Properties of the solution set of generalized polynomial complementarity problems

LIYUN LING, CHEN LING AND HONGJIN HE

Abstract: In this paper, we consider the generalized polynomial complementarity problem (GCP), which covers the recently introduced polynomial complementarity problem (PCP) and the well studied tensor complementarity problem (TCP) as special cases. By exploiting the structure of tensors, we first show that the solution set of GPCPs is nonempty and compact when a pair of leading tensors is cone ER. Then, we study some topological properties of the solution set of GPCPs under the condition that the leading tensor pair is cone ER. With the above notation, the concrete form of TCP is specified as

\[ \langle \cdot, \cdot \rangle := \langle A^\top, A \rangle = \begin{cases} a_{11} x_1^2 + \cdots + a_{1m} x_m^2 & \text{if } (1, 2) \in \mathbb{R}^m, \\ a_{21} x_1 x_2 + \cdots + a_{2m} x_m & \text{if } (2, 0) \in \mathbb{R}^m, \\ \vdots & \text{if } (m, 0) \in \mathbb{R}^m, \\ a_{m1} x_1 + \cdots + a_{mm} & \text{if } (0, m) \in \mathbb{R}^m, \\ a_{m1} x_1 + \cdots + a_{m1} x_m & \text{if } (0, 1) \in \mathbb{R}^m, \\ \cdots & \text{otherwise}. \end{cases} \]

where \( A := (a_{ij}) \in \mathbb{R}^{m \times m} \) and \( x := (x_1, x_2, \ldots, x_m) \in \mathbb{R}^m \). It is easy to see that \( K^* := \{ y \in \mathbb{R}^n \mid \langle y, x \rangle \geq 0, \forall x \in K \} \).

Keywords: Generalized complementarity problem, Polynomial complementarity problem, Error bound, ER-tensor

Mathematics Subject Classification: 15A18, 15A69, 65F15, 90C33

1 Introduction

Let \( F, G : \mathbb{R}^n \to \mathbb{R}^n \) be two given continuous functions and \( K \subseteq \mathbb{R}^n \) be a closed convex cone. The classical generalized complementarity problem (GCP) is to find a vector \( x \in \mathbb{R}^n \) such that

\[ F(x) \in K, \quad G(x) \in K^*, \quad \langle F(x), G(x) \rangle = 0, \quad (1.1) \]

where \( \langle \cdot, \cdot \rangle \) denotes the standard inner product in real Euclidean space, and \( K^* \) is the dual cone of \( K \), which is defined by

\[ K^* := \{ y \in \mathbb{R}^n \mid \langle y, x \rangle \geq 0, \forall x \in K \} . \]

It is easy to see that \( K^* \) is also a closed convex cone in \( \mathbb{R}^n \). In what follows, we denote \( \mathbb{R}^n_+ := \mathbb{R}^n \) by GCP\((F, G, K)\) for simplicity. Clearly, GCP\((F, G, K)\) has a unified form including the typical nonlinear complementarity problem (NCP, \( K := \mathbb{R}^n_+ \) and \( G(x) := x \in \mathbb{R}^n \)) as a special case, which has a large amount of applications in engineering, economics, finance, and robust optimization, e.g., see \( [9, 10, 33, 38] \) and the references therein.

In the past decade, it has been well documented that tensor, which is a natural extension of matrix, is a powerful tool for the treatment of many real-world problems, such as the biomedical data processing \( [2, 4, 23] \), higher-order Markov chains \( [23] \), n-person noncooperative games (also named as multilinear games) \( [14] \), best-rank one approximation in data analysis \( [26] \), hypergraphs \( [6] \), to name just a few. Therefore, the complementarity problem with tensors, which is called tensor complementarity problem (TCP) in the seminal works \( [12, 33] \), also have attracted a lot of considerable attention in optimization community, e.g., see \( [12, 18, 20, 29, 32] \) and the references therein. For given positive integers \( m \) and \( n \), we call \( A = (a_{ijkl}) \in \mathbb{R}^{m \times m} \) where \( a_{ijkl} \in \mathbb{R} \) for \( 1 \leq i, j, k, l \leq m \), an \( m \)-th order \( n \)-dimensional real square tensor and denote by \( T_{m,n} \) the space of \( m \)-th order \( n \)-dimensional real square tensors. For a tensor \( A = (a_{ijkl}) \in \mathbb{R}^{m \times m} \) and a vector \( x = (x_1, x_2, \ldots, x_m)^\top \in \mathbb{R}^m \), we define \( A x^{m-1} \) being a vector whose \( j \)-th component is given by

\[ (A x^{m-1})_j = \sum_{j_2, \ldots, j_m = 1}^n a_{jj_2 \ldots j_m} x_{j_2} \cdots x_{j_m}, \quad j = 1, 2, \ldots, n. \]

With the above notation, the concrete form of TCP is specified as \( F(x) := A x^{m-1} + q \) with a vector \( q \in \mathbb{R}^n \), \( G(x) := x \) and \( K := \mathbb{R}^n_+ \) in \( [33] \), denoted by TCP\((A, q)\). When the order of \( A \) is \( m = 2 \), TCP\((A, q)\) immediately reduces to the deeply developed linear complementarity problem (LCP). Here, we only refer to the monograph \( [7] \) for more information on LCPs.

It is well known that every polynomial \( H : \mathbb{R}^n \to \mathbb{R}^n \) of degree \((s - 1)\) can be expressed in the form of

\[ H(x) := \sum_{k=1}^{s-1} C^{(k)} x^{s-k} + q, \]
where $C^{(k)} \in T_{s-k+1,n}$ for $k = 1, 2, \ldots, s - 1$, and $q \in \mathbb{R}^n$. In this situation, we say that the polynomial $H$ is defined by $(\Delta, q) := (C^{(1)}, \ldots, C^{(s-1)}, q)$. Most recently, Gowda \cite{Gowda98} introduced an interesting model named by polynomial complementarity problem (PCP), which is a specialized NCP with $F$ being a polynomial defined by $(\Lambda, a)$, where $\Lambda := \{A^{(1)}, \ldots, A^{(m-1)}\} \subseteq \mathcal{F}_{m,n} = \mathbb{T}_{m,n} \times \cdots \times \mathbb{T}_{2,n}$ and $a \in \mathbb{R}^n$. As mentioned in \cite{Gowda98}, the PCP appears in polynomial optimization (where a real valued polynomial function is optimized over a constraint set defined by polynomials) and includes the well studied TCPs as its special case. By fully exploiting the polynomial nature of PCPs, some interesting specialized results, which seem better than the results obtained by applying the theory of NCPs to PCPs directly, have been developed, e.g., see \cite{Gowda98, Bertini06, Zheng00, Zheng01, Zheng02, Zheng02b, Zheng03}.

In this paper, we consider an extension of PCPs, namely, the generalized polynomial complementarity problem (GPCP), which is a special kind of GCPs with two polynomials $F(x)$ and $G(x)$. More specifically, both $F(x)$ and $G(x)$ in \cite{Gowda98} are defined by $(\Lambda, a)$ and $(\Theta, b)$, respectively, where

$$
\begin{align*}
\Lambda &:= \{A^{(1)}, \ldots, A^{(m-1)}\} \subseteq \mathcal{F}_{m,n} = \mathbb{T}_{m,n} \times \cdots \times \mathbb{T}_{2,n}, & a &\in \mathbb{R}^n; \\
\Theta &:= \{B^{(1)}, \ldots, B^{(l-1)}\} \subseteq \mathcal{F}_{l,n} = \mathbb{T}_{l,n} \times \cdots \times \mathbb{T}_{2,n}, & b &\in \mathbb{R}^n,
\end{align*}
$$

that is,

$$
F(x) := \sum_{k=1}^{m-1} A^{(k)} x^{m-k} + a \quad \text{and} \quad G(x) := \sum_{p=1}^{l-1} B^{(p)} x^{l-p} + b. \tag{1.2}
$$

In what follows, we use GPCP($\Lambda, a, \Theta, b, K$) to represent the specialized \cite{Gowda98} with $F(x)$ and $G(x)$ given in \cite{Gowda98}. Although the entire theory of GCPs is applicable to GPCPs, one may be interested in the specialized structure-exploiting results. In fact, the appearance of polynomials $F(x)$ and $G(x)$ makes the problem under consideration more challenging than the ones in PCPs and TCPs. Hence, by making use of the polynomial nature (structure of tensors) of \cite{Gowda98}, we have a threefold contribution on the problem under consideration. (i) To the best of our knowledge, this is the first work on GPCPs. Therefore, we give an affirmative answer showing that the solution set of GPCP($\Lambda, a, \Theta, b, K$) is nonempty and compact when a pair of leading tensors is cone ER. (ii) Under the condition that a pair of leading tensors is cone $R_0$, we obtain some topological properties on the solution set of GPCP($\Lambda, a, \Theta, b, K$). (iii) We prove a remarkable global Lipschitzian error bound of the solution set of GPCP($\Lambda, a, \Theta, b, K$). Such a result has an important role in the study of unbounded asymptotics and provides valuable quantitative information about the iterates obtained at the termination of iterative algorithms for computing solutions of GPCPs. Moreover, it is noteworthy that our global error bound is better in the sense that the assumptions of our result are weaker than the ones assumed in the current PCPs and TCPs literature.

The rest of the paper is organized as follows. In Section 2 we recall some definitions and basic facts that will be used in the subsequent analysis. In Section 3 we obtain a sufficient condition relying on a cone ER-tensor pair condition (see \cite{Gowda98}) to guarantee the nonemptiness and compactness of the solution set of GPCP($\Lambda, a, \Theta, b, K$). Note that such a condition reduces to the condition of the ER-tensor in the case of TCPs. In Section 4 we study some more topological properties of the solution set of GPCP($\Lambda, a, \Theta, b, K$). In Section 5 we present a notable global Lipschitzian error bound result for GPCP($\Lambda, a, \Theta, b, K$) with $K := \mathbb{R}_+^n$ under appropriate conditions. Finally, we complete this paper with drawing some concluding remarks in Section 6.

**Notation.** Throughout this paper, for given positive integer $n \geq 2$, let $\mathbb{R}^n$ denote the real Euclidean space of column vectors of length $n$, and let $[n]$ be the index set $\{1, 2, \ldots, n\}$. The small letters $x, y, u, \ldots$ represent scalars and vectors, respectively. In particular, $0$ is the column vector in $\mathbb{R}^n$, whose all entries are zeros. For a given vector $x = (x_1, x_2, \ldots, x_n)^T \in \mathbb{R}^n$, $\|x\|$ denotes the Euclidean norm of $x$, and $x_i$ denotes the orthogonal projection of $x$ on $\mathbb{R}_{+}^n$, that is, $(x_i)_j := \max\{x_i, 0\}$ for $i \in [n]$. For a given tensor $A = (a_{j_1j_2\cdots j_m}) \in \mathbb{T}_{m,n}$, the (squared) Frobenius norm of $A$ is defined by

$$
\|A\|^2 := \sum_{j_1=1}^{m} \sum_{j_2=1}^{m} \cdots \sum_{j_m=1}^{m} a_{j_1j_2\cdots j_m}^2.
$$

In addition, denote by $I = (\delta_{j_1j_2\cdots j_m})$ the unit tensor, where $\delta_{j_1j_2\cdots j_m}$ is the Kronecker symbol

$$
\delta_{j_1j_2\cdots j_m} = \begin{cases}
1, & \text{if } j_1 = j_2 = \cdots = j_m, \\
0, & \text{otherwise},
\end{cases}
$$

In particular, we denote by $I$ the identity matrix when $m = 2$. Given a tensor $A = (a_{j_1j_2\cdots j_m}) \in \mathbb{T}_{m,n}$ and a vector $x \in \mathbb{R}^n$, we define $Ax^m = (x, Ax)^{m-1}$, being the value at $x$ of a homogeneous polynomial. If $F : \mathbb{R}^n \to \mathbb{R}^n$ is a vector valued function, its $j$-th component function is denoted by $F_j$.

## 2 Preliminaries

In this section, we introduce some basic definitions and properties that will be used in the sequel.
For a given closed convex cone $K$ in $\mathbb{R}^n$, it is well known from \cite{19} that the projection operator onto $K$, denoted by $P_K$, is well-defined for every $x \in \mathbb{R}^n$. Moreover, we know that $P_K(x)$ is the unique element in $K$ such that $(P_K(x) - x, P_K(x)) = 0$ and $(P_K(x) - x, y) \geq 0$ for all $y \in K$.

We now recall the concept of exceptional family of elements for a pair of functions with respect to a given closed convex cone, which plays an important role in the existence analysis of solutions of NCPs and GCPs, e.g., see \cite{15,16,17}.

**Definition 2.1.** Let $F, G : \mathbb{R}^n \rightarrow \mathbb{R}^n$ be two given continuous functions. A set of points $\{x^{(i)}\} \subset \mathbb{R}^n$ is called an exceptional family of elements for the pair $(F, G)$ with respect to the cone $K$, if the following conditions are satisfied:

(i) $\|x^{(i)}\| \to \infty$ as $i \to \infty$;
(ii) for every $i$, there exists a real number $\mu_i > 0$ such that $s^{(i)} = \mu_i x^{(i)} + F(x^{(i)}) \in K$, $v^{(i)} = \mu_i x^{(i)} + G(x^{(i)}) \in K^*$, and $(s^{(i)}, v^{(i)}) = 0$.

Using the notion mentioned above, we have the following result (see the proof in \cite{17}). Here, for the sake of completeness, we prove it again in a similar way used for proving \cite{10} Theorem 1.

**Lemma 2.2.** For two given continuous mappings $F, G : \mathbb{R}^n \rightarrow \mathbb{R}^n$ and a closed convex cone $K$ in $\mathbb{R}^n$, there exists either a solution of the problem GCP($F, G, K$) or an exceptional family of elements for the pair $(F, G)$.

**Proof.** Consider the function defined by

$$\Phi(x) := F(x) - P_K(F(x) - G(x))$$

for all $x \in \mathbb{R}^n$. It is easy to show that the problem GCP($F, G, K$) has a solution if and only if the equation $\Phi(x) = 0$ is solvable. For any given $\epsilon > 0$, denote

$$S_\epsilon := \{x \in \mathbb{R}^n \mid \|x\| = \epsilon\} \quad \text{and} \quad B_\epsilon := \{x \in \mathbb{R}^n \mid \|x\| < \epsilon\}.$$  

Consider the homotopy defined by

$$H(x, t) := tx + (1 - t)\Phi(x), \quad 0 \leq t \leq 1. \quad (2.1)$$

From the definition of $\Phi$, we have

$$H(x, t) = tx + (1 - t)F(x) - (1 - t)P_K(F(x) - G(x)), \quad 0 \leq t \leq 1. \quad (2.2)$$

We apply the topological degree theory and the Poincaré-Béhler Theorem in \cite{22} for $y = 0$ and $B_\epsilon (\partial B_\epsilon = S_\epsilon)$. We have the following two situations:

**Case (i).** There exists $\epsilon > 0$ such that $H(x, t) \neq 0$ for any $x \in S_\epsilon$ and $t \in [0, 1]$. In this case, by Poincaré-Béhler, we have that $\deg(\Phi(B_\epsilon, 0)) = \deg(I, B_\epsilon, 0) = 1$, which means that equation $\Phi(x) = 0$ has a solution in $B_\epsilon$, and hence the problem GCP($F, G, K$) has a solution.

**Case (ii).** For any $\epsilon > 0$ there exist $x^{(i)} \in S_\epsilon$ and $t_i \in [0, 1]$ such that

$$H(x^{(i)}, t_i) = 0. \quad (2.3)$$

We first claim that $t_i$ must be different from 1. Indeed, if $t_i = 1$ for some $\epsilon$, then by (2.1) and (2.2), we deduce that $x^{(i)} = 0$, which is impossible since $x^{(i)} \in S_\epsilon$. Secondly, if $t_i = 0$ for some $\epsilon$, then (2.3) becomes $\Phi(x^{(i)}) = 0$, which means that the problem GCP($F, G, K$) has a solution.

Hence, we can say that either the problem GCP($F, G, K$) has a solution, or for any $\epsilon > 0$ there exist $x^{(i)} \in S_\epsilon$ and $t_i \in (0, 1)$ such that $H(x^{(i)}, t_i) = 0$. If GCP($F, G, K$) has no solution, then from (2.2), we have

$$t_i \frac{x^{(i)} + F(x^{(i)})}{1 - t_i} = P_K(F(x^{(i)}) - G(x^{(i)})). \quad (2.4)$$

Consequently, by the basic properties of $P_K$ mentioned at the beginning of this section, it holds that

$$\left\langle \frac{t_i}{1 - t_i} x^{(i)} + F(x^{(i)}) - (F(x^{(i)}) - G(x^{(i)})), y \right\rangle \geq 0, \quad \text{for all } y \in K \quad (2.5)$$

and

$$\left\langle \frac{t_i}{1 - t_i} x^{(i)} + F(x^{(i)}) - (F(x^{(i)}) - G(x^{(i)})), t_i \frac{x^{(i)} + F(x^{(i)})}{1 - t_i} \right\rangle = 0. \quad (2.6)$$

By putting $\mu = t_i / (1 - t_i)$ in (2.5) and (2.6), we deduce

$$\langle \mu x^{(i)} + G(x^{(i)}), y \rangle \geq 0, \quad \text{for all } y \in K \quad (2.7)$$

and

$$\langle \mu x^{(i)} + G(x^{(i)}), \mu x^{(i)} + F(x^{(i)}) \rangle = 0. \quad (2.8)$$

From (2.7), we know that $\mu x^{(i)} + G(x^{(i)}) \in K^*$, which, together with (2.4), (2.8) and the fact that $\|x^{(i)}\| = \epsilon$ for any $\epsilon > 0$, implies that $\{x^{(i)}\}$ is an exceptional family of elements for the pair $(F, G)$. \hfill \Box
Let \( \Lambda = (A^{(1)}, \ldots, A^{(m-1)}) \in \mathcal{F}_{m,n} \), \( \Theta = (B^{(1)}, \ldots, B^{(l-1)}) \in \mathcal{F}_{l,n} \), and \( K \subset \mathbb{R}^n \) be a closed convex cone. Suppose that \((A^{(1)}, B^{(1)})\) is an \( \mathbf{ER}^K\)-tensor pair. If either (i) \( m = l \) or (ii) \( m \neq l \), then the pair \((A^{(1)}, B^{(1)})\) must be an \( \mathbf{ER}^K\)-tensor pair.

To see that \((A^{(1)}, B^{(1)})\) is an \( \mathbf{ER}^K\)-tensor pair, we use the following criterion: A tensor \( A^{(1)} \in \mathcal{F}_{m,n} \) is an \( \mathbf{ER}^K\)-tensor if, for any \( v, t \in \mathbb{R}_+ \), the following inequality holds:

\[
0 \leq \left( x^2 + \frac{x_1^2}{v^2} \right) \left( x^2 + \frac{x_1^2}{t^2} \right) \geq 0,
\]

for all \( x \in \mathbb{R}^n \). This criterion implies that \((A^{(1)}, B^{(1)})\) is an \( \mathbf{ER}^K\)-tensor pair.

### 3 Nonemptiness and compactness of the solution set

In this section, we mainly study the nonemptiness and compactness of the solution set of \( \text{GPCP}(\Lambda, a, \Theta, b, K) \) with structured tensors. Throughout, we denote by \( \text{SOL}(\Lambda, a, \Theta, b, K) \) the solution set of \( \text{GPCP}(\Lambda, a, \Theta, b, K) \) for notational convenience.

**Theorem 3.1.** Let \( \Lambda = (A^{(1)}, \ldots, A^{(m-1)}) \in \mathcal{F}_{m,n} \), \( \Theta = (B^{(1)}, \ldots, B^{(l-1)}) \in \mathcal{F}_{l,n} \), and \( K \subset \mathbb{R}^n \) be a closed convex cone. Suppose that \((A^{(1)}, B^{(1)})\) is an \( \mathbf{ER}^K\)-tensor pair. If either (i) \( m = l \) or (ii) \( m \neq l \), then the pair \((A^{(1)}, B^{(1)})\) must be an \( \mathbf{ER}^K\)-tensor pair.

**Proof.** We first prove the nonemptiness of the solution set \( \text{SOL}(\Lambda, a, \Theta, b, K) \). Suppose, on the contrary, that \( \text{SOL}(\Lambda, a, \Theta, b, K) = \emptyset \). Then, it follows from Lemma 2.2 that there exists an exceptional family of elements for the pair \((F, G)\), i.e., there exists a sequence \( \{x^{(i)}\}_{i=1}^{\infty} \subset \mathbb{R}^n \) satisfying \( \|x^{(i)}\| \to \infty \) as \( i \to \infty \), and there exists a scalar \( \mu_i > 0 \) for each \( i \) such that

\[
\begin{align*}
\sum_{k=1}^{m-1} A^{(k)} (x^{(i)})^{m-k} + a + \mu_i x^{(i)} & \in K, \\
\sum_{p=1}^{l-1} g^{(p)} (x^{(i)})^{l-p} + b + \mu_i x^{(i)} & \in K^*, \\
h_i := \left( \sum_{k=1}^{m-1} A^{(k)} (x^{(i)})^{m-k} + a + \mu_i x^{(i)}, \sum_{p=1}^{l-1} g^{(p)} (x^{(i)})^{l-p} + b + \mu_i x^{(i)} \right) & = 0.
\end{align*}
\]
From the third expression in (3.1), it is clear that \( h_i / \| \xi(i) \|^{m+1-2} = 0 \) for every \( i \), which shows
\[
0 = \frac{h_i}{\| \xi(i) \|^{m+1-2}} = \frac{\left\langle \sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + a, \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + b \right\rangle}{\| \xi(i) \|^{m+1-2}}
+ \frac{t_i \left\langle \xi(i), \sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + a + b \right\rangle}{\| \xi(i) \|^m} + \frac{t_i^2}{\| \xi(i) \|^{m+1-2}},
\tag{3.2}
\]
where \( t_i = \mu_i / \| \xi(i) \|^{l-2} \). We claim that \( \{ t_i \}_{i=1}^{\infty} \) is bounded. Suppose that \( \{ t_i \}_{i=1}^{\infty} \) is unbounded. Without loss of generality, we assume that \( t_i \to +\infty \) as \( i \to \infty \).

**Case (i).** When \( m = l \), by (3.2), it holds that
\[
0 = \frac{\sum_{p=1}^{m-1} A(p) (\xi(i))^{m-p} + a, \sum_{p=1}^{m-1} B(p) (\xi(i))^{m-p} + b}{\| \xi(i) \|^{2(m-1)}}
+ \frac{t_i \left\langle \xi(i), \sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + a + b \right\rangle}{\| \xi(i) \|^m} + 1.
\tag{3.3}
\]
Let \( \xi(i) = \xi(i) / \| \xi(i) \| \). Since \( \| \xi(i) \| = 1 \) for any \( i \), without loss of generality, we assume that \( \xi(i) \to \xi \) as \( i \to \infty \). Consequently, it is easy to see that
\[
\lim_{i \to \infty} \frac{\sum_{p=1}^{m-1} A(p) (\xi(i))^{m-p} + a, \sum_{p=1}^{m-1} B(p) (\xi(i))^{m-p} + b}{\| \xi(i) \|^{2(m-1)}} = \left\langle (A^{1})_{m-1}, (B^{1})_{m-1} \right\rangle
\]
and
\[
\lim_{i \to \infty} \frac{\left\langle \xi(i), \sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + a + b \right\rangle}{\| \xi(i) \|^m} = (A^{1} + B^{1}) \xi^{m},
\]
which, together with (3.3), implies that \( 0 = 1 \). It is a contradiction.

**Case (ii).** When \( m \neq l \), without loss of generality, we assume that \( m > l \). Since \( A^{1} \) is positive definite and \( \xi \in \mathbb{R}^{n} \setminus \{0\} \), it holds that
\[
\lim_{i \to \infty} \frac{\left\langle \xi(i), \sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + a + b \right\rangle}{\| \xi(i) \|^m} = (A^{1})_{m} \xi^{m} > 0.
\]
Consequently, from (3.2), we obtain
\[
0 \geq \frac{\sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + a, \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + b}{\| \xi(i) \|^{m+1-2}}
+ \frac{t_i \left\langle \xi(i), \sum_{k=1}^{m-1} A(k) (\xi(i))^{m-k} + \sum_{p=1}^{l-1} B(p) (\xi(i))^{l-p} + a + b \right\rangle}{\| \xi(i) \|^m}
\to +\infty,
\tag{3.4}
\]
which is also a contradiction.

Since \( \{ t_i \}_{i=1}^{\infty} \) is bounded, without loss of generality, we assume \( \lim_{i \to \infty} t_i = \tilde{t} \). It is clear that \( \tilde{t} \geq 0 \).

By the first two expressions in (3.1), we know that, if \( m = l \), then
\[
A^{1} \xi^{m-1} + \tilde{t} \tilde{a} \in K, \ B^{1} \xi^{l-1} + \tilde{t} \tilde{a} \in K^{*}, \ \left\langle A^{1} \xi^{m-1} + \tilde{t} \tilde{a}, B^{1} \xi^{l-1} + \tilde{t} \tilde{a} \right\rangle = 0,
\]
and if \( m \neq l \), then
\[
\left\{ \begin{array}{ll}
A^{1} \xi^{m-1} \in K, \ B^{1} \xi^{l-1} + \tilde{t} \tilde{a} \in K^{*}, \ \left\langle A^{1} \xi^{m-1}, B^{1} \xi^{l-1} + \tilde{t} \tilde{a} \right\rangle = 0, & \text{if } m > l; \\
A^{1} \xi^{m-1} + \tilde{t} \tilde{a} \in K, \ B^{1} \xi^{l-1} \in K^{*}, \ \left\langle A^{1} \xi^{m-1} + \tilde{t} \tilde{a}, B^{1} \xi^{l-1} \right\rangle = 0, & \text{if } m < l.
\end{array} \right.
\]

From the discussion above, we know that there exists \( (\tilde{x}, \tilde{v}, \tilde{t}) \in (\mathbb{R}^{n} \setminus \{0\}) \times \mathbb{R}_+ \times \mathbb{R}_+ \) satisfying the system (2.9) which contradicts the condition that \( (A^{1}, B^{1}) \) is an \( \mathbb{E}^{K} \)-tensor pair. Thus, \( \text{SOL}(\Lambda, a, \Theta, b, K) \) is nonempty.

Secondly, we prove that \( \text{SOL}(\Lambda, a, \Theta, b, K) \) is compact. Since \( K \) and \( K^{*} \) are closed, it is easy to see that \( \text{SOL}(\Lambda, a, \Theta, b, K) \) is closed. We now prove the boundedness of \( \text{SOL}(\Lambda, a, \Theta, b, K) \). Suppose that
The following two statements are true:

Let $\Lambda = \{ \Lambda_1, \Lambda_2, \cdots, \Lambda_n \}$ be upper semicontinuous at $\bar{w}$. Without loss of generality, we assume that $x^{(i)}/\|x^{(i)}\| \rightarrow \bar{x}$ as $i \rightarrow \infty$. It is clear that $\bar{x} \neq 0$. Furthermore, it follows from the definition of $\text{GPCP}(\Lambda, a, \Theta, b, K)$ that

$$\frac{a}{\|x^{(i)}\|^{m-1}} + \sum_{k=1}^{m-1} \frac{1}{\|x^{(i)}\|^{k-1}} A^{(k)}(x^{(i)}/\|x^{(i)}\|)^{m-k} \in K,$$

$$\frac{b}{\|x^{(i)}\|^{l-1}} + \sum_{p=1}^{l-1} \frac{1}{\|x^{(i)}\|^{p-1}} B^{(p)}(x^{(i)}/\|x^{(i)}\|)^{l-p} \in K^*$$

and

$$\left\langle \sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a, \sum_{p=1}^{l-1} B^{(p)}(x^{(i)})^{l-p} + b \right\rangle = 0, \quad \|x^{(i)}\|^{m+l-2} = 0.$$ 

Consequently, by letting $i \rightarrow \infty$, we have

$$A^{(1)}_x x^{m-1} \in K, \quad B^{(1)}_x y^{l-1} \in K^*, \quad \text{and} \quad \left\langle A^{(1)}_x x^{m-1}, B^{(1)}_x y^{l-1} \right\rangle = 0. \quad (3.5)$$

This means that $\bar{x} \in \mathbb{R}^n \setminus \{0\}$ satisfies the system $\mathcal{S}_0$, which further contradicts the fact that $(A^{(1)}_x, B^{(1)}_x)$ is an $\mathbb{R}^m$-tensor pair, since $(A^{(1)}_x, B^{(1)}_x)$ is an $\mathbb{R}^n$-tensor pair. Thus $\text{SOL}(\Lambda, a, \Theta, b, K)$ is compact. \qed

**Remark 3.2.** When $m > l$, if $S(K) \subseteq K$ where $S(z) := z - F(z)$ for any $z \in \mathbb{R}^n$, then by Remark 3.2 and a similar way to that used in Theorem 3.1, we can obtain that $\text{SOL}(\Lambda, a, \Theta, b, K)$ is nonempty and compact, provided $A^{(1)}_x$ is strictly $K$-positive, i.e., $A^{(1)}_x x^m > 0$ for any $x \in K \setminus \{0\}$. Notice that, in this case, $m$ is not necessarily even.

## 4 Some basic topological properties of the solution set

In this section, we further study some topological properties of $\text{SOL}(\Lambda, a, \Theta, b, K)$. It is obvious that $\mathcal{F}_{m,n}$ is a linear space for any given positive integers $m$ and $n$. The distance between two elements $\Lambda_i = (A^{(1)}_i, A^{(2)}_i, \cdots, A^{(m-1)}_i) \in \mathcal{F}_{m,n}$ ($i = 1, 2$) is measured by means of the expression

$$\|\Lambda_1 - \Lambda_2\|_p = \sqrt{\sum_{k=1}^{m-1} \left\| A^{(k)}_1 - A^{(k)}_2 \right\|_p^2}.$$ 

Denote by $\mathcal{E}(\mathbb{R}^n)$ the set of nonzero closed convex cones in $\mathbb{R}^n$, which is associated with the natural metric defined by

$$\delta(K_1, K_2) := \sup_{\|u\| \leq 1} |\text{dist}(z, K_1) - \text{dist}(z, K_2)|,$$

where $\text{dist}(z, K) := \inf_{u \in K} \|z - u\|$ stands for the distance from $z$ to $K$. An equivalent way of defining $\delta$ is

$$\delta(K_1, K_2) = \text{haus}(K_1 \cap B_n, K_2 \cap B_n),$$

where $B_n$ is the closed unit ball in $\mathbb{R}^n$, and

$$\text{haus}(C_1, C_2) := \max \left\{ \sup_{z \in C_1} \text{dist}(z, C_2), \sup_{z \in C_2} \text{dist}(z, C_1) \right\}$$

stands for the Hausdorff distance between the compact sets $C_1, C_2 \subseteq \mathbb{R}^n$ (see [3] pp. 85-86). General information on the metric $\delta$ can be consulted in the book by Rockafellar and Wets [28]. According to [34], the operation $\delta : K \rightarrow K^*$ is an isometry on the space $(\mathcal{E}(\mathbb{R}^n), \delta)$, that is to say,

$$\delta(K_1^*, K_2^*) = \delta(K_1, K_2), \quad \text{for all } K_1, K_2 \in \mathcal{E}(\mathbb{R}^n).$$

The basic topological properties of the mapping $\text{SOL}(\cdot) : \mathcal{F}_{m,n} \times \mathbb{R}^n \times \mathcal{F}_{l,n} \times \mathbb{R}^n \times \mathcal{E}(\mathbb{R}^n) \rightarrow 2^\mathbb{R}$ are listed in the following propositions. These propositions are some GPCP versions of the results presented in [20]. As far as semicontinuity concepts are concerned, we use the following terminology (see [3] Section 6.2).

**Definition 4.1.** Let $W$ and $Y$ be two topological spaces and $\bar{w} \in W$. The mapping $\Psi : W \rightarrow Y$ is said to be upper semicontinuous at $\bar{w}$ if, for every open set $U$ with $\Psi(\bar{w}) \subseteq U$, there exists an open neighborhood $V$ of $\bar{w}$ such that $\Psi(V) \subseteq U$ for each $w \in V$.

**Proposition 4.2.** The following two statements are true:
Furthermore, by (4.1), we have
we assume that

\[ \text{to prove } (\bar{x}, \bar{\Theta}) \in \text{SOL}(\Lambda, \Theta, b, K). \]

\[ \text{Proof. Item (i).} \] The closedness of \( \Sigma \) amounts to saying that
\[ \Xi_i := \{(\Lambda_i, a^{(i)}, \Theta_i, b^{(i)}, K_i) \} \rightarrow \Xi := \{\bar{\Lambda}, \bar{a}, \bar{\Theta}, \bar{b}, \bar{K}\} \Rightarrow \bar{x} \in \text{SOL}(\Xi). \]

Since \( x^{(i)} \in \text{SOL}(\Xi_i) \) for every \( i \), we have
\[ K_i \ni \left( \sum_{k=1}^{m-1} \bar{A}^{(k)}(x^{(i)})^{m-k} + a^{(i)} \right) \bot \left( \sum_{i=1}^{l-1} \bar{B}^{(p)}(x^{(i)})^{l-p} + b^{(i)} \right) \in K_i^* \quad \text{(1.1)} \]

Consequently, since \( x^{(i)} \rightarrow \bar{x} \) as \( i \rightarrow \infty \) and \( \delta(K_1^*, K_2^*) = \delta(K_1, K_2) \) for any \( K_1, K_2 \in C(R^n) \), by passing to the limit in (1.1), one gets
\[ \bar{K} \ni \left( \sum_{k=1}^{m-1} \bar{A}^{(k)}x^{m-k} + \bar{a} \right) \bot \left( \sum_{i=1}^{l-1} \bar{B}^{(p)}x^{l-p} + \bar{b} \right) \in \bar{K}^* \]

which implies \( \bar{x} \in \text{SOL}(\Xi) \). We proved the first part (i) of this proposition.

**Item (ii).** Suppose that the map \( \text{SOL}(\cdot) \) is not locally bounded at \( \Xi \). Then there exist sequences \( \{\Xi_i = (\Lambda_i, a^{(i)}, \Theta_i, b^{(i)}, K_i)\} \) and \( \{x^{(i)}\} \) satisfying
\[ \|\Lambda_i - \bar{\Lambda}\|_F \rightarrow 0, \quad \|a^{(i)} - \bar{a}\| \rightarrow 0, \quad \|\Theta_i - \bar{\Theta}\|_F \rightarrow 0, \quad \|b^{(i)} - \bar{b}\| \rightarrow 0, \quad \delta(K_i, \bar{K}) \rightarrow 0, \]

and \( \|x^{(i)}\| \rightarrow +\infty \) such that \( x^{(i)} \in \text{SOL}(\Xi_i) \), i.e., (1.1) holds for any \( i = 1, 2, \ldots \). Without loss of generality, we assume that \( x^{(i)} / \|x^{(i)}\| \rightarrow \bar{x} \) as \( i \rightarrow \infty \). It is obvious that \( \|\bar{x}\| = 1 \), which means \( \bar{x} \in R^n \setminus \{0\} \). Furthermore, by (1.1), we have
\[ \left\{ \begin{array}{l}
\frac{\|a^{(i)}\|^{m-1}}{\|x^{(i)}\|^m - 1} + \sum_{k=1}^{m-1} \frac{1}{\|x^{(i)}\|^{k-1}} A^{(k)}(x^{(i)})^{m-k} \in K_i, \\
\frac{\|b^{(i)}\|^{l-1}}{\|x^{(i)}\|^l - 1} + \sum_{i=1}^{l-1} \frac{1}{\|x^{(i)}\|^{i-1}} B^{(p)}(x^{(i)})^{l-p} \in K_i^* \end{array} \right. \]

and
\[ \sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a^{(i)}, \sum_{i=1}^{l-1} B^{(p)}(x^{(i)})^{l-p} + b^{(i)} \leq 0. \]

By passing to the limit in the above expression, it holds that
\[ A^{(1)}x^{m-1} \in K, \quad B^{(1)}x^{l-1} \in K^*, \quad \text{and} \quad \langle A^{(1)}x^{m-1}, B^{(1)}x^{l-1} \rangle = 0. \]

It contradicts the condition that \((A^{(1)}, B^{(1)})\) is an \( R_0^{K^*} \)-tensor pair, because \( \bar{x} \in R^n \setminus \{0\} \).

**Proposition 4.3.** Let \((\Lambda, \Theta, K) \in F_{m,n} \times F_{l,n} \times C(R^n)\). If the leading tensor pair \((A^{(1)}, B^{(1)})\) in \((\Lambda, \Theta)\) is an \( R_0^{K^*} \)-tensor pair, then the set \( D_{\text{SOL}} := \{(a, b) \in R^n \times R^n \mid \text{SOL}(\Lambda, a, \Theta, b, K) \neq \emptyset\} \) is closed.

**Proof.** Take any sequence \( \{(a^{(i)}, b^{(i)})\} \subset D_{\text{SOL}} \) with \( (a^{(i)}, b^{(i)}) \rightarrow (\bar{a}, \bar{b}) \) as \( i \rightarrow \infty \). Then, we just need to prove \((\bar{a}, \bar{b}) \in D_{\text{SOL}}\). Since \( \text{SOL}(\Lambda, a^{(i)}, \Theta, b^{(i)}, K) \neq \emptyset \), let us pick up \( x^{(i)} \in \text{SOL}(\Lambda, a^{(i)}, \Theta, b^{(i)}, K) \) for every \( i \). It follows immediately from **Item (ii) of Proposition 1.1** that \( \{x^{(i)}\} \) is bounded. Without loss of generality, we assume that \( x^{(i)} \rightarrow \bar{x} \) as \( i \rightarrow \infty \). Consequently, by **Item (i) of Proposition 1.1** we know that \( \bar{x} \in \text{SOL}(\Lambda, a, \Theta, b, K) \), which implies \( \text{SOL}(\Lambda, a, \Theta, b, K) \neq \emptyset \). Therefore, we obtain \((\bar{a}, \bar{b}) \in D_{\text{SOL}}\) and complete the proof.
From Theorem \[5.1\] and Proposition \[4.2\] we immediately have the following corollary.

**Corollary 4.4.** Let \((\Lambda, a, \Theta, b, K) \in F_{m,n} \times \mathbb{R}^n \times F_{l,n} \times \mathbb{R}^n \times \mathcal{C}(\mathbb{R}^n)\). If the leading tensor pair \((\bar{A}^{(i)}, \bar{B}^{(i)})\) in \((\Lambda, \Theta)\) is an \(\mathbb{R}_d^+\)-tensor pair, then \(\text{SOL}(\Lambda, a, \Theta, b, K)\) is compact.

**Proposition 4.5.** Let \(\Xi := (\Lambda, a, \Theta, b, K) \in F_{m,n} \times \mathbb{R}^n \times F_{l,n} \times \mathbb{R}^n \times \mathcal{C}(\mathbb{R}^n)\). If the leading tensor pair \((\bar{A}^{(i)}, \bar{B}^{(i)})\) in \((\Lambda, \Theta)\) is an \(\mathbb{R}_d^+\)-tensor pair, then the mapping \(\text{SOL}\) is upper semicontinuous at \(\Xi\).

**Proof.** Suppose, on the contrary, that the mapping \(\text{SOL}\) is not upper semicontinuous at \(\Xi\). Then we could find an open set \(U \subset \mathbb{R}^n\) with \(\text{SOL}(\Xi) \subset U\) and a sequence \(\{\Xi_i := (\Lambda_i, a^{(i)}, \Theta_i, b^{(i)}, K_i)\} \) satisfying \(\Xi_i \to \Xi\), such that \(\text{SOL}(\Xi_i) \cap (\mathbb{R}^n \setminus U) \neq \emptyset\) for any \(i = 1, 2, \cdots\). Now, for each \(i\), pick up \(x^{(i)} \in \text{SOL}(\Xi_i) \cap (\mathbb{R}^n \setminus U)\). It follows from Item (ii) of Proposition \[4.2\] that the sequence \\{\(x^{(i)}\)\} admits a converging subsequence. By Item (i) of Proposition \[4.2\], the corresponding limit must be in \(\text{SOL}(\Xi) \cap (\mathbb{R}^n \setminus U)\), which, together with \(\text{SOL}(\Xi) \subset U\), leads to a contradiction. \(\square\)

## 5 Error bound analysis

Among all the useful tools for theoretical and numerical treatment to NCPs, the global error bound, i.e., an upper bound estimation of the distance from a given point in \(\mathbb{R}^n\) to the solution set of the problem in terms of some residual functions, is an important one. In this section, we focus on studying the global error bound of the solution set of GPCP\((\Lambda, a, \Theta, b, K)\) with \(K := \mathbb{R}_d^+\), and in particular, we denote the resulting model by GPCP\((\Lambda, a, \Theta, b)\) for simplicity. Moreover, we use \(\Omega\) to represent the solution set of GPCP\((\Lambda, a, \Theta, b)\). Let \(r(\cdot) : \mathbb{R}^n \to \mathbb{R}\) be a residual function of GPCP\((\Lambda, a, \Theta, b)\), if \(r(x) \geq 0\), and \(r(x) = 0\) if and only if \(x \in \Omega\). For the two polynomials \(F, G\) given in \[5.2\], let \(\min\{F(x), G(x)\}\) denote the vector in \(\mathbb{R}^n\) whose \(j\)-th component is \(\min\{F_j(x), G_j(x)\}\) for \(j \in [n]\). Obviously, the function \(r(x)\), defined by

\[
r(x) = \|\min\{F(x), G(x)\}\|, \tag{5.1}
\]

provides a residual function of GPCP\((\Lambda, a, \Theta, b)\), and it is called the natural residual for GPCP\((\Lambda, a, \Theta, b)\) (see \[13\]).

**Definition 5.1.** Let \(r(x)\) be a residual function of GPCP\((\Lambda, a, \Theta, b)\). We say \(r(x)\) is a local error bound for GPCP\((\Lambda, a, \Theta, b)\), if there exist three constants \(c > 0, \tau \in (0, 1]\) and \(\varepsilon > 0\) such that

\[
dist(x, \Omega) \leq c \ r(x)\tau, \tag{5.2}
\]

holds for any \(x \in \mathbb{R}^n\) with \(r(x) \leq \varepsilon\), where \(\text{dist}(x, \Omega)\) denotes the distance between the point \(x\) and the set \(\Omega\). Furthermore, if \[5.2\] holds for any \(x \in \mathbb{R}^n\), then \(r(x)\) is called a global error bound for GPCP\((\Lambda, a, \Theta, b)\). If \[5.2\] holds for \(\tau = 1\), \(r(x)\) is called a Lipschitzian error bound.

Below, we first list the fundamental assumption used in \[59\] for the analysis of the global error bound of GCP\((F, G, \mathbb{R}^n)\).

**Assumption 5.1.**

(i) There exists a constant \(\rho > 0\) such that

\[
\max_{j \in [n]} |F_j(x) - F_j(y)| |G_j(x) - G_j(y)| > \rho \|x - y\|^2, \quad \text{for all } x, y \in \mathbb{R}^n. \tag{5.3}
\]

(ii) There exists a constant \(\mu > 0\) such that

\[
|F(x) - F(y)| + |G(x) - G(y)| > \mu \|x - y\|^2, \quad \text{for all } x, y \in \mathbb{R}^n. \tag{5.4}
\]

It is easy to see that a pair of functions \((F, G)\) satisfying \[5.4\] must meet \[5.3\]. In \[13\], the authors proved that the natural residual \(r(x)\) defined by \[5.1\] provides a global error bound for GCP\((F, G, \mathbb{R}^n)\) under Item (i) of Assumption \[5.1\]. Unfortunately, Assumption \[5.1\] often does not hold when we discuss GCP\((F, G, \mathbb{R}^n)\), especially in the case where the related functions \(F\) and \(G\) are both polynomials with high degree. To overcome this inadequacy, we now introduce the following assumption, which is slightly weaker than \[13\] Assumption 5.1.

**Assumption 5.2.** For any sequence \(\{x^{(i)}\}\) in \(\mathbb{R}^n\) with \(x^{(i)} \to x \in \Omega\) as \(i \to \infty\) and \(x^{(i)} \neq \bar{x}\), there exist a subsequence \(\{x^{(i_j)}\}\) of \(\{x^{(i)}\}\) and an index \(j_0 \in [n]\) such that

\[
\lim_{j \to \infty} \frac{\min\{F_{j_0}(x^{(i_j)}), G_{j_0}(x^{(i_j)})\}}{\|x^{(i_j)} - \bar{x}\|} \neq 0. \tag{5.5}
\]
Let $\Lambda = (A^{(1)}, \ldots, A^{(m-1)}) \in F_{m,n}$, $\Theta = (B^{(1)}, \ldots, B^{(l-1)}) \in F_{l,n}$ and $a, b \in \mathbb{R}^n$. If there exists a sequence $\{x^{(i)}\}$ satisfying $\|x^{(i)}\| \to \infty$ such that

$$\lim_{i \to \infty} \frac{-\left(\sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a\right)}{\|x^{(i)}\|} = 0,$$

$$\lim_{i \to \infty} \frac{-\left(\sum_{p=1}^{l-1} B^{(p)}(x^{(i)})^{l-p} + b\right)}{\|x^{(i)}\|} = 0,$$

as $i \to \infty$, then there exists an index $j_0 \in [n]$ such that

$$\limsup_{i \to \infty} \frac{\min \left\{\sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a\right\}_{j_0}}{\|x^{(i)}\|} > 0.$$
Theorem 5.4. Given Lipschitzian error bound for \( \Omega \) defined in (5.1), suppose that Condition 5.1 holds and \( \Omega \) is a global Lipschitzian error bound for GPCP (\( \Lambda = \{ A(1), \ldots, A(m-1) \} \in \mathcal{F}_{m,n}, \Theta = \{ B(1), \ldots, B(l-1) \} \in \mathcal{F}_{l,n} \) and \( a, b \in \mathbb{R}^n \)). Suppose that Condition 5.1 holds and \( \Omega \) is nonempty. If Assumption 5.2 holds, then \( r(\bar{x}) \) is a global Lipschitzian error bound for GPCP (\( \Lambda = \{ A(1), \ldots, A(m-1) \} \in \mathcal{F}_{m,n}, \Theta = \{ B(1), \ldots, B(l-1) \} \in \mathcal{F}_{l,n} \) and \( a, b \in \mathbb{R}^n \)).

Proof. We prove that Condition 5.1 holds by contradiction. Suppose there exists a sequence \( \{ x^{(i)} \} \subset \mathbb{R}^n \) satisfying (5.7), such that \( \lim \sup_{i \to \infty} \left( \sum_{k=1}^{m-1} A(k)(x^{(i)})^{m-k} + a \right)_{j} \geq 0 \), for every given \( \bar{x} \). Then, we have

\[ 0 = \lim_{i \to \infty} \left( \sum_{k=1}^{m-1} A(k)(x^{(i)})^{m-k} + a \right)_{j} \]

otherwise, we obtain

\[ 0 \leq \lim_{i \to \infty} \left( \sum_{k=1}^{m-1} A(k)(x^{(i)})^{m-k} + a \right)_{j} \]

Consequently, we know that \( (A^{(1)} x^{m-1})_{j} \leq 0 \) for every \( j \in [n] \). Similarly, we also can obtain that \( (B^{(1)} x^{l-1})_{j} \geq 0 \) for every \( j \in [n] \).

On the other hand, if there exists a subsequence \( \{ x^{(i)} \} \) of \( \{ x^{(i)} \} \) such that

\[ \sum_{k=1}^{m-1} A(k)(x^{(i)})^{m-k} + a \leq \sum_{p=1}^{l-1} B(p)(x^{(i)})^{l-p} + b \]

then by (5.9), we obtain

\[ \lim_{i \to \infty} \left( \sum_{k=1}^{m-1} A(k)(x^{(i)})^{m-k} + a \right)_{j} \leq 0. \]

Consequently, we know that

\[ (A^{(1)} x^{m-1})_{j} = \lim_{i \to \infty} \frac{\sum_{k=1}^{m-1} A(k)(x^{(i)})^{m-k} + a}{\| x^{(i)} \|_{m-1}^{j}} \leq 0, \]

which, together with the obtained result that \( (A^{(1)} x^{m-1})_{j} \geq 0 \), implies that \( (A^{(1)} x^{m-1})_{j} = 0 \). If (5.10) does not hold, then in a similar way, we may know that \( (B^{(1)} x^{l-1})_{j} \leq 0 \), and hence we have \( (B^{(1)} x^{l-1})_{j} = 0 \).

From the discussion above, we know that \( \bar{x} \in \mathbb{R}^n \setminus \{ 0 \} \), which is a global Lipschitzian error bound for GPCP (\( \Lambda = \{ A(1), \ldots, A(m-1) \} \in \mathcal{F}_{m,n}, \Theta = \{ B(1), \ldots, B(l-1) \} \in \mathcal{F}_{l,n} \) and \( a, b \in \mathbb{R}^n \)).

We now present the main result in this section, which shows that the natural residual function \( r(x) \) defined in (5.1) is a global Lipschitzian error bound for GPCP (\( \Lambda, a, \Theta, b \)) under some appropriate conditions.

Theorem 5.4. Given \( \Lambda = \{ A(1), \ldots, A(m-1) \} \in \mathcal{F}_{m,n}, \Theta = \{ B(1), \ldots, B(l-1) \} \in \mathcal{F}_{l,n} \) and \( a, b \in \mathbb{R}^n \). Suppose that Condition 5.1 holds and \( \Omega \) is nonempty. If Assumption 5.2 holds, then \( r(x) \) is a global Lipschitzian error bound for GPCP (\( \Lambda, a, \Theta, b \)).
Proof. The proof is divided into two parts. Concretely, we first prove that $r(x)$ is a local Lipschitzian error bound for GPCP($\Lambda, a, \Theta, b$). Then, we prove that $r(x)$ is a global Lipschitzian error bound for GPCP($\Lambda, a, \Theta, b$).

Part (i). Suppose, on the contrary, that $r(x)$ is not a local Lipschitzian error bound for GPCP($\Lambda, a, \Theta, b$). It then follows from Definition 4.1 that there is a sequence $\{x^{(i)}\} \subset \mathbb{R}^n$ satisfying $r(x^{(i)}) \leq \varepsilon$ such that

$$\frac{r(x^{(i)})}{\text{dist}(x^{(i)}, \Omega)} = \left\| \min \left\{ \sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a, \sum_{p=1}^{\ell-1} B^{(p)}(x^{(i)})^{l-p} + b \right\} \right\| \to 0 \quad (5.11)$$

as $i \to \infty$. We now show that the sequence $\{x^{(i)}\}$ is bounded. Assume that $\|x^{(i)}\| \to \infty$ as $i \to \infty$, we will derive a contradiction. Obviously, it follows that either $\{x^{(i)}\}$ satisfies (5.7) or $\{x^{(i)}\}$ does not satisfy (5.7). Therefore, we consider the following two cases.

Case (a). If $\{x^{(i)}\}$ satisfies (5.7), it follows from Condition 4.1 that there is an index $i_0 \in [n]$ such that

$$\limsup_{i \to \infty} \frac{\min \left\{ \sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a, \sum_{p=1}^{\ell-1} B^{(p)}(x^{(i)})^{l-p} + b \right\}_{i_0}}{\|x^{(i)}\|} > 0,$$

which implies that exists a subsequence $\{x^{(i_j)}\}$ of $\{x^{(i)}\}$ such that

$$\min \left\{ \sum_{k=1}^{m-1} A^{(k)}(x^{(i_j)})^{m-k} + a, \sum_{p=1}^{\ell-1} B^{(p)}(x^{(i_j)})^{l-p} + b \right\}_{i_0} \to \infty$$

as $i_j \to \infty$. By the definition of $r(x)$ we further obtain that $r(x^{(i_j)}) \to \infty$ as $i_j \to \infty$, which is a contradiction with $r(x^{(i)}) \leq \varepsilon$.

Case (b). If $\{x^{(i)}\}$ does not satisfy (5.7), then we have either

$$\left\| \sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a \right\|_{i_0} \to 0, \quad (5.12)$$

or

$$\left\| \sum_{p=1}^{\ell-1} B^{(p)}(x^{(i)})^{l-p} + b \right\|_{i_0} \to 0. \quad (5.13)$$

When (5.12) holds, there exist an index $j_0 \in [n]$ and a subsequence $\{x^{(i_j)}\}$ of $\{x^{(i)}\}$, such that

$$\sum_{k=1}^{m-1} A^{(k)}(x^{(i_j)})^{m-k} + a \to -\infty \quad \text{as} \quad i_j \to \infty.$$

Consequently, we have

$$\min \left\{ \sum_{k=1}^{m-1} A^{(k)}(x^{(i_j)})^{m-k} + a, \sum_{p=1}^{\ell-1} B^{(p)}(x^{(i_j)})^{l-p} + b \right\}_{j_0} \to -\infty$$

and hence $r(x^{(i_j)}) \to \infty$ as $i_j \to \infty$, which is a contradiction. Similarly, when (5.13) holds, there must be an index $j_0 \in [n]$ and a subsequence $\{x^{(i_k)}\} \subset \{x^{(i)}\}$ such that $\sum_{p=1}^{\ell-1} B^{(p)}(x^{(i_k)})^{l-p} + b \to -\infty$ as $i_k \to \infty$. Hence we obtain that $r(x^{(i_k)}) \to \infty$ as $i_k \to \infty$, which is also a contradiction.

Both Cases (a) and (b) indicate that the sequence $\{x^{(i)}\}$ is bounded. Without loss of generality, we assume $x^{(i)} \to \bar{x}$ as $i \to \infty$. From (5.11), we have

$$r(x^{(i)}) = \left\| \min \left\{ \sum_{k=1}^{m-1} A^{(k)}(x^{(i)})^{m-k} + a, \sum_{p=1}^{\ell-1} B^{(p)}(x^{(i)})^{l-p} + b \right\} \right\| \to 0$$

as $i \to \infty$. Thus, $r(\bar{x}) = 0$, and hence $\bar{x}$ is a solution of GPCP($\Lambda, a, \Theta, b$), i.e., $\bar{x} \in \Omega$. Furthermore, by Assumption 5.2 we know that there exists a subsequence $\{x^{(i_j)}\}$ of $\{x^{(i)}\}$ such that

$$\frac{r(x^{(i_j)})}{\text{dist}(x^{(i_j)}, \Omega)} \to 0 \quad \text{as} \quad i_j \to \infty,$$

which contradicts (5.11). This indicates that $r(x)$ is a local Lipschitzian error bound for GPCP($\Lambda, a, \Theta, b$).
**Part (ii).** In terms of the result of **Part (i),** we now show that \( r(x) \) is a global Lipschitzian error bound for GPCP(\( \Lambda, a, \Theta, b \)). Suppose, on the contrary, that the result does not hold. Then it follows from Definition 5.1 that for each positive integer \( i \), there exists an \( x^{(i)} \in \mathbb{R}^n \) such that
\[
\|x^{(i)} - \bar{x}\| \geq \text{dist}(x^{(i)}, \Omega) > i \cdot r(x^{(i)})
\] (5.14)
where \( \bar{x} \) is a fixed solution of GPCP(\( \Lambda, a, \Theta, b \)). Since \( r(x) \) is a local Lipschitzian error bound for the problem GPCP(\( \Lambda, a, \Theta, b \)) by **Part (i)**, there exists a positive integer \( i_0 \) and a constant \( \varepsilon > 0 \) such that \( r(x^{(i)}) > \varepsilon \) for all \( i > i_0 \), which, together with (5.14), implies that \( \|x^{(i)}\| \to \infty \) as \( i \to \infty \). Obviously, we have either \( \{x^{(i)}\} \) satisfies (5.7) or \( \{x^{(i)}\} \) does not satisfy (5.7). If \( \{x^{(i)}\} \) satisfies (5.7), then (5.8) holds by Condition 5.1. Consequently, by the definition of \( r(x) \), we have
\[
\limsup_{i \to \infty} \frac{r(x^{(i)})}{\|x^{(i)}\|} > 0.
\] (5.15)
If \( \{x^{(i)}\} \) does not satisfy (5.7), then since \( \|x^{(i)}\| \to \infty \) as \( i \to \infty \), we have either (5.12) or (5.13) holds. If (5.12) holds, then there exist positive number \( \varepsilon \), an index \( j_0 \in [n] \) and a subsequence \( \{x^{(i_j)}\} \) of \( \{x^{(i)}\} \) such that
\[
\left( \sum_{k=1}^{m-1} A^{(k)}(x^{(1)})^{m-k} + a \right)_{j_0} \leq -\varepsilon \|x^{(1)}\|
\]
for every \( i_j \), which implies \( r(x^{(1)}) \geq \varepsilon \|x^{(1)}\| \) for every \( i_j \). Hence, (5.16) holds. Similarly, when (5.13) holds, we also can claim that (5.16) holds.

Take any given positive number \( M \). Considering (5.13) with \( i \geq M \) and (5.15), by letting \( i \to \infty \), we have
\[
1 = \lim_{i \to \infty} \frac{\|x^{(i)} - \bar{x}\|}{\|x^{(i)}\|} \geq \limsup_{i \to \infty} \frac{r(x^{(i)})}{\|x^{(i)}\|} \geq M \limsup_{i \to \infty} \frac{r(x^{(i)})}{\|x^{(i)}\|}
\]
which means \( 1 \geq +\infty \) from the arbitrariness of \( M \). A contradiction yields and the proof is complete. \( \square \)

From Theorem 5.1, Lemma 5.3 and Theorem 5.4, we immediately obtain the following global Lipschitzian error bound.

**Theorem 5.5.** Let \( \Lambda = (A^{(1)}, \ldots, A^{(m-1)}) \in \mathcal{F}_{m,n}, \Theta = (B^{(1)}, \ldots, B^{(l-1)}) \in \mathcal{F}_{l,n} \). Suppose that the leading tensor pair \((A^{(1)}, B^{(1)})\) in \((\Lambda, \Theta)\) is an ER-tensor pair. If either (a) \( m = l \) or (b) \( m \neq l \), but the one of \((A^{(1)}, B^{(1)})\), whose order is even and is larger than another, is positive definite, then for any given vectors \( a, b \in \mathbb{R}^n \) such that Assumption 5.2 holds, \( r(x) \) is a global Lipschitzian error bound for GPCP(\( \Lambda, a, \Theta, b \)).

Similarly, based upon Remarks 2.3 and 3.2 we obtain the following theorem.

**Theorem 5.6.** Let \( \Lambda = (A^{(1)}, \ldots, A^{(m-1)}) \in \mathcal{F}_{m,n}, \Theta = (B^{(1)}, \ldots, B^{(l-1)}) \in \mathcal{F}_{l,n} \). Suppose that the leading tensor pair \((A^{(1)}, B^{(1)})\) in \((\Lambda, \Theta)\) is an ER-tensor pair. If \( m > l \) and \( A^{(1)} \) is strictly copositive (see [29]), then for any given vectors \( a, b \in \mathbb{R}^n \) satisfying Assumption 5.2 and the function \( F \) in (1.2) satisfying \( S(\mathbb{R}^n) \subseteq \mathbb{R}^n \), where \( S \) is same to that in Remark 3.2, \( r(x) \) is a global Lipschitzian error bound for GPCP(\( \Lambda, a, \Theta, b \)).

Now we complete this section by considering the TCPs introduced in [22], i.e., the model TCP(\( A, q \)). In this situation, we may prove that, for a given \( A \in \mathbb{T}_{m,n} \) and \( q \in \mathbb{R}^n \), if \( A \) is an \( \mathbb{R}_p \)-tensor, then Condition 5.1 holds. Furthermore, by [35, Theorem 4.2], we know that if \( A \in \mathbb{T}_{m,n} \) is an ER-tensor and \( q \in \mathbb{R}^n \) is given, then the solution set of TCP(\( A, q \)) is nonempty and compact. By [29, Theorem 3.2], we know that if \( A \in \mathbb{T}_{m,n} \) is an R-tensor (see [29, Definition 2.2]) and \( q \in \mathbb{R}^n \) is given, then the solution set of TCP(\( A, q \)) is nonempty. Therefore, by Theorem 5.4, we have the following result.

**Theorem 5.7.** Given \( A \in \mathbb{T}_{m,n} \) and \( q \in \mathbb{R}^n \). Suppose that \( A \) is an ER-tensor (or R-tensor). If Assumption 5.2 with \( F(x) = Ax^{m-1} + q \) and \( G(x) = x \) holds, then \( r(x) \) is a global Lipschitzian error bound for TCP(\( A, q \)).

Note that the result in Theorem 5.7 to our knowledge, is not discussed in the current TCPs and PCPs literature (e.g., see [11, 21, 37]). On the other hand, our Assumption 5.2 is weaker than the conditions assumed in previous papers. Therefore, our result is better.
6 Conclusion

The GPCP under consideration is a natural generalization of TCPs and PCPs, and a special case of GCPs, but with more favorable polynomial nature that we could explore to derive interesting specialized results than the general nonlinear functions in GCPs. In this paper, we obtain some new results on GPCPs, which include the nonemptiness and compactness of the solution set, basic topological properties, and global Lipschitzian error bounds of solutions of GPCP($\Lambda, a, \Theta, b$) with structured (e.g., ER-) tensor pair. In the future, we will pay attention to designing some structure-exploiting algorithms for GPCPs.
