AN INDEFINITE ELLIPTIC PROBLEM ON $\mathbb{R}^N$ AUTONOMOUS AT INFINITY:
THE CROSSING EFFECT OF THE SPECTRUM AND THE NONLINEARITY

MAYRA SOARES AND LILIANE A. MAIA

Abstract. We present a new approach to solve a Schrödinger Equation autonomous at infinity, by identifying the relation between the arrangement of the spectrum of the concerned operator and the behavior of the nonlinearity at zero and at infinity. In order to apply variational methods, we set up a suitable linking structure depending on the growth of the nonlinear term and making use of information about the autonomous problem at infinity. Our method allows us to circumvent the lack of compactness. The main novelty is that none monotonicity assumption is required on the nonlinearity, which may be sign-changing as well as the potential. Furthermore, depending on the nonlinearity, the limit of the potential at infinity may be non-positive, so that zero may be an interior point in the essential spectrum of the Schrödinger operator.

1. Introduction

In this paper we establish the existence of a nontrivial weak solution to the following problem

\[ (P_V) \quad \begin{cases} -\Delta u + V(x)u = f(u), \\ u \in H^1(\mathbb{R}^N) \end{cases} \]

for $N \geq 3$, where $V$ and $f$ may change sign and $f$ is an asymptotically linear nonlinearity. Problem $(P_V)$ has been studied extensively in order to reach the most general hypotheses which grant to solve it. Our goal is to expose the essential interplay between the spectrum of the Schrödinger operator and the nonlinear term, which enable us to waive assumptions of decay and differentiability of $V$ and $f$, or even the monotonicity of $f(s)/s$, as those required in [3, 5, 9, 10, 14], for instance.

The new idea is to use the complete knowledge of the spectrum determined by $V$ and discover the nonlinearities which interact appropriately with this spectrum in order to generate a linking geometry that leads to find a solution. Our approach is different from that applied to this problem on a bounded domain $\Omega$, where the spectrum is discrete and the linking geometry is clearly built by choosing an eigenfunction, see [4, 13]. In fact, exploiting spectral properties we present a linking structure by choosing a special direction $e$, which is not necessarily an eigenfunction. Furthermore, due to the lack of monotonicity on the nonlinearity, a new construction of linking level depending on a continuous function $h_0$ is developed (see (1.8) and (3.11)) in order to succeed in finding a nontrivial critical point to

Date: May 2, 2019.
the functional associated to the problem, despite the lack of compactness. This argument is innovative and can be adapted to other situations to improve results in literature where the monotonicity have been required.

We assume the following hypotheses of behavior on the nonlinear term:

\((f_1)\) \(f \in C(\mathbb{R})\) is odd, \(f(0) = 0\), there exists \(\lim_{s \to 0} \frac{f(s)}{s} = f'(0)\) and \(\frac{f(s)}{s} \geq f'(0)\) for all \(s \in \mathbb{R}^+\);

\((f_2)\) There exists \(a > f'(0)\), such that \(\lim_{|s| \to +\infty} \frac{f(s)}{s} = a\).

Defining operator \(A := -\Delta + V(x)\), as an operator of \(L^2(\mathbb{R}^N)\) and denoting by \(\sigma(A)\) the spectrum, by \(\sigma_p(A)\) the point spectrum and by \(\sigma_{\text{ess}}(A)\) the essential spectrum of \(A\), respectively, we assume the following spectral hypothesis on \(V\):

\((V_1)\) \((f'(0), a) \cap \sigma(A) \neq \emptyset\) and \(a \notin \sigma_p(A)\);

\((V_2)\) \(V \in C(\mathbb{R}^N, \mathbb{R})\) and \(\lim_{|x| \to +\infty} V(x) = V_\infty > f'(0)\).

Assumption \((V_2)\) implies that \(A\) is a self-adjoint operator. Moreover, the limit in \((V_2)\) implies that \(\sigma_{\text{ess}}(A) = [V_\infty, +\infty)\), and since \(f'(0) < V_\infty\) we conclude that \(f'(0) \notin \sigma_{\text{ess}}(A)\).

In addition, \(\sigma(A) \cap (-\infty, V_\infty)\) is the discrete spectrum, composed at most by a sequence of eigenvalues with finite multiplicity, then \(f'(0) \notin \sigma(A)\) or it is one of these eigenvalues.

Assumption \((V_1)\) is a kind of crossing hypothesis, since it requires some intersection between the spectrum of \(A\) and the interval \((f'(0), a)\). Note that if \(\sigma^+ \in (f'(0), a) \cap \sigma(A)\) is such that \((f'(0), \sigma^+) \cap \sigma(A) = \emptyset\), then \(\sigma^+\) is either one of the eigenvalues in the discrete spectrum, or \(\sigma^+ = V_\infty\). Similarly, if \(\sigma^- < f'(0)\) is such that \((\sigma^-, f'(0)) \cap \sigma(A) = \emptyset\), then \(\sigma^-\) is either one of those eigenvalues, or \(\sigma^- = -\infty\), hence \((\sigma^-, \sigma^+\) is a gap in \(\sigma(A)\), which contains \(f'(0)\). Furthermore, if \(a > V_\infty\), then \(a \in \sigma_{\text{ess}}(A)\), namely, it is not necessary to require \(a \notin \sigma_p(A)\). However, if \(\sigma^+ < a < V_\infty\), then we require that \(a\) cannot be one of the eigenvalues of \(A\).

- (eigenvalues) —— (continuous spectrum)

\[
\begin{array}{cccc}
\sigma^- & f'(0) & \sigma^+ & a & V_\infty \\
\hline
\end{array}
\]

Case \(\sigma^+ < a < V_\infty\)

\[
\begin{array}{cccc}
\sigma^- & f'(0) & \sigma^+ & V_\infty & a \\
\hline
\end{array}
\]

Case \(\sigma^+ < V_\infty < a\)

\[
\begin{array}{cccc}
\sigma^- & f'(0) & \sigma^+ = V_\infty & a \\
\hline
\end{array}
\]

Case \(\sigma^+ = V_\infty < a\)
It is important to highlight that the relation between $\sigma(A)$ and $f$ is established by the limits of $f(s)/s$ at the origin and at infinity, which must be in a spectral gap and after the same spectral gap, respectively. For instance, it is straightforward to verify that the asymptotically linear model nonlinearity $f(s) = \frac{as^3}{1+s^2}$ satisfies hypotheses $(f_1) - (f_2)$, with $f''(0) = -1 < a$. In this case, as mentioned above, assumption (V$_2$) implies that $-1 \notin \sigma_{ess}(A)$, but it is not required that $0 \notin \sigma(A)$ as usual, see [3]. Moreover, hypothesis (V$_1$) implies that $a > \sigma^+ > -1$, but does not require $a > 0$ as usual, see [8]. Finally, we point out that potentials $V$ such that $V(x) \to V_\infty \leq 0$ as $|x| \to +\infty$ are included by hypothesis (V$_2$), provided that $f'(0) < 0$.

To the best of our knowledge, these assumptions on problem $(P_V)$ deeply generalize previous works in the literature. Setting

$$F(s) = \int_0^s f(t) \, dt \quad \text{and} \quad \tilde{F}(s) := f(s)s - 2F(s), \quad \text{for all} \quad s \in \mathbb{R}. \quad \text{our main result is stated as follows.}$$

**Theorem 1.1.** Assume that $(V_1) - (V_2), (f_1) - (f_2)$ hold with either

1. $(f_3)$ There exists $\delta > 0$ such that $\frac{f(s)}{s} \leq V_\infty - \delta$ for all $s \in \mathbb{R}$,

   or

2. $(f_3)' \quad \tilde{F}(s) \geq 0$ and there exists $\delta > 0$ such that

   $$\frac{f(s)}{s} > V_\infty - \delta \implies \tilde{F}(s) \geq \delta,$$

   along with

3. $(V_3) \quad V(x) \leq V_\infty.$

Then problem $(P_V)$ has a nontrivial solution.

Hypotheses $(f_3)$ or $(f_3)'$ are required for obtaining the boundedness of Cerami sequences for the functional associated to $(P_V)$ in the variational approach. Nevertheless, we also distinguish the linking structure depending on whether $(f_3)$ or $(f_3)'$ happens. Note that hypothesis $(f_3)$ does not make sense when $V_\infty = \sigma^+ < a$. Indeed, since $f(s)/s \to a$ as $|s| \to +\infty$, then there is no $\delta > 0$ such that $f(s)/s < a - \delta$ for $|s|$ sufficiently large. On the other hand, $(f_3)$ may happen when $V_\infty > a > \sigma^+$. Furthermore, we observe that if there exists a sequence of eigenvalues in the discrete spectrum converging to $V_\infty$, the bottom of the essential spectrum, then we surely have $\sigma^+ < V_\infty$, else, both cases $\sigma^+ < V_\infty$ and $\sigma^+ = V_\infty$ may happen.

Influenced by the existence results obtained in [8,9] by L. Jeanjean and K. Tanaka for definite Schrödinger equations by applying Mountain Pass Theorem, we analyze how to treat the existence of solution to problem $(P_V)$ under the most general assumptions, as for indefinite potentials, for instance. In [8] the authors worked with a asymptotically linear problem satisfying

$$f'(0) = 0 < \inf \sigma(-\Delta + V(x)) < a,$$

whereas in [9] they treated the superlinear case requiring

$$f'(0) < \inf \sigma(-\Delta + V(x)) < a = +\infty.$$
Since we are interested in the asymptotically linear case, we generalize their assumptions requiring
\begin{equation}
 f'(0) < \sigma^+ < a < +\infty, \quad \text{for some} \quad \sigma^+ \in \sigma(-\Delta + V(x)),
\end{equation}
which includes both previous assumptions. Hence, in what concerns to release the interaction between the spectrum and the nonlinear term, our Theorem 1.1 is a wide generalization to Theorems 1.1 and 1.2 in [8], since we only require the crossing assumption in (1.1). Regarding [9], although \( \inf \sigma(-\Delta + V(x)) \) may be negative, since \( f'(0) \) is below this infimum, by making a translation in the problem, it becomes a definite problem, hence it is also possible to obtain a Mountain Pass geometry, see also [7]. Thus, these papers work with definite operators, which allow the authors to find a positive solution to the problem. Since in our case, we treat an indefinite operator, a solution \( u \) to \((PV)\) is an eigenvector associated to the eigenvalue zero of the following Schrödinger operator
\[-\Delta + V(x) - \frac{f(u)}{u},\]
whose infimum of the spectrum is negative. Therefore, such a solution must be sign-changing, for details see [12].

Under our assumptions, Mountain Pass Theorem is not applicable, hence our challenge is to set up a suitable linking geometry to problem \((PV)\), which allows us to find a nontrivial critical point to the functional associated by the variational methodology. Following the approach in [8], we look for information in the limit problem “at infinity”, however, due to the lack of compactness our arguments do not work for a usual linking structure. Establishing an appropriate linking geometry depends strongly on the hypotheses of growth of \( f(s)/s \), since we do not have assumptions of monotonicity, as well as [8]. Thus, we make use of classical results from [1] by H. Berestycki and P. Lions and we also lay hand of a smart construction by L. Jeanjean and K. Tanaka in Proposition 4.1 of [8]. Thereby, we get a proper linking structure to overcome the lack of compactness. Nevertheless, another difficulty is to guarantee that, in fact, this linking geometry produces a Cerami sequence for the associated functional. For this purpose, we need to prove a linking theorem, which do generalize the linking theorems in [6, 13], since our linking structure is not covered by these previous results.

In [10] problem \((PV)\) was treated by L. Maia, J. Oliveira Junior and R. Ruviaro, also in the asymptotically linear case, autonomous at infinity. However, their estimates required more assumptions of decay, differentiability, growth and monotonicity, which enabled them to apply the linking theorem developed by G. Li and C. Wang in [6] and use the monotonicity to get the nontrivial critical point at the end. This argument cannot be employed by us, due to the lack of monotonicity. Furthermore, in [10] the authors require \( 0 \notin \sigma(-\Delta + V(x)) \) and the limit of \( V \) being positive, as usual in the literature, such hypotheses are loosened by us in this paper.

Finally, we would like to mention the paper [7] by Z. Liu, J. Su and T. Weth, where they worked under general assumptions on the potential and nonlinear term, including the asymptotically linear case. Nevertheless, they required a non-crossing assumption, which in our case would mean
\begin{equation}
 [f'(0), a] \cap \sigma_{ess}(A) \subset \left[ \inf_{s \in \mathbb{R}\setminus\{0\}} \frac{f(s)}{s}, \sup_{s \in \mathbb{R}\setminus\{0\}} \frac{f(s)}{s} \right] \cap \sigma_{ess}(A) = \emptyset \quad \text{and} \quad a \notin \sigma(A).
\end{equation}
Hence, their nonlinear term did not cross the essential spectrum, then they were able to get compactness and by making a translation in their problem they could apply Mountain Pass Theorem. We observe that hypothesis \((V_1)\) requires less then condition (1.2), since
we just assume \( a \notin \sigma_p(A) \) and it does not matter how \( f(s)/s \) behaves between zero and infinity, namely it may cross the essential spectrum or not. This shows, for instance, that a nonlinearity satisfying \( (f_3)' \) cannot be tackled by their results, neither the cases \( \sigma^+ \leq V_\infty < a \) and \( \sigma^+ < V_\infty = a \).

Following ideas found in \([7,9,11]\), by making a translation in our problem, we observe that \( u \in H^1(\mathbb{R}^N) \) is a solution to \((P_V)\) if and only if \( u \) is a solution to
\[
(P_{V_0}) \quad \begin{cases} -\Delta u + V_0(x)u = f_0(u), \\ u \in H^1(\mathbb{R}^N), \end{cases}
\]
where
\[
V_0(x) := V(x) - f'(0) \\
f_0(s) := f(s) - f'(0)s, \text{ for all } s \in \mathbb{R}.
\]

Hence, we are going to prove Theorem 1.1 by dealing with \((P_{V_0})\), which is more easygoing to treat, since it satisfies next hypotheses \((V_1)_0 - (V_2)_0, (f_1)_0 - (f_2)_0\) as a consequence of \((V_1) - (V_2), (f_1) - (f_2)\) and either \((f_3)_0\) as a consequence of \((f_3)\), or \((f_3)'_0\) along with \((V_3)_0\) as a consequence of \((f_3)'\) along with \((V_3)\). Setting
\[
F_0(s) := \int_0^s f_0(t) \, dt \quad \text{and} \quad \hat{F}_0(s) := f_0(s)s - 2F_0(s) = \hat{F}(s) \text{ for all } s \in \mathbb{R},
\]
we state these assumptions as follows.

\((f_1)_0\) \( f_0 \in C(\mathbb{R}) \) is odd, \( f_0(0) = 0 \), there exists \( \lim_{s \to 0} \frac{f_0(s)}{s} = 0 \) and \( f_0(s) \geq 0 \) for all \( s \in \mathbb{R}^+ \);

\((f_2)_0\) Setting \( a_0 := a - f'(0) \), it holds
\[
\lim_{|s| \to +\infty} \frac{f_0(s)}{s} = a_0;
\]

\((f_3)_0\) There exists \( \delta > 0 \) such that \( \frac{f_0(s)}{s} \leq V_\infty - f'(0) - \delta =: V_{0,\infty} - \delta \) for all \( s \in \mathbb{R} \);

\((f_3)'_0\) \( \hat{F}_0(s) \geq 0 \) and there exists \( \delta > 0 \) such that
\[
\frac{f_0(s)}{s} > V_{0,\infty} - \delta \implies \hat{F}_0(s) \geq \delta.
\]

Defining \( A_0 := A - f'(0) = -\Delta + V_0(x) \) and denoting the spectrum of \( A_0 \) by \( \sigma(A_0) \),

\((V_1)_0\) \( (0, a_0) \cap \sigma(A_0) \neq \emptyset \), \( a_0 \notin \sigma_p(A_0) \) and \( (\sigma^- - f'(0), \sigma^+ - f'(0)) \) is a spectral gap of \( \sigma(A_0) \) such that \( \sigma^+ - f'(0) \in (0, a_0) \cap \sigma(A_0) \);

\((V_2)_0\) \( V_0 \in C(\mathbb{R}^N, \mathbb{R}) \) and \( \lim_{|x| \to +\infty} V_0(x) = V_{0,\infty} > 0 \);

\((V_3)_0\) \( V_0(x) \leq V_{0,\infty} \).

Theorem 1.1 is going to be proved by applying variational methods. Let us briefly highlight some technical details. Defining the Hilbert space \( E := \left( H^1(\mathbb{R}^N), || \cdot || \right) \), where \( || \cdot || \) is the norm induced by operator \( A_0 \) and considering \( \{ \mathcal{E}(\lambda) : \lambda \in \mathbb{R} \} \) as the spectral family of operator \( A_0 \), we set \( E^+ \subset E \) as the subspace given by \( E^+ := \left( I - \mathcal{E}(0) \right) E \).
where $A_0$ is positive definite and its complement $E^0 \oplus E^- := \mathcal{E}(0)E$, with $E^0$ and $E^-$ the subspaces where $A_0$ is null and negative definite, respectively, hence $E = E^+ \oplus E^0 \oplus E^-$. In view of $(V_1)_0$ there exists $(\sigma^- - f'(0), \sigma^+ - f'(0))$, which is a spectral gap of $A_0$, with 
\[ \sigma^- - f'(0) < 0 < \sigma^+ - f'(0), \]
then by the spectral family definition, one has
\[ (1.4) \quad \int_{\mathbb{R}^N} \left( |\nabla u^+(x)|^2 + V_0(x)|u^+(x)|^2 \right) dx \geq \left( \sigma^+ - f'(0) \right) \int_{\mathbb{R}^N} |u^+(x)|^2 dx, \]
for all $u^+ \in E^+$ and
\[ (1.5) \quad - \int_{\mathbb{R}^N} \left( |\nabla u^-(x)|^2 + V_0(x)|u^-(x)|^2 \right) dx \geq \left( f'(0) - \sigma^- \right) \int_{\mathbb{R}^N} |u^-(x)|^2 dx, \]
for all $u^- \in E^-$. Furthermore, since $f'(0) \notin \sigma_{ess}(A)$, then $0 \notin \sigma_{ess}(A_0)$ and $\ker(A_0)$ is finite dimensional, hence the following inner product is well defined and we are focused on looking for a solution to $(P_{V_0})$ on the Hilbert space $E$ endowed with this suitable inner product
\[ (1.6) \]
\[ (u,v) = \begin{cases} \int_{\mathbb{R}^N} \left( \nabla u(x)\nabla v(x) + V_0(x)u(x)v(x) \right) dx = (A_0u,v)_{L^2(\mathbb{R}^N)} & \text{if } u,v \in E^+, \\ - \int_{\mathbb{R}^N} \left( \nabla u(x)\nabla v(x) + V_0(x)u(x)v(x) \right) dx = -(A_0u,v)_{L^2(\mathbb{R}^N)} & \text{if } u,v \in E^-, \\ \int_{\mathbb{R}^N} u(x)v(x) dx = (u,v)_{L^2(\mathbb{R}^N)} & \text{if } u,v \in E^0, \\ 0 & \text{if } u \in E^i, v \in E^j, i \neq j, \end{cases} \]
and the corresponding norm $||u||^2 := (u,u)$ for all $u \in E$, which is equivalent to the standard norm in $H^1(\mathbb{R}^N)$, see [3], for instance.

**Remark 1.** Observe that hypothesis $(V_1)_0$ is sufficient to guarantee equivalence of the referred norms, in view of (1.4)-(1.5) and that $0 \notin \sigma_{ess}(A)$. Furthermore, it could not be weakened allowing $f'(0) \in \sigma_{ess}(A)$, namely, $0 \in \sigma_{ess}(A_0)$. In fact, if $0 \in \sigma_{ess}(A_0)$, then $E^0 = \ker(A_0)$ is infinite dimensional and the inner product in (1.6) is necessarily not equivalent to the standard inner product in $H^1(\mathbb{R}^N)$.

For the variational approach, we associate to $(P_{V_0})$ the functional $I : E \to \mathbb{R}$ given by
\[ (1.7) \quad I(u) = \frac{1}{2} \left( ||u^+||^2 - ||u^-||^2 \right) - \int_{\mathbb{R}^N} F_0(u(x)) \, dx, \]
which is indefinite and belongs to $C^1(E,\mathbb{R})$ in view of the previous hypotheses. We recall that $u$ is a weak solution to $(P_{V_0})$ if it is a critical point of $I$, namely, if
\[ I'(u)v = (u^+,v^+) - (u^-,v^-) - \int_{\mathbb{R}^N} f_0(u(x))v(x) \, dx = 0, \quad \forall \, v \in E. \]
Moreover, $(u_n) \subset E$ is called a Cerami sequence for $I$ if
\[ \sup_n |I(u_n)| < +\infty \quad \text{and} \quad ||I'(u_n)||_{E'}(1 + ||u_n||) \to 0 \quad \text{as} \quad n \to +\infty, \]
and $(u_n)$ is called a $(C)_c$ sequence, or a Cerami sequence on the level $c$, if besides that it satisfies $I(u_n) \to c$ as $n \to +\infty$. 

Our goal is to prove and apply an abstract linking theorem, which is going to be appropriate for our problem, adapting the linking results presented in [6] due to G. Li and C. Wang, and in [13], due to P. Rabinowitz, in order to provide a Cerami sequence for functional \( I \) associated to \( (P_{k_0}) \) on a positive level \( c \in \mathbb{R} \). Indeed, our abstract result is stated as follows.

**Theorem 1.2** (Abstract Linking Theorem). Let \( E \) be a real Banach space with \( E = V \oplus X \), where \( V \) is finite dimensional. Suppose there exist real constants \( R > \rho > 0 \), \( \alpha > \omega \) and there exists an \( e \in \partial B_1 \cap X \) such that \( I \in C^1(E, \mathbb{R}) \) satisfies,

\[
\begin{align*}
(I_1) & \quad I|_{\partial B_\rho \cap X} \geq \alpha; \\
(I_2) & \quad Setting \( Q := (\bar{B}_R \cap V) \oplus \{r_0 : 0 \leq r \leq R\} \), there exists \( h_0 \in C(Q, E) \) such that \\
(i) & \quad \sup_{u \in Q} I(h_0(u)) < +\infty, \\
(ii) & \quad \sup_{u \in \partial Q} I(h_0(u)) = \omega, \\
(iii) & \quad h_0(\partial Q) \cap (\partial B_\rho \cap X) = \emptyset, \\
(iv) & \quad There exists a unique \( w \in h_0(Q) \cap (\partial B_\rho \cap X) \) and \( \deg(h_0, \text{int}(Q), w) \neq 0 \).
\end{align*}
\]

Then \( I \) possess a Cerami sequence on a level \( c \geq \alpha \), which can be characterized as

\[
(1.8) \quad c := \inf_{h \in \Gamma} \max_{u \in Q} I(h(u)),
\]

where \( \Gamma := \{h \in C(Q, E) : h|_{\partial Q} = h_0\} \).

**Remark 2.** We observe that, if \( h_0 = Id \), the identity map, then Theorem 1.2 is reduced to Theorem 2.10 in [6]. In this sense, our abstract result is a generalization for the abstract results developed in [6] and [13]. In order to apply this result under our assumptions in \( (P_{k_0}) \), we are going to choose a suitable \( h_0 \), which sometimes cannot be the identity map.

Next section is devoted to prove Theorem 1.2. Subsequently, in section 3 we are going to apply Theorem 1.2 and get a \((C)_c\) sequence for \( I \), named \((u_n)\). In virtue of the assumptions on \( f \), in section 4 we are going to be able to show that \((u_n)\) is bounded. Finally, section 5 is designated to obtain a nontrivial critical point for \( I \), which is going to be a nontrivial solution to \( (P_{k_0}) \). Indeed, by means of an indirect argument, lying down on information about the autonomous problem at infinity, we are going to prove that, up to subsequences, \((u_n)\) converges strongly to \( u \neq 0 \), namely, we are going to ensure that \( I \) satisfy the \((C)_c\) condition of compactness.

### 2. An Appropriate Abstract Linking Result

In this section we aim to prove Theorem 1.2 and to do so, we first recall two auxiliary results, which can be found in [6]. For sake of simplicity we change their notation to suit this result in our current notation.

**Proposition 2.1** (Proposition 2.8 [6]). Let \( E \) be a Banach space and \( Q \) a metric space. Let \( Q_0 \) be a closed subspace of \( Q \) and \( \Gamma_0 \subset C(Q_0, E) \). Define

\[
\Gamma := \{h \in C(Q, E) : h|_{Q_0} \in \Gamma_0\}.
\]

If \( I \in C^1(E, \mathbb{R}) \) satisfies

\[
(2.1) \quad +\infty > c := \inf_{h \in \Gamma} \sup_{u \in Q} I(h(u)) > \omega := \sup_{h_0 \in \Gamma_0} \sup_{u \in Q_0} I(h_0(u)),
\]

\[
I|_{\partial B_\rho \cap X} \geq \alpha;
\]

\[
Setting \( Q := (\bar{B}_R \cap V) \oplus \{r_0 : 0 \leq r \leq R\} \), there exists \( h_0 \in C(Q, E) \) such that \\
(i) \quad \sup_{u \in Q} I(h_0(u)) < +\infty, \\
(ii) \quad \sup_{u \in \partial Q} I(h_0(u)) = \omega, \\
(iii) \quad h_0(\partial Q) \cap (\partial B_\rho \cap X) = \emptyset, \\
(iv) \quad There exists a unique \( w \in h_0(Q) \cap (\partial B_\rho \cap X) \) and \( \deg(h_0, \text{int}(Q), w) \neq 0 \).
Then \( I \) possess a Cerami sequence on a level \( c \geq \alpha \), which can be characterized as

\[
(1.8) \quad c := \inf_{h \in \Gamma} \max_{u \in Q} I(h(u)),
\]

where \( \Gamma := \{h \in C(Q, E) : h|_{\partial Q} = h_0\} \).

**Remark 2.** We observe that, if \( h_0 = Id \), the identity map, then Theorem 1.2 is reduced to Theorem 2.10 in [6]. In this sense, our abstract result is a generalization for the abstract results developed in [6] and [13]. In order to apply this result under our assumptions in \( (P_{k_0}) \), we are going to choose a suitable \( h_0 \), which sometimes cannot be the identity map.

Next section is devoted to prove Theorem 1.2. Subsequently, in section 3 we are going to apply Theorem 1.2 and get a \((C)_c\) sequence for \( I \), named \((u_n)\). In virtue of the assumptions on \( f \), in section 4 we are going to be able to show that \((u_n)\) is bounded. Finally, section 5 is designated to obtain a nontrivial critical point for \( I \), which is going to be a nontrivial solution to \( (P_{k_0}) \). Indeed, by means of an indirect argument, lying down on information about the autonomous problem at infinity, we are going to prove that, up to subsequences, \((u_n)\) converges strongly to \( u \neq 0 \), namely, we are going to ensure that \( I \) satisfy the \((C)_c\) condition of compactness.

### 2. An Appropriate Abstract Linking Result

In this section we aim to prove Theorem 1.2 and to do so, we first recall two auxiliary results, which can be found in [6]. For sake of simplicity we change their notation to suit this result in our current notation.

**Proposition 2.1** (Proposition 2.8 [6]). Let \( E \) be a Banach space and \( Q \) a metric space. Let \( Q_0 \) be a closed subspace of \( Q \) and \( \Gamma_0 \subset C(Q_0, E) \). Define

\[
\Gamma := \{h \in C(Q, E) : h_{|Q_0} \in \Gamma_0\}.
\]

If \( I \in C^1(E, \mathbb{R}) \) satisfies

\[
(2.1) \quad +\infty > c := \inf_{h \in \Gamma} \sup_{u \in Q} I(h(u)) > \omega := \sup_{h \in \Gamma_0} \sup_{u \in Q_0} I(h(u)),
\]
then for every \( \varepsilon \in \left(0, \frac{c - \omega}{2}\right) \), \( \delta > 0 \) and \( h \in \Gamma \) such that

\[
\sup_{u \in Q} I(h(u)) \leq c + \varepsilon,
\]

there exists \( u \in E \) such that

a) \( c - 2\varepsilon \leq I(u) \leq c + 2\varepsilon \),
b) \( \text{dist}(u, h(Q)) \leq 2\delta \),
c) \( (1 + ||u||_E)||I'(u)||_{E'} < \frac{8\varepsilon}{\delta} \).

**Corollary 2.2** (Corollary 2.9 [6]). Under the assumptions of Proposition 2.1, there exists a sequence \( (u_n) \subset E \) satisfying

\[
I(u_n) \to c, \quad (1 + ||u_n||_E)||I'(u_n)||_{E'} \to 0.
\]

With the purpose of proving Theorem 1.2, we are going to show that under its assumptions we can apply Proposition 2.1 and Corollary 2.2, obtaining the desired \((C)_c\) sequence for \( I \).

**Proof of Theorem 1.2.** In order to apply Proposition 2.1, we first show that \( c \geq \alpha > \omega \). In fact, we prove that for every \( h \in \Gamma \) there exists \( v_h \in h(Q) \cap (\partial B_\rho \cap X) \). Hence, in view of (I1) we arrive at

\[
\max_{u \in Q} I(h(u)) \geq I(v_h) \geq \alpha, \quad \forall \ h \in \Gamma,
\]

getting \( c \geq \alpha \). Let us obtain such a \( v_h \). Observe that we look for \( v_h \in Q \) such that \( h(v_h) = v_h \in X \) and \( ||v_h|| = \rho \). Defining \( P : E \to V \) as the projector operator on \( V \) and \( H : Q \to \mathbb{R} \oplus V \) given by

\[
H(u) := ||(1 - P)h(u)||e + P(h(u)),
\]

it implies that \( H \in C(Q, \mathbb{R} \oplus V) \) and provided that \( h|_{\partial Q} = h_0 \), for \( u \in \partial Q \) we have

\[
H(u) = ||(1 - P)h_0(u)||e + P(h_0(u)) =: H_0(u) \neq \rho e,
\]

since \( h_0(\partial Q) \cap (\partial B_\rho \cap X) = \emptyset \), from (iii) in (I2). Thus, identifying \( \mathbb{R} \oplus V \) with \( \mathbb{R}^d \) for some \( d \in \mathbb{N} \), the Brouwer’s degree \( \deg(H, \text{int}(Q), \rho e) \) is well defined. Since \( h|_{\partial Q} = h_0 \) then \( H|_{\partial Q} = H_0 \) and

\[
\deg(H, \text{int}(Q), \rho e) = \deg(H_0, \text{int}(Q), \rho e),
\]

in view of the Brouwer’s degree properties. Furthermore, (iv) in (I2) asserts there exists a unique \( w \in h_0(Q) \cap (\partial B_\rho \cap X) \) and \( \deg(h_0, \text{int}(Q), w) \neq 0 \). Hence, for each \( u_0 \in Q \) such that \( h_0(u_0) = w \), it implies that \( H_0(u_0) = \rho e \) and the reverse is also true, then

\[
\deg(H_0, \text{int}(Q), \rho e) = \deg(h_0, \text{int}(Q), w) \neq 0.
\]

Therefore, combining (2.2) and (2.3) we arrive at \( \deg(H, \text{int}(Q), \rho e) \neq 0 \) and there exists \( u_h \in Q \) such that

\[
h(u_h) = \rho e = v_h \in (\partial B_\rho \cap X),
\]

which proves the existence of \( v_h \).

Now we define \( \Gamma_0 := \{h_0\} \) and \( Q_0 := \partial Q \), hence from (ii) in (I2) we have

\[
\sup_{h_0 \in \Gamma_0} \sup_{u \in Q_0} I(h_0(u)) = \sup_{u \in Q_0} I(h_0(u)) = \omega < \alpha \leq c.
\]
In addition, from \((i)\) in \((I_2)\), we conclude that \(c \leq \sup_{u \in Q} I(h_0(u)) < +\infty\), which along with \((2.4)\) provide condition \((2.1)\) in Proposition 2.1. Therefore, applying Proposition 2.1 and Corollary 2.2 we guarantee the existence of \((u_n)\), a \((C)_c\) sequence for \(I\), proving the result. \(\square\)

3. Setting The Linking Structure

In this section we show that functional \(I\) defined in \((1.7)\) satisfies \((I_1)-(I_2)\) in Theorem 1.2. In order to do so, we first establish the necessary notation. In fact, we set \(X := E^+ \oplus V := E^0 \oplus E^-\), since from \((V_2)_0\) we know that \(E^0 \oplus E^-\) is finite dimensional. Secondly, in order to distinguish the cases where either \((f_3)_0\) or \((f_3)'_0\) hold, we study autonomous problems and make use of classical results due to Berestycki and Lions \([1]\) and Jeanjean and Tanaka \([8]\).

We consider the following equation

\[
-\Delta u = g(u), \quad \text{in} \quad \mathbb{R}^N \quad N \geq 3,
\]

where it is assumed on \(h\) that

\((g_0)\) \(g : \mathbb{R} \to \mathbb{R}\) is continuous and odd;

\((g_1)\) There exists the limit \(\lim_{s \to +0^+} \frac{g(s)}{s} \in (-\infty, 0)\);

\((g_2)\) \(\lim_{s \to +\infty} |h(s)|s^{-\frac{N+2}{N-2}} = 0\).

Associated to \((3.1)\) is the functional \(J : H^1(\mathbb{R}^N) \to \mathbb{R}\) given by

\[
J(u) = \frac{1}{2} \int_{\mathbb{R}^N} |\nabla u(x)|^2 \, dx - \int_{\mathbb{R}^N} G(u(x)) \, dx,
\]

where \(G(u) = \int_0^u g(s) \, ds\).

To study this problem, we recall two remarkable results found in \([1,8]\), we observe that we do not state them in their full generality.

**Proposition 3.1** (Proposition 4.1 \([8]\)). Assume \((g_0)-(g_2)\). Then \(J\) is well defined and problem \((3.1)\) has a nontrivial solution if and only if \(G(s_0) > 0\) for some \(s_0 > 0\).

**Proposition 3.2** (Proposition 4.2 \([8]\)). Assume \((g_0)-(g_2)\) and \(G(s_0) > 0\) for some \(s_0 > 0\). Let \(\tilde{u}\) be a critical point of \((3.1)\) with \(\tilde{u}(x) > 0\) for all \(x \in \mathbb{R}^N\). Then, there exists a path \(\gamma \in C([0,1], H^1(\mathbb{R}^N))\) such that \(\gamma(t)(x) > 0\) for all \(x \in \mathbb{R}^N\), \(t \in (0,1]\), \(\gamma(0) = 0\), \(J(\gamma(1)) < 0\), \(\tilde{u} \in \gamma([0,1])\) and

\[
\max_{t \in [0,1]} J(\gamma(t)) = J(\tilde{u}).
\]

Returning to problem \((P_{\gamma_0})\), under assumptions of Theorem 1.1 we consider the associated “problem at infinity”

\[
\Delta u + V_{0,\infty} u = f_0(u), \quad \text{in} \quad \mathbb{R}^N, \quad N \geq 3,
\]

which is equivalent to problem \((3.1)\) with

\[
g(s) = \begin{cases} 
-V_{0,\infty}s + f_0(s), & \text{for } s \geq 0, \\
-g(-s), & \text{for } s < 0,
\end{cases}
\]

since the ground state solution of \((3.2)\) is nonnegative. If \(I_\infty : H^1(\mathbb{R}) \to \mathbb{R}\) is the functional associated to \((3.2)\), applying Proposition 3.1 to \(J = I_\infty\), we conclude that \(I_\infty\) has nontrivial critical points if and only if \((f_3)_0\) is not satisfied.
In case \((f_3)_0\) is satisfied, then problem (3.2) has no nontrivial solutions and in order to prove that \(I\) satisfies \((I_1) - (I_2)\) in Theorem 1.2, we choose \(h_0 \equiv Id\), the identity map. Thereby, from hypothesis \((V_1)_0\) one has \(a_0 > \sigma^{-} - f'(0) > 0\), hence Theorem 1.1’ in [2] asserts the spectral family of operator \(A_0\) ensures the existence of some \(e \in X = E^+\) with \(||e|| = 1\) and satisfying
\[
(3.3) \quad (\sigma^+ - f'(0))||e||^2_{L^2(\mathbb{R}^N)} \leq ||e||^2 = 1 < a_0||e||^2_{L^2(\mathbb{R}^N)}.
\]
Choosing such an \(e\) and defining \(Q\) as in Theorem 1.2, next lemma shows that \(I\) satisfies \((I_1) - (I_2)\) for sufficiently small \(\rho > 0\), for some \(\alpha > 0 = \omega\) and for \(R > \rho\) large enough, in case \((f_3)_0\) holds.

**Lemma 3.3.** Assuming \((f_1)_0 -(f_3)_0\) and \((V_1)_0 -(V_2)_0\), there exist \(\alpha > 0\) and \(R > \rho > 0\) such that

(i) \(I|_{\partial B_\rho \cap X} \geq \alpha;\)

(ii) \(\sup_{u \in Q} I(u) < +\infty;\)

(iii) \(\sup_{u \in \partial Q} I(u) = 0;\)

(iv) \(\partial Q \cap (\partial B_\rho \cap X) = \emptyset;\)

(v) There exists a unique \(w \in Q \cap (\partial B_\rho \cap X)\) and \(\deg(Id, \text{int}(Q), w) = 1 \neq 0.\)

**Proof.** From \((f_1)_0 -(f_2)_0\), given \(\varepsilon > 0\) and \(p \in [2, 2^*)\) there exists \(C_\varepsilon > 0\) such that
\[
|F_0(t)| \leq \frac{1}{2}\varepsilon|t|^2 + \frac{C_\varepsilon}{p}|t|^p \quad \forall t \in [0, 1],
\]
thus, given \(u^+ \in \partial B_\rho \cap X\) one has
\[
I(u^+) = \frac{1}{2}||u^+||^2 - \int_{\mathbb{R}^N} F_0(u^+(x)) \, dx \geq \frac{1}{2}||u^+||^2 - \frac{1}{2}\varepsilon||u^+||^2_{L^2(\mathbb{R}^N)} - \frac{C_\varepsilon}{p}||u^+||^p_{L^p(\mathbb{R}^N)} \geq \frac{r^2}{2}\left(1 - \varepsilon C_2^2 - \frac{C_\varepsilon}{p} C_p r^{p-2}\right) = \alpha > 0,
\]
where, \(C_q > 0\) is the constant given by the continuous embedding \(E \hookrightarrow L^q(\mathbb{R}^N)\) for \(q \in [2, 2^*)\) and we choose \(\varepsilon > 0, \rho > 0\) small enough to guarantee \(\alpha > 0\). Thus, we have just proved (i).

On the other hand, to prove (ii), we observe that \(I\) is continuous and \(Q \subset \mathbb{R} \oplus V\) is a compact set, hence,
\[
\sup_{u \in Q} I(u) = \max_{u \in \mathbb{R} \oplus V} I(u) < +\infty.
\]

To prove (iii), first we note that
\[
\partial Q = (\partial B_R \cap V) \oplus \{re : 0 \leq r \leq R\} \cup (\bar{B}_R \cap V) \cup (\bar{B}_R \cap V) \oplus \{Re\}.
\]
Hence, in case \(u \in (\partial B_R \cap V) \oplus \{re : 0 \leq r \leq R\}\), we have
\[
I(u) = \frac{1}{2} \left[r^2 - R^2\right] - \int_{\mathbb{R}^N} F_0(u) \, dx \leq \frac{1}{2} \left[r^2 - R^2\right] \leq 0.
\]
In case $u \in \bar{B}_R \cap V$, we have

$$I(u) = -\frac{1}{2} \|u\|^2 - \int_{\mathbb{R}^N} F_0(u) \, dx \leq 0.$$ 

Lastly, in case $u \in (\bar{B}_R \cap V) \oplus \{ Re \}$, we can write $u = v + re$ with $v \in \bar{B}_R \cap V$, then

$$I(u) = \frac{1}{2} \left[ R^2 - \|v\|^2 \right] - \int_{\mathbb{R}^N} F_0(Re + v) \, dx \leq \frac{1}{2} R^2 - \int_{\bar{\Omega}} F_0(Re + v) \, dx$$

(3.4)

as $R \to +\infty$, for a arbitrary bounded domain $\Omega \subset \mathbb{R}^N$, provided that $(f_2)_0$ and Lebesgue Dominated Convergence Theorem imply that

$$\lim_{R \to +\infty} \int_{\bar{\Omega}} F_0(Re(x) + v(x)) \left( \frac{Re(x) + v(x)}{\bar{\Omega}(Re(x) + v(x))^2} \right) dx = \frac{a_0}{2} \int_{\bar{\Omega}} (R^2 e^2(x) + v^2(x)) \, dx.$$ 

Since $e$ and $v$ are orthogonal, we arrive at (3.4). Furthermore, from (3.3) we can choose $\Omega$ such that

$$1 - a_0 \int_{\bar{\Omega}} e^2(x) \, dx < 0.$$ 

(3.5)

Combining (3.4) and (3.5) we get

$$I(u) \leq \frac{R^2}{2} \left( 1 - a_0 \int_{\Omega} e^2(x) \, dx \right) + o_R(1) < 0,$$

(3.6)

for $R > \rho > 0$ sufficiently large. Therefore $\sup_{u \in \partial Q} I(u) = 0$, finishing the proof of $(iii)$.

For proving $(iv)$ it is only necessary observe that $R > \rho$, then

$$\partial Q \cap (\partial B_\rho \cap X) = (\partial Q \cap \partial B_\rho) \cap X = (V \cap \partial B_\rho) \cap X = \emptyset.$$ 

Moreover, since $R > \rho$,

$$Q \cap (\partial B_\rho \cap X) = \{ re : 0 \leq r \leq R \} \cap \partial B_\rho = \{ re \} \quad \text{and} \quad re \in \text{int}(Q),$$

we get $(v)$ as consequence of Brouwer’s degree properties. Therefore, we have finished the proof. \qed

Note that the strict inequality in (3.3), inherited from $(V_1)_0$, was essential to obtain the suitable function $e$ to prove $(iii)$ in Lemma 3.3. Furthermore, by Lemma 3.3 $I$ satisfies all assumptions in Theorem 1.2, hence we are able to apply it, getting a $(C)_c$ sequence for $I$ when $(f_3)_0$ holds.

On the other hand, in case $(f_3)'_0$ is satisfied, from Propositions 3.1 and 3.2 problem (3.2) has a positive solution $\bar{u}$, which provides a path

$$\gamma(t)(x) := \bar{u} \left( \frac{x}{tL} \right),$$

for a sufficiently large $L > 0$ to be chosen, the details about $\gamma$ can be found in [8], in the proof of Proposition 4.2. Since $I_\infty$ is invariant by translations, we can redefine $\gamma$ as

$$\gamma(t)(x) := \bar{u} \left( \frac{x - y}{tL} \right),$$

(3.7)
for some \(y \in \mathbb{R}^N\). Now, we claim that for sufficiently large \(|y| > 0\) does not depending on \(t\), it yields \(\gamma(t) \in E^+ = X\) for all \(t \in [0,1]\). In fact, it is only necessary to prove that for each \(t \in [0,1]\) one has

\[
(A_0 \gamma(t), \gamma(t)) = \int_{\mathbb{R}^N} \left[ |\nabla \gamma(t)(x)|^2 + V_0(x) \gamma(t)^2(x) \right] dx \geq (\sigma^+ - f'(0)) \int_{\mathbb{R}^N} \gamma(t)^2 dx.
\]

Changing variables, it is equivalent to show that

\[
(3.8) \quad \int_{\mathbb{R}^N} \left[ |\nabla \tilde{u}(x)|^2 + (tL)^2 (V(tLx + \gamma) \tilde{u}(x)) \right] dx \geq 0.
\]

Since \(V\) is bounded in \(\mathbb{R}^N\), there exists \(\delta > 0\) small enough, such that for all \(0 < t < \delta\), one has

\[
\int_{\mathbb{R}^N} |\nabla \tilde{u}(x)|^2 dx \geq (\delta L)^2 |\sigma^+ - \inf_{z \in \mathbb{R}^N} V(z)| \int_{\mathbb{R}^N} \tilde{u}(x) dx
\]

\[
\geq (tL)^2 (\sigma^+ - \inf_{z \in \mathbb{R}^N} V(z)) \int_{\mathbb{R}^N} \tilde{u}(x) dx
\]

\[
\geq (tL)^2 \int_{\mathbb{R}^N} (\sigma^+ - V(tLx + \gamma)) \tilde{u}^2(x) dx.
\]

Thus, (3.8) holds for sufficiently small \(t\). Furthermore, in view of (V2)0, given \(\varepsilon > 0\), there exists \(\tau > 0\) such that for \(|z| \geq \tau\) it follows that \(|V(z) - V_\infty| < \varepsilon\). Then, concerned to \(t \geq \delta\), one has \(|tLx| \geq \delta L|x| \geq \tau\), when \(|x| \geq \frac{T}{\delta L}\). Hence, for sufficiently small \(\varepsilon\), and provided that \(V_\infty \geq \sigma^+\) we arrive at

\[
(tL)^2 \int_{\mathbb{R}^N \setminus B_{\frac{T}{\delta L}}} (\sigma^+ - V(tLx)) \tilde{u}^2(x - y) dx \leq (tL)^2 \int_{\mathbb{R}^N \setminus B_{\frac{T}{\delta L}}} (\sigma^+ - V_\infty + \varepsilon) \tilde{u}^2(x - y) dx
\]

\[
\leq \varepsilon (tL)^2 \int_{\mathbb{R}^N \setminus B_{\frac{T}{\delta L}}} \tilde{u}^2(x - y) dx
\]

\[
\leq \varepsilon (\delta L)^2 ||\tilde{u}||^2_{L^2(\mathbb{R}^N)}
\]

\[
(3.9) \quad \leq \frac{1}{2} \int_{\mathbb{R}^N} |\nabla \tilde{u}(x)|^2 dx.
\]

On the other hand, if \(|y| \to +\infty\), from the exponential decay of \(\tilde{u}\), we have that

\[
\int_{B_{\frac{T}{\delta L}}} \tilde{u}^2(x - y) dx \to 0.
\]

Hence, for sufficiently large \(|y|\) we get

\[
(tL)^2 \int_{B_{\frac{T}{\delta L}}} (\sigma^+ - V(tLx)) \tilde{u}^2(x - y) dx \leq (tL)^2 (\sigma^+ - \inf_{z \in \mathbb{R}^N} V(z)) \int_{B_{\frac{T}{\delta L}}} \tilde{u}^2(x - y) dx
\]

\[
\leq (\delta L)^2 (\sigma^+ - \inf_{z \in \mathbb{R}^N} V(z)) \int_{B_{\frac{T}{\delta L}}} \tilde{u}^2(x - y) dx
\]

\[
(3.10) \quad \leq \frac{1}{2} \int_{\mathbb{R}^N} |\nabla \tilde{u}(x)|^2 dx.
\]

Finally, combining (3.9)-(3.10) we obtain (3.8) also for \(\delta \leq t \leq 1\). Therefore, \(\gamma(t) \in E^+ = X\), for all \(t \in [0,1]\).
In order to prove that $I$ satisfies $(I_1) - (I_2)$ in Theorem 1.2, we choose
\begin{equation}
(3.11) \quad h_0(u) := \gamma(t) + |v|, \quad \text{for each} \quad u = Rte + v \in Q, \ t \in [0,1],
\end{equation}
where $|v|(x) = |v(x)|$ is the modulus of function $v$. Moreover, choosing $e$ and $Q$ as before, the following lemma gives $(I_1) - (I_2)$ for $I$, in case $(f_3)'_0$ holds.

**Lemma 3.4.** Assuming $(f_1)_0 - (f_2)_0$, $(f_3)'_0$ and $(V_1)_0 - (V_2)_0$, there exist $\alpha > 0$ and $R > \rho > 0$ such that

(i) $I|_{\partial B_R \cap X} \geq \alpha$;
(ii) $\sup_{u \in Q} I(h_0(u)) < +\infty$;
(iii) $\sup_{u \in \partial Q} I(h_0(u)) = 0$;
(iv) $h_0(\partial Q) \cap (\partial B_\rho \cap X) = 0$;
(v) There exists a unique $w \in h_0(Q) \cap (\partial B_\rho \cap X)$ and $\deg(h_0, \text{int}(Q), w) \neq 0$.

**Proof.** Since the proof of (i) does not depend on $h_0$, it is exactly the same as in Lemma 3.3. In order to prove (ii), we also observe that $I \circ h_0$ is continuous and $Q \subset \Re e \oplus V$ is a compact set, hence

\[ \sup_{u \in Q} I(h_0(u)) = \max_{u \in Q} I(h_0(u)) < +\infty. \]

Now, with the purpose of proving (iii), we recall that
\[ \partial Q = (\partial B_R \cap V) \oplus \{re : 0 \leq r \leq R\} \cup (\bar{B}_R \cap V) \cup (\bar{B}_R \cap V) \oplus \{Re\}, \]
hence, if $u = v + Rte \in (\partial B_R \cap V) \oplus \{re : 0 \leq r \leq R\}$ with $v \in \partial B_R \cap V$, we have
\[ I(h_0(u)) = \frac{1}{2} \left[ ||\gamma(t)||^2 - R^2 \right] - \int_{\Re^N} F_0(\gamma(t) + |v|) \, dx \leq \frac{1}{2} \left[ \max_{t \in [0,1]} ||\gamma(t)||^2 - R^2 \right] < 0, \]
for $R > 0$ large enough. If $u = v \in \bar{B}_R \cap V$, we have
\[ I(h_0(v)) = -\frac{1}{2} ||v||^2 - \int_{\Re^N} F_0(|v|) \, dx \leq 0. \]
Lastly, if $u = v + Rte \in (\bar{B}_R \cap V) \oplus \{Re\}$, with $v \in \bar{B}_R \cap V$, then
\[ I(h_0(u)) = \frac{1}{2} \left[ ||\gamma(1)||^2 - ||v||^2 \right] - \int_{\Re^N} F_0(\gamma(1) + |v|) \, dx \leq \int_{\Re^N} F_0(\gamma(1)) \, dx - \int_{\Re^N} F_0(\gamma(1) + |v|) \, dx \]
\[ \leq - \int_{\Re^N} \left[ F_0(\gamma(1) + |v|) - F_0(\gamma(1)) \right] \, dx \]
\[ \leq 0, \]
since $I(\gamma(1)) < 0$ and provided that $f_0(s) \geq 0$ for $s \geq 0$ it implies that $F_0(s)$ is non-decreasing for $s \geq 0$, hence $\gamma(1),|v| \geq 0$ gives $F_0(\gamma(1) + |v|) \geq F_0(\gamma(1))$. Therefore, $\sup_{u \in \partial Q} I(h_0(u)) = 0$.

For obtaining (iv) first we note that
\[ h_0(\partial Q) = (\partial B_R \cap V) \oplus \{\gamma(t) : 0 \leq t \leq 1\} \cup (\bar{B}_R \cap V) \cup (\bar{B}_R \cap V) \oplus \{\gamma(1)\}. \]
Then, since $R > \rho$, choosing sufficiently large $L > 0$ such that
\begin{equation}
(3.13) \quad ||\gamma(1)||^2 = L^{N-2} \int_{\Re^N} \left[ |\nabla \tilde{u}(x)|^2 + (L)^2 (Lx + y)^2 \tilde{u}^2(x) \right] \, dx > \rho^2,
\end{equation}
we conclude that
\[ h_0(\partial Q) \cap (\partial B_\rho \cap X) = (h_0(\partial Q) \cap \partial B_\rho) \cap X = (V \cap \partial B_\rho) \cap X = \emptyset. \]

Finally, since \( t \mapsto \gamma(t) \) is an injective path, defining the function \( \psi : [0, 1] \to \mathbb{R} \), given by \( \psi(t) = ||\gamma(t)|| \), it is also injective. Moreover, \( \psi \) is continuous, \( \psi(0) = 0 \) and from (3.13) we have \( \psi(1) > \rho \). Thus, from the Intermediate Value Theorem there exists some (unique, since \( \psi \) is injective) \( t_0 \in (0, 1) \) such that \( \psi(t_0) = \rho \). Hence,
\[ h_0(Q) \cap (\partial B_\rho \cap X) = \{ \gamma(t) : t \in [0, 1] \} \cap \partial B_\rho = \{ \gamma(t_0) \}, \]

namely, there exists a unique \( w = \gamma(t_0) \in h_0(Q) \cap (\partial B_\rho \cap X) \) and since \( Rte \mapsto h_0(Rte) = \gamma(t) \) is injective, there exists a unique \( u_0 = Rte \in \text{int}(Q) \) such that \( h_0(u_0) = \gamma(t_0) \). Therefore, \( \deg(h_0, \text{int}(Q), w) \neq 0 \), proving \((v)\).

Observe that different from Lemma 3.3, the strict inequality in (3.3) was not essential to obtain \((iii)\) in Lemma 3.4. In fact, now the essential were the properties satisfied by \( \gamma(t) \). Provided that \( I \) satisfies all assumptions in Theorem 1.2, we are able to apply it again, getting a \((C)_c\) sequence for \( I \) also when \( (f_3)_0 \) holds. Finally, we point out that since the linking structure changes according to either \( (f_3)_0 \) or \( (f_3)'_0 \) hold, then the linking level \( c \) may be different in each case.

4. Boundedness of Cerami Sequences

In this section we are going to prove that, under the assumptions of Theorem 1.1, every Cerami sequence for \( I \) is bounded, particularly, those found by Theorem 1.2 in the previous section.

Lemma 4.1. Let \((u_n)\) be a \((C)_c\) sequence for \( I \). Under the assumption of \((V_1)_0 - (V_2)_0\), \((f_1)_0 - (f_2)_0\) and either \((f_3)_0\) or \((f_3)'_0\), it follows that \((u_n)\) is bounded.

Proof. Arguing by contradiction we suppose \( ||u_n|| \to +\infty \) as \( n \to +\infty \) up to subsequences. Defining \( v_n := \frac{u_n}{||u_n||} \), we have \((v_n) \subset E\) bounded, hence \( v_n \to v \) in \( E \) and \( v_n \to v \) in \( L^2_{loc}(\mathbb{R}^N) \) for \( q \in [2, 2^*) \), then \( v_n(x) \to v(x) \) almost everywhere in \( \mathbb{R}^N \). Furthermore, since \((v_n)\) is bounded it must satisfy either

(1) Vanishing: For all \( R > 0 \),
\[ \lim_{n \to +\infty} \sup_{y \in \mathbb{R}^N} \int_{B_{r}(y)} v_n^2(x) \, dx = 0; \]
or
(2) Non-vanishing: There exist \( \eta > 0, 0 < R < +\infty \) and \((y_n) \subset \mathbb{R}^N\) such that
\[ \lim_{n \to +\infty} \int_{B_{r}(y_n)} v_n^2(x) \, dx \geq \eta > 0. \]

We prove that both are impossible for \((v_n)\) arriving at the desired contradiction.

First we prove that (1) is not possible to \((v_n)\). In fact, supposing that \((v_n)\) is a vanishing sequence, in view of \((V_2)_0\) one has
\[ \int_{\mathbb{R}^N} (V_0(x) - V_{0,\infty}) v_n^2(x) \, dx \quad \text{as} \quad n \to +\infty. \]
Then, in view of (4.1) we arrive at
\[
\lim_{n \to +\infty} \int_{\mathbb{R}^N} (|\nabla v_n(x)|^2 + V_{0,\infty}v_n^2(x)) \, dx = \lim_{n \to +\infty} \int_{\mathbb{R}^N} (|\nabla v_n(x)|^2 + V_0v_n^2(x)) \, dx.
\]
Hence,
\[
\limsup_{n \to +\infty} \int_{\mathbb{R}^N} V_{0,\infty}v_n^2(x) \, dx \leq \lim_{n \to +\infty} \int_{\mathbb{R}^N} (|\nabla v_n(x)|^2 + V_{0,\infty}v_n^2(x)) \, dx
= \lim_{n \to +\infty} (||v_n^+||^2 - ||v_n^-||^2)
\leq \lim_{n \to +\infty} ||v_n||^2 = 1
\]
and
\[
(4.2) \quad \limsup_{n \to +\infty} \int_{\mathbb{R}^N} v_n^2(x) \, dx \leq \frac{1}{V_{0,\infty}}.
\]
Furthermore, since \((u_n)\) is a Cerami sequence, it follows that
\[
o_n(1) = \frac{I'(u_n)}{||u_n||} (v_n^+ - v_n^-) = 1 - \int_{\mathbb{R}^N} \frac{f_0(u_n(x))}{u_n(x)} [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx,
\]
then
\[
(4.3) \quad \lim_{n \to +\infty} \int_{\mathbb{R}^N} \frac{f_0(u_n(x))}{u_n(x)} [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx = 1.
\]
Now, if \((f_3)_0\) is satisfied, from (4.2) it implies that
\[
1 = \lim_{n \to +\infty} \int_{\mathbb{R}^N} \frac{f_0(u_n(x))}{u_n(x)} [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx
\leq \limsup_{n \to +\infty} \int_{\mathbb{R}^N} (V_{0,\infty} - \delta) [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx
\leq (V_{0,\infty} - \delta) \limsup_{n \to +\infty} \int_{\mathbb{R}^N} v_n^2(x) \, dx
\leq 1 - \frac{\delta}{V_{0,\infty}},
\]
which is an absurd. On the other hand, if \((f_3)'_0\) holds true, we define
\[
\Omega_n := \left\{ x \in \mathbb{R}^N : \frac{f_0(u_n(x))}{u_n(x)} \leq V_{0,\infty} \right\},
\]
and again from (4.2), we conclude that
\[
(4.5) \quad \int_{\Omega_n} \frac{f_0(u_n(x))}{u_n(x)} [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx \leq (V_{0,\infty} - \delta) \int_{\Omega_n} v_n^2(x) \, dx \leq 1 - \frac{\delta}{V_{0,\infty}}.
\]
Thereby, in virtue of (4.3) and (4.5) we arrive at
\[
(4.6) \quad \liminf_{n \to +\infty} \int_{\mathbb{R}^N \setminus \Omega_n} \frac{f_0(u_n(x))}{u_n(x)} [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx \geq \frac{\delta}{V_{0,\infty}} > 0.
\]
Since \(f(s)/s\) is bounded, it follows that
\[
(4.7) \quad 0 < \liminf_{n \to +\infty} \int_{\mathbb{R}^N \setminus \Omega_n} \frac{f_0(u_n(x))}{u_n(x)} [(v_n^+(x))^2 - (v_n^-(x))^2] \, dx \leq C \liminf_{n \to +\infty} \int_{\mathbb{R}^N \setminus \Omega_n} v_n^2(x) \, dx,
\]
then applying Hölder inequality with some $q \in (2, 2^*)$, we obtain
\begin{equation}
\liminf_{n \to +\infty} \int_{\mathbb{R}^N \setminus \Omega_n} v_n^2(x) \, dx \leq |\mathbb{R}^N \setminus \Omega_n|^{\frac{2^*}{2^* - q}} \|v_n\|_{L^{2^*}}^2,
\end{equation}
and since $(v_n)$ is a vanishing sequence, by Lions’ Lemma, $\|v_n\|_{L^{2^*}}^2 \to 0$ as $n \to +\infty$, hence from (4.8), we conclude that $|\mathbb{R}^N \setminus \Omega_n| \to +\infty$ as $n \to +\infty$ so that
\begin{equation}
\int \hat{F}_0(u_n(x)) \, dx \geq \int \hat{F}_0(u_n(x)) \, dx \geq \delta |\mathbb{R}^N \setminus \Omega_n|
\end{equation}
and (4.9) implies that
\begin{equation}
\lim_{n \to +\infty} \int_{\mathbb{R}^N} \hat{F}_0(u_n(x)) \, dx = +\infty.
\end{equation}
On the other hand,
\begin{equation}
\int_{\mathbb{R}^N} \hat{F}_0(u_n(x)) \, dx = 2I(u_n) - I'(u_n)u_n \to 2c \quad \text{as} \quad n \to +\infty.
\end{equation}
Therefore, (4.11) contradicts (4.10) and $(v_n)$ does not satisfy (1).

Henceforth we show that (2) is also impossible for $(v_n)$. Supposing that $(v_n)$ is non-vanishing we consider two cases:

**Case i:** $(y_n)$ is bounded. Since $(y_n)$ is bounded, then $y_n \to y$, up to subsequences, then considering $\tilde{v}_n(x) := v_n(x + y_n)$ we have $(\tilde{v}_n)$ bounded from the equivalence of norms and then $\tilde{v}_n \rightharpoonup \tilde{v}$ in $E$, up to subsequences. Analogously to $(v_n)$ we have $\tilde{v}_n(x) \to \tilde{v}(x)$ almost everywhere, however, $v_n(x + y_n) \to v(x + y)$ almost everywhere, hence $\tilde{v}(x) = v(x + y)$ almost everywhere in $\mathbb{R}^N$ and $v \equiv 0$ if and only if $\tilde{v} \equiv 0$. Provided that $(v_n)$ satisfies (2) we have
\begin{align}
||\tilde{v}||_{L^2(\mathbb{R}^N)} & \geq ||\tilde{v}||_{L^2(B_R(0))} \\
& = \lim_{n \to +\infty} \int_{B_R(0)} \tilde{v}_n^2(x) \, dx \\
& = \lim_{n \to +\infty} \int_{B_R(0)} v_n^2(x + y_n) \, dx \\
& = \lim_{n \to +\infty} \int_{B_R(y_n)} v_n^2(x) \, dx \\
& \geq \eta > 0,
\end{align}
proving that $\tilde{v} \neq 0$, therefore $v \neq 0$.

Moreover, we claim $v$ is an eigenvector of $A_0$ associated to $a_0$. In fact, given $\varphi \in C_0^\infty(\mathbb{R}^N)$, since $(u_n)$ is a Cerami sequence
\begin{equation}
\int_{\mathbb{R}^N} \nabla v_n(x) \cdot \nabla \varphi(x) \, dx + \int_{\mathbb{R}^N} V_0(x) v_n(x) \varphi(x) \, dx = \int_{\mathbb{R}^N} f_0(u_n(x)) \frac{u_n(x)}{u_n(x)} v_n(x) \varphi(x) \, dx + o_n(1).
\end{equation}
By the weak convergence of $(v_n)$ and from hypothesis $(f_2)_0$, applying Lebesgue Dominated Convergence Theorem, passing (4.13) to the limit we obtain
\begin{equation}
\int_{\mathbb{R}^N} \nabla v(x) \cdot \nabla \varphi(x) \, dx + \int_{\mathbb{R}^N} V_0(x) v(x) \varphi(x) \, dx = a_0 \int_{\mathbb{R}^N} v(x) \varphi(x) \, dx,
\end{equation}
showing the claim.
Finally, to arrive at a contradiction, we observe that since \( a_0 \notin \sigma_p(A_0) \), then \( v \) cannot be an eigenfunction of \( A_0 \) associated to \( a_0 \). Therefore we have proved that (2) cannot occur if \( (y_n) \) is bounded, concluding Case i.

Case ii: \( (y_n) \) is unbounded. Considering again \( \tilde{u}_n(x) = u_n(x+y_n) \) and \( \tilde{v}_n(x) = v_n(x+y_n) \) we are going to show that for all \( \varphi \in C_0^\infty(\mathbb{R}^N) \) one has

\[
(4.14) \quad \int_{\mathbb{R}^N} \nabla \tilde{v}(x) \cdot \nabla \varphi(x) \, dx + \int_{\mathbb{R}^N} V_{0,\infty} \tilde{v}(x) \varphi(x) \, dx = a_0 \int_{\mathbb{R}^N} \tilde{v}(x) \varphi(x) \, dx,
\]

with \( \tilde{v} \neq 0 \) the weak limit of \( (\tilde{v}_n) \), which is nonzero in view of (4.12), provided that \( (v_n) \) is non-vanishing. Then, (4.14) implies that \( \tilde{v} \) is an eigenvector of \(-\Delta + V_{0,\infty}\), with eigenvalue \( a_0 \), which is a contradiction, since operator \(-\Delta\) has no eigenvalues in \( \mathbb{R}^N \).

In order to prove (4.14), given \( \varphi \in C_0^\infty(\mathbb{R}^N) \) we define \( \varphi_n(x) := \varphi(x - y_n) \) for all \( x \in \mathbb{R}^N \), hence \( (\varphi_n) \) is bounded in \( E \), in view of the equivalence of norms. Since \( |y_n| \to +\infty \), up to subsequences, making the necessary change of variables, using the weak convergence information and applying Lebesgue Dominated Convergence Theorem, we obtain

\[
I'(u_n) \varphi_n + \int_{\mathbb{R}^N} \frac{f(u_n(x))}{u_n(x)} v_n(x) \varphi_n(x) \, dx = \int_{\mathbb{R}^N} \nabla v_n(x) \cdot \nabla \varphi_n(x) \, dx + \int_{\mathbb{R}^N} V_0 v_n(x) \varphi_n(x) \, dx
\]

\[
= \int_{\mathbb{R}^N} \nabla \tilde{v}_n(x) \cdot \nabla \varphi(x) \, dx + \int_{\mathbb{R}^N} V_0 (x+y_n) \tilde{v}_n(x) \varphi(x) \, dx
\]

\[
= \int_{\mathbb{R}^N} \nabla \tilde{v}(x) \cdot \nabla \varphi(x) \, dx + \int_{\mathbb{R}^N} V_0,\infty \tilde{v}(x) \varphi(x) \, dx + o_n(1).
\]

On the other hand, in view of \((f_2)'\), provided that \( (u_n) \) is a Cerami sequence, it follows that

\[
I'(u_n) \varphi_n + \int_{\mathbb{R}^N} \frac{f(u_n(x))}{u_n(x)} v_n(x) \varphi_n(x) \, dx = o_n(1) + \int_{\mathbb{R}^N} \frac{f(\tilde{u}_n(x))}{\tilde{u}_n(x)} \tilde{v}_n(x) \varphi(x) \, dx
\]

\[
= o_n(1) + a_0 \int_{\mathbb{R}^N} \tilde{v}(x) \varphi(x) \, dx.
\]

Combining (4.15) and (4.16) we arrive at (4.14). \( \square \)

5. Proof of Main Results

Previous sections have proved the existence of \( (u_n) \) a bounded \((C)_c\) sequence for \( I \) in both cases, when either \((f_3)\) or \((f_3)\)' is satisfied. Now, by analyzing problem (3.2) and applying Propositions 3.1 and 3.2, we are going to be able to prove Theorem 1.1.

Proof of Theorem 1.1. Provided that we have the existence of \( (u_n) \) a \((C)_c\) bounded sequence for \( I \), it implies that \( u_n \rightharpoonup u \text{ in } E \) and \( u_n \to u \text{ in } L^2_{loc}(\mathbb{R}^N) \). Given \( \varphi \in C_0^\infty(\mathbb{R}^N) \), let \( K \subset \mathbb{R}^N \) be the compact support of \( \varphi \). Since \( (u_n) \) is a \((C)_c\) sequence for \( I \), from the weak convergence and the Lebesgue Dominated Convergence Theorem, it follows that

\[
o_n(1) = I'(u_n) \varphi
\]

\[
= (u_n^+ - u_n^- , \varphi) - \int_{\mathbb{R}^N} f_0(u_n(x)) \varphi(x) \, dx
\]

\[
= (u^+ - u^- , \varphi) - \int_K f_0(u(x)) \varphi(x) \, dx + o_n(1)
\]

\[
(5.1) = I'(u) \varphi + o_n(1).
\]
Thus, $I'(u)\varphi = 0$, and since $\varphi$ is arbitrary, by density we obtain $I'(u) \equiv 0$ and therefore $u$ is a critical point of $I$. If $u \neq 0$, we obtain a nontrivial critical point of $I$. Then, we suppose by contradiction that $u \equiv 0$ and we are going to arrive at an absurd.

First, we claim that in this case $(u_n)$ is also a $(C)_c$ sequence for $I_\infty : H^1(\mathbb{R}^N) \to \mathbb{R}$, the functional associated to (3.2). In fact,

$$I_\infty(u_n) = \frac{1}{2} \int_{\mathbb{R}^N} \left( |\nabla u_n(x)|^2 + V_{0,\infty} u_n^2(x) \right) \, dx - \int_{\mathbb{R}^N} F_0(u_n(x)) \, dx$$

$$= I(u_n) - \int_{\mathbb{R}^N} \left( V_{0,\infty} - V_0(x) \right) u_n^2(x) \, dx$$

$$= I(u_n) + o_n(1),$$

in view of (V.2) and since $u_n \to 0$ in $L^2_{\text{loc}}(\mathbb{R}^N)$. Moreover, for the same reasons, we obtain

$$\sup_{||v|| \leq 1} \left| (I'_\infty(u_n) - I'(u_n)) v \right| = \sup_{||v|| \leq 1} \left| \int_{\mathbb{R}^N} \left( V_{0,\infty} - V_0(x) \right) u_n(x)v(x) \, dx \right| \to 0.$$

Now, since $c > 0$ we claim that $(u_n)$ does not vanish. In fact, given $\varepsilon > 0$ from $(f_1)_0 - (f_2)_0$ there exists $C_\varepsilon > 0$ such that

$$\int_{\mathbb{R}^N} |f_0(u(x))u(x)| \, dx \leq \varepsilon ||u||^2_{L^2(\mathbb{R}^N)} + C_\varepsilon ||u||^p_{L^p(\mathbb{R}^N)},$$

thus, if $(u_n)$ vanishes, since $\varepsilon$ is arbitrary, we get that

$$\int_{\mathbb{R}^N} f_0(u_n(x))(u_n^+(x) - u_n^-(x)) \, dx \to 0, \quad \text{as } n \to +\infty.$$

Since $(u_n)$ is a $(C)_c$ sequence for $I$ and in virtue of (5.3) we arrive at

$$o_n(1) = I'(u_n)(u_n^+ - u_n^-) + \int_{\mathbb{R}^N} f_0(u_n(x))(u_n^+(x) - u_n^-(x)) \, dx = ||u_n||^2,$$

contradicting that

$$\liminf_{n \to +\infty} ||u_n||^2 \geq \liminf_{n \to +\infty} ||u_n^+||^2 \geq \lim_{n \to +\infty} 2I(u_n) = c > 0.$$

Thus, $(u_n)$ is a non-vanishing sequence, hence there exist $\eta > 0$, $R > 0$ and $(y_n) \subset \mathbb{R}^N$ such that

$$\int_{B_R(y_n)} u_n^2(x) \, dx \geq \eta > 0.$$

Setting $\tilde{u}_n(x) := u_n(x + y_n)$ as before, since we have proved $(u_n)$ is a $(C)_c$ sequence for $I_\infty$, then so does $(\tilde{u}_n)$, provided that $I_\infty$ is invariant to translations. Moreover, $(\tilde{u}_n)$ is bounded, hence $\tilde{u}_n \to \tilde{u}$ in $E$ and $\tilde{u}_n \to \tilde{u}$, in $L^2_{\text{loc}}(\mathbb{R}^N)$, up to subsequences. Given $\varphi \in C_0^\infty(\mathbb{R}^N)$, let $K \subset \mathbb{R}^N$ be the compact support of $\varphi$. Since $(\tilde{u}_n)$ is a $(C)_c$ sequence for $I_\infty$, from the weak convergence and the Lebesgue Dominated Convergence Theorem, it follows that

$$o_n(1) = I'_\infty(\tilde{u}_n)\varphi$$

$$= \int_{\mathbb{R}^N} \left( \nabla \tilde{u}_n(x) \cdot \nabla \varphi(x) + V_{0,\infty} \tilde{u}_n(x)\varphi(x) \right) \, dx - \int_{\mathbb{R}^N} f_0(u_n(x))\varphi(x) \, dx$$

$$= \int_{\mathbb{R}^N} \left( \nabla \tilde{u}(x) \cdot \nabla \varphi(x) + V_{0,\infty} \tilde{u}(x)\varphi(x) \right) \, dx - \int_K f_0(u(x))\varphi(x) \, dx + o_n(1)$$

$$= I'_\infty(\tilde{u})\varphi + o_n(1).$$
Since \( \varphi \) is arbitrary, in view of (5.5) we conclude that \( I'_\infty(\tilde{u}) \equiv 0 \). In addition, since \((u_n)\) is non-vanishing arguing as in (4.12) with \((u_n)\) and \((\tilde{u}_n)\) instead of \((v_n)\) and \((\tilde{v}_n)\), we get that \( \tilde{u} \neq 0 \), namely \( \tilde{u} \) is a nontrivial critical point to \( I_\infty \).

At this point, if \((f_3)_{0,} \) is satisfied, applying Proposition 3.1 to \( J = I_\infty \), we conclude that \( I_\infty \) has no nontrivial critical points, which is a contradiction, in virtue of \( \tilde{u} \). Therefore, \( u \neq 0 \) is a nontrivial critical point for \( I \). On the other hand, if \((f_3)'_{0,} \) and \((V_3)_{0,} \) hold, we have \( Q_0(s) \geq 0 \) and from Fatou’s Lemma we get that

\[
\begin{align*}
\sup_{n \rightarrow +\infty} \left[ I_\infty(\tilde{u}_n) - \frac{1}{2} I'_\infty(\tilde{u}_n)\tilde{u}_n \right] &= \frac{1}{2} \int_{\mathbb{R}^N} Q_0(\tilde{u}(x)) \, dx \\
&\geq \frac{1}{2} \int_{\mathbb{R}^N} Q_0(\tilde{u}(x)) \, dx \\
&= I_\infty(\tilde{u}) - \frac{1}{2} I'_\infty(\tilde{u})
\end{align*}
\]

(5.6)

Thus, \( \tilde{u} \neq 0 \) is a critical point of \( I_\infty \) with \( I_\infty(\tilde{u}) \leq c \). Now, since \( h_0 \) defined in (3.11) belongs to \( \Gamma \), we obtain

\[
(5.7) \quad c \leq \sup_{u \in Q} I(h_0(u)).
\]

In addition, since \( \gamma(t) \in E^+ \) for all \( t \in [0, 1] \), \( |v| \geq 0 \) and \( F_0(s) \) is nondecreasing for \( s \geq 0 \), then for all \( u = tRe + v \in Q \) we obtain

\[
I(h_0(u)) = \frac{1}{2} \left[ |\gamma(t)|^2 - |v|^2 \right] - \int_{\mathbb{R}^N} F_0(\gamma(t) + |v|) \, dx \\
\leq I(\gamma(t)) - \int_{\mathbb{R}^N} [F_0(\gamma(t) + |v|) - F_0(\gamma(t))] \, dx \\
\leq I(\gamma(t)),
\]

hence

\[
(5.8) \quad \sup_{u \in Q} I(h_0(u)) \leq \sup_{t \in [0, 1]} I(\gamma(t)).
\]

Moreover, if we assume \((V_3)_{0,} \) and also \( V_0(x) \neq V_{0,\infty} \), we have

\[
(5.9) \quad I(v) < I_\infty(v) \quad \text{for all} \quad v \in E.
\]

Therefore, combining (5.7)-(5.9) we arrive at

\[
c \leq \sup_{u \in Q} I(h_0(u)) \leq \sup_{t \in [0, 1]} I(\gamma(t)) < \sup_{t \in [0, 1]} I_\infty(\gamma(t)) = I_\infty(\tilde{u}) \leq c
\]

which provides an absurd. Thus, \( u \neq 0 \) is a nontrivial critical point for \( I \), in case \( V_0(x) \neq V_{0,\infty} \).

In case \( V_0(x) \equiv V_{0,\infty} \), we are looking at the “problem at infinity" and provided that \( \sigma(A_0) = [V_{0,\infty}, +\infty) \), from \((V_1)_{0,} \) we have \( \sigma^+ = V_{\infty} \), hence \((0, a_0) \cap [V_{0,\infty}, +\infty) \neq \emptyset \), then \( a_0 > V_{0,\infty} > 0 \). Thus, if we set \( H(s) := F_0(s) - \frac{1}{2} V_{0,\infty} s^2 \), it satisfies \( H(s_0) > 0 \) for sufficiently large \( s_0 > 0 \) and hence we are able to apply Proposition 3.1 to guarantee the existence of a nontrivial critical point for \( I \). Therefore, in all cases, we obtain a nontrivial critical point for \( I \), which is a nontrivial solution to problem \((P_{f_0})\).  \( \square \)
