EXOTIC MULTIPLICATIONS ON PERIODIC COMPLEX BORDISM

JEREMY HAHN AND ALLEN YUAN

Abstract. Victor Snaith gave a construction of periodic complex bordism by inverting the Bott element in the suspension spectrum of $BU$. This presents an $E_\infty$ structure on periodic complex bordism by different means than the usual Thom spectrum definition of the $E_\infty$-ring $MUP$. Here, we prove that these two $E_\infty$-rings are in fact different, though the underlying $E_2$-rings are equivalent. Nonetheless, we prove that both rings $E_\infty$-orient $KU$ and other forms of $K$-theory.

1. Introduction

The periodic complex bordism spectrum $MUP$ is the Thom spectrum of the tautological bundle over $BU \times \mathbb{Z}$. This is not just a spectrum, but a ring spectrum, and the connection between homotopy commutative ring maps $MUP \rightarrow E$ and formal group laws forms the basis of chromatic homotopy theory. In fact, $MUP$ is not just a homotopy commutative ring spectrum, but an $E_\infty$-ring spectrum. A large amount of attention in recent years [HL18, And95, Wal08, Möl10, Zhu17] has been put into variations of the following fundamental question:

Question 1. What $E_\infty$-ring spectra $E$ receive $E_\infty$-ring homomorphisms $MUP \rightarrow E$?

To make sense of the above question, one must be very clear about how the $E_\infty$-ring structure on $MUP$ is defined. As the authors understand it, the usual definition of this structure, due to [BMMS86], runs as follows:

Consider the unstable $J$-homomorphism, which is the symmetric monoidal functor

$$J : \prod_n BU(n) \simeq \{\text{Complex Vector Spaces}\}^\infty \rightarrow \text{Spaces}$$

that sends a $d$-dimensional complex vector space $V$ to its one-point compactification $S^V$, a $2d$-dimensional sphere. After further composing with the suspension spectrum functor

$$\Sigma^\infty : \text{Spaces} \rightarrow \text{Spectra},$$

the $J$-homomorphism takes values in the subgroupoid of invertible spectra and their automorphisms, known as the Picard category of Spectra. This implies that $J$ factors through the group completion of the category of complex vector spaces, giving a stable $J$ functor

$$J : BU \times \mathbb{Z} \simeq \{\text{Virtual Complex Vector Spaces}\}^\infty \rightarrow \text{Pic(Spectra) \subset Spectra}.$$
Since this stable $J$ functor is symmetric monoidal, its colimit, $MUP$, acquires an $\mathbb{E}_\infty$-ring structure \cite{LMSM86,ACBH19}.

**Convention 1.1.** Throughout this paper, whenever we refer to $MUP$ as an $\mathbb{E}_\infty$-ring spectrum, we always give it the $\mathbb{E}_\infty$-ring structure constructed above.

In contrast, consider the following alternate construction of the periodic complex bordism spectrum by Snaith \cite{Sna81}:

Since $BU \simeq \Omega^\infty \Sigma^2 ku$ is an infinite loop space, $\Sigma^\infty BU$ is an $\mathbb{E}_\infty$-ring spectrum. Given an element in the homotopy of an $\mathbb{E}_\infty$-ring spectrum, we may invert that element to obtain another $\mathbb{E}_\infty$-ring. In particular, we may invert the suspension of the Bott element $\beta : S^2 \to BU$, considered as an element in stable homotopy $\beta \in \pi_2(\Sigma^\infty BU)$.

**Theorem 1.2** (Snaith \cite{Sna81}). There is an equivalence of homotopy commutative ring spectra

$$\Sigma^\infty BU[\beta^{-1}] \simeq MUP.$$ 

Our aim, when beginning this project, was to upgrade Snaith’s theorem to an equivalence of $\mathbb{E}_\infty$-ring spectra. We were thus surprised to obtain the following result, which is the main theorem of this paper:

**Theorem 1.3.** There is an equivalence of $\mathbb{E}_2$-ring spectra

$$\Sigma^\infty BU[\beta^{-1}] \simeq MUP,$$

but there is **NOT** an equivalence of $\mathbb{E}_5$-ring spectra. In particular, there is no equivalence of $\mathbb{E}_\infty$-rings.

**Remark 1.4.** In order to prove Theorem 1.3 we will construct a certain $\mathbb{E}_\infty$-ring structure on $HZP$, by which we denote periodic integral homology. By construction, there will be an $\mathbb{E}_\infty$-ring homomorphism $MUP \to HZP$, but we will show that there can be no $\mathbb{E}_5$-ring homomorphism $\Sigma^\infty BU[\beta^{-1}] \to HZP$. As we will explain, one interpretation of our result is that ‘no choice of total Chern class can be a five-fold loop map.’ This is related to another result of Snaith \cite{Sna77}, which states roughly that ‘the usual choice of total Chern class is not an infinite loop map.’

Despite the plethora of work that has gone into understanding the standard multiplication on $MUP$ \cite{And95,HL18}, there are some reasons to prefer the ‘exotic’ multiplication that is $\Sigma^\infty BU[\beta^{-1}]$. Perhaps the main reason is the latter’s clear connection to topological complex $K$-theory, as mediated through another theorem of Snaith:

**Theorem 1.5** (Snaith \cite{Sna81}). There is an equivalence of homotopy commutative ring spectra

$$\Sigma^\infty CP^\infty[\beta^{-1}] \simeq KU.$$ 

**Remark 1.6.** Unlike with periodic complex bordism, the above equivalence can be lifted to one of $\mathbb{E}_\infty$-ring spectra. This folklore result follows from the existence of a symmetric monoidal inclusion functor

$$CP^\infty \simeq \{\text{Complex Lines, } \odot\}^\infty \to \{\text{Virtual Complex Vector Spaces, } \odot\}^\infty \simeq BU \times \mathbb{Z}.$$ 

Since the determinant map $BU \to BU(1) \simeq CP^\infty$ is an infinite loop map, one has the following theorem:

**Theorem 1.7** (Snaith). There is a map of $\mathbb{E}_\infty$-ring spectra

$$\Sigma^\infty BU[\beta^{-1}] \to \Sigma^\infty CP^\infty[\beta^{-1}] \simeq KU.$$
This construction of an $E_\infty$-orientation of $KU$ is so canonical that it can be ported into other settings, such as motivic homotopy theory [GS09]. In contrast, while it seems to be folklore that there is an $E_\infty$-ring homomorphism

$$MUP \longrightarrow KU,$$

the authors could find no proof of this in the literature. We provide in the final section of this document a computational proof of the slightly weaker result that there is an $E_\infty$-ring map from $MUP$ into the 2-completion of $KU$. We prove this as part of a more general story.

**Definition 1.8.** A form of $K$-theory (at the prime 2) is a Morava $E$-theory corresponding to a height 1 formal group over $F_2$. [Mor89, Sin15]

**Remark 1.9.** Forms of $K$-theory are $E_\infty$-ring spectra. They are 2-periodic, with each odd homotopy group isomorphic to 0 and each even homotopy group isomorphic to the 2-adic integers $\mathbb{Z}_2$. Choosing the multiplicative formal group over $F_2$ yields a form of $K$-theory that is the 2-completion $KU^2_\pi$ of topological complex $K$-theory.

**Theorem 1.10.** Let $E$ denote a form of $K$-theory. Then there is both an $E_\infty$-ring homomorphism

$$MUP \longrightarrow E$$

and an $E_\infty$-ring homomorphism

$$\Sigma^\infty \mathbb{B}[\beta^{-1}] \longrightarrow E.$$

**Remark 1.11.** We believe that slight variants of our arguments work just as well at odd primes $p > 2$. We work at the prime 2 for simplicity. Our arguments do not provide orientations of Morava $E$-theories $E_{(k,G)}$ associated to larger characteristic 2 fields $k$, unless the formal group $G$ over $k$ is isomorphic to one pushed forward from a height 1 formal group over $F_2$.

**Remark 1.12.** Highly structured $MU$ (as opposed to $MUP$) orientations of forms of $K$-theory have been constructed in several locations [Möl10, HL18], with the case of $p$-adic $K$-theory receiving particular attention in [Wal08].

A number of open questions are raised by our work here.

**Question 2.** Is there an $E_4$-equivalence $\Sigma^\infty \mathbb{B}[\beta^{-1}] \simeq MUP$? The authors find such an equivalence very believable, but find difficulties proving it that are related to the difficulties Chadwick and Mandell [CM15] encounter when trying to check whether the Quillen idempotent on $MU$ is $E_4$.

**Question 3.** Is there an $E_\infty$-ring homomorphism $MU \longrightarrow \Sigma^\infty_+ \mathbb{B}[\beta^{-1}]$?

**Remark 1.13.** Tyler Lawson has emphasized to us that there are yet other $E_\infty$-ring spectra that might naturally be called periodic complex bordism, such as the Tate spectrum $MU^2S^1$. It would be enlightening to have a catalogue of various $E_\infty$ ‘forms’ of periodic complex bordism, as well as forms of periodic integral homology such as $H\mathbb{Z}^2S^1$.

**Question 4.** In the sense of the previous remark, which forms of periodic complex bordism orient which forms of periodic integral homology? Is there a form of periodic integral homology that is $E_\infty$-oriented by $\Sigma^\infty_+ \mathbb{B}[\beta^{-1}]$?

**Question 5.** In addition to the famous open question of which Morava $E$-theories are $E_\infty$-oriented by $MU$ [HL18], which Morava $E$-theories are $E_\infty$-oriented by which forms of periodic complex bordism?
EXOTIC MULTIPLICATIONS ON PERIODIC COMPLEX BORDISM

1.1. Acknowledgements. The authors are grateful to David Gepner, Tyler Lawson, Haynes Miller, Eric Peterson, and Andrew Senger for numerous helpful conversations. They would like to extend special thanks to Mike Hopkins and Jacob Lurie for their numerous insights and constant encouragement. The authors were supported by the NSF under Grants DMS-1803273 and DGE-1122374.

2. Preliminaries

2.1. Periodic Thom Spectra.

Definition 2.1. Let $MUP$ denote the $E_\infty$ Thom spectrum \cite{LMSM86} associated to the complex $J$-homomorphism

$$J : ku \to \text{pic } S.$$ 

There is a canonical element $u \in \pi_2(MUP)$ such that $\pi_*(MUP) = \pi_*(MU)[u^{\pm 1}]$.

The spectrum $ku$ fits into a cofiber sequence

$$\Sigma^2 ku \to ku \to H\mathbb{Z},$$

where the Thom spectrum of the composite $\Sigma^2 ku \to ku \to \text{pic } S$ is $MU$. Therefore, $MUP$ may alternately be presented as the Thom spectrum of a map $H\mathbb{Z} \to \text{pic } MU$ (see \cite{ACB19} §2 for details in modern language).

Remark 2.2. Applying $\Omega^2$ to the inclusion $\mathbb{C}P^\infty \to BU$ yields a double loop map $\mathbb{Z} \to BU \times \mathbb{Z}$. The Thom spectrum of this map $\mathbb{Z} \to BU \times \mathbb{Z}$ is an $E_2$-ring spectrum

$$P \simeq \bigvee_{i \in \mathbb{Z}} S^{2i}.$$ 

One has that $MUP \simeq MU \wedge P$ as $E_2$-rings, but since $P$ is not an $E_\infty$-ring, there is no similar expression for $MUP$ as a smash product of $E_\infty$-ring spectra.

Since there is an $E_\infty$-ring map $MU \to H\mathbb{Z}$, there is a composite map of spectra

$$H\mathbb{Z} \to \text{pic } MU \to \text{pic } H\mathbb{Z}$$

that sends $n \in \pi_0(H\mathbb{Z})$ to the invertible $H\mathbb{Z}$-module $\Sigma^{2n} H\mathbb{Z}$.

Definition 2.3. Let $H\mathbb{Z}P$ denote the $E_\infty$ Thom spectrum of the map $H\mathbb{Z} \to \text{pic } H\mathbb{Z}$ described above. By construction, $H\mathbb{Z}P$ comes with a canonical $E_\infty$-ring map $MUP \to H\mathbb{Z}P$.

2.2. Complex orientations and total Chern classes. Recall that the integral cohomology of $BU$ is given by

$$H^*(BU; \mathbb{Z}) \cong \mathbb{Z}[[c_1, c_2, \cdots]].$$

This isomorphism allows one to define the Chern classes of any complex vector bundle $V$ over a space $X$. One may assemble these Chern classes into a total Chern class $c(V)$, which is a power series in the formal variable $u$:

$$c(V) = 1 + c_1(V)u + c_2(V)u^2 + \cdots \in H^*(X; \mathbb{Z})[[u]].$$

The total Chern class construction $V \mapsto c(V)$ takes addition of vector bundles to multiplication of power series.

Definition 2.4. Let $E$ be a homotopy commutative ring spectrum. A complex orientation of $E$ is a map of homotopy commutative ring spectra $MU \to E$. A periodic complex orientation of $E$ is a map of homotopy commutative ring spectra $MUP \to E$. 

Remark 2.5. By Remark 2.2, we have an identification of homotopy commutative rings $MUP \simeq MU \wedge P$. A periodic complex orientation of $E$ is therefore the separate data of a complex orientation of $E$ and the additional choice of a unit in $u \in \pi_2 E$.

Example 2.6. By construction, there is a canonical periodic complex orientation $MUP \to HZP$.

Snith [Sna81] constructed an equivalence of homotopy commutative rings $\Sigma^\infty BU[\beta^{-1}] \to MUP$. Composing with the periodic complex orientation $MUP \to HZP$, we obtain a ring map

$$\Sigma^\infty BU \to HZP$$

which is the same data as a map of $H$-spaces

$$BU \to GL_1 HZP = \prod_{i \geq 1} K(\mathbb{Z}, 2i).$$

Snith’s equivalence is constructed such that the components of this map correspond to the elements $c_i \in H^{2i}(BU; \mathbb{Z})$. Together, they assemble to the usual total Chern class

$$c = 1 + c_1 u + c_2 u^2 + \cdots \in HZP^0(BU).$$

The fact that the map $BU \to GL_1 HZP$ is a map of $H$-spaces encodes the fact that the total Chern class takes sums of vector bundles to multiplication of power series.

Different choices of periodic complex orientation $MUP \to HZP$ beget different notions of total Chern class. We can describe these other total Chern classes in terms of the above one as follows.

By the splitting principle, a total Chern class is determined by its value on line bundles, which is the composite

$$BU(1) \to BU \to GL_1 HZP.$$

For the total Chern class constructed above, this is given by $1 + ut$, where $t \in H^2(\mathbb{C}P^\infty)$ is the generator. Any other periodic complex orientation of $HZP$ arises from this one by changing the coordinate and/or choice of unit. The unit is determined up to sign, and the coordinate can be changed by any series of the form $t \mapsto a_1 t + a_2 u t^2 + a_3 u^2 t^3 + \cdots$ where $a_i \in \mathbb{Z}$ and $a_1 = \pm 1$ is a unit. We can therefore associate to any ring map $MUP \to HZP$ its corresponding total Chern class for line bundles, which is a series

$$r(t) = 1 + a_1 ut + a_2 u^2 t^2 + a_3 u^3 t^3 + \cdots \in HZP^0(\mathbb{C}P^\infty),$$

where $a_i \in \mathbb{Z}$ are integers and $a_1 = \pm 1$ is a unit.

2.3. Power operations on $MUP$. Let $X$ be a space and let $E$ be an $\mathbb{E}_\infty$-ring spectrum. Suppose that we are given a class $\gamma \in E^0(X)$, represented by a map $\gamma : \Sigma^\infty_+ X \to E$. The composite

$$(\Sigma^\infty_+ X)_{hC_2} \to (\Sigma^\infty_+ (X \times X))_{hC_2} \to (E \wedge E)_{hC_2} \to E$$

determines a new cohomology class which we denote $P_2^E(\gamma) \in E^0(X \times \mathbb{R}P^\infty)$ and refer to as the total power operation on $\gamma$. This construction has the following elementary properties:

Lemma 2.7 ([BMMSSS, Corollary II.1.6]). Let $X, E$ as above and $a, b \in E^0(X)$. Then the following formulas hold:

1. $P_2^E(ab) = P_2^E(a)P_2^E(b)$.
2. $P_2^E(a + b) = P_2^E(a) + P_2^E(b) + \text{tr}(ab)$ where $\text{tr} : E^0(X) \to E^0(X \times \mathbb{R}P^\infty)$ is induced by the stable transfer $\Sigma^\infty_+ B\mathbb{C}_2 \to \mathbb{S}$. 
We will be concerned with the special case $X = \mathbb{C}P^\infty$, $E = MUP$, and where $\gamma = ut \in MUP^0(\mathbb{C}P^\infty)$ is the composite
$$\mathbb{C}P^\infty \xrightarrow{t} \Sigma^2 MU \xrightarrow{u} MUP$$
of the canonical class $t \in MU^2(\mathbb{C}P^\infty)$ with the periodicity element. We have that
$$MU^*(\mathbb{C}P^\infty \times \mathbb{R}P^\infty) = MU^*[\{t, z\}/(2)],$$
where $z \in MU^2(\mathbb{R}P^\infty)$ is the pullback of $t$ under the natural map $\mathbb{R}P^\infty \to \mathbb{C}P^\infty$. Analogously,
$$MUP^*(\mathbb{C}P^\infty \times \mathbb{R}P^\infty) \cong MU^*[\{t, z\}/(2)].$$
Quillen essentially computed the total power operation in $MUP$ cohomology:

**Proposition 2.8** ([Qui71]). The total power operation on $ut \in MUP^0(\mathbb{C}P^\infty)$ is given by
$$P^2(ut) = u^2(t + _MU z) \in MUP^0(\mathbb{C}P^\infty \times \mathbb{R}P^\infty).$$

**Proof.** We analyze the diagram
$$\begin{array}{ccc}
\Sigma^\infty_+ (\mathbb{C}P^\infty \times \mathbb{R}P^\infty) & \xrightarrow{s} & \Sigma^\infty_+ (\mathbb{C}P^\infty \times \mathbb{C}P^\infty)_{hC_2} \\
\downarrow d_2(t) & & \downarrow \\
(\Sigma^2 MU \wedge \Sigma^2 MU)_{hC_2} & \xrightarrow{\alpha} & (MUP \wedge MUP)_{hC_2} \\
\downarrow & & \downarrow \\
\Sigma^4 MU & \xrightarrow{u^2} & MUP.
\end{array}$$

The map $\alpha$ is defined to be the composite
$$(\Sigma^2 MU \wedge \Sigma^2 MU)_{hC_2} \cong (\Sigma^2 MU \wedge MU)_{hC_2} \to (\Sigma^4 MU \wedge MU)_{hC_2} \to \Sigma^4 MU$$
of the Thom isomorphism with the multiplication on $MU$. The dashed composite, which we have named $P^2_MU(t)$, was computed by Quillen ([Qui71] (see also [Rud98, Theorem 7.12] and [Pet18, Lemma 2.5.6]) to be $t(t + _MU z)$. It therefore suffices to show that the bottom right square commutes.

To show this, we realize the square as the Thomification of another square. For $n \in \mathbb{Z}$, let $i_n : BU \to BU \times \mathbb{Z}$ be the inclusion of the component corresponding to virtual dimension $n$ complex vector spaces. We have a commutative square
$$\begin{array}{ccc}
(BU \times BU)_{hC_2} & \xrightarrow{i_1 \times i_1} & ((BU \times \mathbb{Z}) \times (BU \times \mathbb{Z}))_{hC_2} \\
\downarrow & & \downarrow \\
BU & \xrightarrow{i_2 \times i_2} & BU \times \mathbb{Z} \\
\downarrow & & \downarrow \\
\text{Pic}(\mathbb{S}) & \xrightarrow{J} & \text{Pic}(MU)
\end{array}$$

where the vertical maps are induced by direct sum of vector spaces. Applying Thom spectra to this diagram, we obtain the desired square. □

**Remark 2.9.** The proof essentially says that the $E_\infty$ structure on $MUP$ extends the classical $H_2^\infty$ structure on $MU$ [RMMSS86, Corollary VIII.5.3]. In the language of [Law18, Problem 1.3.7], the map $\mathbb{Z} \to \text{Pic}(MU)$ defining $MUP$ refines the $H_2^\infty$ structure on $MU$ to an $E_\infty^2$ structure.

Proposition 2.8 also allows us to compute power operations in $E_\infty$-ring spectra which receive an $E_\infty$-ring map from $MUP$. In particular, using the fact that $HZ$ carries the additive formal group law, we deduce the following formula for power operations in $HZP$. 

Corollary 2.9.1. Let \( ut \in H \mathbb{Z}P^0(\mathbb{C}P^\infty) \) be the class coming from the complex orientation. Then
\[
P_{H \mathbb{Z}P}^2(ut) = u^2(t + z).
\]
In addition, we will record the following basic lemma about power operations in \( H \mathbb{Z} P \):

Lemma 2.10. The following formulas hold:

1. Let \( X \) be a space and \( a, b \in H \mathbb{Z}P^0(X) \). Then
   \[
P_{H \mathbb{Z}P}^2(a + b) = P_{H \mathbb{Z}P}^2(a) + P_{H \mathbb{Z}P}^2(b) + 2ab.
   \]
2. The power operation on \( n \in \pi_0(H \mathbb{Z}P) \simeq \mathbb{Z} \) is given by \( P_{H \mathbb{Z}P}^n(a) = n^2 \).

Proof. The first statement follows from the first statement of Lemma 2.1 by observing that the transfer in \( H \mathbb{Z} P \) is just multiplication by 2. The second statement follows by using \( P_{H \mathbb{Z}P}^1(1) = 1 \) and inducting using the first statement. \( \square \)

3. Obstructions

We now turn to the proof of Theorem 1.3. The first half follows from:

Proposition 3.1. Any map of homotopy commutative rings
\[
\Sigma^\infty_+ \text{BU}[\beta^{-1}] \rightarrow MUP
\]
can be promoted to an \( E_2 \)-map.

Proof. Let \( \Sigma^\infty_+ \text{BU}[\beta^{-1}] \rightarrow MUP \) be a map of homotopy commutative rings. The resulting map
\[
\Sigma^\infty_+ \text{BU} \rightarrow \Sigma^\infty_+ \text{BU}[\beta^{-1}] \rightarrow MUP
\]
lifts to an \( E_2 \)-ring map by [HY19, Theorem 6.1] and has the property that the Bott element is inverted. It therefore extends to an \( E_2 \)-ring map \( \Sigma^\infty_+ \text{BU}[\beta^{-1}] \rightarrow MUP \) agreeing with the original map by [MNN15, Theorem A.1]. \( \square \)

For the second half, we note that if there was indeed an equivalence of \( E_5 \)-ring spectra \( \Sigma^\infty_+ \text{BU}[\beta^{-1}] \simeq MUP \), then one would obtain an \( E_5 \)-ring map \( \Sigma^\infty_+ \text{BU}[\beta^{-1}] \rightarrow H \mathbb{Z} P \). Thus, Theorem 1.3 follows from the following stronger claim:

Theorem 3.2. There does not exist a map of \( E_5 \)-rings \( \Sigma^\infty_+ \text{BU}[\beta^{-1}] \rightarrow H \mathbb{Z} P \).

Proof. Let us suppose that such a map existed, arising from a map \( r : \Sigma^\infty_+ \text{BU} \rightarrow H \mathbb{Z} P \). By the discussion following Example 2.10, we obtain a total Chern class for line bundles
\[
r(t) = 1 + a_1 ut + a_2 u^2 + a_3 u^3 + \cdots \in H \mathbb{Z} P^0(\mathbb{C}P^\infty)
\]
where \( a_i \in \mathbb{Z} \) and \( a_1 = \pm 1 \).

There is a canonical map \( \mathbb{C}P^\infty = BU(1) \rightarrow BU \) classifying the bundle \( \mathcal{L} - 1 \). We will prove the theorem by examining the following diagram, which is constructed from \( r \) and the inclusion \( \mathbb{C}P^\infty \rightarrow BU \):

\[
\begin{array}{cccccc}
\mathbb{C}P^\infty \times \mathbb{R}P^4 & \rightarrow & (\Sigma^\infty_+ \text{BU} \wedge \Sigma^\infty_+ \text{BU} \wedge \text{Config}_2(\mathbb{R}^5)_+)_{hC_2} & \rightarrow & (H \mathbb{Z} P \wedge H \mathbb{Z} P \wedge \text{Config}_2(\mathbb{R}^5)_+)_{hC_2} & \rightarrow \\
\downarrow & & \downarrow & & \downarrow & \\
\mathbb{C}P^\infty \times \mathbb{R}P^\infty & \rightarrow & (\Sigma^\infty_+ \text{BU} \wedge \Sigma^\infty_+ \text{BU})_{hC_2} & \rightarrow & (H \mathbb{Z} P \wedge H \mathbb{Z} P)_{hC_2} & \rightarrow \\
\downarrow_{\mu_{\text{BU}}} & & \downarrow & & \downarrow & \\
\Sigma^\infty_+ \text{BU} & \rightarrow & (H \mathbb{Z} P \wedge H \mathbb{Z} P)_{hC_2} & \rightarrow & H \mathbb{Z} P, & \rightarrow \\
\end{array}
\]

where \( \mu \) is the multiplication map. This diagram is constructed from the following diagram, which is constructed from \( r \) and the inclusion \( \mathbb{C}P^\infty \rightarrow BU \):

\[
\begin{array}{cccccc}
\mathbb{C}P^\infty \times \mathbb{R}P^4 & \rightarrow & (\Sigma^\infty_+ \text{BU} \wedge \Sigma^\infty_+ \text{BU} \wedge \text{Config}_2(\mathbb{R}^5)_+)_{hC_2} & \rightarrow & (H \mathbb{Z} P \wedge H \mathbb{Z} P \wedge \text{Config}_2(\mathbb{R}^5)_+)_{hC_2} & \rightarrow \\
\downarrow & & \downarrow & & \downarrow & \\
\mathbb{C}P^\infty \times \mathbb{R}P^\infty & \rightarrow & (\Sigma^\infty_+ \text{BU} \wedge \Sigma^\infty_+ \text{BU})_{hC_2} & \rightarrow & (H \mathbb{Z} P \wedge H \mathbb{Z} P)_{hC_2} & \rightarrow \\
\downarrow_{\mu_{\text{BU}}} & & \downarrow & & \downarrow & \\
\Sigma^\infty_+ \text{BU} & \rightarrow & (H \mathbb{Z} P \wedge H \mathbb{Z} P)_{hC_2} & \rightarrow & H \mathbb{Z} P. & \rightarrow \\
\end{array}
\]
The top left and top right squares tautologically commute. If the map $\Sigma^\infty BU \to H \mathbb{Z} P$ were $\mathbb{E}_\infty$, then the bottom right square would also commute. If that map were only $\mathbb{E}_5$, then the bottom right square need not commute, but we would see that the long composites $\mathbb{C}P^\infty \times \mathbb{R}^4 \to H \mathbb{Z} P$ would agree. We show that this is not the case.

Namely, we compute the maps $r \circ \mu_{BU} \circ \delta$ and $\mu_{H \mathbb{Z} P} \circ D_2(r) \circ \delta$ as elements in the cohomology group

$$H \mathbb{Z} P^0(\mathbb{C}P^\infty \times \mathbb{R}P^\infty) \simeq \mathbb{Z}[[ut, uz]]/(2uz),$$

and then show that they do not agree upon restriction to

$$H \mathbb{Z} P^0(\mathbb{C}P^\infty \times \mathbb{R}P^1) \simeq \mathbb{Z}[[ut, uz]]/(2uz, (uz)^3).$$

**Notation.** For ease of notation, we set $\tilde{t} := ut$ and $\tilde{z} := uz$ for the remainder of the proof.

**Computation 1:** $r \circ \mu_{BU} \circ \delta \in H \mathbb{Z} P^0(\mathbb{C}P^\infty \times \mathbb{R}P^\infty)$.

This amounts to the computation of the total Chern class (as defined by $r$) of a certain vector bundle on $\mathbb{C}P^\infty \times \mathbb{R}P^\infty$. To describe this vector bundle, note that there is a commutative diagram of spaces

$$
\begin{array}{ccc}
\mathbb{C}P^\infty & \to & \mathbb{C}P^\infty \times \mathbb{C}P^\infty \\
\downarrow & & \downarrow \\
\mathbb{C}P^\infty \times \mathbb{R}P^\infty & \to & (\mathbb{C}P^\infty \times \mathbb{C}P^\infty)_{h\Sigma_2} \\
\downarrow & & \downarrow \\
& & BU.
\end{array}
$$

The diagram classifies the bundle $(L - 1) \oplus (L - 1)$ over $\mathbb{C}P^\infty$, and the bottom row arises from observing that this bundle is equivariant with respect to the swap action. Thus, the bundle over $\mathbb{C}P^\infty \times \mathbb{R}P^\infty$ classified by $\mu_{BU} \circ \delta$ is $(L - 1) \otimes \rho$, where $\rho$ is the complex regular representation of $\Sigma_2$ over $\mathbb{R}P^\infty = BC_2$.

Let $\sigma$ denote the complex sign representation, so that $\rho = \sigma \oplus 1$. The bundle then splits into lines as

$$(L - 1) \otimes \rho = L \otimes \sigma + L - \sigma - 1.$$

Then the class of $r \circ \mu_{BU} \circ \delta$ is simply the total Chern class of this bundle, which we can compute as:

$$r(L \otimes \sigma + L - \sigma - 1) = \frac{r(L \otimes \sigma )r(L)}{r(\sigma)} = \frac{r(t + z)r(t)}{r(z)}.$$

**Computation 2:** $\mu_{H \mathbb{Z} P} \circ D_2(r) \circ \delta \in H \mathbb{Z} P^0(\mathbb{C}P^\infty \times \mathbb{R}P^\infty)$.

This is the total power operation on the class in $H \mathbb{Z} P^0(\mathbb{C}P^\infty)$ represented by the composite

$$\Sigma^\infty C \mathbb{P}^\infty = \Sigma^\infty BU(1) \to \Sigma^\infty BU \to H \mathbb{Z} P.$$

In the notation of Section 2, this is $P^2_{H \mathbb{Z} P}(r(t)) = P^2_{H \mathbb{Z} P}(1 + a_1 \tilde{t} + a_2 \tilde{t}^2 + \cdots)$. By part (a) of Lemma 2.10

$$P^2_{H \mathbb{Z} P}(1 + a_1 \tilde{t} + a_2 \tilde{t}^2 + \cdots) = P^2(1) + P^2(a_1 \tilde{t}) + P^2(a_2 \tilde{t}^2) + \cdots + (\text{cross terms})$$

$$= 1 + a_1^2 \tilde{t}(\tilde{t} + \tilde{z}) + a_2^2 \tilde{t}^2(\tilde{t} + \tilde{z})^2 + \cdots + (\text{cross terms}),$$

where we have used the fact that $P^2$ is multiplicative and $P^2_{H \mathbb{Z} P}(a) = a^2$ for $a \in \pi_0 H \mathbb{Z} P$.

To see that the $\mathbb{E}_5$-ring map in the theorem cannot exist, it suffices to show that following:
Claim 3.3. The elements \( \frac{r(t + z)r(t)}{r(t)} \) and \( P^2_{HZP}(r(l)) \) are not equal in \( HZP^0(\mathbb{C}P^\infty \times \mathbb{R}P^\infty) \). In fact, they remain unequal under the map
\[
HZP^0(\mathbb{C}P^\infty \times \mathbb{R}P^\infty) \cong \mathbb{Z}[\bar{t}, \bar{z}]/(2\bar{z}) \twoheadrightarrow \mathbb{Z}[\bar{t}, \bar{z}]/(2\bar{z}, \bar{z}^3) \cong HZP^0(\mathbb{C}P^\infty \times \mathbb{R}P^4).
\]

Suppose the equation
\[
r(t + z)r(t) = P^2_{HZP}(r(t))r(z)
\]
holds modulo \( \bar{z}^3 \) and \( 2\bar{z} \). We explicitly compute part of the \( \bar{z} \) and \( \bar{z}^2 \) coefficients. First, since \( \bar{z} \) and \( \bar{z}^2 \) are 2-torsion in the ring and the cross terms in our computation for \( P^2_{HZP}(r(t)) \) were all divisible by 2, we may safely ignore them in what follows. We are therefore looking to compare the \( \bar{z} \) and \( \bar{z}^2 \) coefficients, mod 2, of the two expressions,
\[
r(t + z)r(t) = (1 + a_1(\bar{t} + \bar{z}) + a_2(\bar{t} + \bar{z})^2 + \cdots)(1 + a_1\bar{t} + a_2\bar{t}^2 + \cdots)
\]
and
\[
(1 + a_1^2\bar{t}(\bar{t} + \bar{z}) + a_2^2(\bar{t} + \bar{z})^2 + \cdots)(1 + a_1\bar{z} + a_2\bar{z}^2 + \cdots).
\]
By comparing \( \bar{z}^2\bar{t} \) coefficients mod 2 (and using that \( a_1^2 \equiv a_1 \pmod{2} \)), we find the relation
\[
a_1a_2 + a_3 = a_1.
\]
Recall that \( a_1 = \pm 1 \), and so \( a_1 \equiv 1 \pmod{2} \). This implies that \( a_2 + a_3 \equiv 1 \pmod{2} \).

On the other hand, by comparing \( \bar{z}^2\bar{t} \) coefficients, we find that
\[
a_2 + a_3a_1 = a_2 + a_1a_2.
\]
This means that \( a_2 + a_3 \equiv 0 \pmod{2} \), which contradicts the previous condition. This proves the claim and the theorem follows. \( \qed \)

4. Orientations

The determinant homomorphism \( BU \to \mathbb{C}P^\infty \) induces an \( E_\infty \)-ring map
\[
\Sigma^\infty_+ BU[\beta^{-1}] \to \Sigma^\infty_+ \mathbb{C}P^\infty[\beta^{-1}] \cong KU.
\]

It seems more delicate to construct an \( E_\infty \)-ring map
\[
MUP \to KU.
\]
In fact, while the authors feel that such an orientation is ‘well-known,’ we could not locate a reference in the literature. We record in this section a simple homotopy-theoretic proof that there is an orientation of at least the 2-completion of \( KU \). In fact, we will prove the stronger result that any form of \( K \)-theory in the sense of Morava \cite{Mor89, Sia15} receives an \( E_\infty \)-\( MUP \)-orientation.

**Definition 4.1.** A form of \( K \)-theory (at the prime 2) is a Morava \( E \)-theory corresponding to a height 1 formal group law over \( \mathbb{F}_2 \).

**Remark 4.2.** Forms of \( K \)-theory are \( E_\infty \)-ring spectra. They are 2-periodic, with each odd homotopy group isomorphic to 0 and each even homotopy group isomorphic to the 2-adic integers \( \mathbb{Z}_2 \). Choosing the multiplicative formal group law over \( \mathbb{F}_2 \) yields a form of \( K \)-theory that is the 2-completion \( KU_2^\wedge \) of topological complex \( K \)-theory.

The remainder of this section will consist of the proof of the following:

**Theorem 4.3.** Let \( E \) denote a form of \( K \)-theory. Then there is both an \( E_\infty \)-ring homomorphism
\[
MUP \to E
\]
and an \( E_\infty \)-ring homomorphism
\[
\Sigma^\infty_+ BU[\beta^{-1}] \to E.
\]

**Remark 4.4.** We leave to the interested reader the variation of the above result for \( p > 2 \).
To produce either of the $\E_\infty$-ring maps promised by Theorem 4.3 it is helpful to record the following lemmas:

**Lemma 4.5.** Let $ku_2^\wedge$ denote the connective cover of $KU_2^\wedge$. Then there are no non-trivial maps of spectra

$$
ku \longrightarrow \Sigma ku_2^\wedge,
$$

$$
ku \longrightarrow \Sigma^3 ku_2^\wedge,
$$

or

$$
ku \longrightarrow \Sigma^5 ku_2^\wedge.
$$

**Proof.** In [AL17] it is remarked that the Adams spectral sequence

$$
\text{Ext}_{E}^{s,t}(H^*(ku;\mathbb{F}_2), H^*(ku;\mathbb{F}_2)) \implies \pi_{t-s} \text{Hom}(ku_2^\wedge, ku_2^\wedge)
$$

converges and has $E_2$-term isomorphic to

$$
\text{Ext}_{E[Q_0, Q_1]}^{s,t}(\mathbb{F}_2, H^*(ku;\mathbb{F}_2)).
$$

By either the final paragraph of [AL17] or [AP76, Lemma 3.8 & Table 3.9], it is seen that there are no classes present on this $E_2$-page with $t-s = -1, -3$, or $-5$. □

**Lemma 4.6.** Suppose that $E$ is a form of $K$-theory. Then there are equivalences of spectra

$$
ku_2^\wedge \simeq \tau_{\geq 0} E,
$$

and

$$
\Sigma^3 ku_2^\wedge \simeq \tau_{\geq 3} gl_1(E).
$$

**Proof.** Our arguments closely follow those in [AP76].

The spectrum $\tau_{\geq 0} E$ has a Postnikov tower with primary $k$-invariants

$$
\Sigma^{2k} \mathbb{H}Z_2 \longrightarrow \Sigma^{2k+3} \mathbb{H}Z_2,
$$

for $k \geq 0$. The 2-periodicity of $E$ implies that all of these primary $k$-invariants are the same up to suspension. Since $E$ is a Morava $E$-theory associated to a height 1 formal group law, there is a homotopy ring map $BP \longrightarrow \tau_{\geq 0} E$ that is non-trivial on $\pi_2$. This is enough to show (by comparison with the $k$-invariants in $BP$) that the primary $k$-invariants in $\tau_{\geq 0} E$ are all suspensions of the Milnor operation $Q_1 : \mathbb{H}Z_2 \longrightarrow \Sigma^3 \mathbb{H}Z_2$.

It follows as in [AP76, Proposition 2.1] that the Postnikov tower spectral sequence

$$
E_1^{s,t} = \bigoplus_s H^*(\Sigma^{2s} \mathbb{H}Z_2; \mathbb{F}_2) \implies H^*(\tau_{\geq 0} E; \mathbb{F}_2)
$$

degenerates on the $E_2$-page onto the 0-line, proving that

$$
H^*(\tau_{\geq 0} E; \mathbb{F}_2) \cong H^*(ku; \mathbb{F}_2) \cong \mathcal{A}/E[Q_0, Q_1]
$$

as modules over the Steenrod algebra $\mathcal{A}$. Applying [AP76, Theorem 1.1], we conclude that $\tau_{\geq 0} E \simeq ku_2^\wedge$. To prove that

$$
\Sigma^3 ku_2^\wedge \simeq \tau_{\geq 3} gl_1(E),
$$

note that $\Omega^\infty \tau_{\geq 3} gl_1(E) \simeq \Omega^\infty \tau_{\geq 3} E \simeq BSU_2^\wedge$ and apply [AP76, Corollary 1.3]. □

**Proof of Theorem 4.3** We are now ready to produce the claimed $\E_\infty$-ring map

$$
\Sigma^\infty BU[\beta^{-1}] \longrightarrow E.
$$

By the universal property of $gl_1$, it suffices to make a spectrum map

$$
\Sigma^2 ku \longrightarrow gl_1(E)
$$
which sends $\beta \in \pi_2(ku)$ to a unit in $\pi_2(gl_1(E)) \cong \pi_2(E)$. This is the same as producing a spectrum map

$$\Sigma^2 ku \to \tau_{\geq 2} gl_1(E)$$

solving the following lifting problem

$$\begin{array}{ccc}
\tau_{\geq 2} gl_1(E) \\
\downarrow \\
\Sigma^2 ku & \xrightarrow{f} & \Sigma^2 H\mathbb{Z} \to \Sigma^2 H\mathbb{Z}_2.
\end{array}$$

The obstruction to making such a lift is the composite map

$$\Sigma^2 ku \to \Sigma^2 H\mathbb{Z} \to \Sigma^2 H\mathbb{Z}_2 \to \Sigma \tau_{\geq 3} gl_1(E).$$

By Lemmas 4.5 and 4.6, this obstruction is necessarily 0.

Next, we turn to the question of producing an $\mathbb{E}_{\infty}$-ring homomorphism from $MUP$ to $E$. By the theory of Thom spectra (due to [LMSM86] and written in more modern language by [ABG14, ACB19]), it suffices to check that the composite

$$ku \to \text{pic}(S) \to \text{pic}(E)$$

is nullhomotopic.

Since $E$ is even periodic, the map $ku \to \text{pic}(E)$ is 0 on $\pi_0$. This ensures the existence of a factorization

$$\begin{array}{ccc}
ku & {\xrightarrow{f}} & \Sigma gl_1(E) \\
\downarrow & & \downarrow \\
\text{pic}(S) & \xrightarrow{f} & \text{pic}(E).
\end{array}$$

Our strategy will be to prove that an arbitrary map

$$ku \xrightarrow{f} \Sigma gl_1(E)$$

must be nullhomotopic.

First, note that the composite

$$\Sigma^4 ku \xrightarrow{\beta^2} ku \xrightarrow{f} \Sigma gl_1(E)$$

must factor through $\Sigma \tau_{\geq 3} gl_1(E)$. By Lemmas 4.5 and 4.6, it is therefore nullhomotopic. This provides a quick proof of an $\mathbb{E}_{\infty}$ $MSU$ orientation of $E$; we will next show an $MU$ orientation, and then finally the desired $MUP$ orientation.

Consider the composite

$$\Sigma^2 ku \xrightarrow{\beta} ku \xrightarrow{f} \Sigma gl_1(E).$$

Since this map is null when pulled back to $\Sigma^4 ku$, it must in fact factor as a composite

$$\Sigma^2 ku \to \Sigma^2 H\mathbb{Z} \to \Sigma gl_1(E).$$

By Lemma 4.6, there is a Postnikov fiber sequence

$$\Sigma^5 ku \xrightarrow{\tau_{\geq 2}} \Sigma^3 gl_1(E) \to \Sigma^3 H\mathbb{Z}_2.$$
and we may conclude from Lemma 4.5 that the bottom composite is null.

It remains to show that the map

$$ku \xrightarrow{f} \Sigma gl_1(E)$$

is itself null. By the above discussion, it factors as a composite

$$ku \to HZ \to \Sigma gl_1(E).$$

There are no non-trivial maps $HZ \to \tau \leq 1 \Sigma gl_1(E) \simeq \Sigma H \mathbb{Z}_2$, and so there is a lift

$$ku \to HZ \to \tau \geq 2 \Sigma gl_1(E).$$

Now consider the fiber sequence

$$\Sigma^5 k_2 \to \tau \geq 2 \Sigma gl_1(E) \to \Sigma^3 H \mathbb{Z}_2.$$

While there is one possible non-trivial map $HZ \to \Sigma^3 H \mathbb{Z}_2$, that map becomes trivial when precomposed along the projection $ku \to HZ$. It follows that the map of interest

$$ku \xrightarrow{f} \Sigma gl_1(E)$$

factors through $\tau \geq 4 \Sigma gl_1(E) \simeq \Sigma^5 k_2$, and we finish by Lemma 4.5. □
