$. Thus, using $\left(\sum_j a_j^2\right)^{1/2} \leq \sum_j |a_j|^{1/2}$ we have

$$\int_{\mathbb{R}} (K_{\alpha,0,\rho}(y,y))^{1/2} \rho(y) \, dy \leq \int_{\mathbb{R}} \left(\sum_{r=1}^{\alpha-1} \frac{|y|^r}{r!} + \frac{1}{\sqrt{\rho(y)}} \frac{|y|^{\alpha-1/2}}{(\alpha-1)!}^{1/2}\right) \rho(y) \, dy \leq \sum_{r=1}^{\alpha-1} \frac{2^{r/2} \Gamma(r/2 + 1/2)}{\sqrt{\pi}} + \frac{2^{\alpha+1/4} \Gamma(\alpha/2 + 1/4)}{\pi^{1/4}} =: M,$$  \hfill (25)

where $\Gamma(\cdot)$ is the Gamma function.

The multivariate space is defined as the tensor product of the one dimensional spaces with the kernel given by

$$K_{\alpha,0,\rho,\omega}(x,y) := \prod_{j=1}^{s} K_{\alpha,0,\rho}(x_j, y_j).$$

The corresponding inner product is

$$\langle F, G \rangle_{H_{\alpha,0,\rho,\omega}(\mathbb{R}^s)} := \sum_{\mathbf{x} \in \{1: s\}} \int_{\mathbb{R}^s} F(x,0_{-\mathbf{v}}) G(x,0_{-\mathbf{v}}) \rho(x) \, dx,$$

where $\rho(x) := \prod_{j \in \mathbf{v}} \rho(x_j)$, $-\mathbf{v} := \{1: s\} \setminus \mathbf{v}$ and $y := (y_\mathbf{v},0_{-\mathbf{v}})$ is a vector of $s$ variables such that $(y)_j = y_j$ for $j \in \mathbf{v}$ and 0 otherwise. In many references, see, e.g., [4, 20], the inner product is usually written as a double sum as follows

$$\langle F, G \rangle_{H_{\alpha,0,\rho,\omega}(\mathbb{R}^s)} = \sum_{\mathbf{w} \subseteq \{1: s\}} \sum_{\mathbf{v} \subseteq \{1: s\}} \int_{\mathbb{R}^s} F(\mathbf{a}_\mathbf{w},0_{-\mathbf{v}}) G(\mathbf{a}_\mathbf{w},0_{-\mathbf{v}}) \rho(\mathbf{x}) \, d\mathbf{x},$$  \hfill (26)

where $\mathbf{w} := (\mathbf{a}_\mathbf{w},0_{-\mathbf{w}})$ is a vector of $s$ variables such that $(\mathbf{w})_j = \tau_j$ for $j \in -\mathbf{v}$ and $\alpha$ otherwise.

The corresponding norm is given by $\| \cdot \|_{H_{\alpha,0,\rho,\omega}(\mathbb{R}^s)} := \sqrt{\langle \cdot, \cdot \rangle_{H_{\alpha,0,\rho,\omega}(\mathbb{R}^s)}}$.

We will also need a function space over the unit cube. Let us define the unanchored Sobolev space over the unit cube $H_{\alpha,0,\omega}([0,1]^s)$. For the one dimensional case its inner product is given by

$$\langle F, G \rangle_{H_{\alpha,0,\omega}([0,1])} := \sum_{\tau=0}^{\alpha-1} \int_0^1 F^{(\tau)}(y) \, dy \int_0^1 G^{(\tau)}(y) \, dy + \int_0^1 F^{(\alpha)}(y) G^{(\alpha)}(y) \, dy,$$

with norm $\| \cdot \|_{H_{\alpha,0,\omega}([0,1])} := \sqrt{\langle \cdot, \cdot \rangle_{H_{\alpha,0,\omega}([0,1])}}$. 

9
The multivariate space is the tensor product of the one dimensional space with inner product
given by
\[
\langle F,G \rangle_{H^\alpha,\rho_s([0,1]^s)} := \sum_{\tau \in \{0,\alpha\}^s} \int_{[0,1]^s} \int_{[0,1]^s} F(\tau)(y) \, dy \, \rho(y) \int_{[0,1]^s} G(\tau)(y) \, dy \, \rho(y),
\]
and norm \( \| \cdot \|_{H^\alpha,\rho_s([0,1]^s)} := \sqrt{\langle \cdot, \cdot \rangle_{H^\alpha,\rho_s([0,1]^s)}} \).

The following result states the relation between norms in \( H^\alpha_{\alpha,s}([0,1]^s) \) and in \( H_{\alpha,0,p,s}(\mathbb{R}^s) \) which is then needed for the QMC error analysis. The proof of this result is presented in the appendix.

**Proposition 2.** For any \( F \in H_{\alpha,0,p,s}(\mathbb{R}^s) \) and \( T \geq 1/2 \), the function \( (F \rho) \circ T : [0,1]^s \to \mathbb{R}^s \) belongs to \( H_{\alpha,s}([0,1]^s) \) and
\[
\| (F \rho) \circ T \|_{H_{\alpha,s}([0,1]^s)} \leq C_{1,\alpha} T^{(\alpha-1/2)s} \| F \|_{H_{\alpha,0,p,s}(\mathbb{R}^s)},
\]
where
\[
C_{1,\alpha} := \alpha! 2^{3\alpha} \left( \frac{\alpha}{2} + 1 \right) \frac{1}{\sqrt{2\pi}} \Gamma(2\alpha) I_0(1/4)^{1/2},
\]
and \( I_\alpha(\cdot) \) is the modified Bessel function of the first kind with \( I_0(1/4) \approx 1.015 \).

### 3.2 Higher-order quasi-Monte Carlo for integration over \( \mathbb{R}^s \)

This subsection investigates the cubature error of approximating integrals over \( \mathbb{R}^s \) with respect to the Gaussian distribution using the truncation strategy and higher-order quasi-Monte Carlo rules. The main result will be given in Theorem 1. A similar analysis, however, for the unanchored Gaussian Sobolev function space was given in [7, Theorem 2, Corollary 1] where infinite-dimensional interlaced digital sequences with integer rates of convergence were used. Nevertheless, because the MDM algorithm needs cubature rules with possibly non-integer convergence rates, we use interlaced polynomial lattice rules. We will provide their error analysis in the next subsection. But first we state our result.

**Theorem 1.** For any \( F \in H_{\alpha,0,p,s}(\mathbb{R}^s) \) with \( \alpha \in \mathbb{N} \) such that \( \alpha \geq 2 \) and any \( m \in \mathbb{N} \), let \( P_n \) be an interlaced polynomial lattice rule of order \( m \) with \( n = 2^m \) points achieving the convergence rate of order \( \lambda \in [1,\alpha) \) as in Theorem 2 below. The cubature rule \( Q_{s,n} \) defined as in (22) with \( T = 2 + 2\sqrt{\lambda \ln(n)} \) and cubature point set \( P_n \) has error bounded by
\[
| I_s(F) - Q_{s,n}(F) | \leq C_{2,\alpha,\lambda,s} \| F \|_{H_{\alpha,0,p,s}(\mathbb{R}^s)} (\ln(n))^{s(\alpha/2+1/4)} n^{-\lambda},
\]
where \( C_{2,\alpha,\lambda,s} \) is a constant independent of \( F \) and \( n \) defined below by (35).

**Proof.** The error splits into two terms
\[
| I_s(F) - Q_{s,n}(F) | \leq | I_s(F) - \int_{[-T,T]^s} F(y) \rho(y) \, dy | + | 2T^s \int_{[0,1]^s} F(T(y)) \rho(T(y)) \, dy - Q_{s,n}(F) |.
\]
The first term is the domain truncation error. Using the reproducing property of $H_{\alpha,0,p,s}(\mathbb{R}^r)$ and the Cauchy–Schwarz inequality we have

\[
\left| I_s(F) - \int_{[-T,T]^r} F(y) \rho(y) \, dy \right| \leq \int_{\mathbb{R}^r \setminus [-T,T]^r} |F(y)| \rho(y) \, dy
\]

\[
= \int_{\mathbb{R}^r \setminus [-T,T]^r} |(F(\cdot), K_{\alpha,0,p,s}(y, \cdot))| \rho(y) \, dy
\]

\[
\leq \|F\|_{H_{\alpha,0,p,s}(\mathbb{R}^r)} \int_{\mathbb{R}^r \setminus [-T,T]^r} \|K_{\alpha,0,p,s}(y, \cdot)\|_{H_{\alpha,0,p,s}(\mathbb{R}^r)} \rho(y) \, dy
\]

\[
= \|F\|_{H_{\alpha,0,p,s}(\mathbb{R}^r)} \int_{\mathbb{R}^r \setminus [-T,T]^r} (K_{\alpha,0,p,s}(y, y))^{1/2} \rho(y) \, dy. \tag{30}
\]

The integral of the right hand side is bounded as

\[
\int_{\mathbb{R}^r \setminus [-T,T]^r} (K_{\alpha,0,p,s}(y, y))^{1/2} \rho(y) \, dy \leq 2 \sum_{j=1}^n \int_T^1 \cdots \int_T^1 \cdots \int_T^1 \prod_{j=1}^n (K_{\alpha,0,p,s}(y_j, y_j))^{1/2} \rho(y_j) \, dy_j. \tag{31}
\]

We will estimate each of the above integrals. Using the same argument as in (25) we have for any $y \geq T \geq 2$

\[
\int_T^1 (K_{\alpha,0,p,s}(y, y))^{1/2} \rho(y) \, dy \leq \int_T^1 \left( \sum_{r=1}^{n-1} \left( \frac{|y|^r}{r!} \right) + \frac{1}{\sqrt{\rho(y)}} \frac{|y|^{\alpha-1/2}}{(\alpha-1)!} \left( \frac{2\alpha-1}{2(\alpha-1)} \right) \right) \rho(y) \, dy
\]

\[
\leq \int_T^1 \left( \sum_{r=1}^{n-1} \left( \frac{|y|^r}{r!} \right) + \frac{|y|^{\alpha}}{(\alpha)!} \left( \frac{1}{\sqrt{\rho(y)}} \right) \frac{\alpha}{T^{1/2}} \left( \frac{2\alpha-1}{2(\alpha-1)} \right) \right) \rho(y) \, dy
\]

\[
\leq \max \left\{ \sqrt{\rho(y)} \left( \frac{1}{T^{1/2}} \left( \frac{2\alpha-1}{2(\alpha-1)} \right) \right) \sum_{r=1}^{n} \left( \frac{|y|^r}{r!} \right) \sqrt{\rho(y)} \right\}
\]

\[
\leq \max \left\{ 1, \frac{1}{2^{1/2}} \left( \frac{\alpha}{2(\alpha-1)^{1/2}} \right) \right\} \int_T^1 \exp(|y|) \sqrt{\rho(y)} \, dy. \tag{32}
\]

Moreover, we have for $T \geq 2$

\[
\int_T^1 \exp(|y|) \sqrt{\rho(y)} \, dy = \frac{e}{(2\pi)^{1/4}} \int_T^1 \exp \left( - \left( \frac{y}{2} - 1 \right)^2 \right) \, dy
\]

\[
\leq \frac{e}{(2\pi)^{1/4}} \left( \frac{2}{T-2} \right) \int_T^1 \exp \left( - \left( \frac{y}{2} - 1 \right)^2 \right) 2 \left( \frac{y}{2} - 1 \right) \, dy
\]

\[
= \frac{2}{(2\pi)^{1/4}} \left( \frac{2}{T-2} \right) e^{-\left( \frac{T}{2} - 1 \right)^2}.
\]

Inserting this into (32) yields

\[
\int_T^1 (K_{\alpha,0,p,s}(y, y))^{1/2} \rho(y) \, dy \leq \max \left\{ 1, \frac{1}{2^{1/2}} \left( \frac{\alpha}{2(\alpha-1)^{1/2}} \right) \right\} \frac{2e}{(2\pi)^{1/4}} \left( \frac{2}{T-2} \right) e^{-\left( \frac{T}{2} - 1 \right)^2}.
\]

Applying the above inequality and (25) into (31) and then (30) to get

\[
\left| I_s(F) - \int_{[-T,T]^r} F(y) \rho(y) \, dy \right|
\]

11
\[ \leq 2sM^{s-1} \max \left\{ 1, \frac{1}{2^{1/2}} \frac{(2\alpha-1)^{1/2}}{2\alpha} \right\} \frac{2e}{(2\pi)^{1/4}} \frac{1}{(T-2)} e^{-\frac{(T/2-1)^2}{2}} \|F\|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} \]
\[ = C_{3,\alpha,s} \frac{1}{(T-2)} e^{-\frac{(T/2-1)^2}{2}} \|F\|_{H_{\alpha,\rho,s}(\mathbb{R}^t)}, \tag{33} \]

with \( C_{3,\alpha,s} := 2sM^{s-1} \max \left\{ 1, \frac{1}{2^{1/2}} \frac{(2\alpha-1)^{1/2}}{2\alpha} \right\} \frac{2e}{(2\pi)^{1/4}}. \)

We move to the second term of the total error which is the cubature error. Using the result of Theorem 2 below and Proposition 2 we have for any \( \lambda \in [1, \alpha) \)

\[ \left| (2T)^s \int_{[0,1]^s} F(T(y))\rho(T(y)) \, dy - Q_{s,n}(F) \right| \]
\[ = (2T)^s \left| \int_{[0,1]^s} F(T(y))\rho(T(y)) \, dy - \frac{1}{n} \sum_{i=0}^{n-1} F(T(y^{(i)}))\rho(T(y^{(i)})) \right| \]
\[ \leq (2T)^s \frac{C_{\alpha,\lambda,s}}{n^\lambda} \| (F\rho) \circ T \|_{H_{\alpha,\rho,s}([0,1]^s)} \leq 2^s C_{\alpha,\lambda,s} C_{1,\alpha} T^{(\alpha+1/2)s} \frac{1}{n^\lambda} \| F \|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} \]
\[ = C_{4,\alpha,s} T^{(\alpha+1/2)s} \frac{1}{n^\lambda} \| F \|_{H_{\alpha,\rho,s}(\mathbb{R}^t)}, \tag{34} \]

where \( C_{4,\alpha,s} := C_{\alpha,\lambda,s} C_{1,\alpha} 2^s \) here \( C_{1,\alpha} \) is the constant defined in \((27)\) and \( C_{\alpha,\lambda,s} \) in \((38)\).

Combining \((29), (33)\) and \((34)\) leads to

\[ |I_s(F) - Q_{s,n}(F)| \leq C_{3,\alpha,s} \frac{1}{(T-2)} e^{-\frac{(T/2-1)^2}{2}} \|F\|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} \]
\[ + C_{4,\alpha,s} (2 + 2\sqrt{\lambda \ln(n)})^{s(\alpha+1/2)} \frac{1}{n^\lambda} \| F \|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} \]
\[ \leq C_{3,\alpha,s} \frac{1}{2\sqrt{\lambda \ln(n)}} \frac{1}{n^\lambda} \| F \|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} + C_{4,\alpha,s} \left( (2/\sqrt{\ln(n)} + 2\sqrt{\lambda}) \sqrt{n} \right)^{s(\alpha+1)} \frac{1}{n^\lambda} \| F \|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} \]
\[ \leq C_{2,\alpha,s} \| F \|_{H_{\alpha,\rho,s}(\mathbb{R}^t)} \frac{\ln(n)^{(s+1/4)/n}}{n^\lambda}, \]

where in the last inequality we use \( 2 + 2\sqrt{\lambda \ln(n)} \leq \left( \frac{2}{\sqrt{\ln(2)}} + 2\sqrt{\lambda} \right) \sqrt{n} \) for any \( n \geq 2 \) and

\[ C_{2,\alpha,\lambda,s} := \max \left\{ \frac{C_{3,\alpha,s}}{2\sqrt{\ln(2)}} C_{4,\alpha,s} \left( \frac{2}{\sqrt{\ln(2)}} + 2\sqrt{\lambda} \right)^{s(\alpha+1/2)} \right\}. \tag{35} \]

The proof is completed. \( \square \)

**Remark 1.** A similar result as in Theorem 1 could also be shown for an anchored Gaussian Sobolev space with first order smoothness, that is, for \( H_{\alpha,\rho,s}(\mathbb{R}^t) \) with \( \alpha = 1 \) using randomized cubature rules. More specifically, the point set \( P_n \) is now a randomly digitally shifted polynomial lattice rule which achieves the optimal convergence rate in \( H_{\alpha,\rho,s}([0,1]^t) \) with \( \alpha = 1 \). Combing such randomized cubature rules with a suitable truncation of the Euclidean domain gives a similar convergence rate as in \((28)\), however, of order \( \lambda \in [\frac{4}{7}, 1] \). The construction and analysis of randomly digitally shifted polynomial lattice rules can be found in \([9, 10]\).
Remark 2. An alternative approach is to embed the function \((F \circ T)\) into the \textit{anchored Sobolev space over the unit cube}, then use \textit{higher-order polynomial lattice rules}, see, e.g., [6, 27]. However, similar to Proposition 2 it is not trivial to obtain an explicit formula for the embedding constant, we need to carefully analyze and estimate the bound of one norm by the other. Doing so we could then exploit \textit{interlaced polynomial lattice rules} instead of higher-order polynomial lattice rules because of the equivalence of the anchored and unanchored Sobolev space over the unit cube, see, e.g., [12, Example 2.1].

4 Interlaced polynomial lattice rules

In this section we consider \textit{interlaced polynomial lattice rules}. They were first introduced in [8, 13] to achieve arbitrarily higher order convergence rates for integration over the unit cube within the classes of \textit{Walsh spaces} and \textit{weighted unanchored Sobolev spaces}. Here, we will extend the error analysis of these rules for the unweighted unanchored Sobolev space \(H_{\alpha,s}^s([0,1]^s)\). The aim is to approximate multivariate integrals over the \(s\)-dimensional unit cube

\[
I_{[0,1]^s}(F) := \int_{[0,1]^s} F(y) dy
\]

by a quasi-Monte Carlo rule of the form

\[
Q_{P_n}(F) := \frac{1}{n} \sum_{i=0}^{n-1} F(y^{(i)}),
\]

where \(P_n := \{y^{(i)}\}_{i=0}^{n-1}\) is the cubature point set. The \textit{worst-case error} of the QMC rule \(Q_{P_n}\) in the normed space \(H_{\alpha,s}^s([0,1]^s)\) is defined by

\[
e_{\text{wor}}(H_{\alpha,s}^s([0,1]^s); P_n) := \sup_{\|F\|_{H_{\alpha,s}^s([0,1]^s)} \leq 1} |I(F) - Q_{P_n}(F)|.
\]

Obviously we have for any \(F \in H_{\alpha,s}^s([0,1]^s)\)

\[
|I_{[0,1]^s}(F) - Q_{P_n}(F)| \leq e_{\text{wor}}(H_{\alpha,s}^s([0,1]^s); P_n) \|F\|_{H_{\alpha,s}^s([0,1]^s)}.
\]

We need to introduce some necessary definitions. For simplicity we restrict ourselves to polynomial lattice rules over the finite field \(Z_2\). Let \(Z_2[\chi]\) denote the set of all polynomials over \(Z_2\) and \(Z_2[\chi^{-1}]\) denote the set of all formal Laurent series over \(Z_2\). For any \(m \in \mathbb{N}\) let us define a mapping \(\vartheta_m : Z_2[\chi^{-1}] \to [0,1)\) by

\[
\vartheta_m \left( \sum_{i=\ell}^{\infty} w_i \chi^{-i} \right) := \sum_{i=\max(1,\ell)}^{m} w_i 2^{-i}.
\]

In follows any \(k = 0, \ldots, 2^m - 1\) with the binary expansion \(k = \kappa_0 + \kappa_1 \chi + \cdots + \kappa_{m-1} \chi^{m-1} \in Z_2[\chi]\) and vice versa.

**Definition 1** (polynomial lattice rule). For any \(m, s \in \mathbb{N}\) let \(p \in Z_2[\chi]\) be an irreducible polynomial such that \(\deg(p) = m\) and let \(q = (q_1, \ldots, q_s) \in \mathcal{G}_m^s\) with

\[
\mathcal{G}_m := \{q(\chi) \in Z_2[\chi] : \deg(q) < m\}.
\]
A polynomial lattice point set $P_{p,m,s}(q)$ is a set of $2^m$ points $y^{(0)}, \ldots, y^{(2^m-1)}$ such that

$$y^{(k)} = \left( \vartheta_m \left( \frac{k(\chi)q_1(\chi)}{p(\chi)} \right), \ldots, \vartheta_m \left( \frac{k(\chi)q_s(\chi)}{p(\chi)} \right) \right).$$

A QMC rule using this point set is called a polynomial lattice rule with generating vector $q$ and modulus $p$.

**Definition 2** (interlaced polynomial lattice rule). Let us define the digit interlacing function $D_\alpha : [0, 1)^\alpha \to [0, 1)$ with interlacing factor $\alpha \in \mathbb{N}$ by

$$D_\alpha(y_1, \ldots, y_\alpha) := \sum_{i=1}^{\infty} \sum_{j=1}^{\alpha} \frac{\xi_{i,j}}{2^{i(2^i-1)+j}},$$

where $y_j = \xi_{1,j}2^{-1} + \xi_{2,j}2^{-2} + \cdots$ for $j = 1, \ldots, \alpha$ and $D_\alpha : [0, 1)^\alpha \to [0, 1)$ as

$$D_\alpha(y_1, \ldots, y_\alpha) := (D_\alpha(y_1, \ldots, y_\alpha), \ldots, D_\alpha(y_{(s-1)\alpha+1}, \ldots, y_{s\alpha})).$$

For any $m, s \in \mathbb{N}$ let $p \in \mathbb{Z}_2[\chi]$ be an irreducible polynomial such that $\deg(p) = m$ and let $q = (q_1, \ldots, q_\alpha) \in G^\alpha_m$. An interlaced polynomial point set (of order $\alpha$) $D_\alpha(P_{p,m,\alpha}(q))$ is a set of $2^m$ points $y^{(0)}, \ldots, y^{(2^m-1)}$ such that

$$y^{(k)} = D_\alpha(x^{(k)}),$$

where $\{x^{(k)}\}_{k=0}^{2^m-1}$ is the polynomial lattice point set $P_{p,m,\alpha}(q)$. A QMC rule using this point set is called an interlaced polynomial lattice rule (of order $\alpha$) with generating vector $q$ and modulus $p$.

**Definition 3** (dual net of a polynomial lattice point set). To any $k \in \mathbb{N}_0$ with dyadic expansion $k = \kappa_0 + \kappa_12 + \cdots + \kappa_\alpha2^{\alpha-1}$ we associate a unique truncated polynomial

$$\text{tr}_m(k) := \kappa_0 + \kappa_1\chi + \cdots + \kappa_\alpha\chi^{m-1}$$

where we set $\kappa_\alpha = \cdots = \kappa_{m-1} = 0$ if $\alpha < m$. For any $k \in \mathbb{N}^s$ we define $\text{tr}_m(k) := (\text{tr}_m(k_1), \ldots, \text{tr}_m(k_s))$. The dual net of the polynomial lattice point set $P$ with modulus $p$ with $\deg(p) = m$ and generating vector $q \in G^\alpha_m$ is given by

$$P^\perp := \{ k \in \mathbb{N}_0^\alpha : \text{tr}_m(k) \cdot q \equiv 0 \pmod{p} \}.$$

We also define the dual net without 0 component denoted by $P^\perp_\ast$ as

$$P^\perp_\ast := \{ k \in \mathbb{N}_0^\alpha : \text{tr}_m(k) \cdot q \equiv 0 \pmod{p} \}.$$
The dual net of the interlaced polynomial lattice point set \( \mathcal{D}_\alpha(P_{p,m,\alpha s}(q)) \) is defined as

\[
(\mathcal{D}_\alpha(P_{p,m,\alpha s}(q)))^\perp := \{ \delta_\alpha(k) : k = (k_1, \ldots, k_\alpha) \in (P_{p,m,\alpha s}(q))^\perp \}
\]

where \((P_{p,m,\alpha s}(q))^\perp\) is the dual net of \(P_{p,m,\alpha s}(q)\) as given in Definition 3. And with \((\mathcal{D}_\alpha(P_{p,m,\alpha s}(q)))^\perp\) we denote the dual net without 0 component.

**Definition 5.** Let \(\alpha \in \mathbb{N}\). For any \(k \in \mathbb{N}\) with the binary expansion \(k = \kappa_12^{m_1-1} + \kappa_22^{m_2-1} + \cdots + \kappa_\alpha2^{m_\alpha-1}\) such that \(m_1 > m_2 > \cdots > m_\alpha > 0\) we define

\[
\mu_\alpha(k) := \sum_{i=1}^{\min(\alpha, \nu)} m_i,
\]

and \(\mu_\alpha(0) = 0\). For any \(k \in \mathbb{N}_0^\alpha\) we define \(\mu_\alpha(k) := \sum_{j=1}^\alpha \mu_\alpha(k_j)\).

**Lemma 2.** For any \(\alpha \in \mathbb{N}\) such that \(\alpha \geq 2\) we have

\[
ed_{\text{wor}}(H'_{\alpha,s}([0,1]^s); \mathcal{D}_\alpha(P_{p,m,\alpha s}(q))) \leq \left(2^{\alpha(\alpha-1)}C_\alpha\right)^{s/2} \sum_{k \in (P_{p,m,\alpha s}(q))^\perp} 2^{-\alpha\mu_1(k)}.
\]

with

\[
C_\alpha := \max_{1 \leq \nu \leq \alpha} \left\{ \sum_{\tau=0}^{\alpha} \frac{C^2_2 \tau^{-\nu}}{2^{2(\alpha-\nu)} + \frac{2C_{2\alpha}}{2^{2(\alpha-\nu)}}} \right\},
\]

where \(C_1 := 1/2\) and \(C_\tau := (5/3)^{\tau-2}\) for \(\tau \geq 2\).

**Proof.** Let us denote by \(K'_{\alpha,s}(:, \cdot)\) the kernel of \(H'_{\alpha,s}([0,1]^s)\) and by \(K'_{\alpha,s}(k, \cdot)\) its \(k\)th Walsh coefficient, that is,

\[
\hat{K}'_{\alpha,s}(k, \cdot) := \int_{[0,1]^s} K'_{\alpha,s}(x, \cdot) \omega_k(y) \, dy.
\]

For these standard definitions see [4]. It was shown in [4, Proof of Theorem 30] that

\[
ed_{\text{wor}}(H'_{\alpha,s}([0,1]^s); \mathcal{D}_\alpha(P_{p,m,\alpha s}(q)))^2 = -1 + \frac{1}{2^m} \sum_{i,i'=0}^{2^m-1} K'_{\alpha,s}(y^{(i)}, y^{(i')})
\]

\[
= -1 + \frac{1}{2^m} \sum_{i,i'=0}^{2^m-1} \sum_{k, \ell \in \mathbb{N}_0^\alpha} K'_{\alpha,s}(k, \ell) \omega_k(y^{(i)}) \omega_\ell(y^{(i')})
\]

\[
= -1 + \sum_{k, \ell \in \mathbb{N}_0^\alpha} \hat{K}'_{\alpha,s}(k, \ell) \frac{1}{2^m} \sum_{i=0}^{2^m-1} \omega_k(y^{(i)}) \frac{1}{2^m} \sum_{i'=0}^{2^m-1} \omega_\ell(y^{(i')}).
\]

Applying [13, Lemma 1] we have

\[
\frac{1}{2^m} \sum_{i=0}^{2^m-1} \omega_k(y^{(i)}) = \begin{cases} 1, & \text{if } k \in \mathcal{D}_\alpha(P_{p,m,\alpha s}(q))^\perp, \\ 0, & \text{otherwise.} \end{cases}
\]
Applying [8, Lemma 3.8] we have
\[ (e_{\text{wor}}(H'_{\alpha,s}([0,1]^s); \mathcal{D}_\alpha(P_{p,m,\alpha}(q))))^2 = -1 + \sum_{k,\ell \in (\mathcal{D}_\alpha(P_{p,m,\alpha}(q)))^s} \hat{K}_{\alpha,s}(k,\ell). \]

Moreover, using [4, Proposition 20] we have \( \hat{K}_{\alpha,s}(0,0) = 1 \), and if \( k,\ell \in \mathbb{N}^s \) then
\[ \hat{K}_{\alpha,s}(k,\ell) \leq \hat{C}_\alpha^s 2^{-\mu_\alpha(k) - \mu_\alpha(\ell)}. \]

Therefore, we have
\[ (e_{\text{wor}}(H'_{\alpha,s}([0,1]^s); \mathcal{D}_\alpha(P_{p,m,\alpha}(q))))^2 \leq \hat{C}_\alpha^s \sum_{k,\ell \in (\mathcal{D}_\alpha(P_{p,m,\alpha}(q)))^s} 2^{-\mu_\alpha(k) - \mu_\alpha(\ell)} \]
\[ \leq \hat{C}_\alpha^s \left( \sum_{k \in (\mathcal{D}_\alpha(P_{p,m,\alpha}(q)))^s} 2^{-\mu_\alpha(k)} \right)^2 = \hat{C}_\alpha^s \left( \sum_{k \in (P_{p,m,\alpha}(q))^s} 2^{-\mu_\alpha(c'_\alpha(k))} \right)^2. \tag{37} \]

Applying [8, Lemma 3.8] we have
\[ \mu_\alpha(c'_\alpha(k)) \geq \alpha \mu_1(k) - \frac{s \alpha (\alpha - 1)}{2}. \]

Inserting into (37) implies
\[ e_{\text{wor}}(H'_{\alpha,s}([0,1]^s); \mathcal{D}_\alpha(P_{p,m,\alpha}(q))) \leq \left( 2^{\alpha (\alpha - 1)} \hat{C}_\alpha^s \right)^{s/2} \sum_{k \in (P_{p,m,\alpha}(q))^s} 2^{-\alpha \mu_1(k)}, \]
which is the needed claim.

Let us denote \( E_{\alpha}(q) := \sum_{k \in (P_{p,m,\alpha}(q))^s} 2^{-\alpha \mu_1(k)} \). This will be used as our search criterion in the component-by-component (CBC) construction. The following result is modified from [8, Theorem 3.9].

**Proposition 3.** For any \( \alpha, m \in \mathbb{N} \) such that \( \alpha \geq 2 \) and any \( p \) being an irreducible polynomial with \( \deg(p) = m \) a generating vector \( q^* = (q_1^*, q_2^*, \ldots, q_m^*) \in \mathcal{O}_m^{\max} \) can be constructed using a CBC approach, minimizing \( E_{\alpha}(q) \) in each step, such that
\[ E_{\alpha}(q^*) \leq \left( \frac{2}{2^m - 1} \right)^\lambda \sum_{\emptyset \neq \alpha \subseteq \{1:m\}} \left( \frac{1}{(2^\alpha \lambda - 2)^{s|\alpha|}} \right) = \left( \frac{2}{2^m - 1} \right)^\lambda \left[ \left( 1 + \frac{1}{2^\alpha \lambda - 2} \right)^{\alpha s} - 1 \right]^\lambda, \]
for all \( \lambda \in [1, \alpha) \)

Applying Proposition 3 and Lemma 2 we receive the following result.

**Theorem 2.** Let \( F \) belong to \( H'_{\alpha,s}([0,1]^s) \) for some \( \alpha \in \mathbb{N} \) with \( \alpha \geq 2 \). For any \( m \in \mathbb{N} \) there exists an interlaced polynomial lattice rule of order \( \alpha \) denoted by \( P_{n,\alpha} \) with \( n = 2^m \) points and the generating vector constructed as in Proposition 3 such that
\[ |l_{[0,1]^s}(F) - Q_{[0,1]^s, P_{n,\alpha}}(F)| \leq \frac{C_{\alpha,\lambda,s}}{n^\lambda} \| F \|_{H'_{\alpha,s}([0,1]^s)}, \quad \forall \lambda \in [1, \alpha), \]
where
\[ C_{\alpha,\lambda,s} := 4^\lambda \left( 2^{\alpha (\alpha - 1)} \hat{C}_\alpha^s \right)^{s/2} \left[ \left( 1 + \frac{1}{2^\alpha \lambda - 2} \right)^{\alpha s} - 1 \right]^\lambda. \tag{38} \]
5 Parametric regularity of the PDE solution

In this section we will show bounds for mixed derivatives of the solution $u(\cdot, y)$ with respect to $y$ and bounds for its Bochner norm. Since the arguments stand on the weak formulation which is satisfied when $V$ is replaced by $V^h \subset V$, these bounds apply also to the finite element approximation $u^h(\cdot, y)$ with constants independent of $h$.

Given $\alpha \in \mathbb{N}$ being the order of the smoothness. Let us first define the Bochner norm

$$
\|u(\cdot, y)\|_{H^{\alpha,0,\rho,|u|}(\mathbb{R}^{|u|}; V)} := \left( \sum_{\tau = 1}^{|\alpha|} \int_{\mathbb{R}^{|u|}} \| (\partial_{yu}^\tau u(\cdot, y)) (\cdot, y_{\alpha_\tau}, \theta_{y_{\alpha_\tau}}) \|_{V_{\alpha_\tau}} \right)^{1/2}.
$$

(39)

For any $y_{\alpha} \in \mathbb{R}^{|u|}$ and $v(\cdot, y_{\alpha}) \in V$ let us introduce the notation

$$
\|v(\cdot, y_{\alpha})\|_{V_{\alpha}} := \sqrt{\int_D a(x, y_{\alpha})|\nabla v(x, y_{\alpha})|^2 \, dx}.
$$

It is easy to see that

$$
\sqrt{a_{\min}(y_{\alpha})} \|u(\cdot, y_{\alpha})\|_{V} \leq \|u(\cdot, y_{\alpha})\|_{V_{\alpha}} \leq \frac{\|f\|_{V^*}}{\sqrt{a_{\min}(y_{\alpha})}}.
$$

(40)

The following result is modified from [19, Proposition 3.1], see also [1, Theorem 4.1], particularly for the $u$-projected solution.

**Proposition 4.** For any $\alpha \in \mathbb{N}$ if there exists a sequence $\{b_j\}_{j \geq 1}$ with $0 < b_j \leq 1$ for all $j$ and a constant $\kappa$ such that

$$
\kappa = \left\| \sum_{j \geq 1} \frac{\phi_j}{b_j} \right\|_{L^\infty(D)} < \frac{\ln(2)}{\alpha},
$$

then for $\mu$-a.s. $y_{\alpha} \in \mathbb{R}^{|u|}$ it holds

$$
\sum_{\tau = 1}^{|\alpha|} b_{\alpha_\tau}^{2\tau} \| (\partial_{yu}^\tau u(\cdot, y) \|_{V_{\alpha_\tau}} \leq C_{\kappa,\alpha} \|u(\cdot, y_{\alpha})\|_{V_{\alpha}},
$$

where $C_{\kappa,\alpha} := \sum_{k=0}^\infty \delta_{\kappa,\alpha}$ with $\delta_{\kappa,\alpha}$ being a constant depending on $\kappa$ and $\alpha$ such that $\frac{\kappa \alpha}{\ln(2)} < \delta_{\kappa,\alpha} < 1$ and $b_{\alpha_\tau} := \prod_{j \in \tau} b_{j}^{\tau_j}$. Using (40) this implies

$$
\sum_{\tau = 1}^{|\alpha|} \| (\partial_{yu}^\tau u(\cdot, y)) \|_{V} \leq b_{\alpha}^{2\tau} C_{\kappa,\alpha} \|f\|_{V^*}.
$$

**Lemma 3.** For any $\alpha \in \mathbb{N}$ and $f \in V^*$ under the assumptions of Proposition 4 and additionally $\{b_j\}_{j \geq 1} \in l^p(N)$ for some $p^* \in (0, 1]$ then it holds

$$
\|u(\cdot, y)\|_{H^{\alpha,0,\rho,|u|}(\mathbb{R}^{|u|}; V)} \leq b_{\alpha} 2^{\alpha/2} C_{\kappa,\alpha} \|f\|_{V^*}
$$

where

$$
C_{\kappa,\alpha} := C_{\kappa,\alpha}^{1/2} \exp \left( \sum_{j \geq 1} (k b_j)^2 + 2 k b_j / \sqrt{2\pi} \right) < \infty.
$$
Proof. Using the definition of the Bochner norm (here for the sake of optimal presentation we use the norm written as a double sum as in (26)) and Proposition 4 we have

$$
\|u(\cdot, u)\|_{H_{\alpha,0,\alpha,0}[u]\mid V]}^2 = \sum_{v \subseteq u} \int_{\mathbb{R}^{|v|}} \sum_{\tau \in \mathbb{R}^{|v|}} \left\| (\delta_{y}^{(\alpha, \tau, y)} y_{u}) u(\cdot, u)(\cdot, y_{u}, 0_{u}) \right\|^2 \rho(y_{u}) dy_{u}
\leq b_{u}' C_{\alpha, \alpha} \|f\|_{V}^2 \sum_{v \subseteq u} \int_{\mathbb{R}^{|v|}} \frac{1}{(a_{\min}(y_{u}, 0_{v}))^2} \rho(y_{v}) dy_{v}.
$$

(41)

Now we estimate the sum in the last expression. Note that for any $y_{u} \in \mathbb{R}^{|u|}$

$$
a_{\min}(y_{u}) \geq \exp \left( -\sup_{x \in D} \sum_{j \in u} |y_{j}||\phi_{j}(x)| \right),
$$

then

$$
\frac{1}{(a_{\min}(y_{u}))^2} \leq \exp \left( 2 \sup_{x \in D} \sum_{j \in u} |y_{j}||\phi_{j}(x)| \right) \leq \exp \left( 2 \sup_{j \in u} |y_{j}| b_{j} \sum_{x \in D} |\phi_{j}(x)| b_{j} \right)
\leq \exp \left( 2 \kappa \sup_{j \in u} |y_{j}| b_{j} \right) \leq \exp \left( 2 \kappa \sum_{j \in u} |y_{j}| b_{j} \right).
$$

Therefore, we have

$$
\int_{\mathbb{R}^{|v|}} \frac{1}{(a_{\min}(y_{u}, 0_{v}))^2} \rho(y_{u}) dy_{u} \leq \int_{\mathbb{R}^{|v|}} \exp \left( 2 \sum_{j \in v} |y_{j}| b_{j} \right) \rho(y_{v}) dy_{v}
= \prod_{j \in v} \left( 2 \exp(2(\kappa b_{j})^2) \int_{0}^{\infty} \frac{\exp(-(y-2\kappa b_{j})^2/2)}{\sqrt{2\pi}} dy \right) = \prod_{j \in v} 2 \exp(2(\kappa b_{j})^2) \Phi(2\kappa b_{j})
\leq \exp \left( 2 \kappa \sum_{j \in v} (2(\kappa b_{j})^2 + 4\kappa b_{j}/\sqrt{2\pi}) \right),
$$

(42)

where $\Phi(\cdot)$ is the cumulative standard normal distribution function and $\Phi(x) \leq 1/2 \exp(2x/\sqrt{2\pi})$ for any $x \geq 0$, see, e.g., [14, p. 355]. Inserting (42) into (41) we get

$$
\|u(\cdot, u)\|_{H_{\alpha,0,\alpha,0}[u]\mid V]}^2 \leq b_{u}' C_{\alpha, \alpha} \|f\|_{V}^2 \sum_{v \subseteq u} \exp \left( 2 \sum_{j \in v} (2(\kappa b_{j})^2 + 4\kappa b_{j}/\sqrt{2\pi}) \right)
\leq b_{u}' C_{\alpha, \alpha} \|f\|_{V}^2 |v|^2 \sum_{j \geq 1} \exp \left( 2 \sum_{j \geq 1} (\kappa b_{j})^2 + 2\kappa b_{j}/\sqrt{2\pi}) \right).
$$

Since $\{b_{j}\}_{j \geq 1} \in \ell^{p^*}(\mathbb{N}) \subseteq \ell^{1}(\mathbb{N}) \subseteq \ell^{2}(\mathbb{N})$ for $p^* \in (0, 1]$ the sum in the last expression is finite. Taking the square root of both sides the needed claim follows.

The following result is derived using the property (14) of the anchored decomposition. A full proof is given in [27, Lemma 4].

18
Lemma 4. For any \( u \in \mathbb{N} \) and \( \alpha \in \mathbb{N} \) it holds
\[
\|u(\cdot, u)\|_{H^{\alpha, u}([u]; V)} = \|u(\cdot, u)\|_{H^{\alpha, u}([u]; V)}.
\]

Since \( G \) is a linear bounded functional on \( V \) for any \( \tau \in \{1 : \alpha\}[u] \) and \( y \in \mathbb{R}^u \) it holds
\[
(\partial y_\tau G(u))(\cdot, y) = (G(\partial y_\tau u)(\cdot, y)) \leq \|G\|_V \|\partial y_\tau u(\cdot, y)\|_V.
\]
Using this and Lemma 4 we receive the following bound for the norm \( \|G(u(\cdot, u))\|_{H^{\alpha, u}([u]; V)} \).

Lemma 5. For any \( f, G \in V^* \), any \( u \in \mathbb{N} \) and any \( \alpha \in \mathbb{N} \) under the assumption of Lemma 3 it holds
\[
\|G(u(\cdot, u))\|_{H^{\alpha, u}([u]; V)} \leq b_u 2^{\|u\|/2} C_{K, \alpha} \|G\|_V \|f\|_V^*.
\]

6 Finite element discretization

In this section we give some results on the FE discretization. The FE method is obtained by solving the weak formulation (5) restricting to a finite-dimensional subspace of \( V \) denoted by \( V^h \). More specifically, the domain \( D \) is partitioned into elements with maximal diameter \( h > 0 \) and \( V^h \) consists of all polynomials that are continuous piecewise on these elements and vanish on the boundary \( \partial D \). The dimension of \( V^h \) is denoted by \( M_h := \dim(V^h) \) and is of order \( h^{-d} \).

The main tools in proving the convergence of the FEM are Cea’s lemma and a best approximation property which depends on the spatial regularity of the solution \( u \), see, e.g., [31, Chapter 3]. This spatial regularity in turn depends on the geometry of the domain \( D \), the smoothness of the coefficient \( a \) and the function \( f \), see [14–16, 31, 32] and references therein. As in [14, Section 2], to simplify the presentation we restrict our analysis to the case \( d = 1, 2 \) and
\[
D \subset \mathbb{R}^d \text{ is a bounded interval or polygon,}
\]
and
\[
a \in L_{p, \rho}(\mathbb{R}^d; C^t(D)) \text{ for some } t \in (0, \infty) \text{ and any } p \in [1, \infty),
\]
this holds under reasonable conditions on the covariance function of \( Z \) or on the system \( \{\phi_j\}_{j \geq 1} \), more details will be provided later. For \( t \) as in (44) we assume that
\[
f \in H^{-1+t}(D) \text{ and } G \in H^{-1+t}(D).
\]

We will recall some results on the spatial regularity of \( u \). The following result was taken from [31, Theorem 2.12] for \( 0 < t \leq 1 \), and from [16, Proof of Proposition 15] for \( t > 1 \). Let \( \beta_{\text{max}} \) be the maximal interior angle of \( D \).

Lemma 6. Under conditions (6), (7), (43), (44) and (45), the solution \( u(\cdot, y) \in H^{1+\tau_0}(D) \) for \( \mu \)-a.s. \( y \in \mathbb{R}^d \) and any \( 0 < \tau_0 < \min\{t, \pi/\beta_{\text{max}}\} \) such that \( \tau_0 \neq \{1/2 + \mathbb{N}_0\} \). Moreover, there exists a positive random variable that satisfies \( \|C_f\|_{L_{p, \rho}(\mathbb{R}^d)} < \infty \) for any \( p \in [1, \infty) \) such that
\[
\|u(\cdot, y)\|_{H^{1+\tau_0}(D)} \leq C_f(y),
\]

Remark 3. As indicated in [32] for the case \( d = 3 \) and \( D \) being a bounded polyhedron we expect a similar result but more elaborated because besides singularities at corners we also need to consider edge singularities.
Applying Cea’s lemma, see, e.g., [31, Lemma 3.1], we have for \( \mu \)-a.s. \( y \)
\[
\left\| (u - u^h)(\cdot, y) \right\|_V \leq \left( \frac{a_{\max}(y)}{a_{\min}(y)} \right)^{1/2} \inf_{v^h \in V_h} \left\| u(\cdot, y) - v^h \right\|_V.
\]  
(47)

Following [2, Corollary 8.3] we assume that for any \( v(\cdot, y) \in H^{1+\tau_0}(D) \cap V \) with some positive parameter \( \tau_0 \) there exists a family of subspaces \( V_h \subset V \) satisfying the following approximation property
\[
\inf_{v^h \in V_h} \left\| v(\cdot, y) - v^h \right\|_V \lesssim \| v(\cdot, y) \|_{H^{1+\tau_0}(D)} h^{\tau_0}.
\]  
(48)

For \( 0 < \tau_0 \leq \min\{ 1, \pi/\beta_{\text{max}} \} \) it is well-known that this best approximation will be achieved using uniform refinements. For \( 0 < \tau_0 \leq 1 \) and \( \tau_0 > \pi/\beta_{\text{max}} \) in the presence of singularities of the domain \( D \) such as corners and edges the above best approximation can not be achieved using uniform refinements. For this case, it was remarked in [15, Section 2.2] that we further need suitable local mesh refinements near the boundary.

Applying (48) into (47) we have
\[
\left\| (u - u^h)(\cdot, y) \right\|_V \lesssim h^{\tau_0} \left( \frac{a_{\max}(y)}{a_{\min}(y)} \right)^{1/2} \| u(\cdot, y) \|_{H^{1+\tau_0}(D)}.
\]

In order to obtain the convergence of FE approximations of functionals of the solution we use the classic Aubin–Nitsche duality argument as in [22, Theorem 7.2] and [32, Lemma 3.1]. Under the conditions of Lemma 6 and in the presence of the approximation property (48) for \( \mu \)-a.s. \( y \) and any \( 0 < \tau_0 < \min\{ 1, \pi/\beta_{\text{max}} \} \) such that \( \tau_0 \neq \{ 1/2 + \mathbb{N}_0 \} \) it holds
\[
\left| G(u(\cdot, y)) - G(u^h(\cdot, y)) \right| \lesssim h^{2\tau_0} \left( \frac{a_{\max}(y)}{a_{\min}(y)} \right)^{1/2} C_f(y) C_G(y),
\]  
(49)

where \( C_G(y) \) is a positive random variable that satisfies \( \| C_G \|_{L_p,\rho(\mathbb{R}^n)} < \infty \) for any \( p \in [1, \infty) \). Taking the \( L_{p,\rho}(\mathbb{R}^n) \) norm, for any \( p \in [1, \infty) \), of both sides of the above inequality, the Cauchy–Schwarz inequality and \( \| \frac{1}{a_{\min}} \|_{L_{p,\rho}(\mathbb{R}^n)} < \infty \) and \( \| a_{\max}(y) \|_{L_{p,\rho}(\mathbb{R}^n)} < \infty \) as in (9) and (10) we get
\[
\left\| G(u) - G(u^h) \right\|_{L_{p,\rho}(\mathbb{R}^n)} \lesssim h^\tau,
\]  
(50)

where \( \tau := 2\tau_0 \) and the hidden constant independent of \( h \) and \( u \).

In the remainder of this section we will discuss when condition (44) is satisfied. By the smoothness of the exponential function, the Hölder regularity of \( a \) is implied from that of the random field \( Z \). Usually a Hölder-like condition is introduced on the covariance function of \( Z \), see [5, 14, 32] and references therein. However, in this paper we investigate the smoothness of \( Z \) via that of the individual \( \phi_j \), see, e.g., [1–3, 16, 19].

Follow [2, Section 8] we restrict to the case when \( \{ \phi_j \}_{j \geq 1} \) is a family of wavelet basis functions of \( L_2(D) \). That is,
\[
\{ \phi_j \}_{j \geq 1} = \{ \phi_{\ell,k} : \ell \geq 1, k \in J_\ell \},
\]

where \( \ell \) indicates the scale level, \( k \) indicates the location of a level-\( \ell \) wavelet and \( J_\ell \) denotes the set of all location indices at level \( \ell \). In what follows we identify the index \( j \) with the corresponding tuple \((\ell, k)\). The diffusion coefficient is now represented in the form
\[
a(x, y) = \exp(Z(x, y)) = \exp \left( \sum_{\ell \geq 1} \sum_{k \in J_\ell} y_{\ell,k} \phi_{\ell,k}(x) \right).
\]
Similar as in [2] we assume that the wavelet system has at most \( \eta \) overlapping basis functions at each level, that is, for any \( x \in D \) and any \( \ell \geq 1 \)

\[
\{ \{ k : \phi_{\ell,k}(x) \neq 0 \} \} \leq \eta. \tag{51}
\]

Moreover, we consider the system \( \{ \phi_j \}_{j \geq 1} \) which is pointwise normalized such that for some positive constants \( \sigma \) and \( \hat{\alpha} \)

\[
\| \phi_{\ell,k} \|_{L^\infty(D)} = \sigma 2^{-\hat{\alpha}\ell}. \tag{52}
\]

Assume further that the wavelets are sufficiently smooth, that is, for any \( \alpha \in \mathbb{N}_0^d \) such that \( |\alpha| \leq L \) for some \( L \geq 1 \)

\[
\| \partial_\alpha^\mathbf{x} \phi_{\ell,k} \|_{L^\infty(D)} \lesssim 2^{\ell(|\alpha|-\hat{\alpha})}. \tag{53}
\]

We know that for such wavelet basis we can define a system \( \{ b_j \}_{j \geq 1} \) satisfying assumption (6) such that \( \{ b_j \}_{j \geq 1} \in \ell^p(\mathbb{N}) \) for any \( p^* < d/\hat{\alpha} \). An explicit formula for each \( b_j \) is provided in [27, Section 1]. We prove in the following proposition that the expansion \( Z \) belongs to a Besov function space, the needed Hölder smoothness is then derived using well-known Besov embedding properties. A similar statement was mentioned in [3, Section 4.3], however, without proof.

**Proposition 5.** Let \( \{ \phi_j \}_{j \geq 1} \) be a family of wavelet basis functions of \( L_2(D) \) satisfying conditions (51), (52), and (53). Then, \( Z \in L_{p,\rho}(\mathbb{R}^N;C^t(\overline{D})) \), and, furthermore, \( a \in L_{p,\rho}(\mathbb{R}^N;C^t(\overline{D})) \) for any \( t \in (0,\hat{\alpha}) \) and any \( p \in [1,\infty) \).

**Proof.** We have, see [16, Proof of Proposition 19], for any \( y \in \mathbb{R}^N \)

\[
\| a(\cdot,y) \|_{C^t(\overline{D})} \lesssim \| a(\cdot,y) \|_{L^\infty(\overline{D})} \left( 1 + \| Z(\cdot,y) \|^{[t]} \right).
\]

Using similar arguments as in [19, Proof of Proposition 5.4] we write

\[
\| a \|_{L_{p,\rho}(\mathbb{R}^N;C^t(\overline{D}))} \lesssim \| a \|_{L_{p,\rho}(\mathbb{R}^N;L^\infty(\overline{D}))} \left( 1 + \| Z \|^{[t]} \right),
\]

with the hidden constant might depend on \( p \). Using the result of Proposition 1 we have \( \| a \|_{L(\mathbb{R}^N;L^\infty(\overline{D}))} < \infty \). Thus, for \( a \in L_{p,\rho}(\mathbb{R}^N;C^t(\overline{D})) \) it suffices to show that \( \| Z \|_{L_{p,\rho}(\mathbb{R}^N;C^t(\overline{D}))} < \infty \).

We will first show that

\[
Z \in L_{p,\rho}(\mathbb{R}^N;B^t_{p,q}(D)) \text{ for some } t \geq t + d/\hat{\rho} \text{ and any } \hat{p},\hat{q} \in [1,\infty], \tag{54}
\]

where \( B^t_{p,q}(D) \) denotes the Besov function space. The claim \( Z \in L_{p,\rho}(\mathbb{R}^N;C^t(\overline{D})) \) in turn follows by continuous embeddings

\[
B^t_{p,q}(D) \hookrightarrow B_{\infty,\infty}^t(D) \hookrightarrow C^t(\overline{D})
\]

for any non-integer \( t \leq \bar{t} - \frac{d}{\hat{p}} \), see [33, (1.300), Theorem 1.107, Theorem 1.122 and (1.311)], and

\[
B^t_{p,1}(D) \hookrightarrow B_{\infty,1}^t(D) \hookrightarrow C^t(\overline{D})
\]

for any integer \( t \leq \bar{t} - \frac{d}{\hat{p}} \), see [33, Proposition 4.5].
Let us denote \((f,g) := \int_D f(x) \overline{g(x)} \, dx\). Applying \([34, \text{Proposition 4.21 and Remark 4.26}]\) for any \(l, \tilde{p}, \tilde{q} \in [1, \infty]\) and any \(y \in \mathbb{R}^N\), let \(l = \sigma + \kappa\) for some \(\kappa \in \mathbb{N}\) such that \(\kappa \leq L\) and \(\sigma \in \mathbb{R}\) we have

\[
\|Z(\cdot, y)\|_{B^\sigma_\tilde{p}_\tilde{q}(D)} = \left\| \sum_{l \geq 1} \sum_{k \in J_l} y_{l,k} \phi_{l,k} \right\|_{B^\sigma_\tilde{p}_\tilde{q}(D)} \\
\lesssim \sum_{|\alpha| \leq \kappa} \left( \sum_{l \geq 1} 2^{l(\sigma-d/p)q} \left( \sum_{k \in J_l} \left\| \sum_{j \geq 1} \sum_{r \in J_j} (-1)^{|\alpha|} (\partial_\alpha \phi_{l,k}, \phi_{j,r}) y_{l,k} \right\|^{\tilde{q}/p} \right)^{1/q} \right) \\
\lesssim \sum_{|\alpha| \leq \kappa} \left( \sum_{l \geq 1} 2^{l(\sigma-d/p)} \sum_{k \in J_l} \left\| \int_D \sum_{j \geq 1} \sum_{r \in J_j} (|\partial_\alpha \phi_{l,k}|, |\phi_{j,r}|) |y_{l,k}| \right\| \right) \\
= \sum_{|\alpha| \leq \kappa} \left( \sum_{l \geq 1} 2^{l(\sigma-d/p)} \sum_{k \in J_l} \left\| \int_D \sum_{j \geq 1} \sum_{r \in J_j} |\partial_\alpha \phi_{l,k}(x)||y_{l,k}| \right\| \right),
\]

where we use \((\sum_j a_j)^{1/p} \leq \sum_j a_j\) for all \(a_j \geq 0\) and \(p \in [1, \infty]\) in the second inequality.

Using (6) for the last term in the sum of the above inequality, taking \(L_{p,q}(\mathbb{R}^N)\) norm on both sides of the above inequality and then using Hölder’s inequality we have

\[
\|Z\|_{L_{p,q}(\mathbb{R}^N; B^\sigma_\tilde{p}_\tilde{q}(D))} \lesssim \left( \int_{\mathbb{R}^N} \left( \sum_{|\alpha| \leq \kappa} \sum_{l \geq 1} 2^{l(\sigma-d/p)} \left\| \sum_{k \in J_l} |\partial_\alpha \phi_{l,k}| |y_{l,k}| \right\|_{L^\infty(D)} \right)^{\tilde{p}} \rho(y) \, dy \right)^{1/p} \\
\lesssim \left( \int_{\mathbb{R}^N} \left( \sum_{|\alpha| \leq \kappa} \sum_{l \geq 1} 2^{l(\sigma-d/p)} \left\| \sum_{k \in J_l} |\partial_\alpha \phi_{l,k}| |y_{l,k}| \right\|_{L^\infty(D)} \right) \rho(y) \, dy \right)^{1/p} \\
= \sum_{|\alpha| \leq \kappa} \left( \sum_{l \geq 1} 2^{l(\sigma-d/p)} \left\| \sum_{k \in J_l} |\partial_\alpha \phi_{l,k}| \right\|_{L^\infty(D)} \right) \\
= \sqrt{\pi/2} \sum_{|\alpha| \leq \kappa} \sum_{l \geq 1} 2^{l(\sigma-d/p)} \left\| \sum_{k \in J_l} |\partial_\alpha \phi_{l,k}| \right\|_{L^\infty(D)}. \tag{55}
\]

Since at each level \(l\) the system \(\{\phi_{l,k}\}_{l,k}\) has a finite number of overlapping functions it is clear that the system \(\{\partial_\alpha \phi_{l,k}\}_{l,k}\) also has a similar property. Due to this using (53) implies

\[
\left\| \sum_{k \in J_l} |\partial_\alpha \phi_{l,k}| \right\|_{L^\infty(D)} \lesssim 2^{l(|\alpha|-\tilde{\alpha})}.
\]

Inserting this into (55) yields

\[
\|Z\|_{L_{p,q}(\mathbb{R}^N; B^\sigma_\tilde{p}_\tilde{q}(D))} \lesssim \sum_{|\alpha| \leq \kappa} \sum_{l \geq 1} 2^{l(\sigma-d/p+|\alpha|-\tilde{\alpha})} \lesssim \sum_{|\alpha| \leq \kappa} \sum_{l \geq 1} 2^{l(\sigma-d/p+\tilde{\alpha})} = \sum_{|\alpha| \leq \kappa} \sum_{l \geq 1} 2^{l(\tilde{\alpha}-\tilde{\alpha})}.
\]
which is finite for any \( \ell - d/p < \alpha \). This implies that \( Z \in L_{p,\rho}(\mathbb{R}^n; B_{p,\rho}^s(D)) \). Together with (54) this in turn implies \( Z \in L_{p,\rho}(\mathbb{R}^n; C^t(\mathcal{D})) \) for any \( t \) such that \( t \leq \ell - d/p < \alpha \), or equivalently, \( t < \hat{\alpha} \). This is the needed claim. \( \square \)

**Remark 4.** If the system \( \{ \phi_j \}_{j \geq 1} \) is obtained by scaling and translation from a mother wavelet which is sufficiently smooth then the conditions (51), (52), and (53) are satisfied. Indeed, let us consider the univariate model problem (just for simplicity) and the system \( \{ \phi_j \}_{j \geq 1} \) being given in the form

\[
\phi_{l,k} = 2^{-\alpha l} \phi(2^l x - k), \quad \ell \geq 1, \; k = 0, \ldots, 2^\ell - 1,
\]

where \( \phi \) is a local supported and bounded function, see also [16, Section 11]. For such wavelet system obviously the conditions (51) and (52) are satisfied. Moreover, if \( \phi \) is sufficiently smooth, that is, it has bounded derivatives up to some order \( L \geq 1 \), then for any \( \alpha \in \mathbb{N} \) such that \( \alpha \leq L \)

\[
\| \partial_{x}^\alpha \phi_{l,k} \|_{L^\infty(D)} = \| 2^{\ell(-\alpha+\alpha)} \partial_{x}^\alpha \phi(2^l \cdot - k) \|_{L^\infty(D)} \lesssim 2^{\ell(\alpha-\hat{\alpha})}
\]

which is exactly the condition (53).

## 7 MDFEM

In the next subsections we introduce the cost model for the MDFEM algorithm, demonstrate how to construct the active set, cubature rules and finite element approximation based on a priori error estimations. We derive the complexity of the MDFEM algorithm in Theorem 3. Finally, we compare the MDFEM with the standard QMCFEM algorithm.

### 7.1 Computational cost

Due to (18) the total computational cost of the MDFEM algorithm is comprised of the costs of computing \( Q_{n,nu}(G(u^n_h)) \) for all \( \nu \in \mathcal{U}(\epsilon) \). For each \( \nu \) the cost of computing \( Q_{n,nu}(G(u^n_h)) \) equals \( n_u \) times the cost of computing \( G(u^n_h) \). Based on the decomposition (19) the cost of evaluating \( G(u^n_h) \) is bounded by \( 2^{[u]} \) times the cost of evaluating the FE approximation of the \( u \)-projected solution. Hence, we have

\[
\text{cost}(Q_{\nu}) = \mathcal{O} \left( \sum_{\nu \in \mathcal{U}(\epsilon)} n_u 2^{[u]} \times \text{cost of evaluating } G(u^n_h(\cdot, \nu)) \right).
\]

For each \( y_u \) the cost of evaluating the FE approximation \( u^n_h(\cdot, y_u) \) equal the cost of assembling the stiffness matrix plus the cost of solving the linear system. Due to the locality of \( V_h^u \) the stiffness matrix is sparse and has at most \( \mathcal{O}(M_{h-u}) = \mathcal{O}(h_u^{-d}) \) nonzero elements, to evaluate each of these elements we need \( \mathcal{O}([u]) \) operators. Besides that the cost for solving the linear system is \( \mathcal{O}(M_{h_u}^{1+\delta}) = \mathcal{O}(h_u^{-d(1+\delta)}) \) for any \( \delta > 0 \), see [16, Section 10]. Thus, we have

\[
\text{cost of evaluating } G(u^n_h(\cdot, \nu)) = \mathcal{O}(h_u^{-d} |u| + h_u^{-d(d+\delta)}) = \mathcal{O}(h_u^{-d} |u|).
\]
Therefore, the total computational cost of the MDFEM is
\[
\text{cost}(Q_c) = O \left( \sum_{u \in \mathcal{U}(e)} n_u h_u^{-d} 2^{|u|} |u| \right).
\]

To simplify the further notation, we will denote \( L_u := 2^{|u|} |u| \) and write
\[
\text{cost}(Q_c) = O \left( \sum_{u \in \mathcal{U}(e)} n_u h_u^{-d} L_u \right).
\]

### 7.2 Error analysis

In this subsection we give an a priori estimation for the total error of the MDFEM algorithm. We have the following result.

**Proposition 6.** For any \( \alpha \in \mathbb{N} \) such that \( \alpha \geq 2 \) under the conditions of Lemma 5 if the MDFEM based on transformed interlaced polynomial lattice rules of order \( \alpha \) with convergence rate of order \( \lambda \in [1, \alpha] \) defined in Theorem 1, and FEM with convergence rate \( \tau \) as in (50) with the particular conditions (43), (44), (45) and (48) then
\[
\left| I(G(u)) - Q_c(G(u)) \right| \lesssim \sum_{u \in \mathcal{U}(e)} \gamma_u M_u + \max \left\{ 1, \max_{u \in \mathcal{U}(e)} \left( \frac{h(n_u)}{|u|} \right)^{\alpha_1 |u|} \right\} \sum_{u \in \mathcal{U}(e)} \left( \gamma_u C_{u, \alpha} |u|^{\alpha_1 |u|} + 2 |u|^2 h_u \right),
\]
where \( \alpha_1 = \alpha/2 + 1/4 \), \( C_{u, \alpha} := C_{2, \alpha, \lambda, |u|} \) given by (35), \( M_u := M |u| \) with \( M \) given by (25) and \( \gamma_u \) given by (35). Given \( \gamma_j = \sqrt{2} b_j \).

**Proof.** The error splits into three terms
\[
I(G(u)) - Q_c(G(u)) = \left( I(G(u)) - \sum_{u \in \mathcal{U}(e)} I_u(G(u_u)) \right) + \left( \sum_{u \in \mathcal{U}(e)} (I_u(G(u_u)) - I_u(G(u^h_u))) \right) + \left( \sum_{u \in \mathcal{U}(e)} (I_u - Q_{u, n_u}) (G(u^h_u)) \right).
\]

The first term is the truncation error which incurs because we take only a finite number of decomposed elements. The second term is the spatial discretization error resulting from the FE approximation. The last term is the cubature error arising from using cubature rules to approximate the integrals.

The truncation error can be easily estimated using the Cauchy–Schwarz inequality and the reproducing property. Let us denote \( K_u(x_u, y_u) := \prod_{j \in u} K_{\alpha, 0, \rho}(x_j, y_j) \) with \( K_{\alpha, 0, \rho}(\cdot, \cdot) \) given by (24). Particularly, we have
\[
I_u(G(u_u)) = \int_{\mathbb{R}^{|u|}} (G(u_u), K_u(y_u, \cdot)) \, d\mu_u(y_u)
\]
\[
\leq \int_{\mathbb{R}^{|u|}} \|G(u_u)\|_{H_{\alpha, 0, \rho, |u|}(\mathbb{R}^{|u|})} \|K_u(y_u, \cdot)\|_{H_{\alpha, 0, \rho, |u|}(\mathbb{R}^{|u|})} \, d\mu_u(y_u).
\]
Therefore, we have
\[
\left| I(G(u)) - \sum_{u \in \mathcal{M}(c)} I_u(G(u)) \right| = \sum_{u \notin \mathcal{M}(c)} I_u(G(u)) \leq \sum_{u \notin \mathcal{M}(c)} \|G(u)\|_{H_{\infty, \alpha}} \sum_{u \notin \mathcal{M}(c)} \gamma_n M_u = \|G(u)\|_{H_{\infty, \gamma_n}} \sum_{u \notin \mathcal{M}(c)} \gamma_n M_u, \tag{58}
\]
where
\[
\|G(u)\|_{H_{\infty, \gamma_n}} := \sup_{|u| < \infty} \gamma_n^{-1} \|G(u)\|_{H_{\infty, \alpha}}.
\]
The spatial discretization error can be bounded as
\[
\left| \sum_{u \in \mathcal{M}(c)} (I_u(G(u)) - I_u(G(u_h^u))) \right| = \sum_{u \in \mathcal{M}(c)} \|G(u) - G(u_h^u)\|
\leq \sum_{u \in \mathcal{M}(c)} \int_{\mathbb{R}^{|u|}} \left| G(u(\cdot, y_u)) - G(u_h^u(\cdot, y_u)) \right| d\mu_n(y_u). \tag{59}
\]
Due to the linearity of $G$ we have for any $y_u \in \mathbb{R}^{|u|}$
\[
\left| G(u(\cdot, y_u)) - G(u_h^u(\cdot, y_u)) \right| = \left| G \left( \sum_{v \subseteq u} (-1)^{|v|-|u|} u(\cdot, y_v) \right) - G \left( \sum_{v \subseteq u} (-1)^{|v|-|u|} u_h^u(\cdot, y_v) \right) \right|
= \left| \sum_{v \subseteq u} (-1)^{|v|-|u|} \left( G(u(\cdot, y_v)) - G(u_h^u(\cdot, y_v)) \right) \right|
\leq \sum_{v \subseteq u} \left| G(u(\cdot, y_v)) - G(u_h^u(\cdot, y_v)) \right|.
\]
Thus, for each $u$ using the FEM approximation with error bound as in (50) we have
\[
\int_{\mathbb{R}^{|u|}} \left| G(u(\cdot, y_u)) - G(u_h^u(\cdot, y_u)) \right| d\mu_n(y_u) \leq \int_{\mathbb{R}^{|u|}} \sum_{v \subseteq u} \left| G(u(\cdot, y_v)) - G(u_h^u(\cdot, y_v)) \right| d\mu_n(y_u)
= \sum_{v \subseteq u} \int_{\mathbb{R}^{|u|}} \left| G(u(\cdot, y_v)) - G(u_h^u(\cdot, y_v)) \right| d\mu_n(y_v) \lesssim \sum_{v \subseteq u} h_v^u \lesssim 2^{|u|} h_u^u,
\]
with the hidden constant independent of $h$ and $u$. Inserting this into (59) yields
\[
\sum_{u \in \mathcal{M}(c)} \left( I_u(G(u)) - I_u(G(u_h^u)) \right) \lesssim \sum_{u \in \mathcal{M}(c)} 2^{|u|} h_u^u, \tag{60}
\]
again with the hidden constant independent of $h$ and $u$. 

25
For each \( u \) using the cubature rule defined in Theorem 1 leads to

\[
\left\| \left( I_u - Q_{u,n_u} \right) \left( G(u^{h_u}) \right) \right\| \leq C_{2,\alpha,\lambda,|u|} \|G(u^{h_u})\|_{H_{\alpha,\lambda,|u|}(\mathbb{R}^n)} \frac{(\ln(n_u))^{\alpha_1|u|}}{n_u^2},
\]

where \( \alpha_1 = \alpha/2 + 1/4 \) and for any \( \lambda \in [1,\alpha) \). Note that \( \lambda \) will be determined later. To simplify the further notation we denote \( C_{u,\alpha} := C_{2,\alpha,\lambda,|u|} \). Therefore, the cubature error is now bounded as

\[
\left\| \sum_{u \in \mathcal{U}(c)} \left( I_u - Q_{u,n_u} \right) (G(u^{h_u})) \right\| \leq \sum_{u \in \mathcal{U}(c)} C_{u,\alpha} \|G(u^{h_u})\|_{H_{\alpha,\lambda,|u|}(\mathbb{R}^n)} \frac{(\ln(n_u))^{\alpha_1|u|}}{n_u^2},
\]

\[
\leq \left( \sup_{u \in \mathcal{U}(c)} \gamma_u^{-1} \|G(u^{h_u})\|_{H_{\alpha,\lambda,|u|}(\mathbb{R}^n)} \right) \max_{u \in \mathcal{U}(c)} \left( \frac{(\ln(n_u))^{\alpha_1|u|}}{|u|} \right) \sum_{u \in \mathcal{U}(c)} \frac{\gamma_u C_{u,\alpha} |u|^{\alpha_1|u|}}{n_u^2},
\]

where

\[
\|G(u^{h})\|_{H_{\alpha,\lambda}^2} := \sup_{|u| < \infty} \gamma_u^{-1} \|G(u^{h_u})\|_{H_{\alpha,\lambda,|u|}(\mathbb{R}^n)}.
\]

We remark that we pulled out \(|u|^{-1}\) to control the logarithm growth later. This idea was firsts used in [27]. Finally, combining (58), (60) and (61) we receive a bound for the total error

\[
|I(G(u)) - Q_r(G(u))| \leq \|G(u)\|_{H_{\alpha,\lambda}^2} \sum_{u \in \mathcal{U}(c)} \gamma_u M_u + \sum_{u \in \mathcal{U}(c)} \frac{2|u|}{h_u^2}
\]

\[
\quad + \|G(u^{h})\|_{H_{\alpha,\lambda}^2} \max_{u \in \mathcal{U}(c)} \left( \frac{(\ln(n_u))^{\alpha_1|u|}}{|u|} \right) \sum_{u \in \mathcal{U}(c)} \frac{\gamma_u C_{u,\alpha} |u|^{\alpha_1|u|}}{n_u^2}.
\]

Using Lemma 5 we have

\[
\|G(u)\|_{H_{\alpha,\lambda}^2} \leq C'_{\alpha,\lambda} \|G\|_{V^*} \|f\|_{V^*} \sup_{|u| < \infty} \gamma_u^{-1} b_u 2^{2|u|^2/2},
\]

which is finite if we choose for all \( j \)

\[
\gamma_j = \sqrt{2} b_j.
\]

Using similar arguments we also have \( \|G(u^{h})\|_{H_{\alpha,\lambda}^2} < \infty \). Applying these into (62) the needed claim follows. \( \square \)

### 7.3 Construction of the MDFEM active set

The active set of the MDFEM is defined by

\[
\mathcal{U}(\epsilon) = \mathcal{U}(\epsilon, p^*) := \left\{ u : \gamma_u M_u > \left( \frac{\epsilon/2}{\sum_{|u| < \infty} (\gamma_0 M_u)^p} \right)^{1/(1-p^*)} \right\},
\]

with \( \gamma_j = \sqrt{2} b_j \) for all \( j \) as in (63).
Proposition 7. Under the conditions of Proposition 6 with $p^* \in (0, 1)$ if the MDFEM active set is constructed as in (64) then the MDFEM truncation error is bounded by

$$|I(G(u)) - \sum_{u \in \mathcal{U}(\epsilon)} I_u(G(u_u))| \lesssim \frac{\epsilon}{2}.$$ 

Proof. Using (58) we have

$$|I(G(u)) - \sum_{u \in \mathcal{U}(\epsilon)} I_u(G(u_u))| \lesssim \sum_{u \in \mathcal{U}(\epsilon,p^*)} \gamma_u M_u = \sum_{u \in \mathcal{U}(\epsilon,p^*)} (\gamma_u M_u)^{(1-p^*)} (\gamma_u M_u)^{p^*}$$

$$< \sum_{u \in \mathcal{U}(\epsilon,p^*)} \frac{\epsilon/2}{\sum_{|u|<\infty} (\gamma_u M_u)^{p^*}} (\gamma_u M_u)^{p^*} \leq \frac{\epsilon}{2},$$

which is the claim. \qed

The following results are taken from [27, Proposition 2 and 3]. It states that the cardinalities both of the active set and each set of the active set increase very slowly with decreasing $\epsilon$.

Proposition 8. Given $\gamma_u = \prod_{j \in u} \gamma_j$ with $\{\gamma_j\} \in \ell^{p^*}(\mathbb{N})$ for some $p^* \in (0, 1)$, and with $M_u = M^{[u]}$, then for any $\epsilon > 0$, it holds

$$|\mathcal{U}(\epsilon, p^*)| \leq \left(\frac{2}{\epsilon}\right)^{p^*/(1-p^*)} \left(\sum_{|u|<\infty} (\gamma_u M_u)^{p^*}\right)^{1/(1-p^*)} \lesssim \epsilon^{-p^*/(1-p^*)},$$

and as $\epsilon \to 0$

$$d(\epsilon, p^*) := \max_{u \in \mathcal{U}(\epsilon,p^*)} |u| = O\left(\frac{\ln(\epsilon^{-1})}{\ln(\ln(\epsilon^{-1}))}\right) = o(\ln(\epsilon^{-1})).$$

7.4 Construction of the MDFEM cubature rules and FEMs

In this subsection we will present how to choose the numbers of the cubature points and the step sizes of the FEMs.

Proposition 9. Under the conditions of Proposition 6 with $p^* \in (0, 1)$ for a given requested error tolerance $\epsilon > 0$, consider the MDFEM algorithm defined in (18) based on FEMs with convergence rate $\tau$ as in (50). Let us define $\lambda = \frac{\tau(1-p^*)}{p^*/(1-p^*)} + d/\tau$, $\alpha = |\lambda| + 1$. For any $p^*$ such that $0 < p^* \leq \frac{1}{2+d/\tau}$, or respectively, $\lambda \geq 1$ and for $\kappa < \frac{\ln(2)}{\alpha}$ the MDFEM bases on transformed interlaced polynomial lattice rules of order $\alpha$ with convergence rate of order $\lambda$. If for each $u \in \mathcal{U}(\epsilon)$ the FEM discretization step $h_u$ is chosen as in (66) and the number of cubature points $n_u$ is chosen as in (68), then the combination of the spatial discretization error and the cubature error is bounded by

$$\sum_{u \in \mathcal{U}(\epsilon,p^*)} |I_u(G(u_u)) - Q_{u,n_u}(G(s^u_u))| \lesssim \max\left\{1, \max_{u \in \mathcal{U}(\epsilon)} \left(\frac{\ln(n_u)}{|u|}\right)^{\alpha_1|u|}\right\} \frac{\epsilon}{2},$$

where $\alpha_1 = \alpha/2 + 1/4$ with computational cost

$$\text{cost}(Q_\epsilon) \lesssim e^{-(1+d/\tau)p^*/(1-p^*)-d/\tau}.$$
Proof. The numbers of the cubature points \( n_u \) and the FEM step sizes \( h_u \) are chosen to minimize the computational cost (56) subject to the sum of the spatial discretization error and the cubature error bounded by \( \epsilon/2 \). Using Proposition 6 such optimization problem is given as: find \( n_u \) and \( h_u \) which minimize

\[
\sum_{u \in \Omega(\epsilon,p^*')} n_u h_u^{-d} \ell_u
\]

subject to

\[
\sum_{u \in \Omega(\epsilon,p^*')} |I_u(G(u_u)) - Q_{u,n_u}(G(u_u^{h_u^n}))| 
\leq \max \left\{ 1, \max_{u \in \Omega(\epsilon,p^*')} \left( \frac{\ln(n_u)}{|u|} \right)^{\alpha_1|u|} \right\} \sum_{u \in \Omega(\epsilon,p^*')} \left( \frac{\gamma_u C_{u,\alpha}|u|^{\alpha_1|u|}}{n_u} + 2|u|h_u^\tau \right) \leq \frac{\epsilon}{2}.
\]

Put \( n_u = \lceil k_u \rceil \) where \( k_u \) are real numbers, the approximated optimization problem then has the form: find \( k_u \) and \( h_u \) which minimize

\[
\sum_{u \in \Omega(\epsilon,p^*')} k_u h_u^{-d} \ell_u
\]

subject to

\[
\sum_{u \in \Omega(\epsilon,p^*')} \left( \frac{\gamma_u C_{u,\alpha}|u|^{\alpha_1|u|}}{k_u} + 2|u|h_u^\tau \right) = \frac{\epsilon}{2}. \tag{65}
\]

The Lagrange multiplier is given by

\[
\Lambda(\xi) = \sum_{u \in \Omega(\epsilon,p^*')} k_u h_u^{-d} \ell_u + \xi \left( \sum_{u \in \Omega(\epsilon,p^*')} \left( \frac{\gamma_u C_{u,\alpha}|u|^{\alpha_1|u|}}{k_u} + 2|u|h_u^\tau \right) - \frac{\epsilon}{2} \right),
\]

where \( \xi \) is a constant whose value is determined by the constraint (65). We need to find the stationary point of the function \( \Lambda \) with respect to \( k_u \) and \( h_u \), that is, to find \( k_u \) and \( h_u \) satisfying

\[
\frac{\partial \Lambda}{\partial k_u} = h_u^{-d} \ell_u - \xi \lambda \gamma_u C_{u,\alpha}|u|^{\alpha_1|u|} k_u^{-\lambda-1} = 0
\]

and

\[
\frac{\partial \Lambda}{\partial h_u} = -d k_u h_u^{-d-1} \ell_u + \xi \tau 2|u|h_u^{-\tau-1} = 0,
\]

for all \( u \in \Omega(\epsilon,p^*') \). Solving the resulting system of equations and the constraint (65) to obtain: for each \( u \in \Omega(\epsilon,p^*') \), see [27, Section 7.6] for more detail,

\[
h_u = \tilde{A} \epsilon^{1/\tau} \left( \frac{\gamma_u C_{u,\lambda}|u|^{\alpha_1|u|} \ell_u^\lambda}{2(\lambda+1)|u|} \right)^{\frac{1}{\lambda(\tau+\delta)\tau}} \left( \sum_{u \in \Omega(\epsilon,p^*')} \left( \frac{\gamma_u^\tau C_{u,\lambda}^\tau|u|^{\alpha_1|u|} 2 \lambda d|u| \ell_u^\lambda}{2^d |u| \ell_u^\tau} \right)^{\lambda(\tau+\delta)\tau} \right)^{-1/\tau}
\]

and

\[
k_u = \tilde{B} \epsilon^{-1/\lambda} \left( \frac{\gamma_u^{\tau+d} C_{u,\lambda}^{\tau+d}|u|^{\alpha_1(\tau+d)|u|}}{2^d |u| \ell_u^\tau} \right)^{\frac{1}{\lambda(\tau+\delta)\tau}}
\]

28
\[
\sum_{\tau \in U} \left( \gamma_u^\tau C_u^{\tau, \lambda} \left| u \right|^{\tau_1 u_1} 2^{\lambda d u} x_u^{\lambda \tau} \right) \left( \frac{\lambda(\tau + d)}{\lambda \tau} \right)^{1/\lambda},
\]

(67)

where \( \tilde{A} := 2^{-1/\tau} A (A^\tau + B^{-\lambda})^{-1/\tau} \) and \( \tilde{B} := 2^{1/\lambda} B (A^\tau + B^{-\lambda})^{1/\lambda} \) with \( A := \left( \frac{\lambda + 1}{\lambda \tau} \right)^{1/\lambda} \) and \( B := \left( \frac{d^{\lambda + d}}{\tau} \right)^{1/\lambda + \tau} \). Reminding that we choose

\[ n_u = \left\lceil k_u \right\rceil. \]

(68)

We require the sum in (66) and (67) to be uniformly bounded for all \( \epsilon \), that is, require

\[
\sum_{|u| < \infty} \left( \gamma_u^\tau C_u^{\tau, \lambda} \left| u \right|^{\tau_1 u_1} 2^{\lambda d u} x_u^{\lambda \tau} \right) \left( \frac{\lambda(\tau + d)}{\lambda \tau} \right)^{1/\lambda} < \infty.
\]

(69)

Because \( \gamma_u = 2^{u/2} \prod_{j \in u} b_j \) with \( \{b_j\}_{j \geq 1} \in \ell^{p^*}(\mathbb{N}) \) for some \( p^* \in (0, 1) \) and for all \( u \) both \( L_u \) and \( C_u, \lambda \) are at most exponentially in \( |u| \), applying [27, Lemma 1] the sum (69) is bounded when

\[
\frac{\alpha_1 \tau}{\lambda(\tau + d) + \tau} < 1, \quad \text{or equivalently,} \quad \alpha_1 < \lambda \left( 1 + \frac{d}{\tau} \right) + 1,
\]

(70)

and

\[
\frac{\tau}{\lambda(\tau + d) + \tau} \geq p^*, \quad \text{or equivalently,} \quad \lambda \leq \frac{\tau(1 - p^*)}{p^*(\tau + d)}.
\]

(71)

Note that it is required in Theorem 1 that \( 1 \leq \lambda \), together with (71) this restricts us to the case when \( p^* \) is sufficiently small, that is,

\[
1 \leq \frac{\tau(1 - p^*)}{p^*(\tau + d)}, \quad \text{or equivalently,} \quad p^* < \frac{1}{2 + d/\tau}.
\]

Assume that \( \epsilon \) is small enough such that \( k_u \geq 1/2 \) then \( n_u \leq 2k_u \). The computational cost is bounded by

\[
\text{cost}(Q_\epsilon) \lesssim 2 \sum_{u \in \Omega(\epsilon, p^*)} k_u h_u^{-d} L_u
\]

\[
= 2 \tilde{A}^{-d} \tilde{B} \epsilon^{-1/\lambda - d/\tau} \left( \sum_{u \in \Omega(\epsilon, p^*)} \left( \gamma_u^\tau C_u^{\tau, \lambda} \left| u \right|^{\tau_1 u_1} 2^{\lambda d u} x_u^{\lambda \tau} \right) \left( \frac{\lambda(\tau + d)}{\lambda \tau} \right)^{1/\lambda} \right)^{\lambda(\tau + d)+\tau} \]

(72)

Due to (69) the sum in (72) is uniformly bounded, hence, we can write

\[
\text{cost}(Q_\epsilon) \lesssim \epsilon^{-1/\lambda - d/\tau}.
\]

It is easy to see that bigger value of \( \lambda \) gives smaller bound for \( \text{cost}(Q_\epsilon) \) so we choose \( \lambda \) as big as possible satisfying (71), i.e.,

\[
\lambda = \frac{\tau(1 - p^*)}{p^*(\tau + d)}.
\]
The interlacing order is then chosen as
\[ \alpha = \lfloor \lambda \rfloor + 1 = \left\lfloor \frac{\tau (1 - p^*)}{p^* (\tau + d)} \right\rfloor + 1. \]

The condition (70) is now satisfied because
\[ \alpha_1 = \frac{\alpha}{4} + 1 = \frac{\lfloor \lambda \rfloor}{4} + 3 < \lambda \left( 1 + \frac{d}{\tau} \right) + 1, \]
for any \( \lambda > 0 \). The needed statements follow.

7.5 Randomized result

For the case \( \frac{1}{2} \leq \lambda < 1 \), or respectively, \( \frac{1}{2} + \frac{d}{\tau} < p^* \leq \frac{1}{2} + \frac{d}{\tau} \), first order cubature rules are used for the MDFEM algorithm. Particularly, we use transformed randomly digitally shifted polynomial lattice rules as cubature rules in the MDFEM algorithm, see also Remark 1. In this paper we will only provide some key results, a full description and analysis for using such randomized cubature rules in the context of the MDFEM algorithm was given in [27].

Using randomly digitally shifted polynomial lattice rules we need to define the total mean square error over all \( \{\delta_u\}_{u \in \mathcal{U}(\epsilon)} \) random shifts as
\[
\mathbb{E}^{\mathcal{U}(\epsilon)} \left[ |I(G(u)) - Q_\epsilon(G(u))|^2 \right] := \left( \prod_{u \in \mathcal{U}(\epsilon)} \mathbb{E}^{\delta_u} \right) \left[ |I(G(u)) - Q_\epsilon(G(u))|^2 \right].
\]

7.6 Main result

We are now able to analyze the complexity of the MDFEM algorithm. The analysis is under the conditions of Proposition 9, for the convenience of the readers we collect these conditions into two groups. The first group is to guarantee the parametric regularity of the PDE solution, that is, \( f, G \in V^* \), and there exists a positive sequence \( \{b_j\}_{j \geq 1} \) with \( 0 < b_j \leq 1 \) for all \( j \) such that the positive constant \( \kappa \), given below, satisfies
\[
\kappa = \sum_{j \geq 1} \frac{|| \phi_j ||_{L^\infty(D)}}{b_j} < \infty,
\]
and \( \{b_j\}_{j \geq 1} \in \ell^{p^*}(N) \) for some \( p^* \in (0, 1) \). The second group is to guarantee the convergence of the FE approximation including the conditions (43), (44), (45) and (48).

**Theorem 3.** Under the above conditions for a given requested error tolerance \( \epsilon > 0 \), consider the MDFEM algorithm defined in (18) where the active set \( \mathcal{U}(\epsilon, p^*) \) is constructed as in (64); and for all \( u \in \mathcal{U}(\epsilon, p^*) \) the discretization step \( h_u \) of the FEM with convergence rate \( \tau \) as in (50) is chosen as in (66), and the number of cubature points \( n_u \) is chosen as in (68) with \( \lambda = \frac{\tau (1 - p^*)}{p^* (\tau + d)} \) and \( \alpha = \lfloor \lambda \rfloor + 1 \). Then, for \( \kappa < \frac{\ln(2)}{2} \), the followings hold

- If \( 0 < p^* \leq \frac{1}{2 + d/\tau} \), or respectively, \( \lambda \geq 1 \), the MDFEM based on transformed interlaced polynomial lattice rules of order \( \alpha \) with convergence rate of order \( \lambda \) achieves
  \[ |I(G(u)) - Q_\epsilon(G(u))| \lesssim \epsilon^{1 - o(1)}. \]
If \( \frac{1}{2+d/\tau} < p^* \leq \frac{1}{2+d/\tau} \), or respectively, \( \frac{1}{2} \leq \lambda < 1 \), the MDFEM based on transformed randomly digitally shifted polynomial lattice rules with convergence rate of order \( \lambda \) achieves

\[
\sqrt{\mathbb{E}[\epsilon]} \left[ |I(G(u)) - Q_{\epsilon}(G(u))|^2 \right] \lesssim \epsilon^{1-o(1)}.
\]

In both cases the computational cost is bounded as

\[
\text{cost}(Q_{\epsilon}) \lesssim \epsilon^{-\alpha_{\text{MDFEM}}},
\]

with \( \alpha_{\text{MDFEM}} = (1 + d/\tau)p^*/(1 - p^*) + d/\tau \).

**Proof.** We first show the statement for the case \( 0 < p^* \leq \frac{1}{2+d/\tau} \). It follows from Proposition 6, Proposition 7 and Proposition 9 that the error of the MDFEM is bounded by

\[
|I(G(u)) - Q_{\epsilon}(G(u))| \lesssim \max \left\{ 1, \max_{u \in \mathbb{U}(\epsilon)} \left( \frac{\ln(nu)}{|u|} \right)^{\alpha_{1}|u|} \right\} \epsilon
\]

with computational cost

\[
\text{cost}(Q_{\epsilon}) \lesssim \epsilon^{-(1+d/\tau)p^*/(1-p^*)-d/\tau}.
\]

Using the same argument as in [27, Theorem 1] we have

\[
\max \left\{ 1, \max_{u \in \mathbb{U}(\epsilon)} \left( \frac{\ln(nu)}{|u|} \right)^{\alpha_{1}|u|} \right\} = \epsilon^{-\delta(\epsilon)},
\]

where \( \delta(\epsilon) = O\left( \ln(\ln(\ln(\epsilon^{-1})))/\ln(\ln(\epsilon^{-1})) \right) = o(1) \) as \( \epsilon \to 0 \). Hence, we can write

\[
|I(G(u)) - Q_{\epsilon}(G(u))| \lesssim \epsilon^{1-o(1)}.
\]

For the case \( \frac{1}{2+d/\tau} < p^* \leq \frac{1}{\sqrt{2+d/\tau}} \) the statement follows using similar arguments, a full proof is provided in [27].

Finally we would like to compare the complexity of the MDFEM and the standard QMCFEM algorithm. The standard QMCFEM is to truncate the parameters \( y \) to some dimension \( s \). Because \( s \) might be arbitrarily large, the standard QMCFEM requires QMC rules with convergence independent of the dimension of the integrand. Such QMC rules over the Euclidean space \( \mathbb{R}^s \) with the Gaussian distribution were developed in [23] by mapping randomly shifted lattice rules over the unit cube to \( \mathbb{R}^s \) by the inverse of the normal cumulative distribution. However, because this mapping might damage the smoothness of the integrand, the convergence rate of these QMC rules was limited to first order (with respect to the numbers of QMC points). Particularly, under the same conditions of Theorem 3 the standard QMCFEM was shown in [16, (37)] to achieve a “probabilistic” error

\[
\text{error}(Q_{\text{QMCFEM}}) \lesssim s^{-\left( \frac{d}{2} + \frac{1}{4} \right) + \delta} + N^{-\left( \frac{1}{2} \min\{ \frac{d}{2}, \frac{d}{3} \} + \frac{1}{2} \right) + \delta} + h^{\tau},
\]

where \( \delta \) is a parameter that might be chosen arbitrarily small (but then increases the hidden constant towards infinity), \( N \) is the number of cubature points, \( h \) is the finite element step size and \( s \) is the truncation dimension. The cost model in [16, Section 10] taking advantage of the wavelet decomposition to obtain a discretization of the random field is then

\[
\text{cost}(Q_{\text{QMCFEM}}) \lesssim N(s + h^{-d})
\]
Therefore, consider the limit case $\delta = 0$ to ensure an error of $\epsilon$ the standard QMCFEM requires
\[
\text{cost}(Q_{\text{QMCFEM}}) \lesssim \epsilon^{- \frac{1}{2} \min\left(\frac{2}{p^*}, \frac{2}{p^* + d/\tau}\right)} \left(\epsilon^{- \frac{2}{p^* + d/\tau}} + \epsilon^{- \frac{d}{7}}\right) := \epsilon^{- a_{\text{QMCFEM}}}.
\]

To compare the performance of the two methods we will consider the sign of $a_{\text{QMCFEM}} - a_{\text{MDFEM}}$. If it is non-negative, i.e., $a_{\text{MDFEM}} \leq a_{\text{QMCFEM}}$, the cost of the MDFEM algorithm is asymptotically smaller than or equal to the cost of the standard QMCFEM, in other words, the MDFEM performs better than or equal to the standard QMCFEM. Indeed, for $0 < p^* \leq \frac{4d}{7 + d/\tau}$ the cost of the standard QMCFEM is of order $\epsilon^{- a_{\text{QMCFEM}}}$ with
\[
a_{\text{QMCFEM}} = 1 + \max \left\{ \frac{2p^*}{4 - p^*}, \frac{d}{7} \right\} = \begin{cases} 1 + \frac{2p^*}{4 - p^*}, & \text{if } p^* > \frac{4d}{7 + d/\tau}, \\ 1 + \frac{d}{7}, & \text{if } p^* \leq \frac{4d}{7 + d/\tau}. \end{cases}
\]

It is easy to see that if $d/\tau \geq 1/4$ then for any $p^*$ such that $0 < p^* \leq \frac{1}{2 + d/\tau} \leq \frac{4d}{7 + d/\tau}$
\[
a_{\text{QMCFEM}} - a_{\text{MDFEM}} = 1 - \left(1 + \frac{d}{7}\right) \frac{p^*}{1 - p^*} \geq 0 \iff p^* \leq \frac{1}{2 + d/\tau}.
\]

If $d/\tau < 1/4$ then there are two cases to be considered. For $0 < p^* \leq \frac{4d}{7 + d/\tau} < \frac{1}{2 + d/\tau}$ we have
\[
a_{\text{QMCFEM}} - a_{\text{MDFEM}} = 1 - \left(1 + \frac{d}{7}\right) \frac{p^*}{1 - p^*} \geq 0.
\]

For $\frac{4d}{7 + d/\tau} < p^* \leq \frac{1}{2 + d/\tau}$ we have
\[
a_{\text{QMCFEM}} - a_{\text{MDFEM}} = \frac{4 - 4d/\tau - p^*(7 - d/\tau)}{(4 - p^*)(1 - p^*)} \geq 0 \iff p^* \leq \frac{4 - 4d/\tau}{7 - d/\tau},
\]

which is always satisfied because $p^* \leq \frac{1}{2 + d/\tau} \leq \frac{4d}{7 + d/\tau}$ for all $d/\tau < 1/4$.

Hence, for any $p^*$ such that $0 < p^* \leq \frac{1}{2 + d/\tau}$ the MDFEM performs better than or equal to the standard QMCFEM.

**Appendix**

**Proof of Lemma 1**

*Proof of Lemma 1.* The first two properties (13) and (14) are shown in [25] and [27, Proof of Lemma 4], respectively. The third property (15) is new and essential in evaluating the norm of $u_u$. Observing that for any $\mathbf{w}, \mathbf{v} \subset \mathbb{N}$
\[
\partial_{\mathbf{w} \cdot \mathbf{v}} u(\cdot, \cdot) = 0 \text{ for any } \mathbf{w} \subset \mathbf{v}.
\]

Hence, in the following sum there remain only the indices $\mathbf{v}$ such that $\mathbf{w} \subset \mathbf{v} \subset \mathbf{u}$ as
\[
(\partial^{\mathbf{w} \cdot \mathbf{v}} u) (\cdot, \mathbf{0}_u) = \sum_{\mathbf{v} \subset \mathbf{u}} (-1)^{|\mathbf{u}| - |\mathbf{v}|} (\partial^{\mathbf{w} \cdot \mathbf{v}} u(\cdot, \cdot)) (\cdot, \mathbf{0}_u) = \sum_{\mathbf{w} \subset \mathbf{v} \subset \mathbf{u}} (-1)^{|\mathbf{u}| - |\mathbf{v}|} (\partial^{\mathbf{w} \cdot \mathbf{v}} u(\cdot, \cdot)) (\cdot, \mathbf{0}_u).
\]
Exploiting the analyticity of the solution $u$ we have $(\partial^{m}_{y_{a}} u (\cdot, \cdot)) (\cdot, 0_{a}) = \partial^{m}_{y_{a}} u (\cdot, 0)$ for any $w \subseteq v \subseteq u$. Inserting this into the above equation to get

$$
(\partial^{m}_{y_{a}} u_{a}) (\cdot, 0_{a}) = \sum_{w \subseteq v \subseteq u} (-1)^{|u|-|v|} (\partial^{m}_{y_{a}} u (\cdot, \cdot)) (\cdot, 0_{a}) = \partial^{m}_{y_{a}} u (\cdot, 0) \sum_{w \subseteq v \subseteq u} (-1)^{|u|-|v|}.
$$

Moreover, we have

$$
\sum_{w \subseteq v \subseteq u} (-1)^{|u|-|v|} = \sum_{k=0}^{|v|} \binom{|v|}{k} (-1)^{|v|-k} = \begin{cases} 1, & \text{if } w = u \\ 0, & \text{if } w \subset u \end{cases}.
$$

Applying this into (73) the claim (15) follows.

**Derivation of the anchored Gaussian Sobolev kernel**

We derive the reproducing kernel of the anchored Gaussian Sobolev space $H_{a, 0, \rho}(\mathbb{R})$ of functions satisfying the special properties of the anchored decomposition. Following [25, Example 4.4], we only need to construct a reproducing kernel $K_{a, 0, \rho}$ such that $H(K_{a, 0, \rho})$ is separable and does not consist of any constant function except zero. For this we use similar arguments as in [35, Section 1.1] which was developed for finding the kernel of the anchored Sobolev space over the unit cube. Here, we slightly modified for the case of the anchored Gaussian Sobolev space. By Taylor’s theorem knowing that $F(0) = 0$ we write

$$
F(y) = \sum_{\tau=1}^{\alpha-1} \frac{y^{\tau}}{\tau!} F^{(\tau)}(0) + \int_{0}^{y} \frac{(y-t)^{\alpha-1}}{(\alpha-1)!} F^{(\alpha)}(t) \, dt = \sum_{\tau=1}^{\alpha-1} \frac{y^{\tau}}{\tau!} F^{(\tau)}(0) + \int_{0}^{y} \frac{(y-t)^{\alpha-1}}{(\alpha-1)!} F^{(\alpha)}(t) \, dt.
$$

On the other hand by the reproducing property we have

$$
F(y) = \langle F, K_{a, 0, \rho}(\cdot, y) \rangle_{H_{a, 0, \rho}(\mathbb{R})} = \sum_{\tau=1}^{\alpha-1} F^{(\tau)}(0) K_{a, 0, \rho}^{(\tau)}(0, y) + \int_{\mathbb{R}} F^{(\alpha)}(t) K_{a, 0, \rho}^{(\alpha)}(t, y) \rho(t) \, dt
$$

$$
= \sum_{\tau=1}^{\alpha-1} F^{(\tau)}(0) K_{a, 0, \rho}^{(\tau)}(0, y) + \int_{-\infty}^{0} F^{(\alpha)}(t) K_{a, 0, \rho}^{(\alpha)}(t, y) \rho(t) \, dt + \int_{0}^{\infty} F^{(\alpha)}(t) K_{a, 0, \rho}^{(\alpha)}(t, y) \rho(t) \, dt,
$$

here the derivatives of $K_{a, 0, \rho}$ are taken with respect to the first variable.

By comparing the two representations of $F$ it leads to choose the kernel $K_{a, 0, \rho}$ such that

$$
K_{a, 0, \rho}^{(\tau)}(0, y) = \frac{y^{\tau}}{\tau!}, \text{ for any } \tau = 1, \ldots, \alpha - 1 \text{ and any } y \in \mathbb{R}
$$

and for any $t \in \mathbb{R}$

$$
K_{a, 0, \rho}^{(\alpha)}(t, y) = \begin{cases} \frac{(y-t)^{\alpha-1}}{(\alpha-1)!} \rho(t) \mathbb{1}_{[0, y]}(t), & \text{if } y > 0, \\ \frac{-\left((-t)^{\alpha-1}/(\alpha-1)\right) \rho(t) \mathbb{1}_{[y, 0]}(t), & \text{if } y < 0, \\ 0, & \text{if } y = 0,
\end{cases}
$$

here again $\mathbb{1}_{X}(\cdot)$ is the indicator function on the set $X$. Inserting these into the Taylor’s expansion of $K_{a, 0, \rho}$ with respect to the first variable, noting that $K_{a, 0, \rho}(0, y) = 0$ for any $y$ we have

$$
K_{a, 0, \rho}(x, y) = \sum_{\tau=1}^{\alpha-1} \frac{x^{\tau}}{\tau!} K_{a, 0, \rho}^{(\tau)}(0, y) + \int_{0}^{x} \frac{(x-t)^{\alpha-1}}{(\alpha-1)!} K_{a, 0, \rho}^{(\alpha)}(t, y) \, dt,
$$

33
For $y > 0$ we write
\[
K_{\alpha,0,p}(x,y) = \sum_{\tau=1}^{\alpha-1} \frac{x\tau y\tau}{\tau!} + \int_0^x \frac{(x-t)^{\alpha-1} (y-t)^{\alpha-1}}{(\alpha-1)! \rho(t)} I_{[0,y)}(t) \, dt,
\]
which can be written as
\[
K_{\alpha,0,p}(x,y) = \begin{cases} \sum_{\tau=1}^{\alpha-1} \frac{x\tau y\tau}{\tau!} + \int_0^{\min\{x,y\}} \frac{(x-t)^{\alpha-1} (y-t)^{\alpha-1}}{(\alpha-1)! \rho(t)} \, dt & \text{if } x, y > 0 \\ \sum_{\tau=1}^{\alpha-1} \frac{x\tau y\tau}{\tau!} + \int_0^{\max\{x,y\}} \frac{(x-t)^{\alpha-1} (y-t)^{\alpha-1}}{(\alpha-1)! \rho(t)} \, dt & \text{if } x \leq 0 \text{ and } y > 0 \end{cases}
\]
Similarly for $y < 0$ we have
\[
K_{\alpha,0,p}(x,y) = \begin{cases} \sum_{\tau=1}^{\alpha-1} \frac{x\tau y\tau}{\tau!} + \int_0^{0} \frac{(x-t)^{\alpha-1} (y-t)^{\alpha-1}}{(\alpha-1)! \rho(t)} \, dt & \text{if } x, y > 0 \\ \sum_{\tau=1}^{\alpha-1} \frac{x\tau y\tau}{\tau!} + \int_0^{0} \frac{(x-t)^{\alpha-1} (y-t)^{\alpha-1}}{(\alpha-1)! \rho(t)} \, dt & \text{if } x \geq 0 \text{ and } y < 0 \end{cases}
\]
Hence, the explicit formula for $K_{\alpha,0,p}$ can be written as
\[
K_{\alpha,0,p}(x,y) = \sum_{\tau=1}^{\alpha-1} \frac{x\tau y\tau}{\tau!} + I_{\{xy > 0\}}(xy) \int_0^{+\infty} \frac{|x-t|^{\alpha-1} (|y-t|)^{\alpha-1}}{(\alpha-1)! \rho(t)} \, dt.
\]

**Proof of Proposition 2**

We first show some results that will be used in this section. The following result is taken from [7, Lemma 3].

**Lemma 7.** For any $\tau \in \{0 : \alpha\}^*$ we have
\[
(F\rho)^{\tau}(y) = \rho(y) \sum_{\omega \leq \tau} (-1)^{\tau-\omega} c(\tau, \omega) H_{\tau-\omega}(y) F^{(\omega)}(y),
\]
where the sum is over $\omega \in \mathbb{N}_0$, $c(\tau, \omega) := (\tau/\omega)\sqrt{(\tau-\omega)!} := \prod_{j=1}^{\tau} (\tau_j - \omega_j) \sqrt{(\tau_j - \omega_j)!}$ and $H_{\tau}(y) := \prod_{j=1}^{\tau} H_{\tau_j}(y_j)$. Here, $H_\tau$ is the $\tau$-th normalized probabilistic Hermite polynomial given as
\[
H_{\tau}(y) := \sqrt{\tau!} \sum_{k=0}^{\lfloor \tau/2 \rfloor} \frac{(-1)^k y^{\tau-2k}}{k!(\tau-2k)!}. \tag{74}
\]

**Lemma 8.** For any $\alpha \in \mathbb{N}$ such that $\alpha \geq 2$, any $\tau \in \{0 : \alpha\}$ and $\eta \in \{0 : 2\alpha - 1\}$ we have
\[
\int_{\mathbb{R}} |H_{\tau}(y)|^2 |y|^{\eta} \rho(y) \, dy \leq c! (\alpha/2 + 1) \frac{2^{2\alpha}}{\sqrt{2\pi}} \Gamma(2\alpha) I_0(1/4) =: C_{\alpha, \alpha}.
\]

**Proof.** Using (74), the Cauchy–Schwarz inequality and $\int_{\mathbb{R}} |y|^p \rho(y) \, dy = 2^{p/2} \Gamma(p/2 + 1/2)/\sqrt{\pi}$ for any $p \in \mathbb{N}_0$ we have
\[
\int_{-T}^T |H_{\tau}(y)|^2 q(y) \rho(y) \, dy = \int_{-T}^T \tau! \left( \sum_{k=0}^{\lfloor \tau/2 \rfloor} \frac{(-1)^k y^{\tau-2k}}{k!(\tau-2k)!} \right)^2 |y|^{\eta} \rho(y) \, dy
\]
\[
\int_{-T}^T |H_{\tau}(y)|^2 q(y) \rho(y) \, dy = \int_{-T}^T \tau! \left( \sum_{k=0}^{\lfloor \tau/2 \rfloor} \frac{(-1)^k y^{\tau-2k}}{k!(\tau-2k)!} \right)^2 |y|^{\eta} \rho(y) \, dy
\]

34
Applying Lemma 7 into the last inequality we then write

$$
\leq \tau!([\tau/2] + 1) \sum_{k=0}^{[\tau/2]} \frac{2^{-2k}}{(k!(\tau - 2k)!)^2} \int_{\mathbb{R}} |y|^{2(\tau - 2k) + \eta} \rho(y) \, dy
$$

$$
= \tau!([\tau/2] + 1) \sum_{k=0}^{[\tau/2]} \frac{2^{-2k}}{\sqrt{\pi}} \Gamma(\tau - 2k + \eta/2 + 1/2)
$$

$$
\leq \alpha!(\alpha/2 + 1) \frac{2^{2\alpha}}{\sqrt{2\pi}} \frac{\Gamma(2\alpha)}{\Gamma(\alpha)} \sum_{k=0}^{\infty} \frac{2^{-4k}}{(k!)^2}
$$

$$
= \alpha!(\alpha/2 + 1) \frac{2^{2\alpha}}{\sqrt{2\pi}} \Gamma(2\alpha) I_0(1/4).
\square
$$

We are now ready to give the proof of Proposition 2.

**Proof of Proposition 2.** Using the Cauchy–Schwarz inequality and then the chain rule \(((F \rho) \circ T)^{(\tau)}(y) = (2T)^{(\tau)}(F \rho)^{(\tau)}(y)\) we have

$$
\|F \rho \circ T\|_{H_{\alpha,\rho}^+([0,1]^s)}^2 = \sum_{\tau \in \{0,1,2,\ldots\}} \left( \int_{[0,1]^s} ((F \rho) \circ T)^{(\tau)}(y) \, dy \right)^2 dy_\omega
$$

$$
\leq \sum_{\tau \in \{0,1,2,\ldots\}} \left( \int_{[0,1]^s} \left( \int_{[0,1]^s} 1^2 \, dy_\omega \right)^2 \left( \int_{[0,1]^s} ((F \rho) \circ T)^{(\tau)}(y) \, dy \right)^2 dy_\omega \right) dy_\omega
$$

$$
= \sum_{\tau \in \{0,1,2,\ldots\}} \left( ((F \rho) \circ T)^{(\tau)}(y) \right)^2 dy
$$

$$
= \frac{1}{(2T)^s} \sum_{\tau \in \{0,1,2,\ldots\}} (2T)^{2|\tau|} \int_{[-T,T]^s} ((F \rho)^{(\tau)})(y) \, dy.
(75)
$$

Applying Lemma 7 into the last inequality we then write

$$
\|F \rho \circ T\|_{H_{\alpha,\rho}^+([0,1]^s)}^2
$$

$$
\leq \frac{1}{(2T)^s} \sum_{\tau \in \{0,1,2,\ldots\}} (2T)^{2|\tau|} \int_{[-T,T]^s} \left( \rho(y) \sum_{\omega \leq \tau} c(\tau, \omega) \|H_{\tau-\omega}(y)\| \|F^{(\omega)}(y)\| \right)^2 dy
$$

$$
= \frac{1}{(2T)^s} \sum_{\tau \in \{0,1,2,\ldots\}} (2T)^{2|\tau|} \sum_{\omega \leq \tau} c(\tau, \omega) \sum_{\omega' \leq \tau} c(\tau, \omega')
$$

$$
\times \int_{[-T,T]^s} |H_{\tau-\omega}(y)||H_{\tau-\omega'}(y)||F^{(\omega)}(y)||F^{(\omega')}(y)||\rho^2(y) \, dy.
(76)
$$

Using the Cauchy–Schwarz inequality to the integral in (76) leads to

$$
\|F \rho \circ T\|_{H_{\alpha,\rho}^+([0,1]^s)}^2
$$

$$
\leq \frac{1}{(2T)^s} \sum_{\tau \in \{0,1,2,\ldots\}} (2T)^{2|\tau|} \sum_{\omega \leq \tau} c(\tau, \omega) \left[ \int_{[-T,T]^s} |H_{\tau-\omega}(y)|^2 \|F^{(\omega)}(y)\|^2 \rho^2(y) \, dy \right]^{1/2}
$$

35
\[ \left( \sum_{\omega \leq \tau} c(\tau, \omega) \right)^2 = \prod_{j=1}^s \left( \sum_{\omega_j=0}^{\tau_j} \left( \frac{\tau_j - \omega_j}{\tau_j} \right) \right)^2 \leq \prod_{j=1}^s \alpha! \left( \sum_{\omega_j=0}^{\tau_j} \left( \frac{\tau_j - \omega_j}{\omega_j} \right) \right)^2 = \alpha!^s \prod_{j=1}^s 2^{2\tau_j}. \]

Inserting this into (79) implies
\[ \| (F \rho) \circ T \|_{H_{a,\alpha}^s([0,1]^s)}^2 \leq C_{*\alpha}^s \| F \|_{H_{a,\alpha}^s([0,1]^s)}^2 \| 2^{2|\tau|} \|_{H_{a,\alpha}^s([0,1]^s)} \]
\[ = C_{*\alpha}^s \| F \|_{H_{a,\alpha}^s([0,1]^s)}^2 \left( \sum_{\tau \in \{0,1\}^s} \left( \frac{4T}{\tau} \right)^2 \right)^s \]
\[ = C_{*\alpha}^s (\alpha!)^s \| F \|_{H_{a,\alpha}^s([0,1]^s)}^2 \left( \frac{16^{\alpha+1} T^{2\alpha-2} - 1}{16T^2 - 1} \right)^s \]
\[ \leq C_{1\alpha}^s \| F \|_{H_{a,\alpha}^s([0,1]^s)}^2 \]

with
\[ C_{1\alpha} = (C_{*\alpha} \alpha! 16^\alpha)^{1/2} = \left( \frac{1}{\sqrt{2\pi}} \Gamma(2\alpha) I_0(1/4) \alpha! 2^{4\alpha} \right)^{1/2} \]
\[ = \alpha!^{2\alpha} \left( \frac{1}{\sqrt{2\pi}} \Gamma(2\alpha) I_0(1/4) \right)^{1/2}. \]

This is the needed claim.
To complete the proof we only need to show (78). Applying Taylor’s theorem for the function \( F \) we get

\[
F(y) = \sum_{\nu \in \{0 : \alpha \}^s \atop \upsilon \in \{0 : \alpha \}^s} \frac{y^\nu}{\nu!} \int_{0}^{y} F^{(\nu)}(t_u, 0-u) \prod_{j \in \alpha} (y_j - t_j)^{\alpha-1} (\alpha-1)! \, dt_u,
\]

where \( \tau_{\upsilon} := \prod_{j \in \upsilon} \tau_j \) and then for the function \( F(\omega) \) with \( \omega \in \{0 : \alpha \}^s \) we obtain

\[
F^{(\omega)}(y) = \sum_{\nu \in \{0 : \alpha \}^s \atop \upsilon \geq \omega \atop \upsilon = \{j : \upsilon_j = \alpha\}} \prod_{j \in \upsilon} \frac{y_j^{\upsilon_j - \omega_j}}{(\upsilon_j - \omega_j)!} \int_{0}^{y} F^{(\nu)}(t_\upsilon, y_\upsilon, 0-u) \prod_{j \in \omega} (y_j - t_j)^{\alpha-1} (\alpha-1 - \omega_j)! \, dt_\upsilon.
\]

Note that because \( F(y) = 0 \) if any component of \( y \) is equal to 0, and \( F^{(\nu_m)}(0) = 0 \) for any \( \nu_m \in \{1 : \alpha \}^{|m|} \) such that \( m \) is a proper subset of \( \{1 : s\} \), we will cancel the associated terms in the Taylor expansions. As a result, the indices \( \nu \) in the representations (80) and (81) will be summed over \( \nu \in \{1 : \alpha \}^s \) instead of \( \nu \in \{0 : \alpha \}^s \).

In follows, for any \( y \in \mathbb{R}^s \) we write \([0, y]^s = [0, y] \) if \( y \geq 0 \) and \([0, y]^s = [y, 0] \) if \( y < 0 \). For any \( y \in \mathbb{R}^s \) we write \( [0, y] = [0, y_1] \times \cdots \times [0, y_s] \). Using the Cauchy–Schwarz inequality twice, note that for each \( \omega \) the subset \( \upsilon = \{j : \upsilon_j = \alpha\} \) is fixed so we omit it from the sum, we have

\[
|F^{(\omega)}(y)|^2 \leq \alpha^s \sum_{\nu \in \{1 : \alpha \}^s \atop \upsilon \geq \omega \atop \upsilon = \{j : \upsilon_j = \alpha\}} \left( \prod_{j \in \upsilon} \frac{y_j^{\upsilon_j - \omega_j}}{(\upsilon_j - \omega_j)!} \right)^2 \left( \int_{0}^{y} F^{(\nu)}(t_\upsilon, y_\upsilon, 0-u) \prod_{j \in \omega} (y_j - t_j)^{\alpha-1} (\alpha-1 - \omega_j)! \, dt_\upsilon \right)^2
\]

\[
\leq \alpha^s \sum_{\nu \in \{1 : \alpha \}^s \atop \upsilon \geq \omega \atop \upsilon = \{j : \upsilon_j = \alpha\}} \left( \prod_{j \in \upsilon} \frac{y_j^{\upsilon_j - \omega_j}}{(\upsilon_j - \omega_j)!} \right)^2 \left( \int_{0}^{y} |F^{(\nu)}(t_\upsilon, y_\upsilon, 0-u)|^2 \, dt_\upsilon \right) \times \prod_{j \in \omega} \int_{0}^{y_j} \left( \frac{(y_j - t_j)^{\alpha-1} (\alpha-1 - \omega_j)!}{(\alpha-1 - \omega_j)!} \right)^2 \, dy_j
\]

\[
\leq \alpha^s \sum_{\nu \in \{1 : \alpha \}^s \atop \upsilon \geq \omega \atop \upsilon = \{j : \upsilon_j = \alpha\}} \left( \prod_{j \in \upsilon} \frac{y_j^{\upsilon_j - \omega_j}}{(\upsilon_j - \omega_j)!} \right)^2 \left( \int_{0}^{y} |F^{(\nu)}(t_\upsilon, y_\upsilon, 0-u)|^2 \, dt_\upsilon \right)
\]
This is possible because they are independent of each other due to \( \{1 : s\} = u \cup u = (v \cup w) \cup u \). As a result, we write

\[
A(\nu, \tau, \omega) = \prod_{j \in u} \int_{\mathbb{R}} |H_{\tau_j - \omega_j}(y_j)|^2 |y_j|^{2(\nu_j - \omega_j)} \rho(y_j) \, dy_j \prod_{j \in v} \int_{\mathbb{R}} |H_{\tau_j - \omega_j}(y_j)|^2 |y_j|^{2(\nu_j - \omega_j)} \rho(y_j) \, dy_j \prod_{j \in w} \int_{\mathbb{R}} |y_j|^{2(\alpha - 1 - 2\nu_j)} \rho(y_j) \, dy_j
\]

\[
\times \prod_{j \in \varnothing} |y_j|^{2(\alpha - 1 - 2\omega_j)} \int_{\mathbb{R}} |y_j|^{2(\alpha - 1 - 2\omega_j)} \rho(y_j) \, dy_j
\]

Inserting this into \( \mathcal{J}^2(\tau, \omega) \) we have

\[
\mathcal{J}^2(\tau, \omega) = \int_{[0, T]^s} |H_{\tau - \omega}(y)|^2 |F(\omega)(y)|^2 \rho^2(y) \, dy
\]

\[
\leq \alpha^s \sum_{\nu \in \{1 : s\}^s \atop \text{s.t. } \nu \subseteq \omega} \int_{[0, T]^s} |H_{\tau - \omega}(y)|^2 \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in v} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in w} |y_j|^{2(\nu_j - \omega_j)} \rho^2(y) \, dy
\]

\[
\leq \alpha^s \sum_{\nu \in \{1 : s\}^s \atop \text{s.t. } \nu \subseteq \omega} \int_{[0, T]^s} |H_{\tau - \omega}(y)|^2 \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in v} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in w} |y_j|^{2(\nu_j - \omega_j)} \rho^2(y) \, dy
\]

\[
\int_{\mathbb{R}^s} |H_{\tau - \omega}(y)|^2 \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in v} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in w} |y_j|^{2(\nu_j - \omega_j)} \rho(y) \, dy
\]

\[
\leq \alpha^s \sum_{\nu \in \{1 : s\}^s \atop \text{s.t. } \nu \subseteq \omega} \int_{[0, T]^s} |H_{\tau - \omega}(y)|^2 \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in v} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in w} |y_j|^{2(\nu_j - \omega_j)} \rho(y) \, dy
\]

\[
\leq \alpha^s \sum_{\nu \in \{1 : s\}^s \atop \text{s.t. } \nu \subseteq \omega} \int_{[0, T]^s} |H_{\tau - \omega}(y)|^2 \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in v} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in w} |y_j|^{2(\nu_j - \omega_j)} \rho(y) \, dy
\]

\[
\int_{\mathbb{R}^s} |H_{\tau - \omega}(y)|^2 \prod_{j \in u} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in v} |y_j|^{2(\nu_j - \omega_j)} \prod_{j \in w} |y_j|^{2(\nu_j - \omega_j)} \rho(y) \, dy
\]

\[
\int_{\mathbb{R}^s} |y_j|^{2(\alpha - 1 - 2\nu_j)} \rho(y_j) \, dy_j
\]

\[
38
\]
\[
\leq \left[ \prod_{j \in -u} \int_{\mathbb{R}} |H_{\omega_j}(y_j)^2| y_j^{2(\nu_j - \omega_j)} \rho(y_j) \, dy_j \right] \left[ \prod_{j \in u} \int_{\mathbb{R}} |H_{\omega_j}(y_j)^2| y_j^{2\alpha - 2\omega_j} \rho(y_j) \, dy_j \right] \\
\times \left[ \int_{\mathbb{R}^{|u|}} \left( \int_{\mathbb{R}^{|w|}} |F(\nu)(y_u, y_0, 0 - u)|^2 \rho_0(t_u) \, dt_u \right) \rho_w(y_w) \, dy_w \right] \\
= C_{-u} C_v \left[ \int_{\mathbb{R}^{|u|}} |F(\nu)(y_u, 0 - u)|^2 \rho_0(y_u) \, dy_u \right], \tag{83}
\]

where we use \( H_T(y) \sqrt{\rho(y)} \leq 1 \) for any \( \tau \in \mathbb{N}_0^s \) and any \( y \in \mathbb{R}^s \), see [7, Lemma 1]. Remember that \( \nu \in \{1: \alpha\}^s \) such that \( \nu \geq \omega, u = \{ j : \nu_j = \alpha \}, w = \{ j : \omega_j = \alpha \} \) and \( v = u \setminus w \), therefore, for \( \alpha = 1 \) the sets \( -u \) and \( v \) are empty. The constants can be bound by Lemma 8

\[
C_{-u} C_v \leq C_{\alpha, \alpha}^s.
\]

Inserting (83) into (82) leads to

\[
\gamma^2(\tau, \omega) \leq \alpha^s C_{\alpha, \alpha}^s \sum_{\nu \in \{1: \alpha\}^s} \left[ \int_{\mathbb{R}^{|u|}} |F(\nu)(y_u, 0 - u)|^2 \rho_0(y_u) \, dy_u \right] \\
= \alpha^s C_{\alpha, \alpha}^s \sum_{\nu \in \{1: \alpha\}^s} \left[ \int_{\mathbb{R}^{|u|}} |F(\nu)(y_u, 0 - u)|^2 \rho_0(y_u) \, dy_u \right] \leq \alpha^s C_{\alpha, \alpha}^s \| F \|^2_{H_{0, 0, \rho, s}(\mathbb{R}^s)}.
\]

The proof is complete. \( \square \)
